1.0 Introduction

The Tchentlo Claims (LO 1 to LO 11) were staked in 1988 to cover an area of anomalous gold-in-silt samples that are located along a splay of the Pinchi Fault.

This report deals with the follow-up work that was conducted on the property from August 19 to September 23, 1988 by G. Shevchenko, assisted by D. Travers. The exploration program was designed to define the geology and mineralizing environment and follow-up the existing gold-in-silt anomalies with the aim of better defining areas anomalous in gold.

The geophysical portion of the report is written by R. Cannon, while the remainder of the report is written by G. Shevchenko.

1.1 Location and Access (Figure #1)

The property, centred at UTM coordinates 35800E 611800N, is located on the south shore of Tchentlo Lake, approximately 106 kilometres northwest of Fort St. James, British Columbia.

Access from Fort St. James is provided by the Tachie, Leo Creek and Leo-Tchentlo logging roads. The Leo-Tchentlo Road, which is currently under construction, affords direct access onto the claims. The condition of the roads are excellent as logging in the area is currently under way.

1.2 Topography and Physiography

The property is situated on the Nechako Plateau which is defined by rolling terrain that has elevations varying from 900 to 1525 meters above sea level. The ridges and lakes generally have a northwesterly grain, and the areas between the ridges can be swamp-filled or thickly covered with overburden. Hence rock exposure in the plateau is usually at a minimum.

Timber in the vicinity is mostly lodgepole pine and spruce. The forests vary from open to heavily underbrushed with alder and devils club.

1.3 Work History

There is no record of exploration having been done on the claims prior to 1988. However, the areas north and northwest of the property has had extensive porphyry copper and some epithermal gold exploration.

1.4 Summary of Work Done

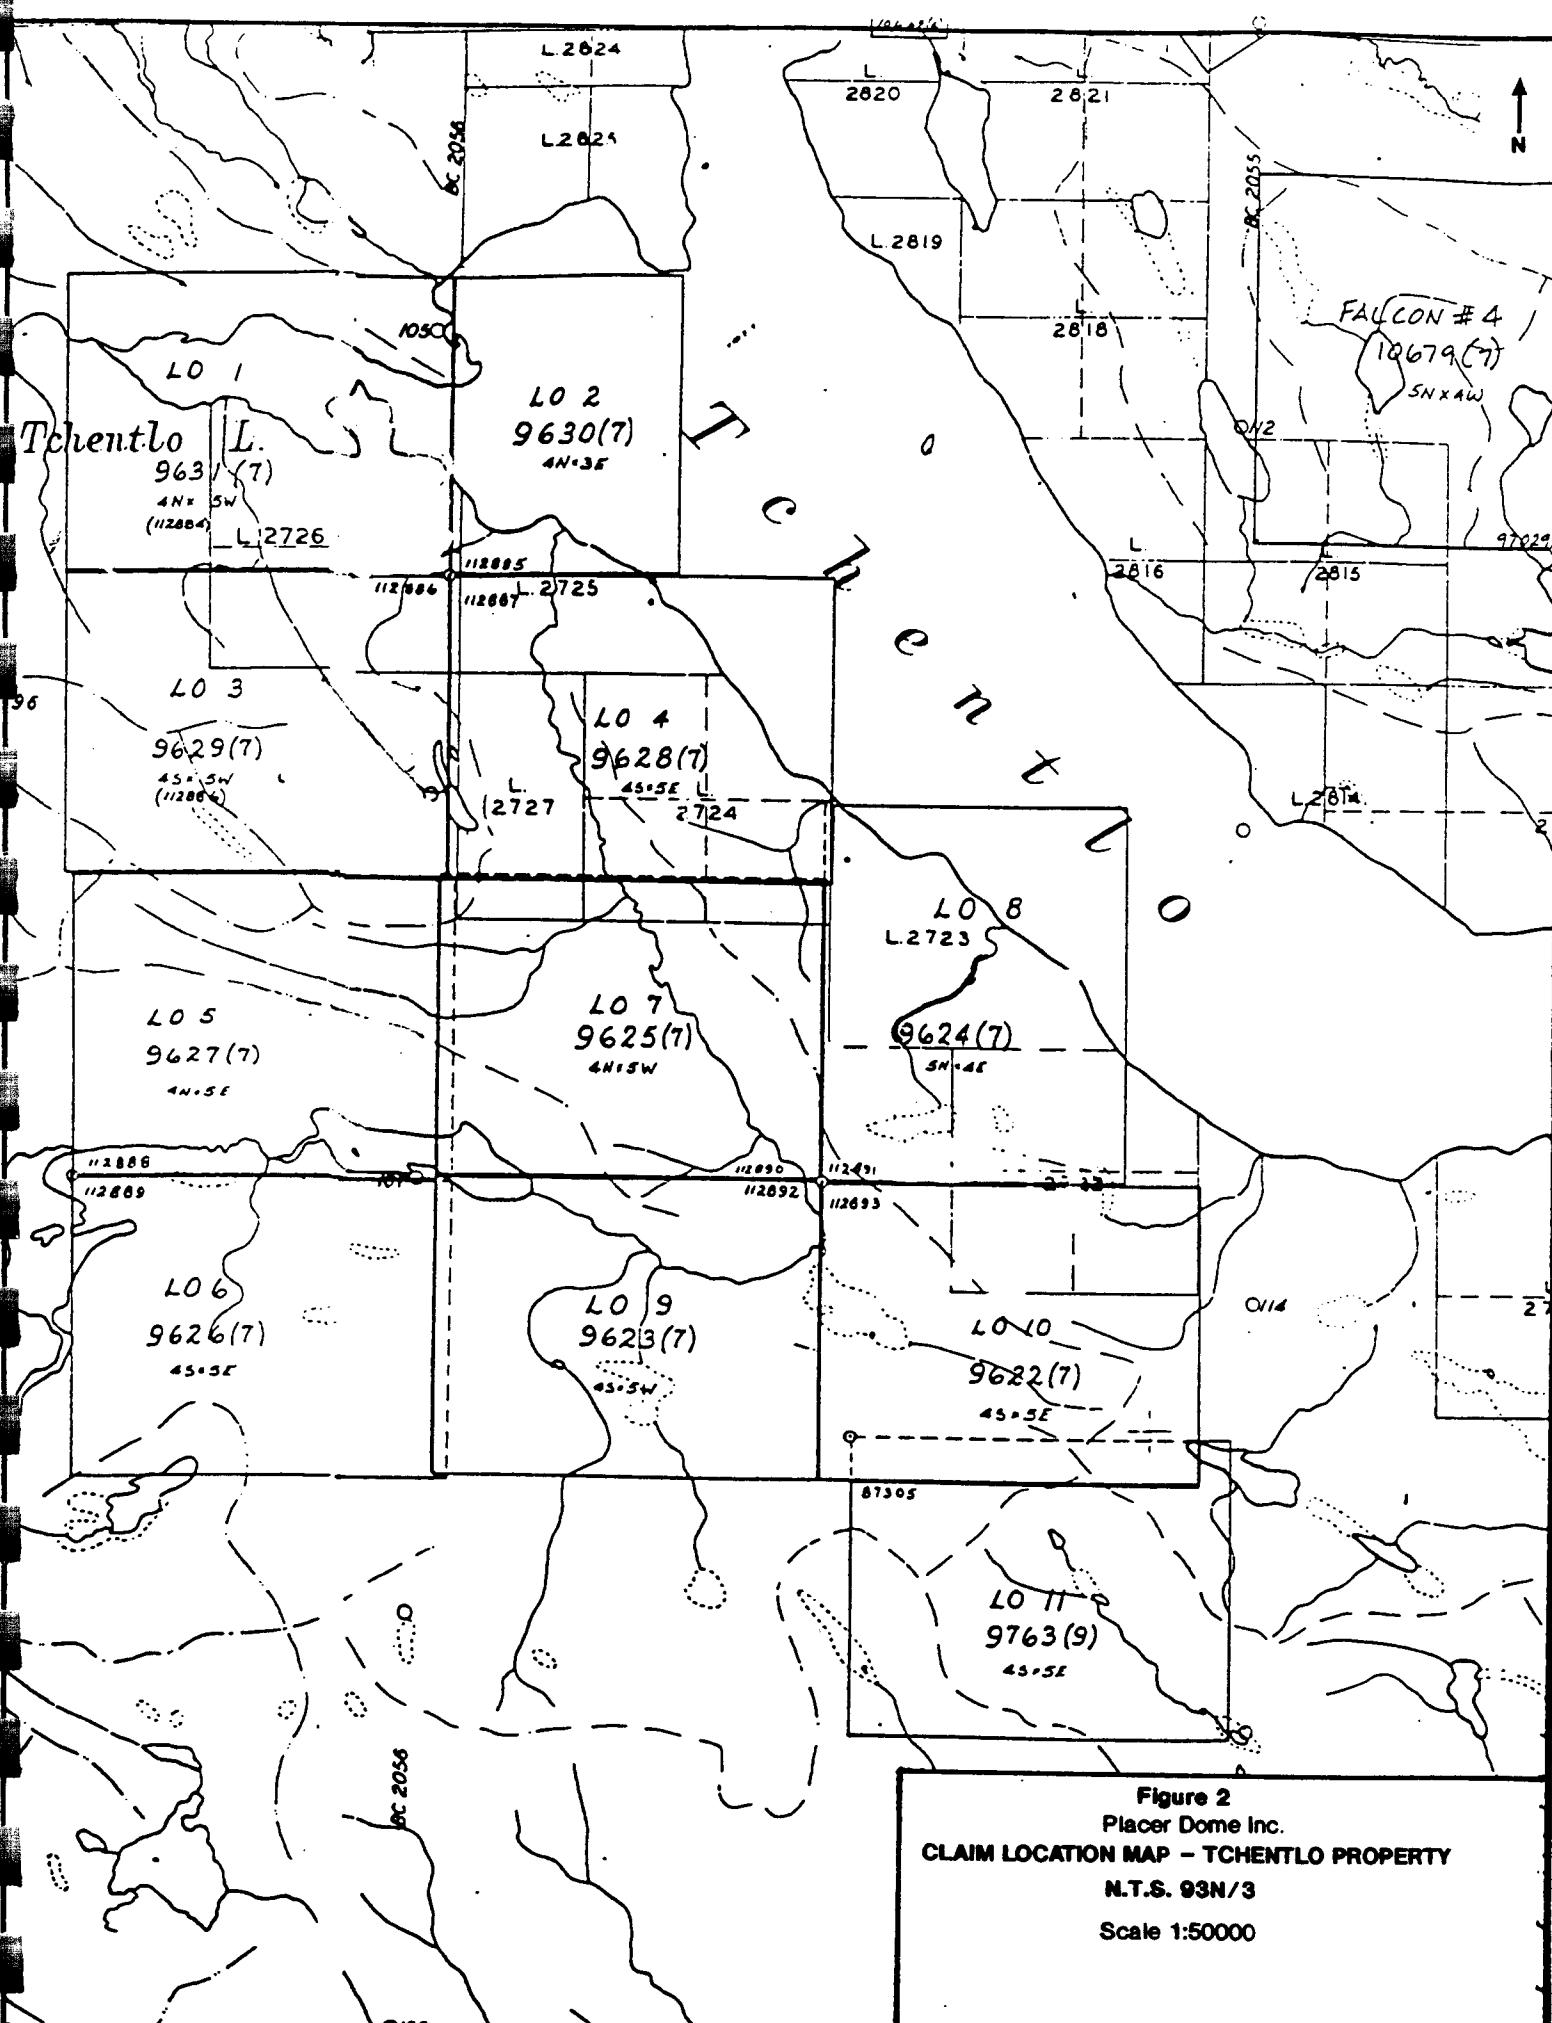

The exploration program consisted of bulk sediment and heavy mineral sampling (44 bulk samples, 3 heavy mineral samples) along creeks, sampling of rock outcrop and float (28 samples), geological mapping (the property at a scale of 1:10,000, the

Figure 1

PROPERTY LOCATION MAP

0 100 200 300 400 500 Kilometres

grid at a scale of 1:2,500), line cutting (6.7 line-kilometres), a VLF-EM survey (5.78 line-kilometres) and a soil orientation survey (318 samples).

1.5 Claim Status (Figure #2)

The claims are wholly owned by Placer Dome Inc. of Vancouver, British Columbia. The following table outlines the specifics for each of the claims:

Claim Name	Record No.	Units	Record Date	Expiry Date
Lo 1	9631	20	July 29/88	July 29/90
Lo 2	9630	12	"	"

Lo 11	9763	20	Sept. 1/88	Sept. 1/91

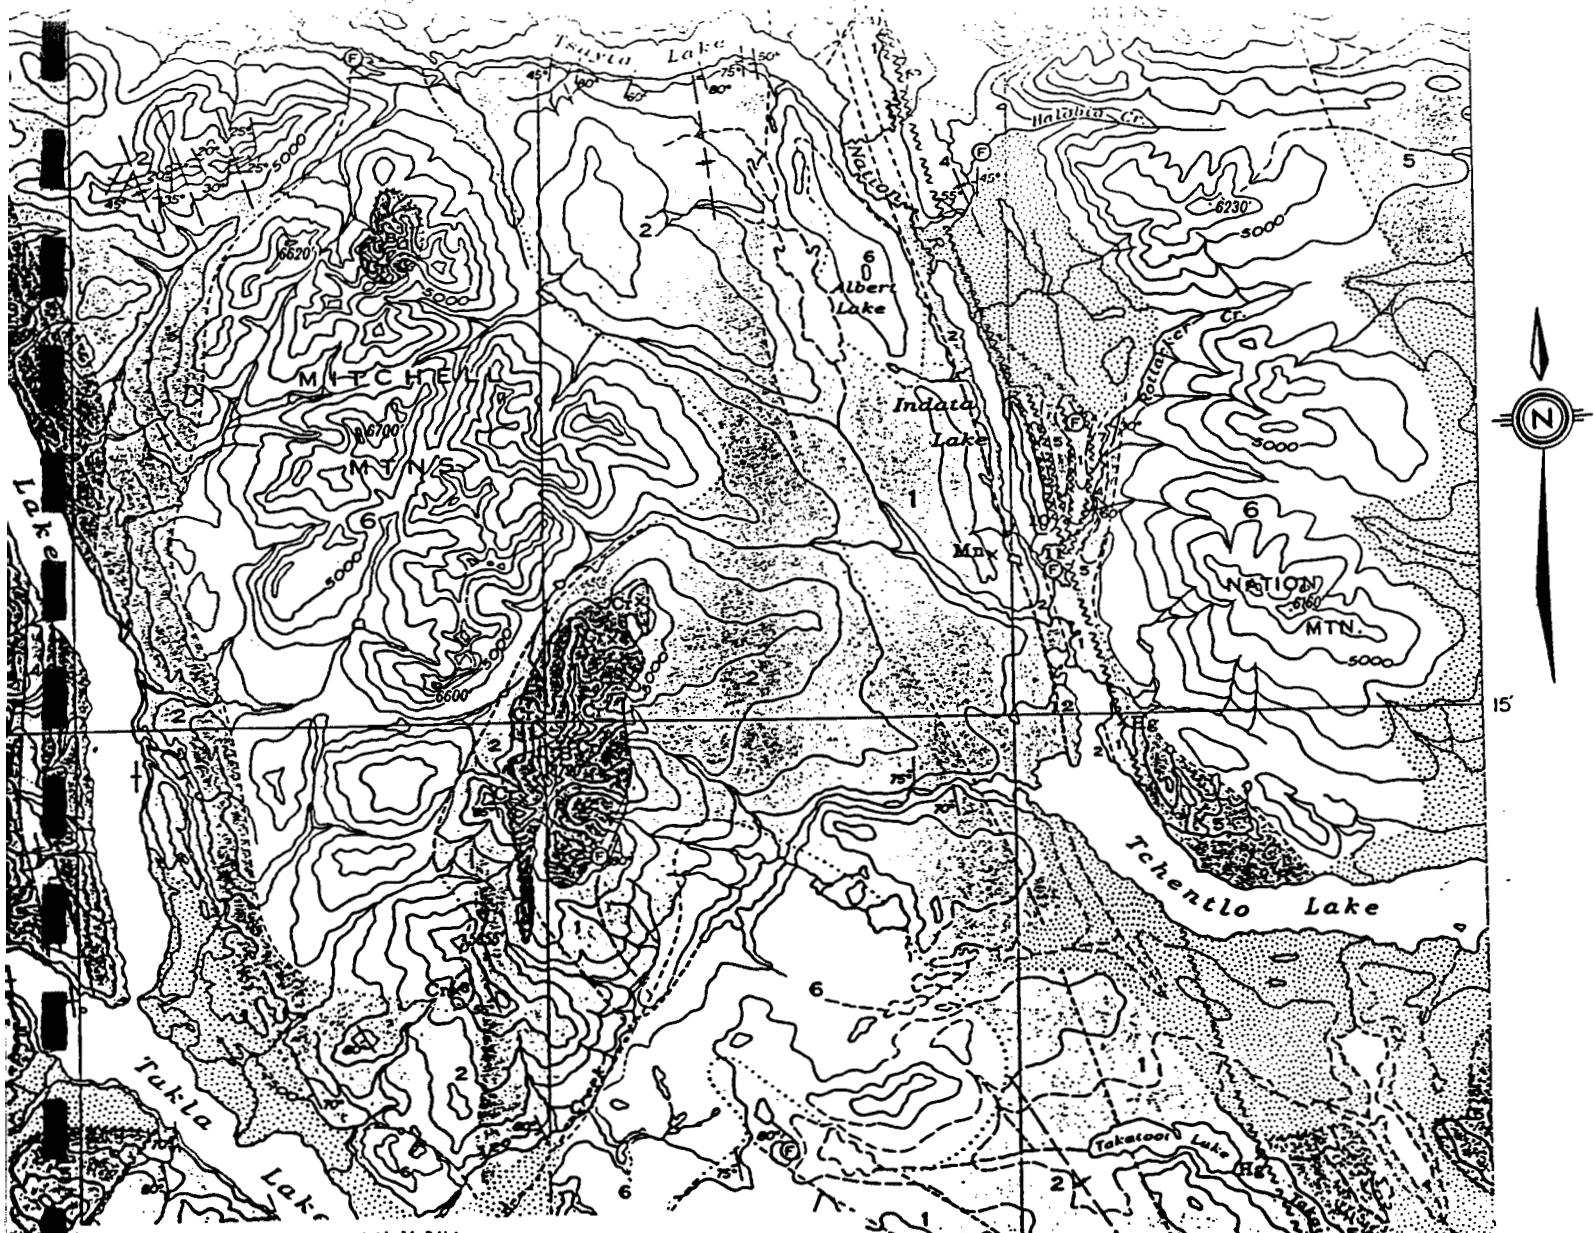

2.0 Geology

2.1 Regional Geology (Figure #3)

The Tchentlo Property is located near the northern end of the Pinchi Fault which separates the Upper Paleozoic metavolcanic and sedimentary strata of the Cache Creek Group to the west from the Mesozoic volcanic strata of the Takla Group to the east.

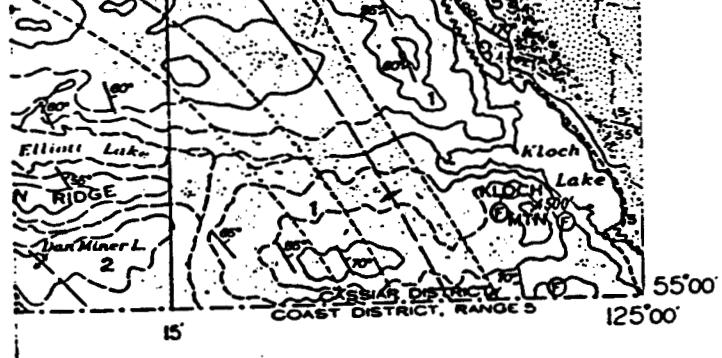

"The presence of ultramafic bodies along the regional structure infers a zone of deep crustal weakness favourable for the generation of hydrothermal-related precious metal deposits. A linear belt of mercury occurrences, including the Pinchi Lake and Bralorne Takla Mines, coincides with the trace of the fault. The mercury and placer gold bearing streams substantiate that the geological environment along the Pinchi Fault has the potential to host precious metal deposits. A hot spring situated at the north end of Tchentlo Lake is currently depositing mercury-laden mud, illustrating that geothermal cells are still active along the fault."¹

Property Geology

Figure #3

NTS 93N

2.2 Property Geology (Figure #4 & #5)

Exposure on the property is quite limited (less than 5%) with outcrops mainly occurring along creeks, road cuts and ridge tops.

Geological mapping has been restricted to the central portion of the property and was conducted at a scale of 1:10,000.

The claims are underlain by a north-northwesterly trending package of Upper Paleozoic Cache Creek rocks (consisting of massive limestone with lesser sandstone and chert), which has been intruded by Mesozoic ultramafic rocks (mainly pyroxenite). Structural measurements on the attitude of these units are generally unattainable.

Local brecciation and shearing occurs within both the ultramafic and Cache Creek rocks, and is a result of a moderate to steeply dipping north-northwesterly trending shear that is parallel to the strike of the Pinchi Fault. Hydrothermal fluids have resulted in local listwanitic and quartz-carbonate alteration of the ultramafic rocks. The minimal percentage of quartz, carbonate and chalcedonic veinlets suggests that the system was rather dry after the initial stage of shearing and alteration.

Sulphides along the structure are rare, however, local disseminations of pyrite and trace cinnabar do occur with the quartz, carbonate and chalcedonic veinlets.

A central north-norhtwesterly striking shear structure lines up quite nicely with the hot springs to the north, the main creek in the centre, and various alteration and shear textures occurring on the Bar Grid in the south part of the property. As a result the overall structure may have a strike length of some 7 kilometres.

2.3 Grid Geology (Figure #6)

The grid, located in the southeastern corner of the property (see figure #5), trends at 150 degrees true north and totals 6.7 line-kilometres. The baseline is 1 kilometre long and has six crosslines spaced 200 meters apart with a station interval of 20 meters.

Geological mapping was carried out at a scale of 1:2,500. Rock exposure on the grid is limited, hence the geological interpretation is based upon mapping as well as the results from the VLF-EM survey.

The primary rock types which underlie the grid are comprised of a northwest trending package of pyroxenite and olivine basalt intercalated with a thin slice of immature sandstone. In the central portion of the grid just east of the baseline the rocks have been sheared and hydrothermally altered resulting in a zone of listwanitic and quartz-carbonate altered mylonite of varying degree. The altered area may vary in width from 140 to 240 meters.

As interpreted from the VLF-EM map, there appears to be evidence of

northeast cross faulting around lines 5100N and 4900N.

Sulphide mineralization is rare with 1% to 2% very fine grained pyrite occurring in the area of line 4600N, station 10240E, while trace amounts of cinnabar (4800N, 10230E and 5050N, 10060E) occur within the quartz and chalcedonic veinlets which are hosted in the listwanitically altered pyroxenite unit (A-1).

In conclusion, the minimal percentage of quartz, carbonate and chalcedonic veinlets within the listwanitic zone, the trace presence of cinnabar, and the general lack of sulphides indicates that the system was rather dry after the initial stage of shearing and alteration. This suggests that the area would be high up within an epithermal model.

3.0 Geochemistry

Bulk sediment, heavy mineral, lithogeochemical and soil orientation sampling surveys were conducted over various portions of the property. The following sections (3.1 to 3.4) deals individually with each of the type surveys.

3.1 Bulk Sediment Sampling Survey

A sampling technique called bulk stream sediment sampling was developed "in-house" by Placer Dome's exploration personnel. It is specifically designed for use in detailed and semi-detailed stream sediment geochemical surveys where gold mineralization is the target of interest. This exploration technique was employed on the Tchentlo property.

A total of 44 bulk samples were taken on the property, resulting in the main creeks being sampled at an interval of 250 to 500 meters and the tributaries sampled just upstream from the mouth.

3.1.1 Bulk Sample Collection, Preparation and Analyses

Bulk stream sediment samples were collected from natural drop-out sites for heavy minerals in the stream channels; examples of these sites include plunge pools, riffles and the upstream side of channel bars. Clastic stream sediments from the selected sites were wet sieved through a -20 mesh stainless steel screen and caught in an aluminum basin. A steel shovel was used to dig up the sediment. A single deep excavation is preferable to take advantage of multiple depositional cycles and to avoid undue influence from very local additions to the stream bed load. Approximately two to three kilograms of sieved fraction were collected.

The bulk stream sediment samples were forwarded to Placer Dome's analytical laboratory in Vancouver, British Columbia, where they were oven-dried and sieved to produce a -150 mesh fraction. This fraction was geochemically analyzed for Au, Ag, As, Cu, Zn, Pb, Mo, Ni, and in some cases Ba and Sb. Each sample was

analyzed three times for gold in an attempt to address the problem of erratic gold distribution in natural materials (i.e. the "nugget-effect"). The table in Appendix 5 summarizes the extraction and detection techniques used by the laboratory.

3.1.2 Discussion of Bulk Sediment Results

Upon review of the results, the only elements of significance are gold (Au) and arsenic (As). The results are tabled in Appendix 1, as well they may be viewed on figures #7 and #8, where gold and arsenic values are plotted along with the sample number.

Gold

Out of 44 samples taken, only 6 samples returned gold values which were within detection limits, and are tabled as follows:

Sample Number	Au Value (ppb)
BS-11	10
BS-21	15
BS-22	15
BS-26	1480
BS-27	85
BS-37	205

Although the anomalous samples are few, the area of greatest significance, which is outlined by samples BS-21, BS-22, BS-26 and BS-27, is located in the central portion of the property where the main creek makes a sharp turn to the west.

Sample BS-37 is situated close to the mouth of a creek that is located just west of the hot springs. This is the only anomaly on this creek, as samples further upstream did not produce any anomalous gold values.

Arsenic

The arsenic values are generally quite low as they range from less than 2 parts per million to 18 parts per million (ppm). Values of 12 ppm and greater are considered anomalous, and hence only four anomalous sample sites occur:

Sample Number	Value (ppm)
BS-11	15
BS-17	12
BS-18	18
BS-26	14

Although the relationship is somewhat tenuous, there is a partial correlation of increased arsenic values with increased gold values, as indicated by BS-11 and BS-26.

Samples BS-11, BS-17 and BS-18 occur in an area where minor northwesterly shearing and/or listwanitic alteration have been mapped. Sample BS-26 occurs along the inferred main northwesterly shear structure.

3.1.3 Interpretation of Bulk Sample Results

There appears to be a correlation of increased gold and arsenic values in areas of shearing or inferred shearing. The large anomalous area on the main creek, which was discussed above, may be a result of an east-west cross structure intersecting the main northwesterly shear (as defined by the trend of the main creek). This intersection of structures may act as a structural trap for mineralizing fluids.

3.2 Heavy Mineral Sampling Survey

3.2.1 Heavy Mineral Sample Collection, Preparation and Analysis

Heavy mineral samples were collected by wet sieving clastic material through a -20 mesh stainless steel screen. A steel shovel was used to obtain the raw material. The sieved fraction was retained in a large plastic bag. Approximately 7-8 kilograms of sieved material was collected for each heavy mineral sample. Sample sites were chosen to take advantage of natures concentration of heavy minerals (i.e. native gold, sulphides within specific flow regimes of the active streams).

The heavy mineral samples were shipped to C.F. Minerals in Kelowna, B.C. for preparation in to 18 different fractions for each sample. These fractions were made from the original samples by separation first on size (sieving), second on specific gravity (heavy liquid) and finally on magnetic susceptibility (electro magnetic separator). Explanation of the code for heavy mineral separates is given with the results in Appendix 2. The heavy mineral fractions were shipped to Activation Laboratories Ltd. in Brantford, Ontario.

The entire sample fractions were irradiated for four hours at a thermal neutron flux of $1 \times 10^{12} \text{ n cm}^{-2}\text{s}^{-1}$. After a decay period of seven days, to allow for the activity from Na-24 to decay, the samples were then counted on a high purity germanium detector and the gamma spectrum then analyzed on line by computer. Samples deemed to be anomalous and random samples were then remeasured as a quality control feature. Multi-element reports were then generated for the elements required automatically by computer.

3.2.2 Discussion of Heavy Mineral Results

The sample location and gold results are plotted on Figure #7, as well they are tabled in Appendix 2. Two out of the 18 sample fractions analyzed are anomalous in gold, HM-1351 (-150 HN) is 2510 parts per billion (ppb), and, HM-1352 (-150 HN) is 823 ppb.

3.2.3 Interpretation of Heavy Mineral Results

Both of the anomalous sample fractions are located in creeks that drain the main northwesterly shear, and are in the vicinity of the area of anomalous gold-in-bulk samples.

3.3 Lithogeochemical Sampling Survey

3.3.1 Rock Sample Collection, Preparation and Analysis

Grab samples were collected from float and bedrock exposures and sent to Placer Dome's Vancouver laboratory for analysis. The samples were crushed and pulverized, a subsample was weighed, then digested, and finally analyzed geochemically for Mo, Cu, Zn, Pb, Ni, Ag, As and Au, and in some cases Ba and Sb. The table in appendix 5 summarizes the extraction and detection techniques used by the laboratory.

3.3.2 Discussion of Lithogeochemical Results

The analytical results and rock sample descriptions are found in Appendix 3.

None of the rock samples collected turned out to be anomalous in Au, Ag, Ba, Mo, Cu, Zn or Pb.

The nickel values range from 18 ppm to 0.25 %. The high nickel values are not considered anomalous, as they occur in the ultramafic rocks, or altered facies thereof, and thus are a result of the inherent high nickel content of them.

The arsenic values range from less than detection limits to 450 ppm, while the antimony values range from 1 to 32 ppm. In all cases, the elevated arsenic and antimony values occur in the altered facies (listwanitic and/or quartz carbonate) of the ultramafic rocks.

3.3.3 Interpretation of Lithogeochemical Results

The anomalous arsenic and antimony values found within the listwanitic and quartz-carbonate altered rocks suggest that an epithermal process has been active.

Thus, these two elements should be good pathfinder elements for a soil geochemical survey.

3.4 Soil Geochemical Orientation Survey

A soil geochemical orientation survey was conducted on lines 5000N, 4800N and a portion of 4600N of the Bar Grid, which is located in the southeastern area of the claims. The purpose was decide which soil horizon and size fraction is most suited for the concentration of gold, arsenic and antimony, and thus govern the procedures for future soil sampling surveys on the grid.

3.4.1 Soil Sample Collection, Preparation and Analysis

Soil samples were obtained by digging holes with a shovel to depths of 80 to 120 centimetres. Wherever possible, Ao, B and C horizons were sampled and placed in "Hi Wet Strength Kraft 3.5 inch x 6 inch Open End envelopes". Horizon type and grid co-ordinates were marked on the envelopes with a permanent ink felt marker.

The B and C-horizon soil samples were prepared and analyzed by Placer Dome's Geochemical Laboratory at Vancouver, B.C. The A-horizon soil samples were prepared and analyzed by Activation Laboratories Limited at Brantford, Ontario.

The B and C-horizon soil samples are first dried in a hot air dryer and then separated by sieving to coarse (-10 to +80 mesh) and fine (-80 mesh) fractions. The table in Appendix 5 summarizes the extraction and detection techniques used by the laboratory.

The Ao-horizon samples were dried at 60 degrees centigrade for 24 hours or longer depending on how wet the samples were. The dried material was then macerated in a Wyllie mill. Eight grams were then weighed on a Kimwipe which was placed into a briquetting press and compressed under 30,000 PSI to form a wafer enclosed in a Kimwipe. The briquettes were then irradiated for four hours at a thermal neutron flux of $1 \times 10^{12} \text{ n cm}^{-2}\text{s}^{-1}$. After a decay period of seven days, to allow for the activity from Na-24 to decay, the samples were then counted on a high purity germanium detector and the gamma spectrum then analyzed on line by computer. Samples deemed to be anomalous and random samples were then remeasured as a quality control feature. Multi-element reports were then generated for the elements required automatically by computer.

3.4.2 Discussion of Soil Orientation Survey Results

The analytical results are tabled in Appendix 4, as well, the profiles are plotted on figures #9 to #17 (incl.).

For the purposes of this survey, only gold, arsenic and antimony were deemed

significant and thus are discussed.

The following table summarizes the statistical analysis for the gold, arsenic and antimony content in each of the soil horizon/fractions:

Element	Horizon	#Samples	Min Value	Max Value	Mean	Std. Dev.
Au	Ao	120	< 1 ppb	8.0 ppb	0.7	0.8
Au	B-Coarse	93	< 5 ppb	20.0 ppb	3.2	3.3
Au	B-Fine	93	< 5 ppb	20.0 ppb	3.0	2.4
Au	C-Coarse	105	< 5 ppb	50.0 ppb	4.7	5.9
Au	C-Fine	105	< 5 ppb	75.0 ppb	4.4	8.0
As	Ao	120	< 1 ppm	40.0 ppm	1.5	3.9
As	B-Coarse	93	< 2 ppm	56.0 ppm	8.5	11.1
As	B-Fine	93	< 2 ppm	63.0 ppm	9.9	10.6
As	C-Coarse	105	< 2 ppm	550.0 ppm	14.8	54.5
As	C-Fine	105	< 2 ppm	1020.0 ppm	20.6	99.5
Sb	Ao	120	< 0.1 ppm	14.0 ppm	0.9	2.4
Sb	B-Coarse	93	< 2 ppm	35.0 ppm	2.2	5.1
Sb	B-Fine	93	< 2 ppm	16.0 ppm	1.6	2.5
Sb	C-Coarse	105	< 2 ppm	30.0 ppm	2.0	3.9
Sb	C-Fine	105	< 2 ppm	23.0 ppm	1.8	2.8

Gold (Figures #9, #12 & #15)

The Ao-horizon and the coarse and fine fractions of the B-horizon yielded only spot anomalies and/or anomalies of very low order.

On line 4800N both the coarse and fine fractions of the C-horizon produced multiple station anomalies of moderate order, however, on lines 4600N and 5000N the fine fraction did not host any gold anomalies whereas the coarse fraction at least had some gold response. Thus it is found that the coarse fraction of the C-horizon produced the best overall response with respect to the concentration of gold.

Arsenic (Figures #10, #13 & #16)

The Ao-horizon generated only small anomalies of low magnitude.

The coarse and fine fractions of both the B and C-horizons had very similar responses with respect to the concentration of arsenic. The resulting anomalies are quite widespread (ie: up to 350 metres in width) and generally moderate to high in magnitude. Although the arsenic anomalies are coincident with respect to each of the horizon-fractions, it is found that the fine fraction of the C-horizon has a marginally better response as the magnitude of the anomalies are slightly greater.

Antimony (Figures #11, #14 & #17)

The Ao-horizon consistently hosts multiple station antimony anomalies on all three lines. Though the anomalies are subtle, as the Ao-horizon would inherently have a lower background than the corresponding B and C-horizons, they are quite anomalous in nature.

The coarse and fine fractions of the B-horizon host moderate intensity anomalies, however they do not depict all of the anomalous areas, and the ones which are delineated are not as widespread as the corresponding anomalies that are hosted in the Ao and C-horizons.

The coarse and fine fractions of the C-horizon depict most of the anomalies on lines 4800N and 5000N, however on line 4600N only the coarse fraction hosts areas of anomalous antimony. The anomalies are generally of moderate magnitude.

It would appear that the Ao-horizon is best suited for hosting antimony anomalies, with the coarse fraction of the C-horizon being a close second choice.

3.4.3 Interpretation of the Soil Orientation Survey

Overall, the coarse fraction of the C-horizon is best suited to host anomalous concentrations of gold, arsenic and antimony.

4.0 VLF-EM Survey (Figures #18 & #19)

A VLF-EM survey was conducted along 5.78 km of line and covered six lines. This survey used the Seattle transmitting station NLK (24.8 kHz) with readings being taken at 20 m stations. The direction to the Seattle station was 165° Az and therefore readings were taken facing 075°. The grid lines were at 060° Az.

4.1 Instrumentation and Procedure

The VLF-EM survey was conducted using a Geonics EM-16 which used the Seattle transmitting station. VLF readings were recorded in a notebook and subsequently entered onto the Sun Microsystems work station for final processing and plotting.

4.2 Survey Results

The VLF survey results were plotted as stacked In-phase, Quadrature and Fraser Filter profiles on a plan map at a scale of 1:2500. Contoured Fraser Filter data has also been presented as a plan map. The Fraser Filter data was calculated

as per the method put forth by D.C. Fraser (1969, Contouring of VLF-EM data: Geophysics, v.34, p. 958-967). See maps in the folder at the back of report.

4.3 Discussion of VLF-EM Results

Numerous conductors were detected by the VLF survey. These conductors, as seen on the accompanying plates, trend at approximately right angles to the grid lines (330° Az). The conductor axes tend to be offset by two major breaks which trend at approximately 095° true azimuth.

5.0 Conclusions

The property, which covers a north-northwest trending splay of the Pinchi Fault, is underlain by Cache Creek sediments that have been intruded by later stage ultramafic sills. The main shear structure, which represents a conduit for an epithermal system, appears to be defined by the main central creek and lines up with the hot springs and various alteration and shear textures that have been mapped. As a result the overall structure may have a strike length of some 12 kilometres. Listwanitic alteration, minor quartz-carbonate and chalcedonic veining, trace to occasional occurrences of cinnabar and pyrite, and, anomalous concentrations of arsenic and antimony suggest that an epithermal process has been active along the shear zone. However, the minimal amount of veining, the trace presence of cinnabar, and the general lack of sulphides indicates that the system was rather dry after the initial stage of shearing and alteration and that the areas exposed so far are rather high up in an epithermal system.

The bulk and heavy mineral sampling survey outlined an area of anomalous gold values which is located in the central portion of the property where the main creek makes a sharp turn to the west. This area may be a result of an east-west cross structure intersecting the main northwesterly shear (as defined by the trend of the main creek). This intersection of structures may act as a structural trap for mineralizing fluids.

The soil orientation survey results indicate that, overall, the coarse fraction of the C-horizon is best suited to host anomalous concentrations of gold, arsenic and antimony.

The area of the Bar Grid that is located east of the baseline is much more geochemically anomalous than that which is located west of the baseline.

The gold-in-soil anomalies are coincident with the area of listwanitic alteration, as well as with some of the VLF conductors.

The antimony-in-soil anomalies generally occur in areas in between the VLF conductors (ie: areas of relative non-conductivity).

The arsenic-in-soil anomalies occur over VLF conductors as well as in between

them. The anomalies are also coincident with areas of listwanitic alteration.

The VLF-EM survey has defined numerous bedrock conductors which trend parallel to the baseline. The conductor axes mainly occur in areas of topographic lows, and may be partially coincident with zones of listwanitic alteration and shearing.

6.0 Recommendations

The Bar Grid should be extended to the northwest for a distance of 2.5 kilometres to cover the area of anomalous gold that was outlined in the bulk and heavy mineral sampling surveys. It should also be extended to the southeast for a distance of 0.5 kilometres to cover any strike extensions of the listwanitically altered rock. The lines should be spaced 100 meters apart with a station interval of 20 meters.

Geological mapping, soil sampling, VLF-EM and magnetometer surveys should be carried out on the entire grid.

Reconnaissance mapping should be conducted on the remainder of the property.

PLEASE DISTRIBUTE RESULTS TO: G SHEVCHENKO
 B. HODGSON M. GAREAU E. KIMURA L. REINERTSON

REMARKS:
 "ALL AU RESULTS REPORTED IN PPB; 3 AU ANALYSES PER SAMPLE"
 "SAMPLE BS-12 IS MISSING; AND THERE ARE TWO SAMPLES WITH THE NUMBER BS-13"
 "THEY HAVE BEEN CALLED BS-13A & BS-13B"

STANDARD ANALYSIS METHODS USED BY PDL GEOCHEM LAB ARE LISTED BELOW:
 ALL RESULTS EXPRESSED AS INDICATED IN UNITS COLUMN BELOW
 ANY EXCEPTIONS FOR THIS PROJECT ARE NOTED ABOVE

REMARKS: INTERNAL LAB STANDARDS HAVE BEEN INCLUDED FOR REFERENCE.
 SAMPLE NUMBERS FOLLOWED BY * ARE DUPLICATE ANALYSES.

APPENDIX VII
Statement of Qualifications

STATEMENT OF QUALIFICATIONS

I, Glenn Shevchenko, of the municipality of Surrey, British Columbia, do hereby certify that:

1. I am a graduate of Concordia University where I received a B.Sc. in Geology in May 1982.
2. I have practiced my profession part-time since 1977, and full-time since 1984.
3. I am a member in good standing with the Geological Association of Canada.
4. I am currently employed by Placer Dome Incorporated and was responsible for the field exploration on the Tchentlo property.

Oct 24, 1989
Date

Glenn Shevchenko

STATEMENT OF QUALIFICATIONS

I, Richard W. Cannon, of the City of Vancouver, Province of British Columbia, hereby certify as follows:

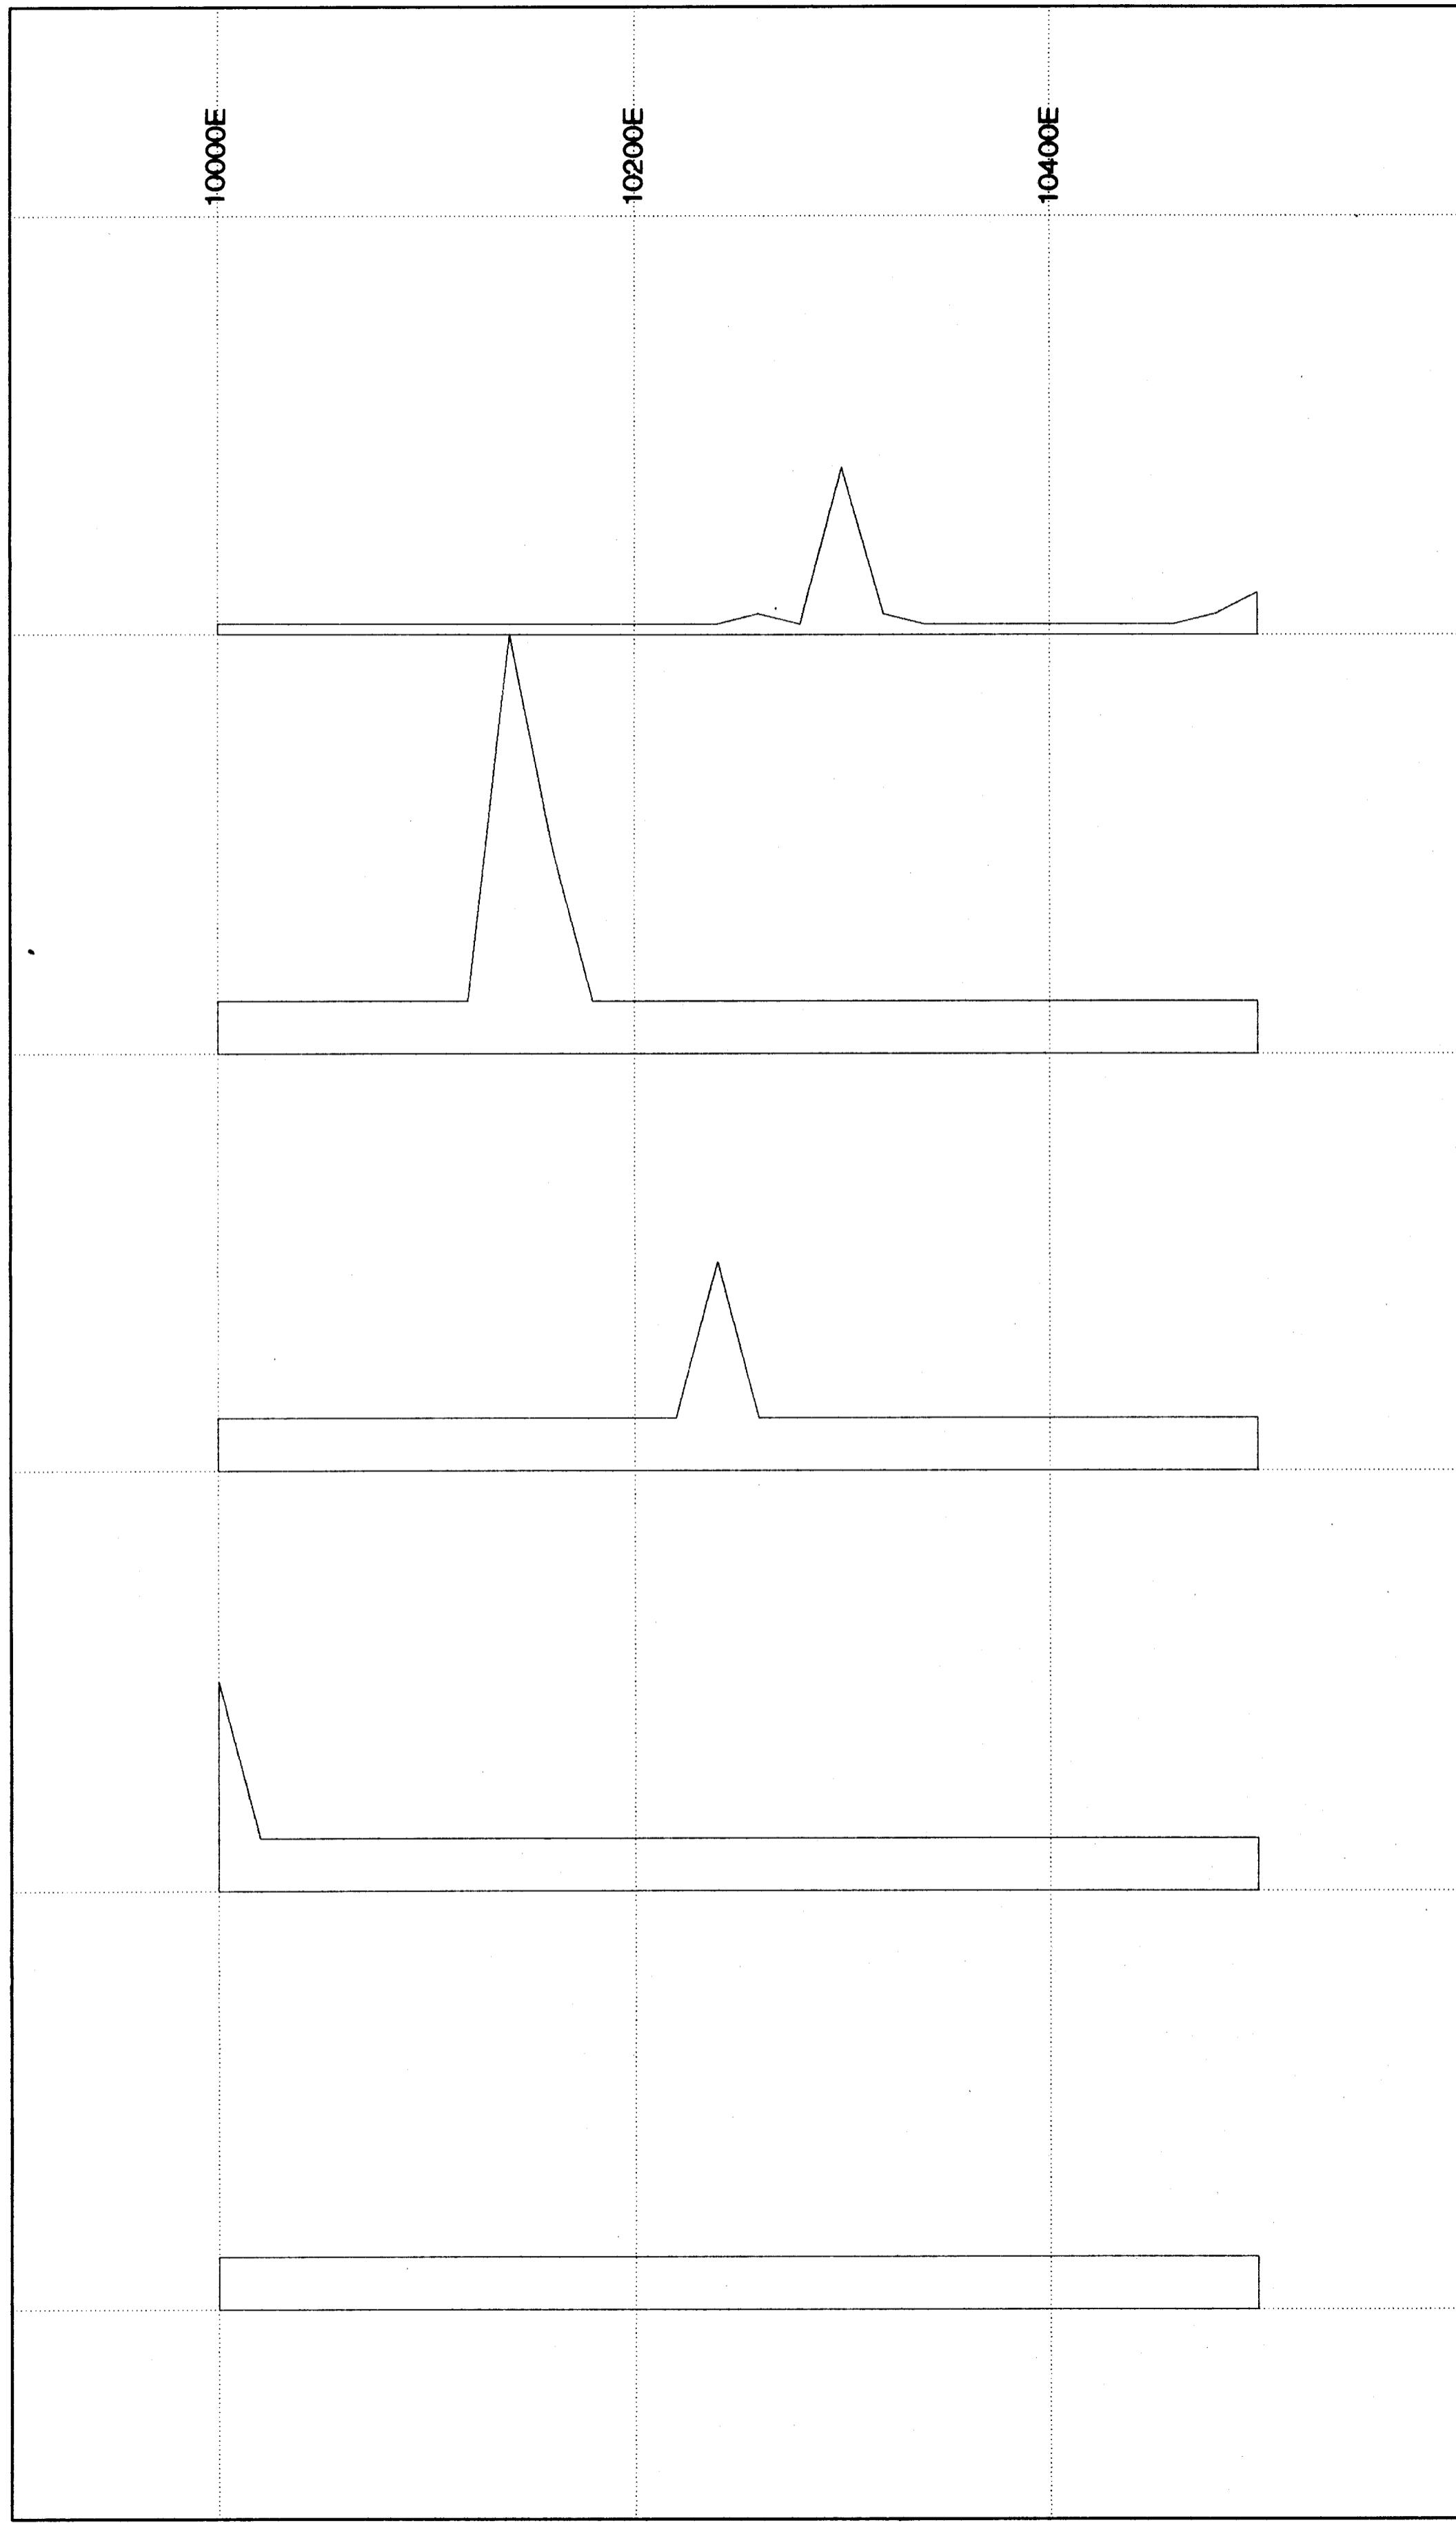

1. I am a graduate of the University of British Columbia where I received a B. A. Sc. in Geological Engineering (Geophysics Option) in May 1966.
2. I am a member of the Association of Professional Engineers of British Columbia and have been so since 1968. Registration No. 6742.
3. I am a member of the Canadian Institute of Mining and Metallurgy, Society of Exploration Geophysicists, and the B. C. Geophysical Society.
4. I have practiced my profession since 1966.

LITHOLOGIES.

Mesozoic

Ultramafic Rocks

Olivine Basalt - medium grey with beige, pink and olive green spots. Weathering to a maroon - Inequigranular, porphyritic, amygdaloidal and massive. - 5 to 20% phenocrysts comprised of aggregates of very fine grained olivine are set in an aphanitic matrix of colour index 70. - The rock also contains up to 20% amphiboles (0.2 to 1.0 mm in diameter) comprised of ilmenite and occasional calcite.

Pyroxenite - medium to dark green with olive green spots, weathering to a medium grey. - Essentially equigranular and massive. - Comprised of medium grained subidiomict augite (75 to 90%) and fine grained anhedral olivine (10 to 25%).

Cache Creek

Sedimentary Rocks

Limestone - Medium grey, weathering to a light grey colour. Massive with occasional thick bedding.

Chert - Light to medium grey, weathering to a medium grey. Equigranular and aphanitic with a distinct rock cleavage. - Comprised of cryptocrystalline silica (97%), very fine grained pyrite (1 to 2%) occurring as disseminations and fracture fillings, and 1 to 2% calcite along fractures.

Feldspathic Sandstone - Maroon with occasional beige bands, weathering to a dark brown with some rusty areas. - Thinly bedded with fine grained sand - sized particles set in an aphanitic, hemispherical clastic matrix. - The sand is comprised of subangular feldspar, quartz, and amphibole.

ALTERATION / SHEAR ZONE FACIES.

A-3 Listwanitic Alteration - Mottled medium grey, dark grey and beige grey with green spots, weathering to a beige or orange beige colour. May be inconspicuous with a distinct sheared appearance. The phenocrysts are 20% to 30% of the rock volume and are comprised of fuchsite. In some cases there is only partial alteration of pyroxene to fuchsite. The phenocrysts are set in an aphanitic matrix (color index 30 to 70%) which may have an indistinct banding.

- May contain up to 5% quartz and chalcocite veining with occasional very fine grained cassiterite.

A-2 Quartz-Carbonate Alteration - Same as rock type A-1, but no fuchsite present.

A-3 Limestone Breccia - Medium grey, weathering to a light grey. Massive with a moderate to distinct brecciated appearance. - Clasts are angular and range from less than 1cm to 15cm in length. - Calcite (10 to 60%) inines fractures between clast.

A-4 Serpentinite - Medium to dark green, weathering to a medium grey to greenish grey. - Equigranular to inequigranular. - Contains 50 to 100% serpentinite. - The serpentinite is a result of shearing in an ultramafic rock, thus depending on the degree of shearing clasts of pyroxene may remain.
