UTM 10 5538635 673873
NTS 092H15E

CLAIM(S): Snowflake 7, Snowflake 10

OPERATOR(S): Gerle Gold

AUTHOR(S): Smitheringale, W.G.

REPORT YEAR: 1988, 63 Pages

COMMODITIES

SEARCHED FOR: Gold, Silver, Copper

GEOLOGICAL

SUMMARY: Andesitic and dacitic lahar deposits, agglomerates, tuffs and associated argillaceous limestone of the Upper Triassic Nicola Group strike northward and dip west. These rocks are cut by north-striking faults, and cross faults. The volcanics show sericite, chlorite and epidote alteration. Gold and silver values accompany chalcopyrite in thin carbonate fracture-controlled veinlets.

INTRODUCTION

Property Location and Definition

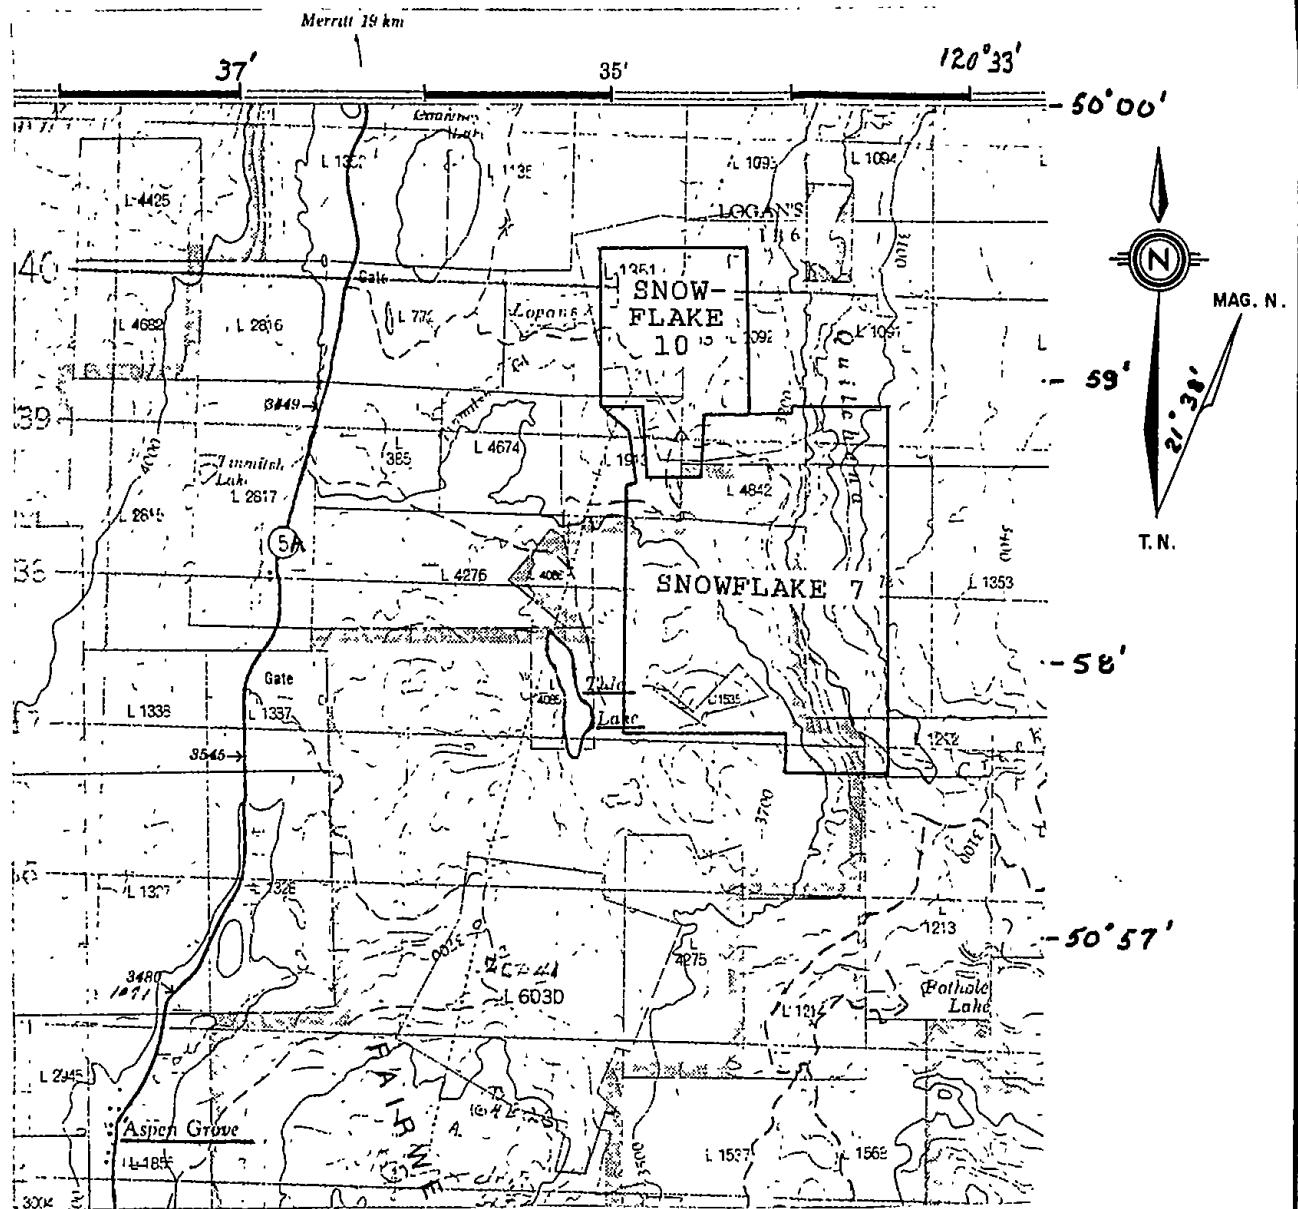

The Snowflake 7 and 10 claims lie in south-central B.C., 21 km SE of Merritt and 6 km NNE of Aspen Grove (Fig. 1). Access is from Hwy. 5A by 2 km of dirt road.

TABLE 1: Claims Covered by Gerle Gold Ltd.'s Option Agreement.

| Claim | No.of | Record | | Expiry |
|--------------|-------|--------|-------|----------------|
| Name | Units | Number | Group | Date* |
| Snowflake | 6 | 8 | A | May 13, 1994 |
| Snowflake 2 | 4 | 93 | B | April 14, 1996 |
| Snowflake 3 | 6 | 167 | A | Aug 20, 1994 |
| Snowflake 4 | 8 | 211 | B | Feb 11, 1996 |
| Snowflake 5 | 2 | 212 | B | Feb 11, 1996 |
| Snowflake 6 | 6 | 321 | A | Sept 16, 1994 |
| Snowflake 7 | 20 | 470 | B | June 15, 1996 |
| Snowflake 10 | 6 | 514 | A | Oct 25, 1996 |
| Tule 10 | 4 | 322 | A | Sept 16, 1994 |

* The work described in this report will change the anniversary year of all the claims to 1998.

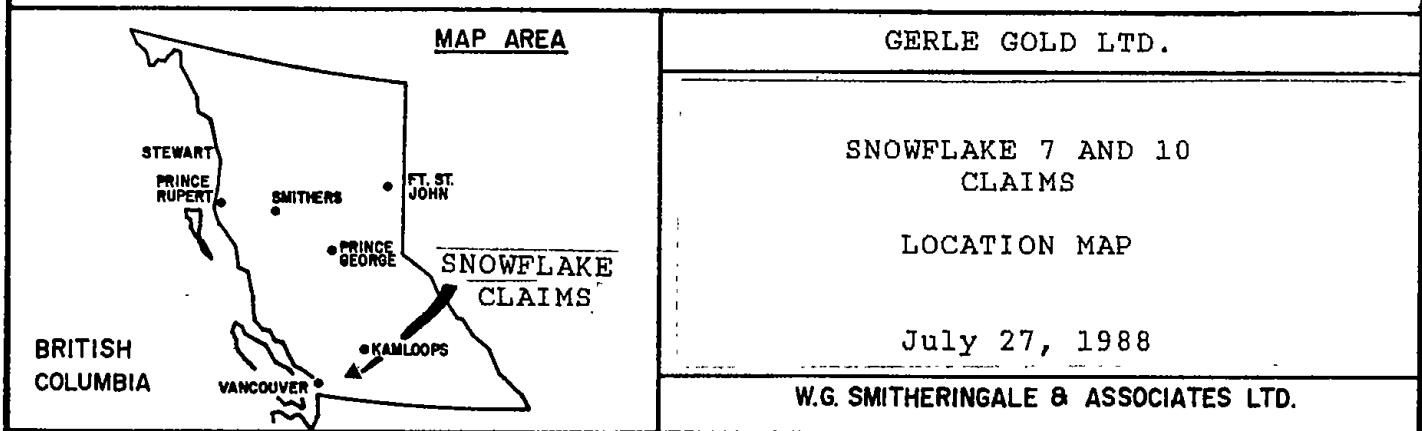

The claims are at the 1000 m level in prime grazing land containing aspen groves and small stands of fir. Tule lake, the nearest reliable source of water, is about 1.5 km south of the 1988 drill sites. Portions of the claims lie within the boundaries of Douglas Lake Cattle Company Ltd., and permission from the company is required to drill within these boundaries. The Snowflake 7 and Snowflake 10 claims, on which the drilling described in this report was done, are two of nine claims covered by an option agreement between Quilchena Resources Ltd., the owner, and Gerle Gold Ltd., the operator. These claims are listed in Table 1. The Snowflake 7 and Snowflake 10 have been grouped, respectively, with the Snowflake B Group, comprising 94 units, and the Snowflake A

Group, comprising 98 units. The claims in Groups A and B not covered by the option agreement are not listed in Table 1.

History

Numerous showings of copper minerals are known in the Aspen Grove area. The 1901 Annual Report of the Minister of Mines, B.C.(p. 1179) describes the "Aspen Grove Camp" as being a year old and including 100 or more claims. Most of the early exploration in the area was done between 1912 and 1928, and is described in the Annual Reports of the Minister of Mines, B.C. for those years. The area was explored again between 1965 and 1975 for porphyry copper deposits, this work being described in Annual Reports of the Minister of Mines, B.C., in annual issues of Geology, Exploration and Mining in B.C. and in Assessment Reports. Complete bibliographies are given by Rice (1947) and Preto (1979). The closest of these old properties to the Snowflake property is the Blue Jay (Preto, 1979, pp. 75-77), which overlapped the western portion of the Snowflake claims, about 300 m west of the drill sites described herein.

The recent exploration history of the area now covered by the Snowflake claims dates from 1983, when an old report describing interesting gold values obtained during a 1967 drill program prompted Laramide Resources Ltd. to option the claims. The values reported were 10 ft. of 0.130 oz/ton Au, 60 ft. of 0.150 oz/ton Au and 10 ft. of 0.115 oz/ton Au, all from one hole for which the collar location was not reported. Laramide conducted I.P. and magnetometer surveys and a 12 hole diamond drill program of 996 m in 1983 and continued their work in 1985. In 1985 the property was acquired by Quilchena Resources Ltd. In 1986 part of the property was optioned by Lornex Mining Corporation who extended the I.P. survey and diamond drilled six holes totalling 577 m. Lornex dropped their option and in 1987 Gerle Gold Ltd. optioned the claims listed in Table 1 and conducted a 16 hole, 1,239 m diamond drill program. The exploration conducted since 1983

on the Snowflake claims is documented in detail by I.M. Watson (1988).

During June and July, 1988, Gerle Gold Ltd. conducted a 3 hole, 304 m diamond drill program, which is the subject of this report.

GEOLOGY

Regional

The Aspen Grove Camp lies in the Princeton-Merritt copper belt, which includes the Ingerbelle and Afton porphyry copper deposits. This belt is underlain by andesitic and basaltic volcanic rocks, intrusive bodies of diorite and syenite that are comagmatic with the volcanic rocks and associated volcaniclastic and sedimentary rocks. All of these units belong to the Upper Triassic Nicola Group (Preto, 1979). In the Quesnel Trough Nicola rocks host the QR gold prospect as well as numerous other copper-gold occurrences.

Mineralization in the Aspen Grove area consists principally of pyrite, chalcopyrite, bornite, chalcocite, native copper and malachite. It occurs in breccia zones and as disseminations, replacements and fillings in small fractures in Nicola volcanic and related intrusive rocks and in associated argillaceous and limey sediments. Copper mineralization is widespread but low grade, and is often accompanied by minor gold and silver values. For example, on the former Blue Jay property chalcopyrite, bornite, chalcocite and native copper with pyrite and secondary malachite occurs finely disseminated and in fracture fillings in Nicola volcanic rocks and in dioritic intrusive rocks (Preto, 1979).

Property

The geology of the Snowflake 7, Snowflake 10 and surrounding claims consists of dominantly andesitic to dacitic tuff, agglomerate and lahar deposits and a sequence of dark grey,

argillaceous sediments that vary from argillaceous and limey feldspar crystal tuff to argillaceous limestone to argillite. Lesser amounts of andesite flows and several small stocks of diorite and monzonite-syenite complete the assemblage. Agglomerates and lahar deposits with a dominantly green matrix are interpreted as being subaqueous and those with a dominantly red matrix are interpreted as being subaerial. The stratified rocks strike northward and dip moderately steeply to the west. The claims straddle or lie immediately east of the northern end of the Kentucky-Alleyne fault, which is a regional, north trending fault. Cross faults, probably with minor displacement, are present.

The stratigraphic section intersected by drilling on the Snowflake 10 claim consists of green polymict agglomerate (and possibly lahar deposits) and andesite tuff and flow rocks overlain by a sedimentary sequence consisting of argillaceous and tuffaceous limestone and limey feldspar crystal tuff, which in turn is overlain by more andesitic agglomerate and tuff. An argillite unit commonly occurs at the base of the sedimentary sequence and in places a monolithic felsite lapilli tuff with lapilli varying up to 1.5 cm across occurs just below the main sediment-agglomerate contact.

Alteration observed in drill core includes sericitization, chloritization, epidotization and possibly some kaoilinization. Alteration appears to be zoned in so far as moderate pervasive sericitization and chloritization without epidote is present in the upper 10 m to 40 m of the volcanic sequence that underlies the sediments and epidotization and hematite in fractures (see below) appears to be confined to the lower portion of the volcanic sequence. Intense sericitization adjacent to some, but not all, fractures and faults has produced bleached zones superimposed on the pervasive alteration.

Conjugate fractures and small breccia zones adjacent to relatively strong fractures and slips are filled with calcite with or without lesser quartz, talc(?), hematite and in places unidentified clay minerals and/or zeolites. These veinlets vary in thickness from hairline to several centimetres, but most are less than 0.5 cm.

Mineralization observed in drill core consists of minor disseminated pyrite, principally in the argillaceous and limey sediments, and sparse pyrite, chalcopyrite, bornite and sphalerite, and even more sparse galena, in the carbonate veins and breccia fillings. Gold and silver values accompany the vein and breccia mineralization in two fairly well defined zones, one at the base of the sedimentary sequence and the other in the volcanics about 5 m below the base of the sedimentary sequence, and also in several much less clearly defined zones lower in the volcanic sequence.

THE 1988 DIAMOND DRILL PROGRAM

Description

Three NQ wireline holes totalling 304 m were drilled with a Longyear '38' during the 1988 program by P.W. Diamond Drilling Ltd. of McLure, B.C. The core is stored in covered racks on the Willow Heights Ranch, property of Mr. Les Bryant, at Aspen Grove.

The drill program was supervised in the field by W.G. Smitheringale, the core was logged by him and was split for sampling under his supervision. Samples were submitted to CDN Resource Laboratories Ltd. of Burnaby, B.C. for geochemical analysis for gold, silver and copper. The core logs and assay certificates are presented in Appendix 1.

The orientation and other details of each hole are given in Table 2. The collar locations are shown on Fig. 2, a

diamond drill hole plan prepared by I.M. Watson (1988).

TABLE 2: Details of 1988 Diamond Drill Holes

| Drill | Grid | Collar | | | |
|-------|----------|---------|-----------|--------------|--------------|
| Hole | Location | Azimuth | Elevation | Inclination | Length |
| 88-1 | 205+83N | 067.5 | 1008.3m | collar:-45 | 101m |
| | 194+77E | | | @ 65m :-53 | |
| | | | | @ 101m:-52 | |
| 88-2 | 205+39N | 041.5 | 1012.5m | collar:-79 | 85m |
| | 194+48E | | | @ 85m :-80 | |
| 88-3 | 204+06N | 065 | approx. | collar:-44.5 | 118m |
| | | | 1000m | | @ 118m:-51.5 |

Purpose

None of the 34 holes drilled during the 1983 to 1987 programs succeeded in duplicating the gold bearing intercepts reported in 1967. Before the 1988 program one of the drillers on the 1967 program visited the drill site with Gerle Gold personnel, where he identified an old drill collar that he recalled as being the hole that produced the good assays.

The primary purpose of the 1988 program was to re-drill the 1967 gold bearing intercept, and accordingly the first hole was collared 1.5 m SW of the hole identified by the 1967 driller and drilled parallel to it. The purpose of the second hole was to trace several gold bearing zones intersected in section 205+40N by previous drilling down dip. The intersections in question are:

| Drill | Assays in oz/ton | | | |
|-------|------------------|-------|-------|------|
| Hole | Interval | Width | Au | Aq |
| 83-8 | 42.6-44.0 | 1.4 | 1.05 | 12.0 |
| 87-3 | 36.0-37.5 | 1.5 | 0.803 | |
| | 43.5-45.0 | 1.5 | 0.218 | |
| 87-4 | 67.5-69.0 | 1.5 | 0.038 | |

The purpose of the third hole drilled was to explore an untested I.P. anomaly that runs northwesterly through 204+00N, 191+50E.

Interpretation and Conclusions

1. Drill hole 88-1 did not duplicate the gold assays reported from the 1967 drilling, so it is unlikely that the old hole collared at the site of DDH 88-1 was the hole in question. Most likely the 1967 hole that had the good intersection was drilled towards the southwest, not the northeast, down the dip of one of the southwestward dipping gold bearing zones identified by the 1983, 1986 and 1987 drilling.

2. Drill hole 88-2 extended the gold bearing zones intersected by drill holes 83-8, 87-3 and 87-4 some 30 m down dip from hole 87-4. The drill hole 88-2 intersections are detailed in the following table.

| Mineralized | | DH 88-2 | Ore | Geochemical Analysis | | |
|-------------|--------------|----------|--------|----------------------|--------|--------|
| Zone | Intersection | Minerals | Gold | Silver | Copper | |
| upper | 65m to | chalco- | 80ppb | 0.3ppm | 120ppm | |
| | 67m | pyrite | 110ppb | 0.1ppm | 130ppm | |
| lower | 78m to | chalco- | <5ppb | 0.1ppm | 370ppm | |
| | 81m | pyrite & | <5ppb | 0.2ppm | 90ppm | |
| | | bornite | <.002 | <0.1ppm | 160ppm | oz/ton |

The zones are geochemically anomalous at these points, but their gold and silver contents are economically unimportant.

3. Although minor amounts of chalcopyrite are present in DDH 88-3 core, no mineralization of significance was encountered. The cause of the I.P. anomaly at this location is

unexplained.

4. Although this drill program was unsuccessful in intersecting economically important mineralization, it has further confirmed the presence of geochemically anomalous gold in association with copper mineralization in zones of fracture controlled carbonate veining.

5. The general geology of the claims under option to Gerle Gold Ltd., and of the surrounding region, constitutes a favourable environment for gold exploration. The geological similarities between the Snowflake claims and the QR deposit southeast of Quesnel listed by Watson (1984) have been supported by the work to date. On this basis the I.P. anomalies that have not been explored remain valid drill targets. Specifically, anomalies A on line 190N and 191N, A1 on lines 186N and 187N, B on lines 193N to 196N, C1 on line 190N and D1 on line 208N, all of which are discussed by Cartwright (1986), warrant investigation. Anomaly A1 lies just outside the boundary of Gerle Gold's option. This land should be optioned, if a reasonable agreement can be drawn, before further drilling is undertaken.

6. The author quickly examined some of the previous year's drill core and found a degree of disparity in terminology and interpretation of details among the different geologists that have logged the core, although the general interpretation from year to year seems consistent. A clearer concept of the controls of mineralization might be forthcoming if all the core were re-logged by one person.

RECOMMENDATIONS

1. All the core should be re-logged and the data acquired to date should be reviewed by one geologist in an effort to formulate an hypothesis for the control of mineralization on the Snowflake claims.

2. Before further drilling is undertaken outcrops should be mapped for features that are highlighted by the study in 1 above.

3. The suitability of the area for gold exploration should be re-evaluated on the basis of the results of recommendations 1 and 2. If the potential of the area is considered to be good, recommendations 4 and 5 should be carried out, otherwise the option on the Snowflake claims should be dropped.

4. The claim on which I.P. anomaly A1 occurs should be acquired.

5. I.P. anomalies A, A1, B, C1, and D1 (described above) should be drilled.

ITEMIZED COST STATEMENT

| | |
|--------------------------------|-----------------------|
| 1000 ft. @ 27.49/ft. all found | <u>27489.33</u> |
| Total | \$42643.17 |

APPORTIONMENT OF COST

The apportionment of cost between the Snowflake 10 claim, which belongs to Snowflake Group A, and the Snowflake 7 claim, which belongs to Snowflake Group B, is made on the basis of the footage drilled on each claim.

Total drilling cost and footage drilled ... \$42,643/1000 ft.

Snowflake 10 (613 ft. drilled):

apportionment of cost is $613/1000 \times 42,643 = \$26,140$

Snowflake 7 (387 ft. drilled):

apportionment of cost is $387/1000 \times 42,643 = \$16,503$

CERTIFICATION

I, William G. Smitheringale, hereby certify that:

I am a practising Professional Geological Engineer, resident at 4611 Hoskins Road, North Vancouver, B.C.

I am a graduate of the University of British Columbia with the degree of Geological Engineer (B.Ap.Sc., 1955) and of the Massachusetts Institute of Technology with the degree of Doctor of Philosophy in Geology (Ph.D., 1962).

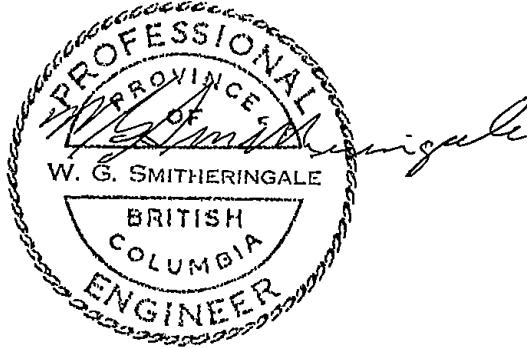

I have practised my profession continuously for twenty six years as Geologist with the Geological Survey of Canada, as Assistant and Associate Professor, Department of Geology, Memorial University of Newfoundland and, since 1974, as a Consulting Geologist.

I am a member in good standing of the Association of Professional Engineers of the Province of British Columbia (Registration No. 10802).

This report is based on field and office work conducted by me and under my supervision between June 8 and July 27, 1988.

W.G. SMITHERINGALE, Ph.D., P.Eng.

July 27, 1988

APPENDIX 1
Assay Certificates

Geochemical analysis for Au, Ag and Cu was carried out by CDN Resource Laboratories Ltd. of Burnaby, B.C.

The core samples were crushed, subsampled and the subsample was pulverized to pass a 100 mesh screen. Gold was determined on a 15 gm portion of the pulp that was fused to produce a gold bead which was then leached with HNO₃ to remove Ag. The remaining bead was dissolved in aqua regia and the gold content was determined using atomic absorption. Ag and Cu were determined using HNO₃ extraction and atomic absorption analysis.

| FLAG | METRES from | to | DESCRIPTION | ALTERATION | SULPHIDES | SAMPLE |
| | | | | O Cabo Chl Spx | Or %Py %Cp | No. from to |
| | 0 | 17.1 | CASING: | | | |
| | 17.1 | 19.7 | ANDESITIC XYLE TUFF: red grey, f.gr. 60% feldspar, 20% amphibole, 20% matrix. No py. There was 0.5% finely disseminated magnetite, but it's now altered to hematite. | | | |
| | | | Alteration: feldspars sericitized (cloudy); amphibole altered to hematite! Slight lineyness probably due to calcite from alt. of plagioclase. Weathering has produced limonite in the matrix. | | | |
| | | | 19.1-19.7: matrix is largely hematitic. Can't tell if hematite is an alteration product or if matrix was derived from subaerial hematite flows. | | | |
| | | | Veining hairline to 5mm thick calcite (with or without qtz, talc and chlorite) form 5% of core. Tiny grains of hematite pseudomorphous after magnetite occur along vein margins just as py occurs in other holes. | | | |
| Int | | | Has py replaced by magnetite, or was magnetite the primary vein mineral? I think pyrite was replaced by magnetite here and in matrix. | | | |

| | | 47.3-51.0: mainly dx and gouge. Red matrix is bleached adjacent to some, but not all veins and gouge zones. | | | | | | | | | | | | | | | | |
| Fit | | 47.1: Icm dx; minor fault. | | | | | | | | | | | | | | | | |
| | | Pale grey or green kaotintite for some clay mineral alteration is abundant in some gouge zones. | | | | | | | | | | | | | | | | |
| | | Veins in this interval (42.3 to 51.0) comprise about 5% of the core. Many are fragmented by the dx. They have the same general orientation as higher in the hole. N.B. Veins containing mainly qtz are common. Sulfides absent except for small patches of pyrite and pyrrhotite between 47.5 and 47.7. These were deposited in micro-fractures in qtz veins. This probably has a distinctly different habit f.v.d. | | | | | | | | 50673 | 42.0 | 43.8 | 1.8 | 53 | <5 | 0.1 | 10 | |
