INTRODUCTION

Location, Access and Physiography

The STEVEN property is located on Ghost Creek, 26 km NW of Queen Charlotte City on Graham Island. The claims are on NTS map sheet 103F/8 at longitude 132°21'E and latitude 53°25'N.

Access to the property is by private logging roads controlled by MacMillan Bloedel Limited. Use of these roads during working hours can usually be arranged with MacMillan Bloedel management based in Queen Charlotte City. Access in 1988 was provided by 4-wheel drive truck.

The local topography is dominated by rounded hills with relief of 430 metres. Elevations on the property range from 90 metres in the southeast to 520 metres in the northwest. Vegetation consists mainly of spruce and yellow cedar; large portions throughout the property have been and are currently being logged.

Property Definition and Claim Status

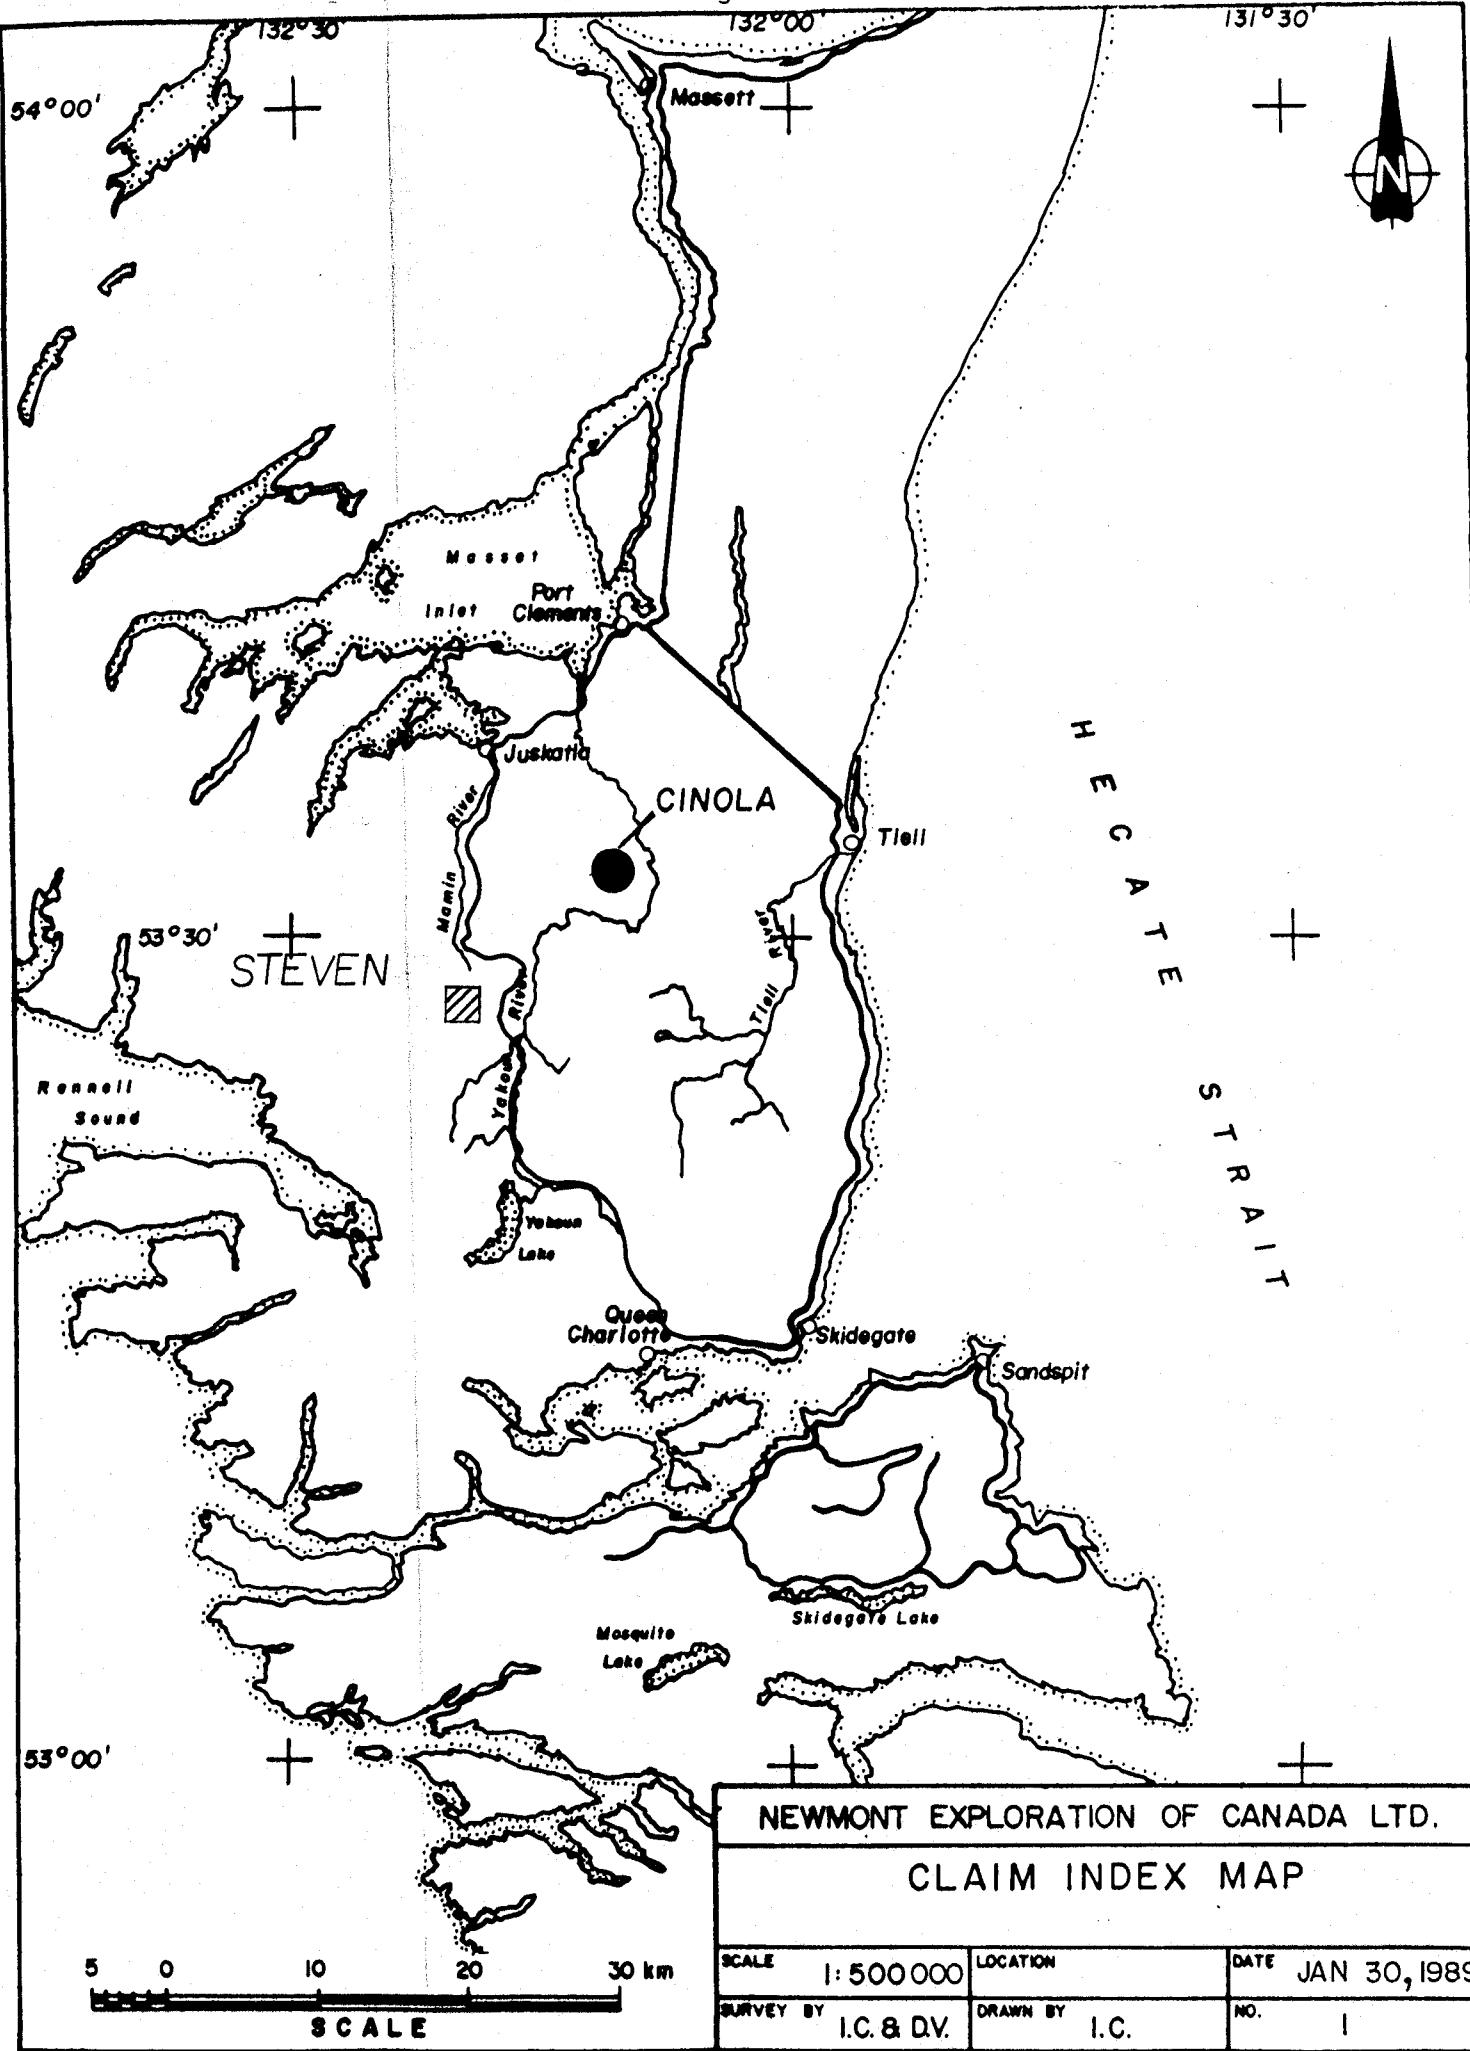

The STEVEN property consists of 4 grid claims of 78 units and 8 2-post claims of 8 units. Total 86 units. They are:

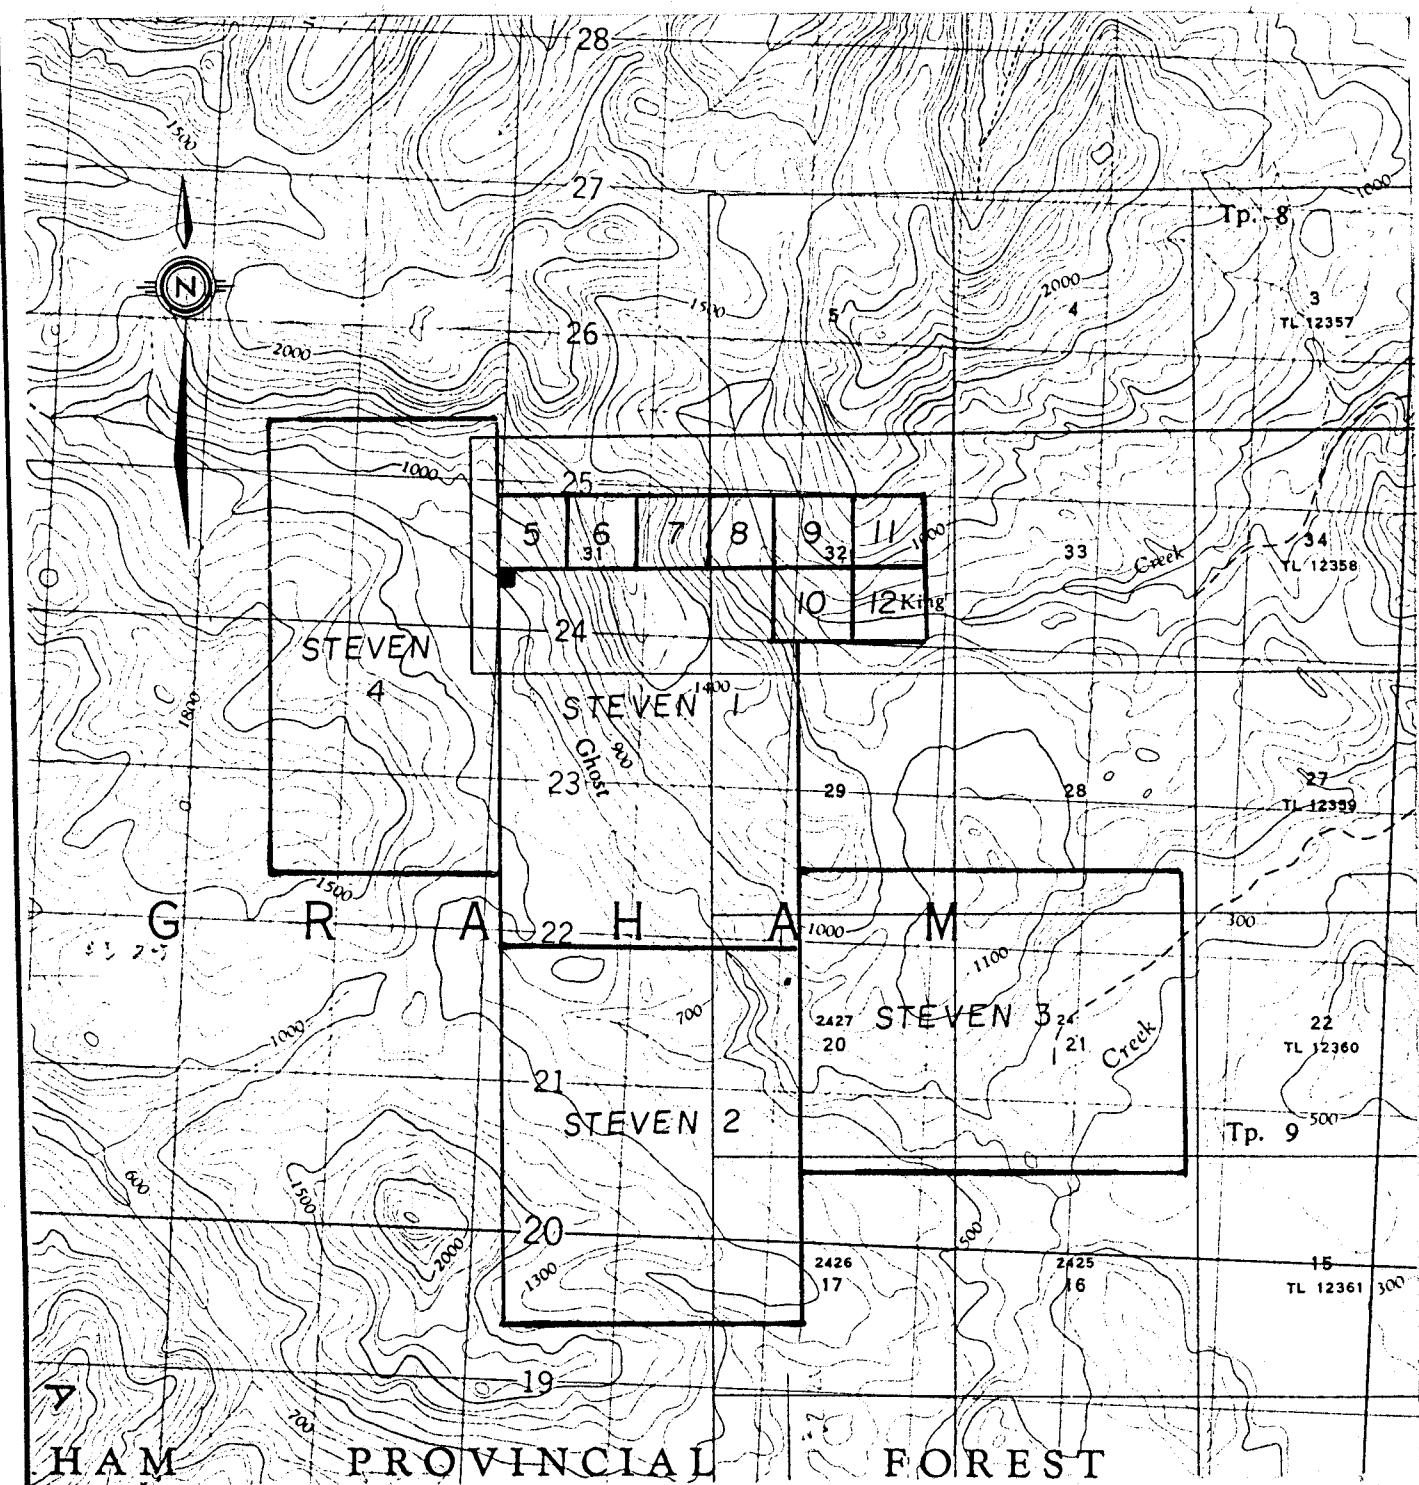

<u>Claim</u>	<u>No. of Units</u>	<u>Record Date</u>	<u>Record Number</u>

History

The earliest known work done in the area is by JMT Services, who worked on their King claims. The Steven property covers an area once owned by JMT Services. The history of the King property is as follows:

- June 1977 - King 1 claim staked to cover anomalous Hg and As in stream silts
- Sept. - King 1 claim re-staked and King 2 & 3 staked to cover a geochemical anomaly.
- Oct. - Newmont optioned the property and contracts JMT Services to complete geochemical sampling and geologic mapping.
- 1978 - Newmont dropped its option.
- March 1979 - JMT stakes King 4 - 6 claims
 - Chevron Canada Limited optioned the property.
- Sept. - Chevron stakes King 8 and 9 claims.
- Oct. - JMT Services completes geologic mapping, geochemical sampling and commences percussion drilling 22 holes on King 1.
- March 1980 - King 7 was abandoned and King 10 was staked in its place.
 - Chevron drills 5 diamond drill holes and King 1 and 10 claims for a total of 895 metres.
- Dec. - King 11 - 13 claims were staked.
- Nov. 1981 - Chevron drills 3 diamond drill holes on King 1 and 10 claims for a total of 418 metres.
- 1982 - Chevron drops their option

May 1988 - King 1, 2 and 3 in good standing

May-

June

- Newmont stakes Steven 1 - 12 claims (old King 6, 10, 11 claims) and conducts a limited geological and geochemical program.

Work Summary

In May and June 1988, a two man crew spent 20 days on the Steven property. Limited geologic mapping and geochemical sampling was done along newly constructed logging roads. A total of 142 soil, 10 silt and 33 rock samples were collected. The results of the survey are plotted on Figures 3 - 5 and Maps 1 - 4.

GEOLOGY

Regional

The geology of the Queen Charlotte Islands is described in detail in the B.C. Department of Mines Bulletin No. 54 by A. Sutherland-Brown. The central portion of Graham Island is underlain mainly by a northwest striking sequence of middle Jurassic volcanics and sediments of the Yakoun Formation (Upper Vancouver Group). These rocks consist of porphyritic andesite, pyroclastics and volcanic sandstones. Unconformably overlying the Yakoun are flat lying Tertiary basalt and rhyolite flows of the Massett Formation. Intruding these units are Tertiary feldspar porphyry dykes and sills, diorite stocks and gabbro plugs. North, northeast and northwest trending faults and linears are prominent features of the area.

Property

Reconnaissance geologic mapping was conducted along logging roads and the preliminary results are presented on Figure 3 at a scale of 1:10,000.

The oldest exposed unit on the Steven property consists of fine grained, green mafic volcanics of the Lower Jurassic Yakoun Formation which is part of the Vancouver Group. Towards the top of the Yakoun the rocks are more of a volcanic sandstone. They are well exposed along Ghost Creek where they strike about 110° and dip about 10° NE. Slickenside measurements demonstrate a major structure along Ghost Creek. Very minor pyrite mineralization was found in these rocks.

Overlying the Yakoun Formation are dark coloured, fine grain, well bedded, rusty argillites and mudstones of the Upper Cretaceous Haida Formation which is part of the Queen Charlotte Group. They are best classified as turbidites. Locally the rocks are cherty, silicified and clay altered. The rocks occur in the central part of the Steven 1 claim where the strike at 140° and dip 30° NE. These rocks are quite sheared and faulted with low angle thrusts, at 140° , high angle normal shears at 140° and high angle normal cross faults at 230° . Massive and disseminated realgar, stibnite pyrite and cinnabar mineralization occurs near the top of the Haida in a slightly chloritic and argillaceous sandy turbidite sequence. This showing is called the Victory Zone as shown on Figure 4 and 5 and discussed below.

Unconformably overlying the Haida rocks is a medium green to dark green, coarse grained, framework supported cobble conglomerate of the Upper Cretaceous Honna Formation which is also part of the Queen Charlotte Group. The cobbles are made up of Yakoun volcanics Haida sandstone and Tertiary intrusive fragments.

Chlorite and clay are the main alteration minerals. The rocks occur in the central area of Steven 1 about halfway up a northwest trending ridge. They strike about 148° and dip $\sim 46^{\circ}$ into the hill (NE). The conglomerate is also sheared and faulted. Disseminated pyrite occurs throughout and minor chalcopyrite occurs in some intrusive cobbles.

The above units also contain Tertiary feldspar porphyry dykes and sills which occupy low angle thrusts (sills) and high angle ($\sim 55^{\circ}$ SE) normal crosscutting faults (dykes).

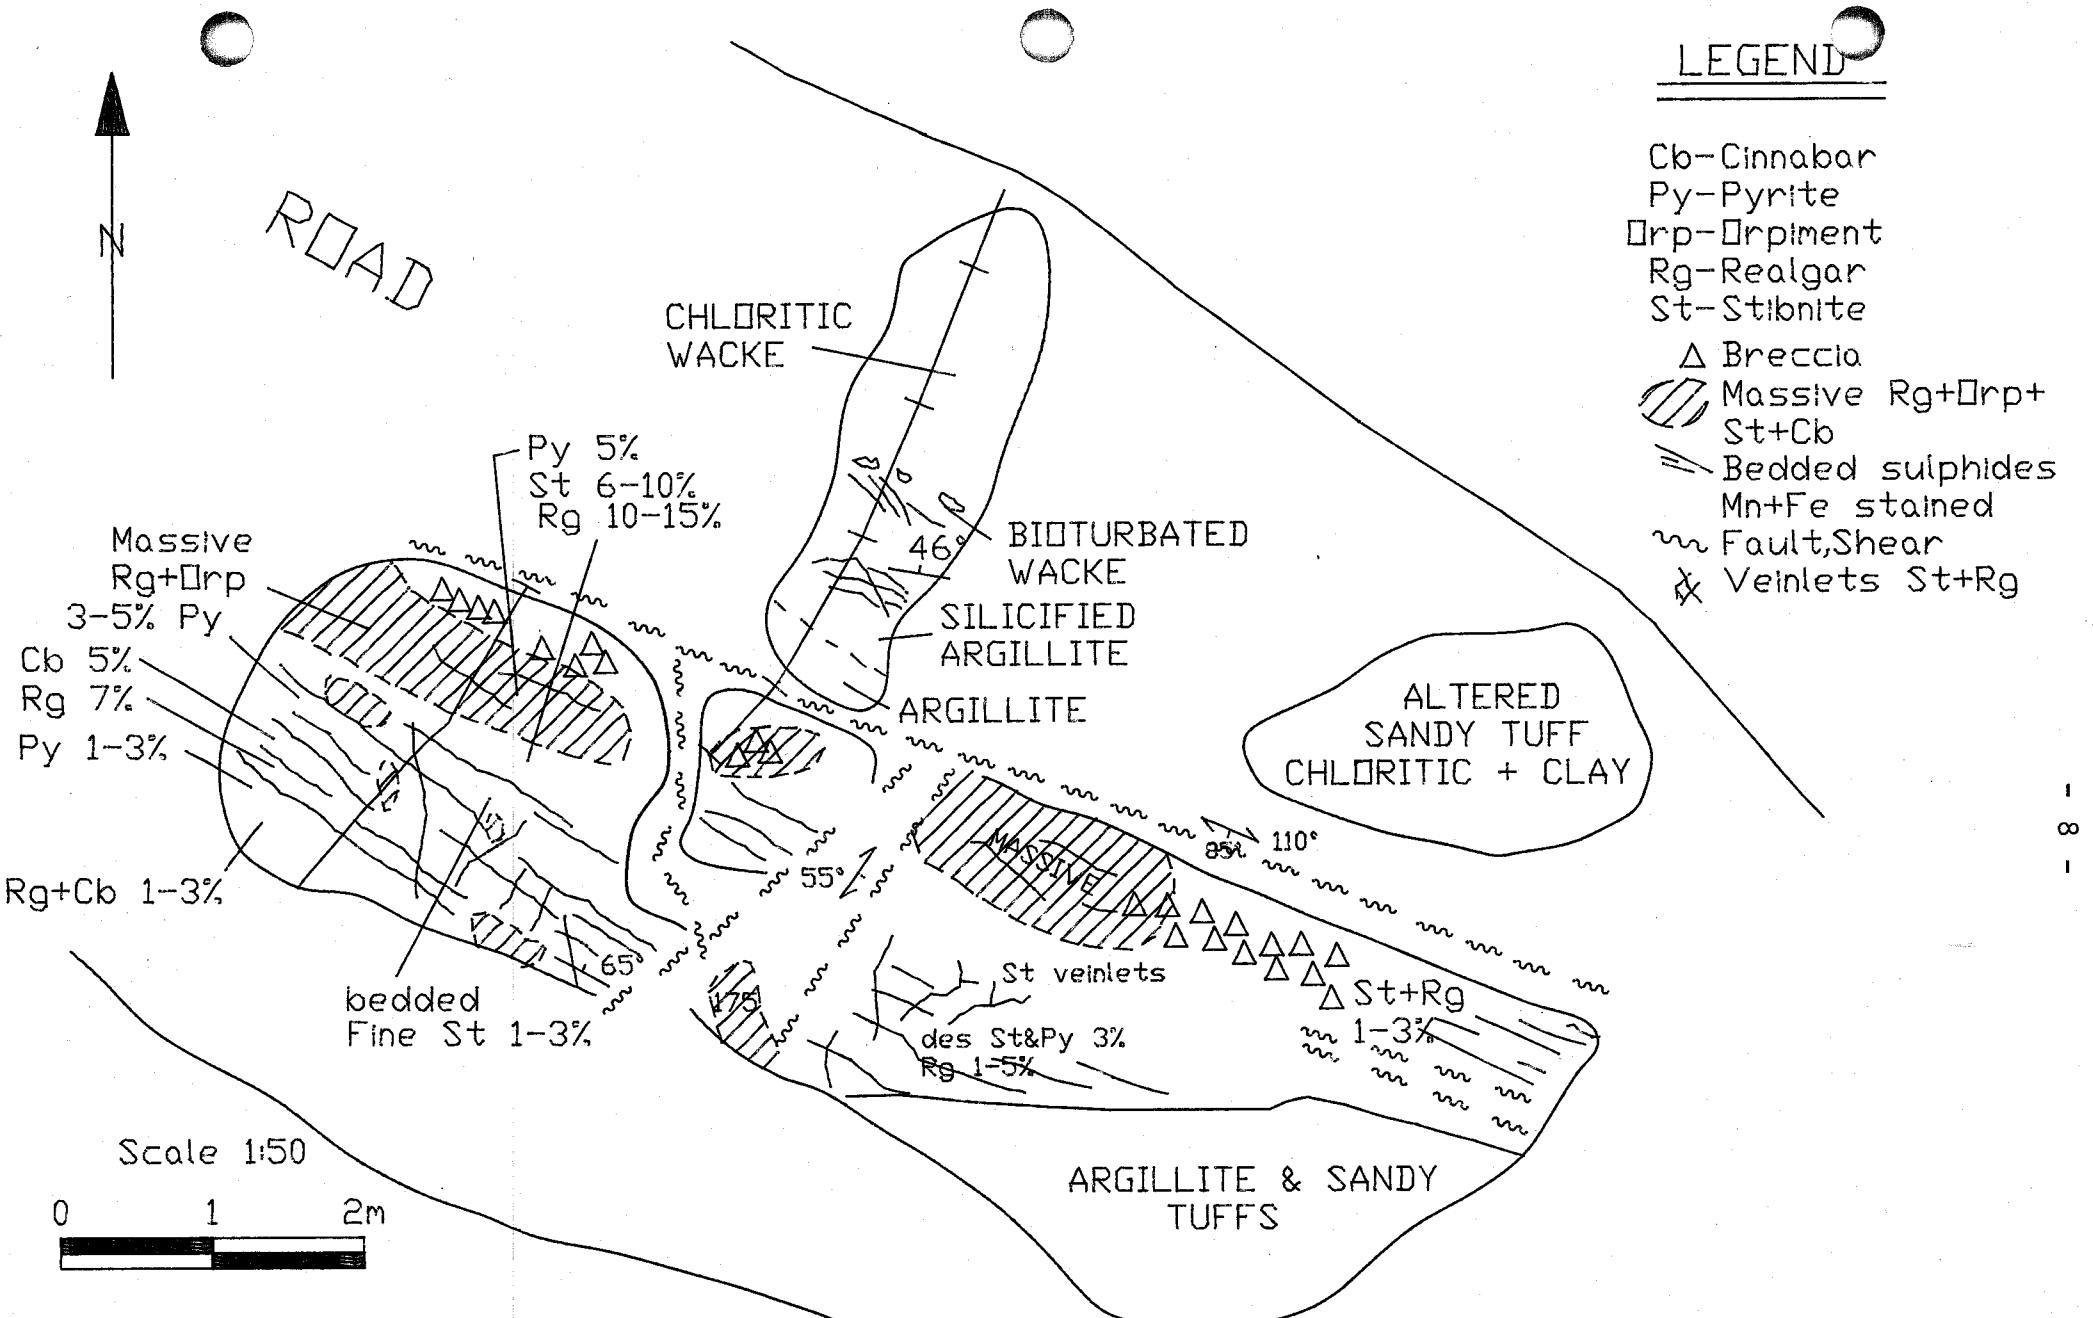

Victory Zone

The Victory Zone was found while prospecting along a newly constructed logging road. Up to 30% realgar, 5% stibnite and 5% orpiment with lesser pyrite and cinnabar occur, as massive pods, disseminations, veinlets and fracture fillings within a cherty argillaceous sandstone near the top of the Haida Formation. The showing is about $2\frac{1}{2}$ - 3 metres in width and 10 - 12 metres in length. It strikes about 110° and dips into the hill at 46° (N). The sediments are well bedded and near the top of the zone cross bedding can be observed. Bioturbation textures are common. Bedding of realgar, frambooidal pyrite and marcasite could indicate a stratabound nature of the mineralization but replacement textures also occur.

The mineralization appears to be cut off by a 110° striking 85° SW shear. Brecciated mineralization occurs on one side of the shear and is approximately 1/2 metre wide. (Figure 4)

VICTORY ZONE
GEOLOGY

GEOCHEMISTRY

Field Procedure

Soil samples were collected from road cuts in areas where favourable geology was observed. At each site, at least one "B" soil horizon sample was taken. When two samples were taken at one site, one was at 25 cm depth "B" the other at 75 cm or "C" horizon. The samples were collected using a mattock or an trowel and placed in Kraft paper bags and dried. As seen along logging roads, overburden cover is generally fairly thin (less than 1 or 2 m).

Measured representative rock chip samples were collected, using a hammer and moil, from outcrops or from the Victory showing. Fourteen rock chips were from slightly altered outcrops along a newly constructed logging road. This occurs in the central portion of Steven 1 along a northwest trending ridge. One rock sample was taken just above Ghost Creek along a logging road. The samples in general weighed 2-3 kg and consisted of small chips and fragments.

Silt samples were taken from the middle of creeks using a trowel and were placed on Kraft paper bags and dried.

The samples were sent to Chemex Labs, 212 Brooksbank Avenue, North Vancouver for analysis.

Laboratory Procedure

All samples were analyzed using Chemex's 32 element Inductively Coupled Plasma I.C.P. method, with gold being determined by a combination of both Fire Assay (F.A.) and Atomic Absorption (A.A.) technique. Mercury was analyzed by A.A. Ten samples were assayed for Au, As and Hg, and three were assayed for Sb.

Prior to analysis all soil and silt samples were dried at 60° and then sieved to -80 mesh. For the rock chips the procedure prior to analysis is as shown below.

1. Samples are sorted, then listed on assay sheets.
2. The entire sample is crushed first in a primary jaw crusher, then in a secondary cone crusher.
3. The crushed sample is reduced to a 200 - 400 gm subsample in a Jones Riffler, then dried.
4. The dried material is pulverized to pass a 100 mesh screen, then rolled to homogenize.

Analytical methods are as below:

For the 32 element ICP analysis, a 1/2 gram sample is digested with 3 ml of 3:1:3 nitric acid to hydrochloric acid to water at 90°C for 2 1/2 hours. The sample is then diluted to 10 mls with demineralized water and analyzed. The reported values for Al, Sb, Ba, Be, Ca, Cr, Ga, La, Mg, K, Na, Sr, Tl, Ti, W and U are considered to be semi-quantitative as the leach is only partial for these elements.

In the F.A. - A.A. combination method for gold, ten gram samples are fused in litharge, carbonate and siliceous flux with the addition of 10 mg of Au-free Ag metal and cupelled. The Ag bead is parted with dilute HNO₃, and then treated with aqua regia. The salts are dissolved in dilute HCl and analyzed for Au on an atomic absorption spectrophotometer. Detection limit: 5 ppb.

For mercury analysis, a 1/2 gram sample is digested with nitric and perchloric acid and diluted with 20% HCl. The mercury content is determined by cold vapor AA using a F & J scientific Hg assembly. An aliquot is added to a stannous chloride-hydrochloric acid solution. The reduced Hg is carried by bubbling air through the solution and passed into the Hg cell determined by A.A.

Fire assay techniques were used on ten rock samples for Au, As, Hg and Sb.

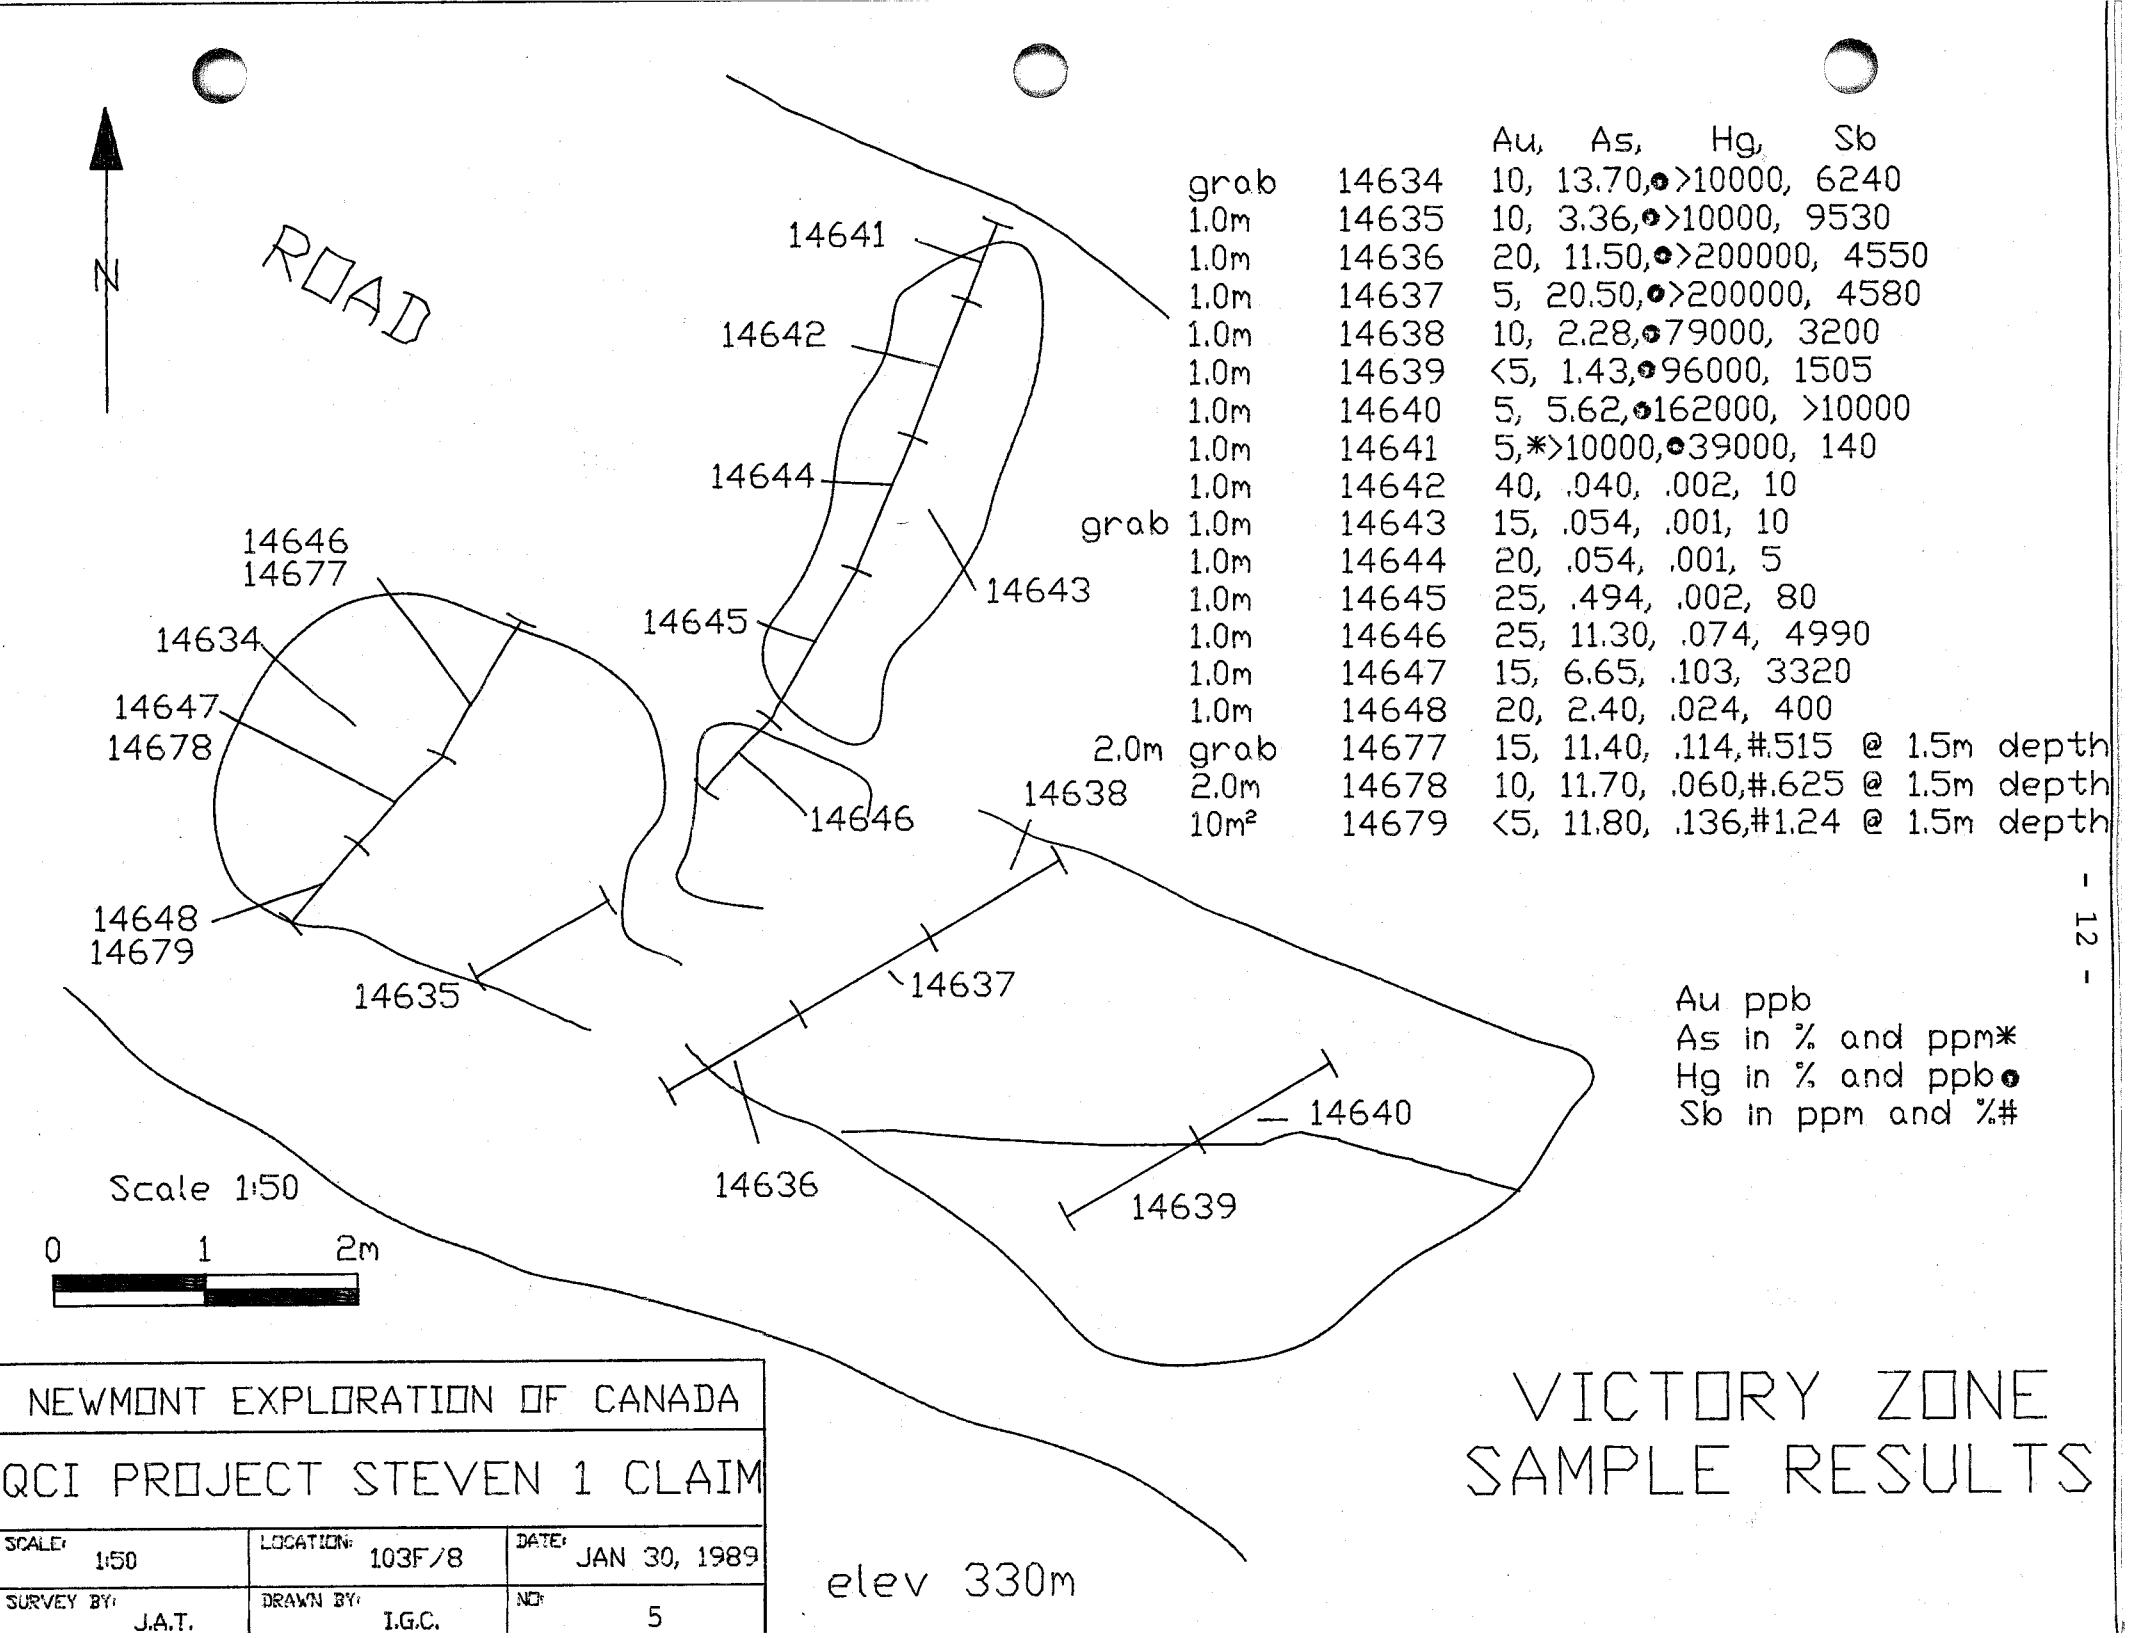

Results and Interpretation

The analytical results for rock, soil and stream sediment samples were examined, and it was decided that gold, mercury and arsenic values were of most significance and would be plotted. The sample locations are shown on Map 1 and the results plotted on Maps 2-4.

A rigorous statistical treatment of the data was not performed. From previous experience, anomalous values were arbitrarily chosen and are the same for all sample types:
Au > 10 ppb, As > 30 ppm, Hg > 1000 ppb. The results are summarized below:

Type	N = no. of samples	Au (ppb) Range	N	As (ppm) Range	N	Hg (ppb) Range	N	Sb (ppm) Range	N
Soils -									
Silts	152	<5-<10	139	1- <30	57	30-<1000	123	1-10	152
		10-50	13	30-1705	95	1000-28000	29		
Rock	33	1-<10	11	5-<30	6	20-<1000	17	5-<80	19
		10-40	22	30-20.5% 27	27	1000->.2%	16	80-.625% 14	

% percent where indicated

Soils and Silts

Gold content of the samples is low, with only 13 samples at >10 ppb. Two samples of 34 and 50 ppb occur together 1000m SE of the Victory Zone. A large As and Hg anomaly also occurs here. Sheared argillites of the Haida Formation are mapped nearby.

A large 3 km long x 300m wide As and Hg anomaly occur along a NW trending logging road. Values run up to 1705 ppm As and 28000 ppb Hg. The Victory Zone occurs near the northwest end of this anomaly. Haida Formation argillites and sandstones underlie this anomalous zone.

Several samples came from a well developed C horizon and inspection of the data shows enhanced values for both Hg and As.

Other elements analyzed by the ICP technique show low overall results.

Rock Samples - Victory Zone

The Victory Zone was found while prospecting along a newly constructed logging road. The first set of samples #14634 to #14640 were taken during construction when only part of the showing was visible. Blasting nearby hampered sampling. The second set of samples 14641 to 14648 were taken after hand trenching, Figure 5. The third set of samples #14677 to #14679 were taken after rock blasting by the logging road contractor. Fortunately, about 1.5 metres of rock was removed revealing large boulders of massive to semi-massive realgar mineralization. A 2 metre chip of one boulder yielded 11.7% As, .625% Sb,.06% Hg and 10 ppb Au. A chip from several boulders over a 10m square area yielded 11.8% As, 1.24% Sb, .136% Hg and <5 ppb Au. The mineralization is well bedded (realgar) and fracture controlled. Realgar + stibnite and the more massive (fractures) sections contain up to 10 cm of 20.7% As or 30% realgar.

On the next visit to the showing the road was fully constructed and all bedrock exposure was infilled. Only mineralized boulders remain on the side of the road.

Other elements analysed by the ICP technique show low overall results.

Rock Samples - Conglomerate Unit

Fifteen rock chip samples were taken along a newly constructed logging road along a NW trending ridge where rock exposure is about 40%. The chips were spaced about 10m apart and were 2 - 3 metres in width.

Gold content of the samples is low and all were at or below detection limit.

Mercury was quite low and the values ranged from 200 ppb to 530 ppb. The conglomerate contains chlorite - pyrite and varying amounts of clay.

Arsenic was only slightly anomalous with 9 of 15 samples >30 ppm. Five samples of >100 ppm were from the top ridge where one 2m chip ran 535 ppm As. This sample is from an argillically altered sandstone.

Antimony was quite low in all rock samples. The values were all <5 ppm Sb.

Other elements analyzed by the ICP technique show low overall results.

SUMMARY AND CONCLUSION

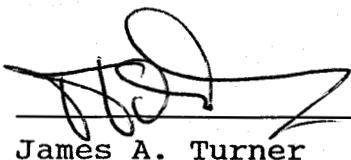

Twenty days in 1988 were spent by Newmont personnel on the STEVEN property conducting a limited amount of roadside prospecting, geological mapping and geochemical sampling. The purpose of the program was to explore the property for epithermal style gold mineralization.

A new arsenic showing, the Victory Zone, was discovered along a logging road. The showing runs about 11.7% As over 2m with minor amounts of Sb and Hg and low Au. A large 3 km x 200m soil anomaly extends NW-SE along this road. Values run as high as 28000 ppb Hg, 1705 ppm As and 50 ppb Au. This anomaly is almost parallel to a argillaceous sandstone-cobble conglomerate contact.

It is felt that this environment, although not anomalous for Au, has all the right indicators for an epithermal style Au deposit.

RECOMMENDATION

It is purposed to complete the geologic mapping over the entire property, rock chip sample all outcrops and thoroughly prospect the area.

James A. Turner
