TABLE OF CONTENTS cont'd

INTRODUCTION.

Between August 1st and 23rd, 1989, Peter E. Walcott & Associates Limited carried out an induced polarization (I.P.) survey over part of a property located in the Iskut area of British Columbia for Placer Dome Inc.

The survey was carried out over mostly flagged N 25° W lines that were primarily established by personnel of Placer Dome Inc.

Measurements (first to fourth separation) of apparent chargeability - the I.P. response parameter - and resistivity were made using the pole-dipole method of surveying with a 60 metre dipole.

The I.P. data are presented in pseudo-section form on individual line profiles that are bound in this report. In addition the data from respective separations as well as the filtered data has been contoured and presented on plan maps of the line grid - Maps W-457-1 to 10 - that accompany this report.

PROPERTY, LOCATION & ACCESS.

The property, known as the Ball Creek property, is located in the Liard Mining District of British Columbia.

It is situated between elevations of 700 to 2000 metres on the north side of Ball Creek, some six kilometres west of Hwy 37.

Access was obtained by truck along the above highway, and thence by helicopter, based at Tatogga Lake some 65 kilometres to the north.

PREVIOUS WORK.

Previous work on the property, to the best of the writer's knowledge, consisted of geological and geochemical surveying, induced polarization surveying, some of which was conducted by the writer in 1975, and diamond drilling.

For further details of the above the reader is referred to reports on the same now held by Placer Dome Inc.

PURPOSE.

The purpose of the survey was to define by the I.P. method the extent of sulphide mineralization around the monzonite intrusion in an effort to locate an economic porphyry deposit.

GEOLOGY.

The writer is not at the present time familiar with the geology of the area, and thus the reader is referred to the previously mentioned reports held by Placer Dome.

SURVEY SPECIFICATIONS.

The induced polarization (I.P.) survey was carried out using a pulse type system, the principal components of which are manufactured by Huntec Limited and EDA Instruments Ltd. of Metropolitan Toronto, Ontario.

The system consists basically of three units, a receiver (EDA), a transmitter and a motor generator (Huntec). The transmitter, which provided a maximum of 2.5 kw d.c. to the ground, obtains its power from a 2.5 kw 400 c.p.s. three phase alternator driven by a gasoline engine. The cycling rate of the transmitter is 2 seconds "current-on" and 2 seconds "current-off" with the pulses reversing continuously in polarity. The data recorded in the field consists of careful measurements of the current (I) in amperes flowing through the current electrodes C_1 and C_2, the primary voltage (V) appearing between the two potential electrodes, P_1 and P_2, during the "current-on" part of the cycle, and the apparent chargeability (M_a) presented as a direct readout in millivolts per volt using a 160 millisecond delay and a 1580 millisecond sample window by the receiver, a digital receiver controlled by a micro-processor.

The apparent resistivity (P_a) in ohm metres is proportional to the ratio of the primary voltage and the measured current, the proportionality factor depending on the geometry of the array used. The chargeability and resistivity are called apparent as they are values which that portion of the earth sampled would have if it were homogeneous. As the earth sampled is usually inhomogeneous the calculated apparent chargeability and resistivity are functions of the actual chargeability and resistivity of the rocks.

The survey was carried out using the "pole-dipole" method of surveying. In this method the current electrode C_1, and the potential electrodes, P_1 through P_2, are moved in unison along the survey lines at a spacing "a" (the dipole) apart, while the second current electrode C_2 is kept constant at "infinity". The distance, "na", between C_1 and the nearest potential electrode generally controls the depth to be explored by the particular separation, "n", traverse.

The survey was carried out using a 60 metre dipole, and first to fourth separation measurements were made at

SURVEY SPECIFICATIONS cont'd.

60 metre intervals along the lines. In addition some fifth separation measurements were made on two short lines, Lines 1100 and 1300 W respectively.

In all some 22 kilometres of surveying were carried out using the above method.

DISCUSSION OF RESULTS.

The results of the I.P. survey showed the property to exhibit a low chargeability background above which two complex zones of higher chargeability are clearly discernible, one a roughly elliptical zone in the centre of the grid, outlined by the 8 mv/v contour on the filtered chargeability plot - as illustrated on the three tenths size coloured reduction in the appendix - and the other, a stronger more linear zone undefined to the south and the west, in the southwest corner of the grid.

On correlating the results with the geology from the map provided by Placer Dome, on which several occurrences of potassic and propylitic alterations have been noted, a case can be made to fit the 1000 by 1200 metre elliptically shaped zone to a porphyry model with the phyllic and propylitic annuli being better defined by the higher chargeabilities on the north, west and south sides, more evident on the first and second separation contoured plans - it should be mentioned here that due to the asymmetry of the array the respective "n" separation maps should be shifted one half of the "na" spacing to the south for comparison as suggested on the pseudosection plots.

The smaller, stronger chargeability zone, particularly evident on Lines 2200 and 2400 W, correlates with sulphides known as the Cliff Zone.

The resistivity survey results appear to show that the intrusive rocks exhibit higher resistivities. In fact on the down scaled coloured plots of the second and fourth separation resistivities it can be seen that the outline of the anomalous chargeability response is also coincident with the areas of higher resistivities.

The lower resistivities to the east on Line 600 W could also be partially attributable to higher conductivity associated with thicker overburden cover as this line is well into the valley as well as to underlying volcanics. Similarily the large resistivity low on the west, south of the baseline, obtained over some of the highest ground surveyed, could be partly due to increased overburden cover on this flatter part of the grid, as evidenced from the black swampy soil, as well as to

DISCUSSION OF RESULTS cont'd

underlying volcanics.

The higher chargeability readings observed on the larger separations associated with lower resistivities on Lines 1200, 1300 and 1400 W just north of the baseline are probably due to increased sulphide mineralization in an inner shell of more porous rock.

On the whole the chargeability and resistivity results showed good correlation with those of the limited 1975 survey carried out by the writer with a 400 foot dipole on lines approximately perpendicular to those of the present grid.

SUMMARY, CONCLUSIONS & RECOMMENDATIONS.

Between August 1st and 23rd, 1989, Peter E. Walcott & Associates Limited carried out an induced polarization survey over part of a property, located in the Iskut area of British Columbia, for Placer Dome Inc.

The survey outlined the presence of two complex anomalous zones on the property, which correspond to areas of past and present investigation known respectively as the Camp and Cliff Zones.

The chargeability signature of the Camp Zone with its outer ring of higher readings was somewhat typical of that expected from a porphyry style mineralized occurrence.

The Cliff Zone anomaly was undefined to the south and west, and could be the subject of further geophysical work.

As a result the writer recommends that the results of the survey be studied with those of the magnetic survey known to have been carried out this summer as well as those of the geology and geochemical surveys in an effort to identify the alteration and metal zonations before commitment to further borehole investigation.

Respectfully submitted,

APPENDIX NO. 2

Petrographic Report

by

Vancouver Petrographics Ltd.

PREFACE

Thirty rock specimens described in the Petrographic Report were taken from the following locations. The six specimens of drill core are identified by hole and footage number.

Sample No.	Approximate Grid Coordinate Westing	Southing	Location
89T10			In Camp Creek at 1175 m elevation. Lower Dyke at 2+3a outcrop.
89T20	1030W	2260S	At 2a outcrop.
89T22			At 2 outcrop at Little Red Hill.
89T23	1030W	2200S	At 3a outcrop on Lower Dyke.
89T32	850W	1620S	At 3a outcrop on Lower Dyke.
89T34	760W	1540S	At 2 outcrop.
89T46			In East Cliff Creek at 1350 m elevation at 3 outcrop.
89T60	1550W	1680S	At 2 outcrop.
89T65			In Fossil Creek at 1260 m elevation at 3 outcrop.
89T72	1180W	1620S	At 2Bxx, Kspar alt outcrop.
89T73	1320W	1860S	At 2Bxx, Kspar alt outcrop.
89T75			At 3b(2?) outcrop on Upper Dyke at 1420 m elevation.
89T79	1300W	1420S	At 3b(2?) outcrop on Upper Dyke at 1370 m elevation.
89T83B	1120W	1450S	At 2Bxx outcrop.
89T85	1080W	1770S	At 3a outcrop on Lower Dyke.
89T93			At 2 outcrop at Little Red Hill.
89T101	1350W	2040S	At 2a outcrop.
89T108	1500W	2060S	At 2? outcrop at Big Red Hill.
89T109	1500W	2060S	Same location as 89T108.
89T122			In Fossil Creek at 1560 m elevation at 3 outcrop.
89T125			At 3a outcrop on Upper Dyke at 1480m elevation.
89T132	1610W	2630S	At 3b? outcrop.
89T134	1700W	1860S	At 3b outcrop on Upper Dyke at Big Red Hill.
89T139	1680W	2140S	At 3b? outcrop.
89T164	1180W	3060S	At 4a outcrop at Trachyte Knob.
89T184	2400W	2280S	At 4b outcrop above Cliff Zone.
89T186	2250W	2250S	At 4b outcrop at 1680 m elevation.
89T194	2490W	2020S	At 3c outcrop on Ridge Dyke.
89T197			At 3c outcrop on Ridge Dyke at 1650 m elevation.
89T208	1450W	2040S	At 2+3d outcrop at Big Red Hill.

SAMPLES:

36 rock samples for sectioning and petrographic description.

Samples are numbered as follows:

89T 10	89T 72	89T 109	89T 194
20	73	122	197
22	75	125*	208
23	79	132	DDH 73-2 252'
32*	83B	134	463.5'
34	85*	139	DDH 73-3 238'
46*	93	164	DDH 75-2 698.5'*
60*	101*	184	822'
65	108*	186	DDH 75-5 145'

The samples marked with an asterisk in the above list were prepared as polished thin sections to allow observations on the contained opaques. The remainder were prepared as conventional thin sections.

SUMMARY:

The great majority of the rocks of this suite are abundantly porphyritic, quartz-poor, igneous rocks of monzonitic composition, made up of phenocrysts of plagioclase, plus minor K-feldspar and mafics, in a groundmass composed mainly of K-feldspar. They have the textural aspect of hypabyssal intrusives.

In most of these rocks K-feldspar, as a percentage of total feldspars, ranges from about 30-50%. Those rocks with percentages of 35% or more are classified as monzonites. Those with somewhat

lower ratios (but still, in my opinion, too potassic to be classed as normal diorites) have been designated monzo-diorite. These rocks represent a continuum, and may well grade from one compositional group to the other within a given dyke.

Quartz is generally absent or, in a few cases, is present as a minor component, in the range 1 -5%. Only one sample contains abundant primary quartz, making it classifiable as a granodiorite.

In general, these rocks are only weakly altered. Plagioclase phenocrysts show from very weak to moderate pervasive sericitization (or, occasionally, argillization); in a few cases they show carbonate alteration. K-spar is generally fresh, but in rare cases shows carbonate alteration.

The minor mafics are typically strongly to totally altered. They apparently originated as biotite, amphibole and pyroxenes, in various proportions. They are now altered to various combinations of chlorite, carbonate, and secondary biotite or amphibole.

In a few cases the rocks show quartz veining and associated localized K-feldspathization.

Many of the porphyries contain traces of disseminated pyrite - in a few cases reaching 1-2% of the rock. Higher pyrite contents occur in some of the keratophyrici and andesitic country rocks.

A few of the monzonite porphyry samples contain xenoliths - generally of plagioclase-rich material (probably representing keratophyric country rock). Partial assimilation of xenoliths produces hybrid rocks. Some of these are of fine-grained, K-rich composition, possibly representing contact and/or potassic-altered phases of the intrusives.

Other lithotypes represented in the suite (country rocks to the intrusives) are sodic igneous rocks of probable keratophyric affinities, tuffs and andesites.

Groupings based on the petrographic study are as follows:

Granodiorite porphyry: Sample 46

Monzo-diorite porphyry: Samples 10, 23, 79, 85, 125, 134. (#134 approaches diorite in composition).

Monzonite porphyry: Samples 22, 32, 65, 72, 75, 122, 132, 139, 184, 186, 194, 197 and 73-3 238'. (#72 approaches syenite in composition).

Monzonite porphyry with xenoliths: Samples 34, 164 and 73-2 252'.

Syenitic rocks (hybrids and/or K-metasomatites): Samples 73, 93

Monzonite porphyry with quartz veins and potassic alteration: Samples 83B, 73-2 463.5' and 75-5 145'.

Albitite or keratophyre: Samples 60, 101, 108, 109.

Tuff: Samples 20, 208

Andesite: Samples 75-2 698.5' and 822'

Please refer to the individual petrographic descriptions (attached) for details of variations in primary composition and texture, and style and intensity of alteration.

The necessary information to answer your specific queries will, I think, be forthcoming from study and compilation of the relevant descriptions.

Some consistency in the characteristics of the samples representing the three postulated major dyke structures is apparent. The recognition of a sodic igneous (keratophyric?) lithotype in the country rocks may be new information. Tuffs do not seem prominent - at least as far as is discernable on the thin section scale.

SAMPLE 89T 10 **MONZO-DIORITE PORPHYRY**

Estimated mode

Plagioclase	73
K-feldspar	16
Quartz	trace
Sericite	trace
Biotite	4
Chlorite	4
Epidote	1
Carbonate	1
Apatite	trace
Opaques	1

This is a strongly porphyritic igneous rock of quartz-poor composition.

Phenocrysts make up about 75% of the rock. They are predominantly euhedral plagioclase crystals, 0.2 - 4.0mm or more in size. They are stumpy, prismatic in form and randomly oriented.

The plagioclase phenocrysts are essentially fresh but for a faint dusting of fine-grained sericite, and occasional wisps of carbonate - typically picking out an incipient concentric growth zoning in the feldspar.

An accessory phenocryst type consists of altered mafics. These include clumps of partially chloritized biotite, and clusters and partial prismatic pseudomorphs (after original hornblende?). The latter are made up of secondary biotite, chlorite, epidote, carbonate and opaques in various proportions. The same assemblage occurs in more dispersed form as interstitial patches filling between the plagioclase phenocrysts.

The groundmass is a felsitic to feathery-textured aggregate of K-feldspar, probably with an indeterminate proportion of intergrown plagioclase. Its grain size is in the range 5 - 30 microns. The only other groundmass constituent is micron-sized opaques and/or rutile.

The rock contains rare traces of quartz, as tiny clumps associated with the altered mafic clusters.

SAMPLE 89T 20 **ANDESITIC LITHIC TUFF**

Estimated mode

Plagioclase	30
K-feldspar	10
Sericite	3
Chlorite	25
Carbonate	28
Apatite	trace
Sub-opaques	2
Opaques	2

Macroscopic examination of the stained cut-off block clearly indicates the fragmental character of this rock.

Somewhat rounded lithic clasts, up to 6 or 7mm in size, are readily distinguishable. These include a rock of apparent trachyandesite composition (with plagioclase phenocrysts in a potassic matrix) and a sodic rock (composed essentially of plagioclase). The coarser clasts are set in a matrix of more finely comminuted fragments of the same rock types, with the non-potassic type predominating.

In thin section the rock is found to contain notably abundant chlorite and carbonate, and to be poly-lithic - with a variety of different textural/mineralogical types distinguishable. The overall composition throughout is in the andesite-trachyandesite range.

The coarser trachyandesitic clasts consist of abundant euhedral phenocrysts of plagioclase, to 1.0mm in size, in a microgranular K-feldspathic groundmass. The plagioclase phenocrysts are weakly to totally altered to carbonate, and the groundmass contains varying proportions of finely intergrown chlorite.

Other variants are seen in which groundmass is minimal, or is of minutely fine-grained, felsitic to trachytic texture. Some clasts show strongly flow-oriented phenocrysts.

Another prominent form of clast - especially in the finer size ranges - is a fine-grained felsitic or microlitic andesite with abundant chlorite-filled vesicles defining a flow-oriented pumiceous texture, and sparse, small, altered plagioclase phenocrysts.

This rock is unmistakably a lithic tuff.

SAMPLE 89T 22 LEUCOCRATIC MONZONITE PORPHYRY

Estimated mode

Plagioclase	48
K-feldspar	35
Quartz	1
Sericite	12
Clays(?)	2
Opaques	2

This is a porphyritic igneous rock of notably leucocratic composition.

Phenocrysts, 0.2 - 3.0mm in size, make up about 60-65% of the rock. They are predominantly plagioclase, but also include occasional K-feldspar. The latter tends to form mainly relatively coarse euhedra - sometimes with included smaller plagioclase crystals.

The groundmass is an evenly microgranular, felsitic aggregate, of grain size 5 -30 microns, composed predominantly of K-feldspar.

The plagioclase phenocrysts show weak to moderate pervasive alteration to fine-grained sericite and brownish sub-opaque material (clays?).

Sericite is also a relatively abundant component of the groundmass, especially as an interstitial constituent of patches of somewhat coarser crystallization developed between some of the feldspar phenocrysts. These patches also include a little accessory fine-grained quartz.

A few prismatic pseudomorphs, composed entirely of sericite, may represent the alteration of rare biotite phenocrysts.

Pyrite occurs as randomly disseminated, irregular-shaped grains, 0.2 - 1.5mm in size, which are typically poikilitically sieved with groundmass inclusions.

Estimated mode

Plagioclase	57
K-feldspar	23
Quartz	2
Sericite	5
Chlorite) Secondary biotite)	7
Carbonate	5
Apatite	trace
Opaques	1

This is another quartz-poor, porphyritic igneous rock, but with some distinctive features compared with previous examples in the suite.

Phenocrysts make up some 70-80% of the rock. They range in size from 0.2 - 2.5mm, but a high proportion are in the lower end of this range (0.2 - 0.8mm in size).

The phenocrysts are principally plagioclase, but also include a lesser proportion of K-feldspar and rather abundant small, well-formed, pale brown pseudomorphs composed of minutely felted secondary biotite and/or chlorite. The latter lack the relict laminar texture normally recognizable in altered biotite, and show forms more suggestive of probable origin as amphibole or pyroxene.

The plagioclase phenocrysts show variable degrees of pervasive alteration (from weak to rather strong) to fine-grained sericite and minor carbonate. The K-feldspar phenocrysts typically show strong alteration to carbonate.

The groundmass is a feathery/felsitic aggregate of K-spar plus minor plagioclase, of grain size 5 - 15 microns. It shows pervasive flecking by sericite.

Small clumps of quartz are a trace accessory, and tiny euhedra of apatite are also prominent.

Disseminated opaques (mainly pyrite) form small, discrete euhedra, 10 - 200 microns in size, closely associated with the altered mafic pseudomorphs.

SAMPLE 89T 32 **MONZONITE PORPHYRY**

K-feldspar	35
Quartz	trace
Sericite	1
Secondary biotite	10
Epidote	1
Sphene	trace
Apatite	trace
Rutile	1
Pyrite	trace

Phenocrysts make up some 75% of this rock. As in many of the rocks of the suite, they consist principally of plagioclase, with lesser proportions of K-feldspar and mafics. The phenocrysts are sharply defined euhedra, apparently without any tendency for preferred orientation.

Size range of the phenocrysts is 0.1 - 4.0mm, though the majority of them are no more than 1.5mm in size.

The feldspar phenocrysts are essentially fresh, but for a faint dusting of sericite and rare zonal flecks of secondary biotite in the plagioclase, and a slight argillic turbidity in the K-spar. The plagioclase contains occasional discrete grains of epidote, which is also seen occasionally as independent grains in the groundmass.

The mafic phenocrysts are composed largely of brown, somewhat altered-looking biotite, sometimes with interlaminated rutile. Some probably originated as primary biotite; others are composed of minutely felted secondary biotite, and have the characteristic outlines of amphibole and pyroxene.

The groundmass is a homogenous, minutely feathery/felsitic aggregate, of grain size 5 - 20 microns, composed of K-feldspar with accessory plagioclase and minute flecks of biotite and rutile.

The rock contains traces of quartz, as rare, irregular grains and small clumps of phenocrystic aspect. It also contains sphene of distinctive form, as scattered, sharply-defined, tiny, light brown euhedral crystals.

Epidote	trace
Apatite	trace
Rutile	trace
Sphene	trace
Opaques	1

The clumpy, heterogenous appearance of this rock (see stained cut-off block) indicates that it is of hybrid character. The thin section reveals that it includes abundant xenolithic fragments, 1 - 10mm or more in size.

One of the two principal lithotypes is a leucocratic porphyry, having abundant, euhedral phenocrysts of fresh plagioclase, 0.1 - 2.0mm in size, in a minutely felsitic/cryptocrystalline matrix. Minor mafics are represented by clumps of scrappy sericite and/or secondary biotite, with opaque granules. This probably represents the white-etched phase in the cut-off block.

The other is a similar leucocratic rock, but with more sporadically developed, less well-formed plagioclase phenocrysts, in a microgranular matrix of K-feldspar with minor accessory quartz. This (the yellow stained, dominant phase in the cut-off block) shows patchy variations in proportions of phenocrysts - possibly representing fragments of slightly different textural character.

A single sub-rounded fragment of granular quartz, 3mm in size, was also seen.

The constituent lithotypes in this rock appear to be of hypabyssal rather than extrusive type, and the rock is probably a form of intrusive or contact breccia.

It is only very weakly altered.

SAMPLE 89T 46 **GRANODIORITE PORPHYRY**

K-feldspar	27
Quartz	11
Sericite	2
Chlorite	6
Hornblende	1
Carbonate	2
Sphene	trace
Apatite	trace
Pyrite	1
Magnetite	trace

This is an abundantly porphyritic igneous rock of significantly coarser averge average grain size than the majority of the suite. It is of distinctive composition in that the ground mass is also relatively coarse and contains substantial quartz.

Phenocrysts make up about 70% of the rock. They consist predominantly of subhedral-euhedral plagioclase, as crystals 0.3 - 4.0mm in size. K-feldspar phenocrysts are fewer in number, but include some coarse euhedra up to 12.0mm in size.

Mafic phenocryts make up 8-9% of the rock. These are composed of felted chlorite or secondary biotite with intergrown carbonate. Their shapes clearly indicate that they are pseudomorphous after hornblende. A few grains are, in fact, composed largely of relict hornblende.

The plagioclase phenocrysts typically show an even, very light dusting of minutely fine-grained sericite and traces of carbonate. The K-spar phenocrysts are totally fresh.

The groundmass consists of an evenly granular, equant aggregate, of grain size 0.05 - 0.15mm, made up of roughly equal proportions of quartz, K-feldspar and plagioclase, with minor intergrown chloritized mafics.

Pyrite occurs as disseminated, small clumps and irregular, poikilitic grains, mostly associated with altered mafics. Occasionally the pyrite forms lines of grains indicative of incipient microfracture control. The rock is also cut by rare hairline veinlets of carbonate.

SAMPLE 89T 60 ALBITITE OR KERATOPHYRE

Estimated mode

Plagioclase	85
Sericite	7
Rutile	trace
Pyrite	8
Limonite	trace

This sample differs from the majority of the suite in that it contains no K-feldspar (see stained cut-off block). It also has a notably high content of disseminated pyrite.

In thin section it is seen to exhibit a porphyritic texture, with about 60-70% of the rock composed of randomly oriented plagioclase phenocrysts, 0.2 - 2.0mm in size. These are set in a fine microgranular groundmass also composed of plagioclase, as an anhedral, interlocking aggregate, of grain size 10 - 100 microns.

Sericite occurs as a very faint, pervasive dusting of some of the phenocrysts and, more abundantly, as random clusters and elongate masses in the groundmass. These show relict lamellar textures defined by fine-grained rutile and limonite, and probably represent altered biotite phenocrysts.

The refractive index of the plagioclase is lower than that of the mounting medium - suggesting that it is probably of albititic composition.

The pyrite occurs in distinctive manner as randomly disseminated subhedral grains and rather coarse coalescent/poikilitic patches, 0.2 - 1.5mm in size. The latter are typically sieved with abundant inclusions of incorporated groundmass. The pyrite sometimes shows marginal limonitization. The petrographic character of this rock is not consistent with the field description as intensely altered (phyllic) bedded country rock. It may be an albitite - of dyke origin - or a keratophyric volcanic.

SAMPLE 89T 65 **MONZONITE PORPHYRY**

Rutile)	1
Opaques)	

This is another abundantly porphyritic rock of similar macroscopic aspect to many others in the suite. About 70% of the rock consists of euhedral phenocrysts, ranging in size from 0.2 - 5.0mm.

The majority of the phenocrysts are plagioclase, lightly dusted with minutely fine-grained sericite. A small proportion are K-feldspar - totally fresh or, rarely, mildly altered to carbonate.

Mafics are minor and, as usual, are strongly altered - in this case to intimate intergrowths of chlorite and carbonate. Rare remnants of hornblende survive, indicating that this was the predominant original mafic.

Small individual flakes of reddish biotite with rutile inclusions - or similar rutile in felted secondary products - are also seen.

Occasional quartz is present, generally associated with altered mafics and/or the trace accessory minerals sphene and apatite. The sphene is in the form of well-crystallized brown euhedra (often twinned), as remarked in other rocks of the suite.

The groundmass is a feathery/felsitic aggregate, of grain size 5 - 30 microns, composed of fresh K-feldspar and plagioclase, and including tiny sub-porphyritic feldspar euhedra to 0.1mm or so in size. Dust-sized opaques or rutile, and rare tiny flecks of carbonate, are the other groundmass constituents.

SAMPLE 89T 72 **MONZONITE PORPHYRY**

Estimated mode

Plagioclase	20
K-feldspar	60
Quartz	5
Sericite	3
Chlorite) Secondary biotite)	12
Apatite	trace
Opaques	trace

This is a rock of more potassic composition than the majority of the suite. It shows a rather patchy, heterogenous texture which may indicate a hybrid origin.

The predominant assemblage consists of small, stumpy, subhedral phenocrysts of plagioclase and lesser K-spar, 0.2 - 2.0mm in size, scattered through a microgranular groundmass of fresh, anhedral/ interlocking K-feldspar, of grain size 5 - 50 microns. Other groundmass constituents are minor interstitial chlorite and quartz.

Many of the phenocrysts show rather strong alteration of a distinctive type - to patches and core zones of compact, brownish felted chlorite or secondary biotite, and/or sericite.

These same alteration minerals also occur concentrated as more or less extensive patches of diffuse fibrous growth. These are sometimes set in a matrix which shows extensive intergranular permeation by the chloritic/secondary biotite alteration. These areas appear texturally, as well as mineralogically, distinct from the rest of the rock, and may represent xenoliths or areas of assimilation/hybridization.

The rock is cut by a few hairline stringers of quartz. Quartz also concentrates as localized patchy areas of granular intergrowth with K-spar, and as sporadic discrete clumps throughout the rock. It is unclear what proportion of the quartz is primary as opposed to being incipient silicification of an introduced or late magmatic/ redistributional type.

Though somewhat finer-grained and more potassic than most of the comparable rocks of the suite, there appears no justification for naming this rock any differently.

Potassic phase	
K-feldspar	48
Plagioclase	2
Quartz	1
Biotite	7
Limonite	2
Sodic phase	
Plagioclase	28
K-feldspar	2
Biotite	8
Limonite	2

This is a rock of heterogenous texture whose origin and alteration history is somewhat uncertain. It appears to be of igneous character.

The stained cut-off block includes an extensive area of plagioclase-rich composition (white-etched and generally lacking yellow stain). This shows partly sharp and partly diffuse/gradational contacts against the K-rich (strongly yellow stained) phase which makes up the bulk of the slide. The latter phase also includes several smaller, more or less diffuse, unstained areas, which appear to be partially assimilated patches or fragments of the first rock type.

This relationship is best explained as xenoliths of the plagioclase-rich (albitite?) rock, engulfed and partly assimilated by a potassic phase (fine-grained syenite?).

In thin section, both lithotypes are found to consist essentially of leucocratic aggregates of feldspar, and distinction between the two is sometimes difficult - especially in view of the more or less extensive hybridization.

The sodic phase most often seems to be a blocky subhedral aggregate of plagioclase, of grain size 0.1 - 0.5mm. This shows more or less intense pervasive alteration to minutely fine-grained, brown, secondary material (biotite?). Shreds of pale secondary-type biotite also form an intergranular permeation, and the rock contains small patches and microfracture fillings of limonite.

Minor development of very fine-grained felsitic interstitial material probably represents the early stages of penetration and assimilation by the potassic phase.

The potassic phase is more heterogenous. It is predominantly a felsitic aggregate of K-feldspar, of grain size 10 - 30 microns, grading to patches of coarser granular texture up to 100 microns or so. Minor interstitial quartz is recognizable. There are also

Sample 89T 73 cont.

scattered phenocrysts of cloudy K-feldspar (and possible altered plagioclase) up to 1.0mm in size.

Fine-grained biotite (possibly with some intergrown chlorite and sericite) forms scrappy pseudomorphs, and occurs as a fine, pervasive, intergranular component throughout the felsitic K-feldspar.

Limonite-filled microfractures and small pockets also cut the potassic lithotype.

The biotitic/ferruginous alteration appears to be superimposed on both constituent phases i.e. it is post-hybridization.

SAMPLE 89T 75 **MONZONITE PORPHYRY**

Estimated mode

Plagioclase	57
K-feldspar	30
Sericite	3
Biotite	4
Chlorite	4
Carbonate	1
Apatite	trace
Opaques	1

This is another example of a very common rock-type in this suite. It consists of abundant euhedral phenocrysts - making up as much of 80% of the rock - in a fine-grained potassic groundmass.

Phenocrysts range in size from 0.2 - 5.0mm. The majority of them are plagioclase, but K-feldspar is also seen as phenocrysts - sometimes notably coarse and with inclusions of smaller plagioclase crystals.

The plagioclase phenocrysts are lightly dusted with minutely fine-grained sericite, whilst the K-spar phenocrysts are totally fresh. Some plagioclase crystals also show concentric zonal inclusions of minutely fine-grained chlorite/secondary biotite.

Small mafic phenocrysts (seldom more than 1mm in size) occur scattered throughout, between the abundant, coarser feldspar phenocrysts. They consist of somewhat bleached and chloritized biotite, and another type (probably after hornblende), totally altered and composed of various proportions of felted chlorite, secondary biotite and carbonate.

The groundmass is a microgranular aggregate of anhedral K-feldspar, on a scale of 10 - 50 microns, with interstitial flecks of chlorite and biotite.

Apatite is a prominent accessory, as randomly scattered, tiny euhedra. Opaques form sporadically disseminated, small, equant grains, 0.05 - 0.3mm in size, and clusters of such grains. They appear to be mainly oxides rather than pyrite.

SAMPLE 89T 79 MONZO-DIORITE PORPHYRY

K-feldspar	28
Quartz	1
Sericite) Clays)	6
Chlorite	5
Biotite	2
Epidote	3
Apatite	trace
Sphene	trace
Opaques) Limonite)	1

This is a closely similar type of rock to the previous sample (#75), being an abundantly porphyritic rock made up of euhedral prismatic phenocrysts of plagioclase and lesser K-feldspar, plus small altered mafics, in a fine-grained, somewhat potassic groundmass.

Phenocrysts range in size from 0.3 - 3.5mm and constitute 80-85% of the rock. There is a weak tendency for preferred orientation on the part of the plagioclase phenocrysts.

The plagioclase shows even, weak to moderate pervasive alteration to fine-grained sericite and brownish sub-opaque material (clays?). The K-feldspar phenocrysts are generally unaltered, except that a few contain sporadic small clumps of well-crystallized epidote.

Mafics include some small, well-formed flakes of essentially fresh biotite, but consist principally of prismatic pseudomorphs of felted chlorite, sometimes with associated epidote and opaques, which are probably after original hornblende.

The groundmass is the usual felsitic aggregate of grain size 5 - 50 microns, composed mainly of K-feldspar with accessory intergrown plagioclase (partly as tiny euhedral sub-phenocryts) and small flecks of mafics.

Quartz is a minor but noticeable accessory, as sporadic small grains and clumps in the groundmass - often associated with epidote or with the trace constituents sphene and/or apatite.

Opaques in this rock appear to be mainly Fe-Ti oxides.

SAMPLE 89T 83B ALTERED MONZONITE PORPHYRY

Estimated mode

Brecciated host rock		
	Plagioclase	18
	K-feldspar	35
	Sericite	5
	Biotite	5
	Chlorite	2
Veining		
	Quartz	35

This rock appears to have originated as a porphyritic monzonite of similar general type to many others of the suite. However, it shows evidence of modification by metasomatic K-feldspathization, and is cut by a system of quartz veins and replacements.

The host rock consists of plagioclase and K-feldspar phenocrysts in a microgranular matrix of K-spar with minor accessory quartz and altered biotite.

Plagioclase phenocrysts, up to about 3mm in size, are recognizable but many show peripheral conversion to K-feldspar, and/or are cut by hairline networks of that mineral. Some which consist wholly of K-spar may be original, or may be totally altered plagioclase phenocrysts. Generally the euhedral shapes, characteristic of the feldspar phenocrysts in other less altered rocks of the suite, are lacking in this sample.

The veinlike zones of silicification consist partly of anhedral mosaic quartz, of grain size 20 - 100 microns, which shows diffuse, gradational/assimilative contacts with the host rock. There are also more discretely veniform zones of coarser granular quartz which may be superimposed on the more diffuse silicification.

Threads of quartz cross-cut the altered host rock (including the feldspathized phenocrysts), indicating that the silicification at least partly post-dates the K-metasomation.

Feldspar phenocrysts in host rock slices between the quartz zones, and in narrow zones peripheral to them, show strong pervasive alteration to sericite and felted secondary biotite. The same alteration also affects the groundmass - though to a lesser degree.

SAMPLE 89T 85 **MONZO-DIORITE PORPHYRY**

Estimated mode

Plagioclase	54
K-feldspar	22
Quartz	4
Sericite	10
Biotite	6
Chlorite	2
Pyrite	2
Chalcopyrite	trace
Limonite	trace

This is another crowded porphyry, macroscopically similar to many others of the suite.

It differs from, say, #79 in that the phenocrysts include only very rare K-feldspar. It also has significant amounts of accessory quartz in a microgranular groundmass, and contains prominent disseminated sulfides.

Phenocrysts make up about 70% of the rock. They are mainly prismatic plagioclase crystals, 0.2 - 3.0mm in size, which show a weak tendency towards preferred orientation.

The plagioclase phenocrysts show relatively strong pervasive alteration to minutely fine-grained sericite. This forms disseminated flecks and patchy replacements, sometimes controlled by cleavage and/or growth zoning in the host crystals.

The rare K-spar phenocrysts are essentially fresh.

Mafics (relatively minor in total, as is generally the case with this rock type throughout the suite) consist of small, well-formed, equant flakes of relatively fresh biotite, and larger, irregular to sub-prismatic patches of brownish sericite and/or secondary biotite, sometimes with intergrown chlorite. These patches are commonly host to concentrations of disseminated pyrite.

The groundmass is a microgranular aggregate of grain size 15 - 100 microns. It is composed mainly of K-feldspar, but includes notable amounts of quartz, as intimate, locally sub-graphic intergrowths, and as sporadic, small, segregated clumps.

Pyrite occurs as irregular grains and poikilitic clumps, 0.1 - 1.0mm or more in size. The larger pyrite clumps are typically associated with or mantled by secondary biotite. The lack of euhedral form is a characteristic of the pyrite in this and many other rocks of the suite.

Very rare tiny grains of chalcopyrite are also seen, generally independent of pyrite.

SAMPLE 89T 93 SILICIFIED TRACHYTE AUTOBRECCIA

Estimated mode

Plagioclase	1
K-feldspar	72
Quartz	12
Sericite	12
Rutile	1
Pyrite	1
Limonite) Jarosite)	1

This is a rock of distinctive type, being composed predominantly of K-feldspar, and lacking the prominent plagioclase phenocrysts seen in the majority of the suite. A network of apparent microbrecciation is recognizable in the stained cut-off block.

In thin section the rock is found to consist essentially of an even, minutely felsitic matrix of K-feldspar, of grain size 2 - 10 microns.

Microphenocrysts, 0.1 - 0.5mm in size, make up about 50-60% of this lithotype. They are predominantly K-feldspar, showing highly variable degrees of pervasive sericitization (weak to strong). Very rare small plagioclase phenocrysts are also seen.

Mafics are very minor, being represented by occasional small pseudomorphs after original biotite, now composed of sericite and fine-grained rutile.

This trachytic host is broken up - probably by a form of autobrecciation - into more or less distinct, irregular fragments defined by a network of silicification - sometimes in the form of diffuse zones of minutely fine-grained, pervasive replacement (or possibly a late-crystallizing magmatic phase of more siliceous composition), and sometimes as more discrete veinlets and pockets of quartz showing a grain size up to 0.1mm. Quartz is also seen as partial or complete pseudomorphs of felspar phenocrysts in the trachyte.

The rock contains minor disseminated pyrite, as individual subhedra, 0.05 - 0.3mm in size. These sometimes occur as small strings (fracture controlled?), but are generally random. The pyrite distribution shows no consistent relation to the silicification, and tends, in fact, to concentrate in the trachytic areas.

Pyrite grains are sometimes rimmed by shells of jarosite, or are leached out. Associated diffuse limonitization is common.

SAMPLE 89T 101 **KERATOPHYRE**

Plagioclase	72
K-feldspar	10
Quartz	trace
Sericite	3
Chlorite)	10
Biotite)	
Epidote	trace
Rutile	1
Pyrite	4
Pyrrhotite	trace

This is a fine-grained rock which, judging from the stained cut-off block, is of relatively weakly potassic composition. It has a heterogenous texture, especially as regards the distribution of K-feldspar in the groundmass, and in the abundance and size of phenocrysts, but is not obviously fragmental.

Plagioclase phenocrysts make up about 70% of the rock. They are predominantly in the size range 0.1 - 0.8mm, but occasionally reach 1.5mm. They are subhedral-euhedral in form, but sometimes show diffuse outlines, tending to merge with, or be partially assimilated by, the groundmass. They show only very weak alteration, in the form of a light dusting of sericite.

The phenocrysts are set in a minutely felsitic groundmass, of grain size 5 - 20 microns, composed essentially of plagioclase with relatively abundant flecks of chlorite or sericite and of fine-grained rutile. Small, well-defined sub-phenocrysts of plagioclase are common. The groundmass locally shows cryptofragmental fabric.

The groundmass also includes an indeterminate and irregularly distributed proportion of fine-grained K-feldspar, which locally forms small pockety concentrations and incipient phenocrysts.

Ill-defined clumps of felted chlorite or altered biotite presumably represent altered mafic phenocrysts. The same material occurs in dispersed form throughout the groundmass.

Pyrite (with rare tiny inclusions of pyrrhotite) forms irregular, poikilitic clumps up to 2.0mm in size, and sometimes occurs as small strings and elongate bodies. It is disseminated in the feldspathic matrix, without any associated alteration.

The plagioclase shows the low RI characteristic of albite, and the rock appears to be of keratophyric composition.

SAMPLE 89T 108 **KERATOPHYRE**

Estimated mode

Plagioclase	85
Quartz	1
Sericite	9
Chlorite	2
Rutile	trace
Pyrite	3
Chalcopyrite	trace

This is another pyritic plagioclase-rich rock (like the previous sample) but, in this case, totally devoid of K-feldspar.

It is extremely leucocratic and of simple composition, consisting of plagioclase phenocrysts in a felsitic plagioclase groundmass.

Phenocrysts constitute some 60-70% of the rock. They range in size from 0.1 - 2.5mm, and consist of fresh, subhedral-euhedral plagioclase. They show a weak tendency for preferred orientation.

They are set in a groundmass of grain size 5 - 30 microns, locally developing a minutely lath-like sub-trachytic fabric. There are also diffuse patchy variation in grain size, with some microgranular areas containing a little recognizable minutely intergrown and clumpily segregated quartz.

The groundmass is rather strongly and pervasively flecked throughout with sericite (in contrast to the unsericitized phenocrysts).

The rock contains only very minor, totally altered mafics - in the form of sporadic clumps of felted chlorite.

Pyrite is relatively abundant, as disseminated, irregular grains or clumps, 0.1 - 1.0mm in size. The irregular, amoeboid or network form of the pyrite, poikilitically sieved with matrix inclusions, is characteristic of the sulfides in many rocks of this suite. The pyrite appears to occur independently of the host fabric - sometimes in the groundmass, sometimes moulded around, or including portions of, phenocrysts.

The plagioclase making up this rock (both phenocrysts and groundmass) has the low refractive index characteristic of albite. The fabric suggests that it is a flow of keratophyric affinities, rather than a hypabyssal albitite.

Estimated mode

Plagioclase	79
K-feldspar	10
Sericite	9
Rutile	1
Pyrite)	1
Limonite)	

This is another leucocratic rock of somewhat similar macroscopic appearance (in the stained cut-off block) to Sample 101 - being predominantly a white-etched mass of fine-grained plagioclase, with diffuse patches of intimately intergrown K-feldspar.

In thin section the resemblance is confirmed.

Plagioclase phenocrysts (albite), 0.1 - 2.0mm in size, make up about 60% of the rock. They are subhedral-euhedral in shape, but rather ill-defined (because of the similarity in composition with the enclosing groundmass). In a few cases, they appear to show embayment and partial resorption by the groundmass.

The phenocrysts are irregularly distributed (abundant in some areas, sparse in others), and show random orientation.

They are set in a minutely interlocking/microgranular (locally meshwork-textured) groundmass of albite, of grain size 5 - 50 microns. K-feldspar is an intimately intergrown accessory, generally occult, but locally developing as small clumps or incipient phenocrysts. K-spar also forms diffuse, irregular patches (replacements?) in some of the albite phenocrysts.

Both phenocrysts and groundmass appear essentially free of pervasive alteration.

Sericite in this rock is concentrated as sporadic, felted-textured segregations which appear to be localized centres of strong replacement. It also occurs as a few areas of wispy network impregnation.

Disseminate pyrite is relatively sparse and partially altered to limonite. It forms irregular clumps, to 0.3mm in size, sieved with matrix inclusions. It shows random distribution, without relation to the patches of intense sericitization.

The rather diffuse, heterogenous aspect of this rock in thin section suggests possible tuffaceous affinities, but no actual fragmental features are distinguishable.

It is texturally very similar to Sample 101.

SAMPLE 89T 122 **MONZONITE PORPHYRY**

Estimated mode

Plagioclase	59
K-feldspar	31
Sericite	4
Chlorite	6
Sphene	trace
Apatite	trace
Pyrite	trace

This is another example of the weakly altered, abundantly porphyritic monzonite, which is by far the commonest lithotype of this suite.

Phenocrysts, 0.2 - 5.0mm in size, make up about 70% of the rock. They are predominantly plagioclase, but also include some K-feldspar and altered mafics. They are sharply euhedral in all cases, and show random orientation.

The mafic phenocrysts consist of stubby to elongate, prismatic pseudomorphs, composed of minutely felted chlorite. Their shapes indicate derivation from primary amphiboles and/or pyroxenes.

The groundmass is a homogenous, minutely felsitic aggregate of K-feldspar, of grain size 5 - 10 microns, dusted with minute flecks of chlorite and opaques.

The plagioclase phenocrysts show a very mild, even, pervasive dusting of fine-grained sericite. The K-feldspar phenocrysts show partial argillic turbidity. The groundmass is essentially fresh.

Accessories include well-crystallized sphene and small euhedra of apatite.

The rock contains sparsely and randomly disseminated traces of pyrite.

K-feldspar	26
Sericite	2
Biotite	trace
Chlorite	5
Epidote	trace
Apatite	trace
Rutile	trace
Magnetite	2
Hematite	trace
Pyrite	trace

This rock is of essentially identical macroscopic appearance to the previous sample (#122) except that the proportion of K-feldspar phenocrysts is slightly lower.

Phenocrysts are abundant (70-75% of the rock), randomly oriented, euhedral prismatic in form, and range from 0.2 - 4.5mm in size. They consist predominantly of plagioclase, together with minor mafics and occasional K-feldspar.

The plagioclase phenocrysts are essentially fresh, but for a very light dusting with fine-grained sericite and a faint argillic turbidity - sometimes following concentric growth zones. The few K-spar phenocrysts are fresh and clear. They occasionally contain small plagioclase grains as inclusions.

The mafics are principally pseudomorphs (after probable hornblende) composed of felted sericite, commonly with inclusions of granular and lath-like opaques (magnetite and hematite). A few scrappy flakes of partially leached and rutilized biotite were also seen.

The disseminated opaques in this rock are mainly oxides, though occasional irregular clumps of pyrite were also noted. These include some patches of minute intergranular network impregnation of the groundmass.

The groundmass is a homogenous, interlocking to meshwork-textured, microgranular aggregate, of grain size 20 - 100 microns. It is composed predominantly of fresh K-feldspar, with intergrown accessory plagioclase (recognizable by its slight dusting of sericite) and sparsely disseminated micron-sized opaques.

SAMPLE 89T 132 **MONZONITE PORPHYRY**

Estimated mode

Plagioclase	32
K-feldspar	58
Sericite	2
Chlorite	2
Secondary amphibole(?)	1
Carbonate	5
Apatite	trace
Opaques)	trace
Limonite)	

This rock differs from the preceding two samples by virtue of its distinctly higher ratio of K-feldspar to plagioclase.

Euhedral phenocrysts make up about 60% of the rock. These include approximately equal proportions of plagioclase and K-feldspar - the former ranging in size from 0.2 - 3.0mm, and the latter consisting of relatively fewer but much larger crystals, in the range 1.5 - 9.0mm (often totally or partially including smaller plagioclase euhedra).

The rock shows the same weakly altered character as most of the others of the suite, with plagioclase phenocrysts very mildly and evenly dusted with minute flecks of sericite and K-spar phenocrysts (and groundmass) totally fresh.

Mafics - as is the norm for the suite - are mainly in the form of sparse, totally altered phenocrysts. The mode of alteration is, however, distinctive in this sample - including a substantial component of carbonate. This occurs alone, or intimately intergrown with felted chlorite or yellow-green secondary amphibole(?) as pseudomorphs (after probable amphibole or pyroxene) and as occasional diffuse clumps in the groundmass.

The groundmass is an even, minutely felsitic aggregate of K-feldspar, of grain size 5 - 20 microns, containing tiny plagioclase and K-spar sub-phenocrysts to 0.1mm in size.

Opaques are sparse. They include a few randomly disseminated euhedral grains of pyrite, 0.05 - 0.5mm in size - partially altered to limonite.

SAMPLE 89T 134 MONZO-DIORITE PORPHYRY

Estimated mode

Plagioclase	70
K-feldspar	15
Quartz	1
Sericite	8
Clays	1
Chlorite	3
Biotite	trace
Pyrite	2

The stained cut-off block of this sample indicates that it is a variant of the familiar feldspathic porphyries of the suite. The groundmass contains a relatively low proportion of K-feldspar, and the composition of the rock approaches that of a leuco-diorite.

Phenocrysts are somewhat less abundant and a little smaller than in many of the samples, making up about 60% of the rock. They consist of the usual assemblage of plagioclase (strongly predominant) plus minor K-spar and altered mafics. Phenocryst size is in the rage 0.1 - 3.0mm, and orientation is random.

Plagioclase phenocrysts show the usual very light dusting of minutely fine-grained sericite, with occasional brownish concentration in cores and concentric growth zones: there is also some development of sub-opaque clouding, presumed to be of argillic character. A few plagioclase crystals show much stronger pervasive sericitization. K-spar phenocrysts are fresh.

Mafic phenocrysts consist mainly of rather poorly formed pseudomorphs composed of felted chlorite. There are also a few flakes of altered (bleached) biotite.

The chloritized mafics are strongly favoured as sites for the relatively abundant disseminated pyrite in this sample. The pyrite occurs as clusters of granules within the chlorite or, in many cases, forms the bulk of the pseudomorph, as coalescent poikilitic patches with included and mantling chlorite.

The groundmass is a minutely felsitic aggregate of grain size 5 - 15mm, composed mainly of plagioclase, with an indeterminate proportion of intimately intergrown K-spar and occasional small clumps of microgranular quartz. Small sub-phenocrysts of feldspar are abundant.

The plagioclase-rich composition of this groundmass is emphasized by a noticeable, even, pervasive sericitization - contrasting with the clear, unaltered appearance of the groundmasses in the samples of more potassic composition.

SAMPLE 89T 139 **MONZONITE PORPHYRY**

Estimated mode

Plagioclase	53
K-feldspar	38
Sericite	2
Clays	1
Secondary biotite	1
Chlorite	4
Apatite	trace
Sphene	trace
Rutile	trace
Pyrite	1

This is yet another example of the familiar monzonite porphyry lithotype which dominates the suite.

Phenocrysts (totally about 60% of the rock) are mainly plagioclase, as subhedral-euhedral crystals 0.2 - 2.5mm in size. K-feldspar phenocrysts are few in number, but reach much larger sizes (to 8.0mm) - similar, for example, to those in Sample 132.

The plagioclase phenocrysts show the usual faint dusting of sericite. In addition they, not uncommonly, show cores or concentric growth zones defined by felted olive-brown material (secondary biotite?), and some are clouded with sub-opaque dust - possibly representing dispersed clays and/or leucoxene.

The occasional K-spar phenocrysts are fresh, and the larger ones typically incorporate small, stubby euhedra of sericitized plagioclase within them.

Mafic pheocrysts are totally pseudomorphed by felted chlorite, sometimes with granules of rutile.

The groundmass is a feathery/felsitic aggregate of K-feldspar, of grain size 5 - 15 microns, with tiny diffuse to euhedral sub-phenocrysts of K-spar and plagioclase. As seems typical of this lithotype, the groundmass is essentially devoid of intergrown mafics.

The rock contains well-crystallized, twinned grains of sphene and tiny euhedra of apatite as trace accessories.

Minor pyrite forms sparsely disseminated, individual subhedra - not showing the close association with altered mafics observed in Sample 134.

SAMPLE 89T 164 **MONZONITE PORPHYRY**

Estimated mode

Coarse phase	
Plagioclase	43
K-feldspar	30
Sericite	1
Secondary biotite) Secondary amphibole)	11
Carbonate	14
Sphene) Rutile)	1
Apatite	trace
Fine phase (xenolith)	
Plagioclase	45
K-feldspar	15
Secondary biotite) Secondary amphibole)	30
Carbonate	9
Sphene) Rutile)	1

The sectioned portion of this sample consists predominantly of a porphyritic phase, of similar appearance to the prevalent monzonite lithotype of the suite, but showing rather strong, preferred orientation of the phenocrysts. At one end of the slide, this unit is seen in apparent sharp contact with a fine-grained, non-porphyritic phase.

Reference to the hand specimens of this sample suggests that the fine-grained phase is part of a xenolith.

The porphyritic phase consists of phenocrysts of plagioclase and occasional K-feldspar, plus rather abundant smaller phenocrysts of totally altered mafics. Together, these constitute about 60% of the rock.

Plagioclase phenocrysts are 0.5 - 6.0mm in size, and are essentially fresh but for a faint cloudiness and rare, tiny flecks of carbonate. Some show patchy intergrowths and cores of more potassic composition.

K-feldspar phenocrysts, in the thin section, are rare and of comparable size to the plagioclase; however, the hand specimen shows that scattered, much coarser, euhedral K-spar individuals also occur.

Mafic phenocrysts are mainly in the size range 0.2 - 1.0mm (but occasionally to 3.0mm). They consist of sharply defined, euhedral pseudomorphs, now composed entirely of carbonate, but showing

crystal shapes and relict cleavage indicative of origin as hornblende.

Finer-grained mafics, in the form of a strong yellow-brown, felted material (secondary biotite?) occur as an intimately intergrown (alteration?) phase throughout the groundmass, and also often rim - and impregnate relict cleavages in - the carbonate pseudomorphs.

The groundmass matrix consists of felsitic K-feldspar, of grain size 10 - 50 microns, with tiny sub-phenocrysts of plagioclase.

This rock is a monzonite porphyry of similar general composition to many others of the suite. The distinctive preferred orientation of the phenocrysts is presumably a flow feature, related to intrusion of a highly fluid magma.

The xenolithic area is of similar overall composition, but distinctive texture. It is a blocky-textured, microgranular aggregate of intergrown subhedral-euhedral plagioclase and K-feldspar, of grain size 0.1 - 0.5mm, with abundant intergranular carbonate and secondary biotite or amphibole. It contains sparsely scattered phenocrysts (to 1.5mm) of plagioclase and totally altered mafics. Possibly it is an included fragment of a chilled margin phase.

Estimated mode

Plagioclase	50
K-feldspar	31
Biotite	1
Pyroxene	1
Carbonate	10
Secondary biotite) Secondary amphibole)	4
Apatite	trace
Opaques	3

This sample is distinguished from other rocks of similar general type in the suite by a somewhat higher proportion of mafics, and a rather dark (opaque-dusted) groundmass.

Phenocrysts, 0.2 -3.0mm in size, constitute about 55-60% of the rock. They are predominantly plagioclase - essentially fresh, and often well-twinned (indicated composition: andesine). There are also a few fresh K-spar phenocrysts. There is a weak tendency for local preferred orientation of the phenocrysts.

Mafics - entirely as phenocrysts - make up some 16% of the rock. They are mainly strongly altered to pseudomorphs of intimately intergrown carbonate and an olive-brown, felted/crustified product which may be a form of secondary amphibole or biotite. Many of the mafic pseudomorphs show small, ragged, remnant patches of colourless to pale brown clino-pyroxene; this was clearly the dominant primary mafic silicate. Occasional equant grains of brown biotite, with lamellar intergrowths of opaque dust, are also seen.

The groundmass is a homogenous, minutely felsitic aggregate of K-feldspar, of grain size 5 - 15 microns, occasionally including slender microlites of plagioclase. It is evenly dusted throughout with minute opaque granules, 2 - 10 microns in size.

Coarser disseminated opaques, in the form of individual equant subhedra, 0.05 - 0.7mm in size, are rather common. They are sometimes associated with altered mafics, but also occur randomly scattered through the groundmass. They appear to be entirely Fe oxides - pyrite being notable by its absence.

Carbonate	9
Apatite	trace
Opaques	2

This rock is closely similar to the previous one (Sample 184). It has a dark, opaque-dusted groundmass and shows a similar mode of alteration of the mafic phenocrysts (though no pyroxene remnants survive).

The portion sectioned includes a single large (1.5 cm) phenocryst of K-feldspar, which boosts the overall K-spar/plagioclase ratio in the estimated mode. The predominant plagioclase phenocrysts are 0.2 - 3.5mm in size, and show a weak, but perceptible, partial parallelism of orientation - presumably related to flow.

No specific indications of extrusive origin (such as amygdules or glass) are seen, and the rock is texturally comparable with the many other examples of monzonite porphyries in the suite.

Plagioclase phenocrysts are very lightly dusted with fine-grained sericite, and sometimes have included flecks and patches of green secondary mafics. K-spar phenocrysts are commonly weakly to moderately replaced by carbonate (a distinctive feature, in that K-spar phenocrysts are notably unaffected by alteration in most other samples of the suite. (Sample 89T 23 is an exception, like the present sample).

Mafic phenocrysts are totally pseudomorphed by various combinations of carbonate and a green felted secondary product. Many have associated grains of oxidic opaques.

The groundmass is a sub-trachytic aggregate of tiny lath-like feldspars in a felsitic K-spar matrix, of grain size 5 - 50 microns. It is evenly dusted with micron-sized opaques and sparsely flecked with minute specks of sericite or secondary mafics.

K-feldspar	31
Quartz	trace
Sericite	1
Biotite	1
Secondary amphibole) Chlorite)	2
Carbonate	4
Apatite	trace
Rutile) Opaques)	1

This is a rock of similar features to the previous two samples - particularly as regards the predominance of carbonate as a mafic alteration product, and the presence of a light dusting of micron-sized opaques throughout the groundmass.

Phenocrysts, 0.2 - 4.5mm in size, make up about 60% of the rock. They are principally plagioclase, plus a minor proportion of K-feldspar and altered mafics. They show random orientation.

Plagioclase phenocrysts show an even, faint dusting of pervasive sericitization. K-spar phenocrysts are fresh.

Mafic phenocrysts include some small flakes of somewhat altered, but recognizable, biotite. The principal type is pseudomorphed by carbonate with patchily intergrown felted chlorite or secondary amphibole. A few small, equant pseudomorphs are composed entirely of the felted green mineral, and there are also occasional irregular patches of carbonate without chlorite.

The groundmass is a felsitic aggregate of K-feldspar, of grain size 5 - 20 microns, with abundant tiny, blocky, sub-phenocrysts of plagioclase to 0.1mm in size. It is flecked by minutely fine-grained carbonate and sparse opaque dust.

Opaques are sparse. They consist of disseminated, discrete, equant grains, 0.05 - 0.2mm in size, which appear to be entirely oxides.

SAMPLE 89T 197 **MONZONITE PORPHYRY**

Estimated mode

Plagioclase	54
K-feldspar	33
Quartz	trace
Sericite	2
Chlorite	2
Carbonate	8
Sphene	trace
Apatite	trace
Opaques	1

This rock is identical, in all essential respects, to the previous sample (#194).

Phenocrysts make up about 60% of the rock. They are 0.2 - 5.0mm in size, and are randomly oriented. Plagioclase is by far the commonest phenocryst type, but, as usual, a few K-spar phenocrysts are also present.

The plagioclase may be marginally more strongly flecked with sericite than in the previous sample, and there is also very minor carbonate alteration. The K-spar phenocrysts, in particular, often show minor patchy replacement by carbonate.

Altered mafic phenocrysts are pseudomorphed by carbonate and felted chlorite. There are also a few micaceous flakes - now composed of muscovite with interlaminar rutile, but probably derived by alteration of original biotite.

Carbonate also forms a few, sporadic, irregular, sparry pockets, to 1mm in size, (replacement patches in the groundmass?) with tiny included euhedra of quartz.

The groundmass is identical to that of Sample 194, except that dust-sized opaques are still rarer. Disseminated opaques are sparse, discrete, equant grains of magnetite.

SAMPLE 89T 208 SERICITIZED FELSIC TUFF

Estimated mode

Plagioclase	60
K-feldspar	12
Quartz	2
Sericite	25
Apatite	trace
Opaques) Limonite)	1

This is a fragmental rock made up of abundant, sub-angular, lithic clasts of widely varying size (0.2 - 15.0mm or more), in a matrix of similar composition.

The clasts contain subhedral, sometimes flow-oriented phenocrysts of plagioclase, to 1.0mm in size, in a turbid, minutely felsitic groundmass. Both phenocrysts and groundmass show strong pervasive sericitization. The groundmass includes ill-defined clumps and wisps of microgranular K-spar and minor quartz. No mafics are recognizable except for disseminated granules and clumps of fine-grained opaques.

The clasts, distinguishable by their micro-porphyritic character and by variations in the degree of clouding (sericitization) of the groundmass, are set in a matrix or interstitial phase of felsitic plagioclase. The clasts include occasional disaggregated coarse plagioclase phenocrysts.

This rock is a lithic tuff of strongly sericitized leuco-andesite or keratophyre fragments. It does not have the siliceous and K-rich composition of a rhyolite.

SAMPLE DDH 73-2 252' MONZONITE PORPHYRY WITH XENOLITHS

Estimated mode

Plagioclase	43
K-feldspar	34
Quartz	2
Sericite) Secondary biotite)	20
Apatite	trace
Rutile	1
Limonite	trace

The macroscopic appearance of this rock(see stained cut-off block) is somewhat heterogenous. It appears to contain several sodic xenoliths, up to 5.0mm in size, and the assimilation of other (smaller) xenoliths may contribute to the "messy" appearance.

The predominant (host) phase is a monzonite porphyry of similar general type to many other rocks of the suite, but distinctive for its lack of accessory mafic phenocrysts. In this respect it resembles 89T 22.

Phenocrysts constitute about 50-60% of this lithotype. They appear to be entirely plagioclase, as subhedral-anhedral crystals, of rather widely ranging size (0.2 - 5.0mm).

The phenocrysts are set in an anhedral microgranular groundmass of fresh K-feldspar, of grain size 20 - 100 microns, with minor intergrown accessory quartz. Fine-grained, olive-green to pale brown sericite and/or secondary biotite, form intergranular wisps and pockets, sometimes with associated rutile.

The plagioclase phenocrysts are rather strongly altered to similar brownish-greenish secondary products, as pervasive flecks and concentric zonal concentrations.

The rock is cut by a network of hairline fractures which are penetrated by the sericitic alteration and locally by limonite.

There are also a few hairline veinlets of quartz which, together with occasional pockety microgranular concentrations, suggests the effect of mild silicification as well as the prevalent sericitization/biotitization.

The xenolithic inclusions are a leucocratic, sodic lithotype (keratophyre?) composed of fine-grained felsitic plagioclase, with interstitial greenish sericite/biotite. This is host to irregularly distributed clumps of rather ill-defined plagioclase microphenocrysts, 0.1 - 0.5mm in size.

SAMPLE DDH 73-2 463.5' MONZONITE PORPHYRY WITH A QUARTZ VEINLET

K-feldspar	40
Quartz	3
Sericite	3
Biotite	trace
Secondary biotite	4
Carbonate	trace
Apatite	trace
Opaques	trace
Veinlets	
Quartz	12
Carbonate	1

This sample appears, from macroscopic examination of the stained cut-off block, to be a feldspathic porphyry of monzonitic composition - not recognizably different from many others of the suite, except for a crudely banded variation (possibly a settling effect?) in the abundance and size of phenocrysts.

The rock is cut by a 3.5mm veinlet of quartz and some irregular, wispy, hairline veinlets of carbonate.

It resembles Samples #72 and 85 in having appreciable amounts of accessory quartz in the groundmass, and in displaying a carbonate-free alteration style. As regards K-spar/plagioclase ratio, it is intermediate between these two samples.

There is no obvious evidence on the thin section scale to indicate that this rock exhibits "intense K alteration" as suggested in your covering letter.

It is of distinctly leucocratic composition. Phenocrysts - which make up about 50% of the rock on average - are almost entirely plagioclase, as randomly-oriented, prismatic euhedra, 0.2 - 3.5mm in size. No K-spar phenocrysts were noted, and mafic phenocrysts are confined to rare, tiny flakes of partially altered biotite.

The plagioclase phenocrysts show the usual very light (to occasionally moderate) pervasive dusting with fine-grained sericite.

The groundmass is somewhat variable in texture, ranging from a minutely interlocking/felsitic aggregate of K-feldspar, of grain size 5 - 10 microns, to a slightly coarser microgranular intergrowth, on the scale 10 - 100 microns, which includes a significant component of granular quartz. Scattered, tiny microphenocrysts of plagioclase in the groundmass tend to be more strongly sericitized than the larger phenocrysts, but the dominant K-spar is unaltered.

Sample 73.2 463.5 cont.

The rock shows a 5mm envelope of alteration marginal to the main quartz vein, in which the groundmass is pervasively replaced by wisps and clumps of minutely felted, pale brown secondary-type biotite.

A few thin, semi-continuous stringers of quartz and of carbonate cut the slide, and are sometimes difficult to differentiate from the pockety quartz (and rare carbonate) of primary aspect in the groundmass.

Coarser and more abundant groundmass quartz and K-spar occur interstitial to a localized patch of unusually close-packed plagioclase phenocrysts.

SAMPLE DDH 73-3 238' MONZONITE PORPHYRY

Estimated mode

Plagioclase	50
K-feldspar	35
Quartz	4
Sericite	6
Jarosite(?)	2
Limonite	1
Opaque dust	2

This is an abundantly porphyritic monzonite of similar macroscopic aspect to many of the rocks of the suite.

Phenocrysts make up 60% of the rock. They are 0.2 - 4.0mm in size, and show a weak, imperfect, preferred orientation. They consist predominantly of plagioclase, plus a few of K-feldspar.

Thin section examination shows that this rock has some features which distinguish it from others of the suite.

The plagioclase phenocrysts show the usual mild dusting of pervasive sericite but, in part, are also notably clouded by micron-sized opaque/sub-opaque material (ferruginous clays? hematite?).

Mafics consist - rather than the usual chlorite or carbonate - of sparsely distributed, scrappy wisps and clumps of sericite - often intergrown with limonite and/or a high-relief, yellow-brown material which has the appearance of jarosite. These altered mafics probably originated as biotite.

The groundmass is a blocky, microgranular aggregate of fresh K-feldspar, with a significant content of intergrown quartz, as scattered, small clumps and pockets. In this respect, it resembles Samples 72, 85 and 73-2 463.5'.

The rock is cut by a network of hairline microfractures, sometimes infilled by limonite and/or with associated pockets of the microgranular/spherulitic-textured jarositic component.

SAMPLE DDH 75-2 698.5' ANDESITE PORPHYRY

K-feldspar	1
Amphibole	22
Chlorite	10
Carbonate	6
Epidote	trace
Apatite	trace
Sphene)	1
Rutile)	
Pyrite	8
Chalcopyrite	trace

This sample is of a type not previously represented in the suite.

It is a rather fine-grained porphyritic rock of dioritic (or andesitic) composition. It is quartz-free and essentially devoid of K-feldspar, and is distinguished by a substantial content of fresh amphibole.

Phenocrysts make up some 60% of the rock. They are mostly in the size range 0.2 - 1.0mm, but show a gradation in size, through smaller phenocrysts, to merge with the granularity of the rather heterogenous, felsitic groundmass. They show a rather irregular distribution, with a tendency to concentrate as close-packed clusters separated by phenocryst-poor areas.

Phenocrysts consist of approximately equal proportions of plagioclase and amphibole. The latter is a pale olive-green hornblende, showing partial alteration to fine-grained carbonate. The plagioclase is mildly dusted with fine-grained carbonate and/or contains flecks of secondary amphibole or chlorite.

The groundmass is composed of felsitic plagioclase with diffuse intergrowths of fine-grained amphibole and chlorite, and micron-sized rutile.

The rock contains extensive patches in which the groundmass is permeated (totally replaced?) by pyrite, to form emulsion-textured or amoeboid networks, enveloping and cementing phenocrysts of plagioclase and amphibole. To some degree, the pyrite also penetrates and partially replaces the phenocrysts in these areas. Minor development of K-feldspar appears to be associated with the peripheries of these pyrite "sponges".

Scattered small clumps of fine-grained chalcopyrite (10 - 100 microns) are seen as impregnations of the host groundmass, independent of the pyrite.

SAMPLE DDH 75-2 822' **ANDESITE**

Amphibole	18
Chlorite	3
Epidote	1
Apatite	trace
Sphene	1
Pyrite	2
Veinlets	
Carbonate	1
Alunite(?)	trace
K-feldspar	trace

This is a very similar rock to the previous sample (at 698.5').

It is a rather fine-grained, sub-porphyritic rock, showing grain size up to 1.0mm. It is composed of aggregates of subhedral plagioclase and accessory hornblende, with an interstitial matrix of the same minerals of much finer grain size (down to 10 - 50 microns). Patches of relatively coarser average grain size alternate gradationally with areas in which the felsitic form predominates.

The content of amphibole in this rock is slightly lower than in the previous sample, and it is free of pervasive carbonate alteration - but shows marginal breakdown to olive-green, felted, secondary amphibole and/or chlorite. This altered form of amphibole is predominant as a fine-grained, interstitial phase in the finer felsitic matrix areas. It also occurs as more or less abundant flecks included in many of the coarser plagioclase phenocrysts.

Epidote occurs as scattered, small, random clumps. Sphene, of similar anhedral cluster form, is a prominent disseminated accessory, along with tiny euhedra of apatite.

Minor disseminated pyrite occurs as amoeboid/poikilitic impregnations, similar to those in the previous sample, but much less extensive.

The rock is cut by rare hairline veinlets of carbonate and a colourless, flaky/aggregate mineral which resembles alunite. This occurs as core zones to carbonate veinlets, or as tiny threads in its own right.

This rock could be a fine-grained dyke, or an extrusive - possibly mildly autobrecciated.

SAMPLE DDH 75-5 145' ALTERED MONZONITE PORPHYRY, WITH QUARTZ VEINLETS

Plagioclase	8
K-feldspar	42
Quartz	45
Sericite	4
Biotite	1
Chlorite	trace
Rutile	trace
Apatite	trace
Fluorite	trace

As far as can be determined on the thin section scale, this sample consists of a zone of irregular, anastomosing quartz veining, cutting a porphyritic monzonite of familiar type.

The silicified zone appears to be mantled by a thin (1 - 5mm) envelope of potassic alteration, in which the host rock is largely converted to fine-grained K-feldspar - as are included islands of the host within and between the quartz stringers.

This relationship is clearly displayed in the stained cut-off block, where a thin remnant of the original porphyritic monzonite is still recognizable at one side.

The latter consists of weakly parallel-oriented plagioclase phenocrysts, 0.2 - 2.5mm in size, in a blocky microgranular groundmass of K-feldspar, of grain size 20 - 100 microns, with minor intergrown quartz. Mafics consist of sparse, small flakes of partially chloritized or bleached biotite. Apatite is a prominent trace accessory.

Proximal to the quartz veins, this rock type is modified to the extent that the plagioclase phenocrysts are replaced by similar-sized subhedral crystals of turbid K-feldspar. The groundmass (which is already composed mainly of K-feldspar) is not recognizably affected, except that accessories and mafics are essentially absent.

The quartz veinlets consist of monomineralic quartz as a somewhat crenulate-margined mosaic, of grain size 0.1 - 0.6mm. They exhibit complex, invasive contacts against the altered host rock - which shows localized pervasive silicification, as small, irregular quartz clumps.

One or two tiny (0.2mm), angular/interstitial pockets of fluorite were seen in the quartz mosaic.

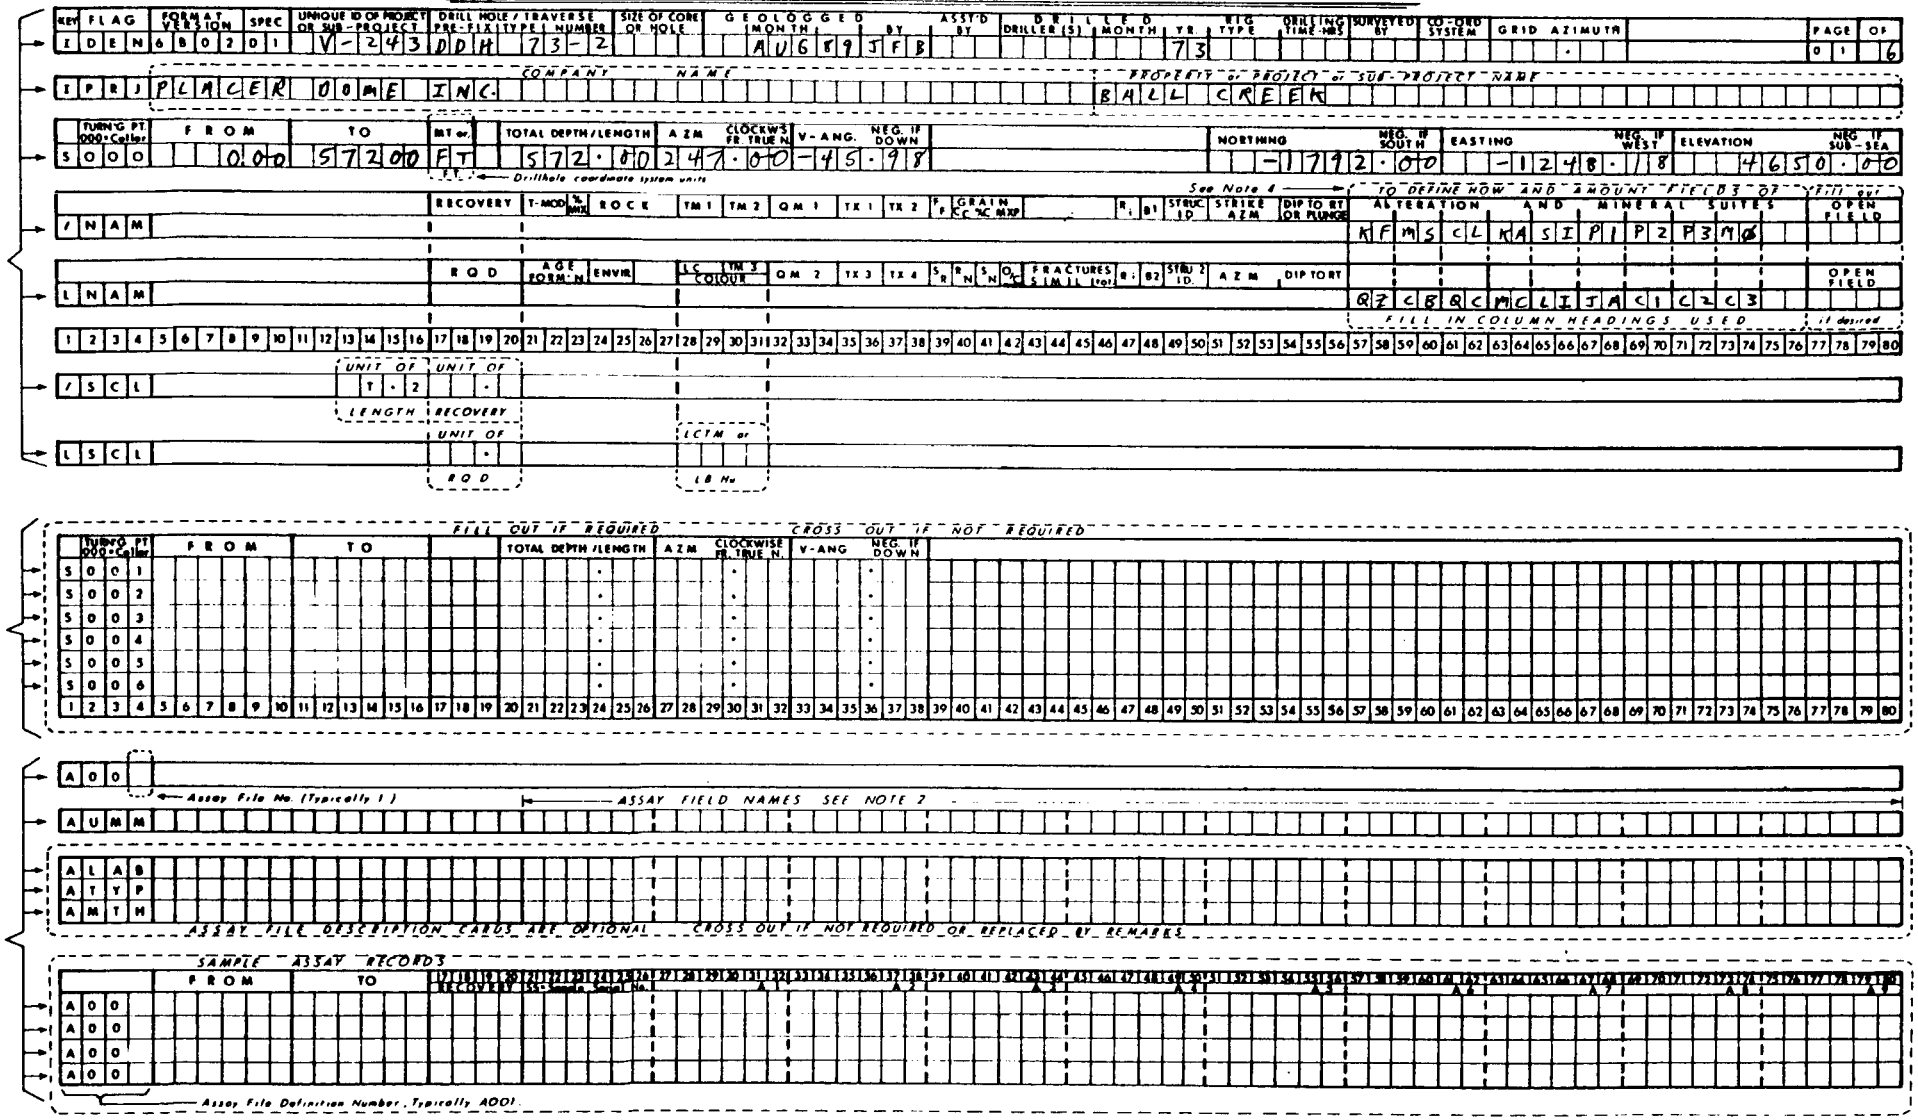
PLACER DOME INC. GEOLOG DRILLHOLE HEADER FORM



Notes:

1. - Do not change /NAM, LNAM, /SCL, LSCL, or AUMM card definitions durin a project. Blanks may be changed howe
2. - On AUMM card, right adjust names so that R H 4 letters make sense. They will be "stats" header names
3. - Units of distance on S000 card are for survey coordinates, those on /SCL card are for downhole distances.
4. - To define XX type field put XX in upper tier, lower tier then becomes corresponding How and amount field
5. - If additional "S" or "A" cards are required use another header form and cross out unwanted portions or enter "S" or "A" cards on keypunched portion on Form 7.

DESCRIPTIVE REMARKS

(452.5'-881.6') PORPHYRITIC ALTERED ANDESITE BRECCIA

Colour varies from medium greenish-grey to medium greenish-greyish-pink to medium greenish-greyish-whitish-pink.
452.5'-510': Core is bleached.
474': 2 blebs of fluorite occur in a qtz vein.

520'-530': Local fluorite blebs occur in the quartz veins.

SP 1988

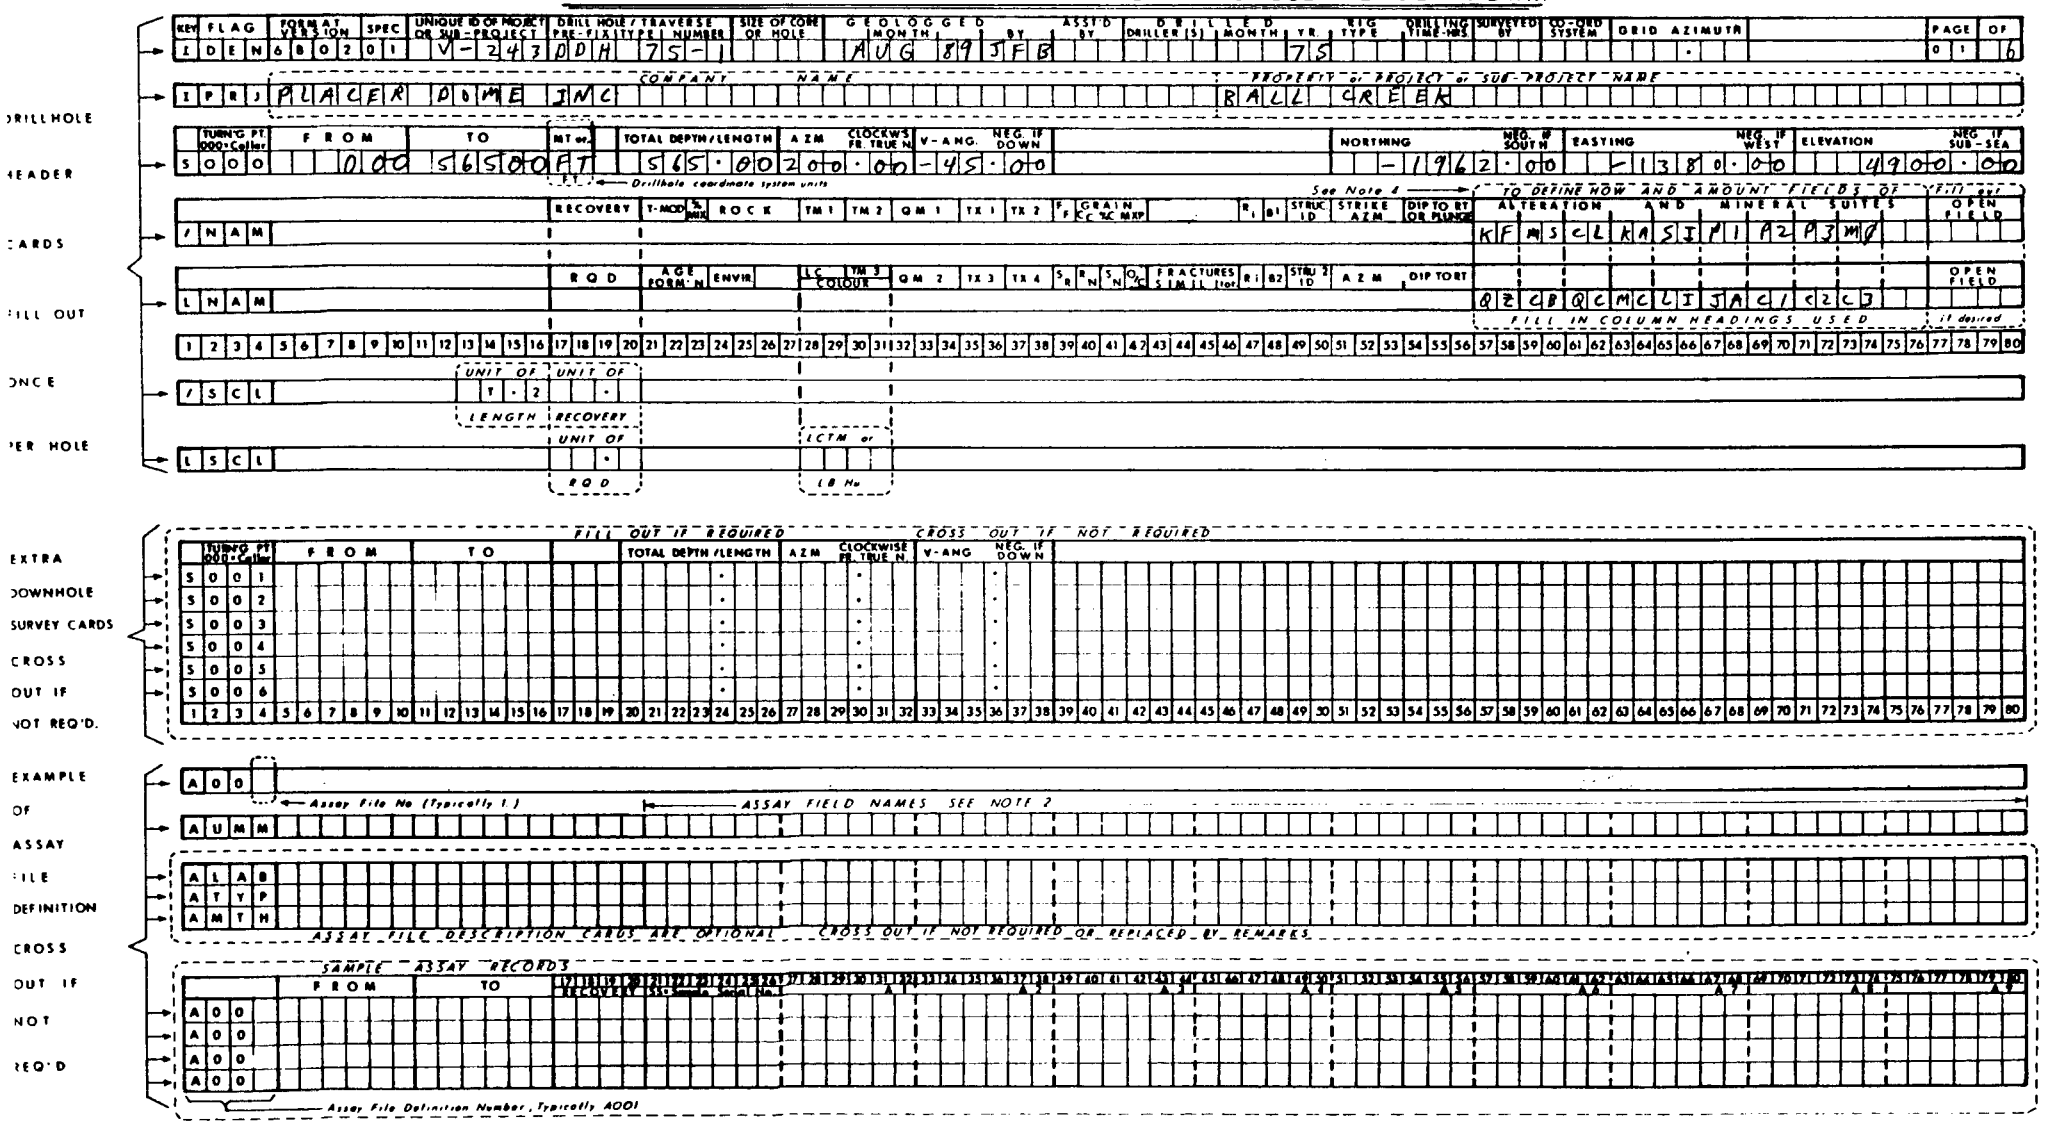
PLACER DOME INC. GEOLOG DRILLHOLE HEADER FORM



DRILLHOLE HEADER CARDS FILL OUT ONCE PER HOLE

EXTRA DOWNHOLE SURVEY CARDS CROSS OUT IF NOT REQ'D.

EXAMPLE OF ASSAY FILE DEFINITION CROSS OUT IF NOT REQ'D

Notes

1 - Do not change /NAM, LNAM, /SCL, LSCL, or AUMM card definitions durin a project. Blanks may be changed howe.

2 - On AUMM card, right adjust names so that R H 4 letters make sense. They will be " stats" header names.

3 - Units of distance on 5000 card are for survey coordinates, those on /SCL card are for downhole distances.

4 - To define XX type field put XX in upper tier, lower tier then becomes corresponding How and amount field

5 - If additional "S" or "A" cards are required use another header form and cross out unwanted portions or enter "S" or "A" cards on keypunched portion on Form 7.

DESCRIPTIVE REMARKS

240' - 243' : Sheared and brecciated.

(243' - 311') ALTERED ANDESITE AND ALTERED ANDESITE BRECCIA.
Colour is medium to light greenish - greyish - orange.
250' - 260' : Core is locally bleached.

270' - 300' : Core is locally bleached.

(311' - 590') DACITE LAPILLI TUFF
Colour varies from dark to medium greenish - greyish - orange to dark greenish - grey to dark greenish - black.

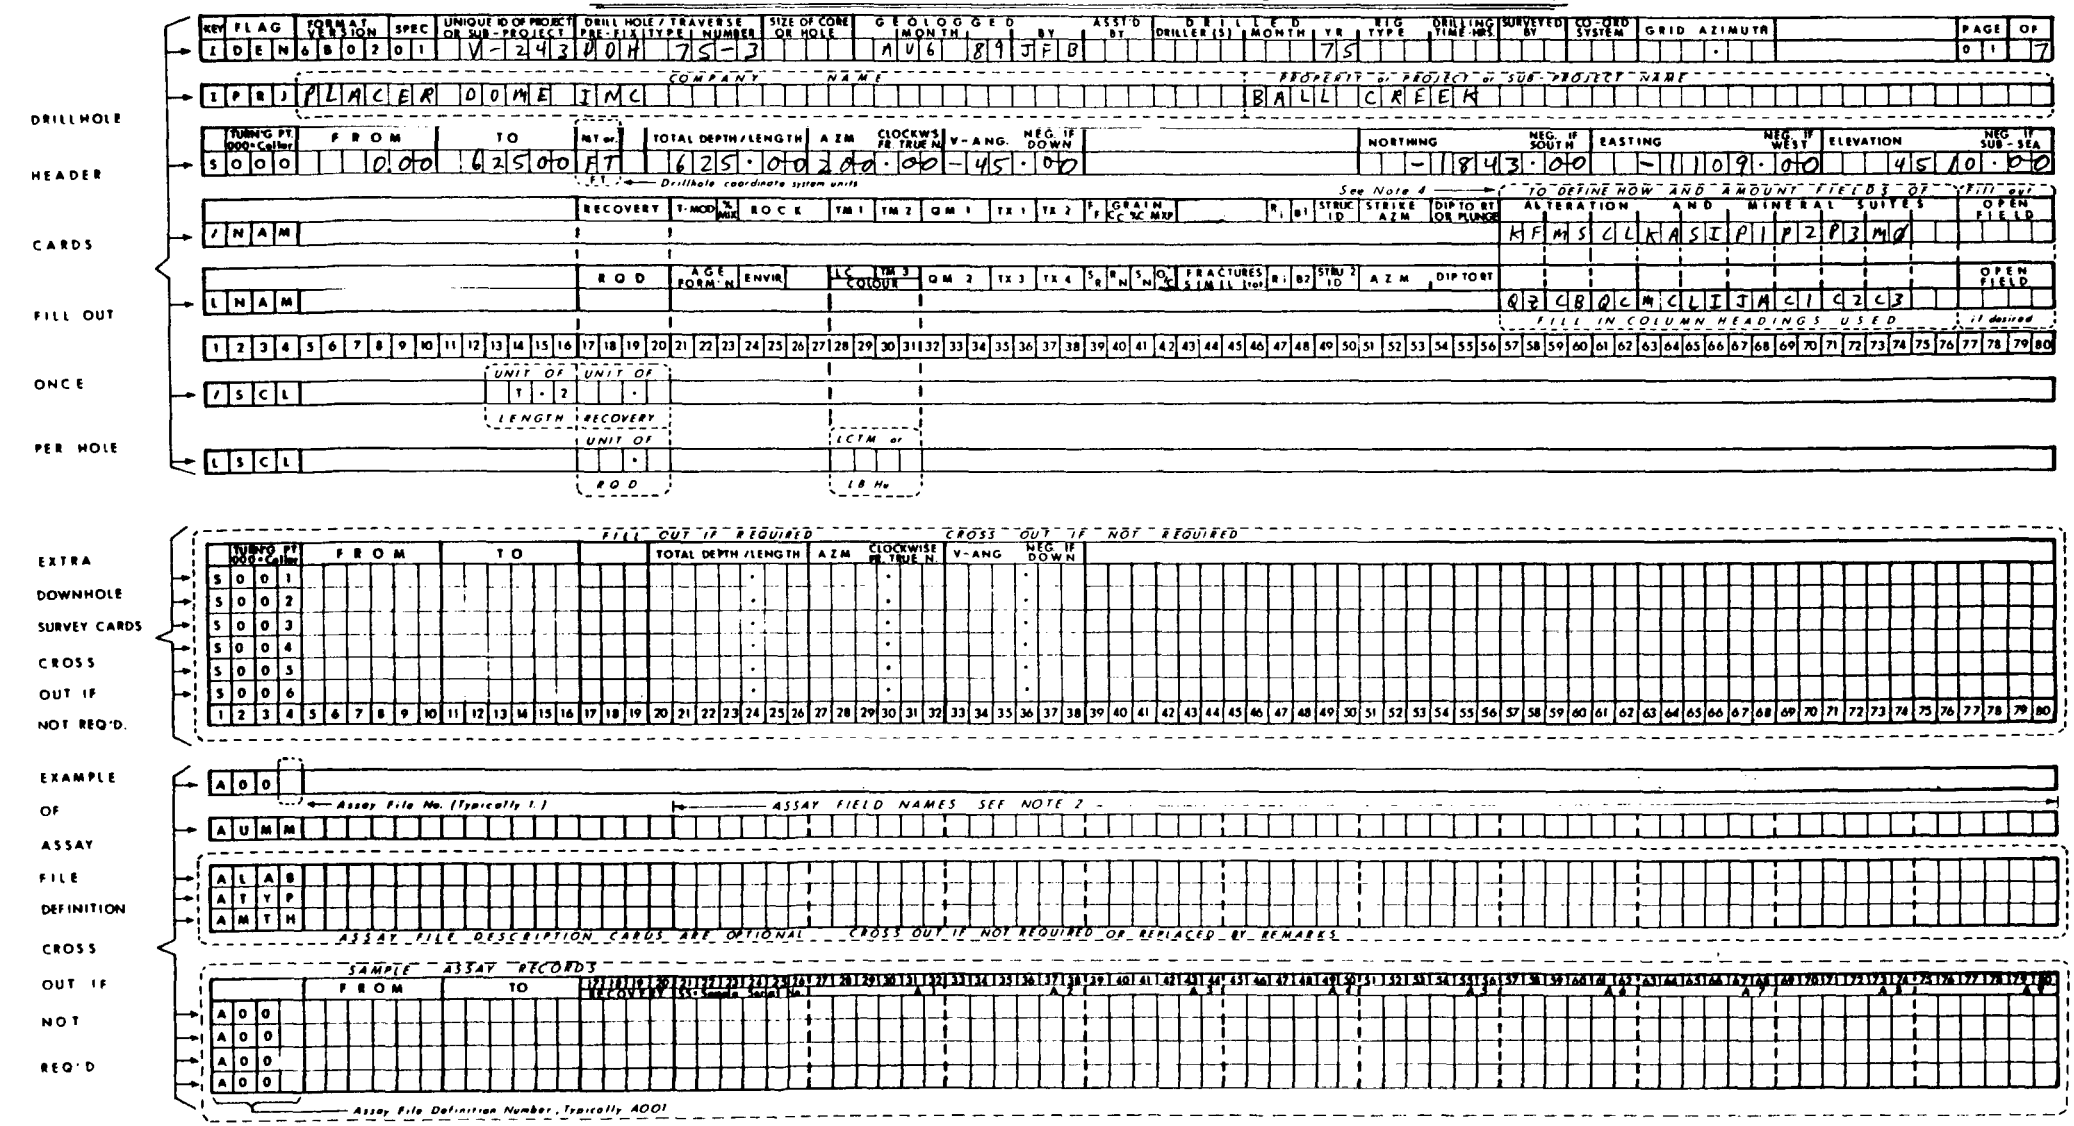
PLACER DOME INC. GEOLOG DRILLHOLE HEADER FORM



Notes

1 - Do not change INAM, LNAM, ISCL, LSCL, or AUMM card definitions durin a project. Blanks may be changed howe
2 - On AUMM card, right adjust names so that R H 4 letters make sense. They will be " stats" header names.
3 - Units of distance on 5000 card are for survey coordinates, those on ISCL card are for downhole distances.
4 - To define XX type field put XX in upper tier, lower tier then becomes corresponding How and amount field
5 - If additional "S" or "A" cards are required use another header form and cross out unwanted portions or enter "S" or "A" cards on keypunched portion on Form 2.

DESCRIPTIVE REMARKS

(0'-22') OVERBURDEN

(22'-100.5') ALTERED ANDESITE AND ALTERED ANDESITE BRECCIA.
Colour varies from light greyish-whitrish-orange to medium greenish-greyish-orange to light greenish-greyish-orange-pink.
22'-36': Intensely sheared / brecciated and bleached.

62.2'-70': Bleached QZMZ inclusion.

70'-80': This interval consists of 90% bleached QZMZ.

80'-92.5': Minor QZMZ fragments are present.

90'-100': Local bleaching occurs.

(100.5'-167') QUARTZ MONZONITE PORPHYRY
Colour varies from light greenish-greyish-orange to light greenish-greyish-whitrish-orangeish-pink.

Notes:

1. - Do not change /NAM, LNAM, /SCL, LSCL, or AUMM card definitions durin a project. Blanks may be changed lower.
2. - On AUMM card, right adjust names so that RH 4 letters make sense. They will be "stars" header names.
3. - Units of distance on 5000 card are for survey coordinates, those on /SCL card are for downhole distances.
4. - To define XX type field put XX in upper tier, lower tier then becomes corresponding How and amount field.
5. - If additional "S" or "A" cards are required use another header form and cross out unwanted portions or enter "S" or "A" cards on keypunched portion on Form 2.

DESCRIPTIVE REMARKS

(0'-26') OVERBURDEN

(26'-90') PORPHYRITIC DACITE

Colour varies from dark greenish-grey to dark greenish-greyish-orange.

50'-60': Locally brecciation is present.

(90'-91') QUARTZ MONZONITE PORPHYRY

Colour is dark greenish-grey.

(91'-97') FAULT

Core is now missing, however a fault was recorded in the A75 drill log.

(97'-219') QUARTZ MONZONITE PORPHYRY

Colour is medium brownish-greenish-grey.

APPENDIX NO 4

Analysis Techniques

GENERAL TEST.

GEOCHEM

GENERAL TEST

Elements: Mo Cu Zn Pb Cd Ni Co Ag Mn

Procedure:

1. Weigh 0.50 g of -80 mesh soil, sediment or -100 mesh pulverized rock into numbered 16 x 150 test tubes. Every tenth sample should be a duplicate sample or an internal known reference standard.

2. Add 1 mL of HNO_3 followed by 2 mL $HClO_4$. Samples containing carbonates may react vigorously at first so add 1 mL HNO_3 and let stand until the reaction stops before adding 2 mL $HClO_4$.

3. Place tubes in test tube block on hot plate at 160°C. The samples will boil vigorously at first and then decrease as the HNO_3 boils away. Organic samples should be watched to see that they do not foam. If they do foam, then take the test tube out of the block and gently tap the bottom of the tube on an asbestos pad. Highly organic soils can be handled by adding the acid and letting them stand overnight.

   The temperature of the hot plate should be set so that after the HNO_3 boils away (45 min ⟶ 1 h), then the $HClO_4$ boils gently and refluxes down the sides of the test tube. Total digestion time is 4 hours.

4. Cool the sample by adding 6 mL demineralized water and immersing the test tube rack in cold water for 2 min. After cooling, bring the volume up to 10 mL, cap, and shake.

5. Read on AA using air/acetylene flame for all elements except Mo which should be run using N_2O/acetylene flame. Background correction should be used on Pb, Cd, Ag. Turn burner head for Zn.

..... /2

Mo, Cu, Zn, Pb, Ag
GEOCHEM.

Standards:

- all standards are made in 15% $HClO_4$
- factor is 20

	Standard Concentrate (µg/ml)	AA Setting (ppm)
Cu Zn Pb Co Ni Mn	5.0	100
	10.0	200
Mo	1.0	20
	2.0	40
	4.0	80
Cd	0.10	2.0
	0.50	10.0
	1.00	20.0
Ag	0.50	1.0
	0.10	2.0
	0.20	4.0

add 2ml per 100
20% $AlCl_3$ to
STD

Samples giving a reading above the high standard are diluted 1 to 10 with 15% $HClO_4$ and re-analyzed.

Wavelengths:

Mo	313.3 nm
Cu	324.7
Zn	213.8
Pb	283.3
Cd	228.0
Ni	232.0
Co	240.7
Mn	279.5
Ag	328.0

Au

GEOCHEM

GOLD TEST

Procedure:

1. Weigh 10.0 g sample into #07 crucible.
2. Heat in furnace for 1 1/2 h @ 600°C.
3. Cool, transfer to 150 mL glass beaker and add 30 mL Aqua Regia (3 parts HCl, 2 parts H_2O, add 1 part HNO_3).
4. Digest at just off the boil for 2 hours.
5. Cool, and bulk up to 110 mL mark on beaker.
6. Stir and leave overnight to settle.
7. Decant 50 mL of sample solution into 25 x 200 mm test tube.
8. Add 7 mL MIBK, cap, and shake in shaker for 3 min.
9. Read organic layer on A.A.

Standards:

1. In 250 mL separate funnel add 10 mL H_2O, 1 mL HCL, 2 drops of HNO_3 and the following amounts of Au:

   0.1 mL of 1000µg/mL Au standard = 1 ppm
   0.2 mL of 1000µg/mL Au standard = 2 ppm
   0.4 mL of 1000µg/mL Au standard = 4 ppm

2. Add 100 mL MIBK and shake for 3 min.
3. Drain aqueous layer.

   For higher samples, standards can be made in 30% aqua regia and the remaining half of the sample can be run in the aqueous phase.

1987-11-24

Au
ASSAY METHO

DETERMINATION OF AU BY FIRE ASSAY & ATOMIC ABSORPTION

1. Weigh out 25 g sample into a 40 g fire assay crucible containing 150 g flux (2 parts PbO:1 part Na_2CO_3), and 25 g silica flour.

2. Add 1 1/2 tsp flour (~4.5 g) and 1 silver inquart.

3. Mix thoroughly with a large spatula until homogeneous and cover with a thin layer of flux.

4. Place the crucible in a preheated (2000°F) furnace for 45 min.

5. Remove the molten assay from the furnace and pour into an iron mold. Allow to cool for ~20 min.

6. Break the slag from the lead button and hammer into a cube for cupellation.

7. Place the lead button on a preheated cupel.

8. When cupellation has been completed, the cupel is removed from the furnace and allowed to cool.

9. The prill is removed from the cupel and transferred to a graduated test tube.

10. 5 mL 25% HNO_3 is added to each test tube and the test tube rack is placed in a boiling water bath.

11. Continue heating until all Ag is in solution (no bubbling, and Au appears as black speck.)

12. Cool, decant off acid solution. Wash once with 10 mL deionized H_2O, and decant off H_2O.

13. To each test tube add 0.3 mL acid mixture (5 HCl:1 HNO_3) using a pipette.

File No. M-002

HU
ASSAY METHOD

14. Return test tube rack to water bath and heat until all Au is in solution.

15. Wash down the side of test tube, heat for another 15 min.

16. Remove, cool, and bulk to appropriate volume; making sure the final acid strength is 5% HCl and 1% HNO_3.

17. Stopper test tube & mix by shaking.

18. Run on Atomic Absorption instrument vs Au standards (0-15 ppm).

19. Calculate amount of gold present in sample.

$$\text{ppm Au} = \frac{(\text{AA Reading [ug/mL]})}{\text{Wt Sample (g)}} \times (\text{Volume [mL]})$$

LEGEND

GROUP TWO (Lower Jurassic ?) Mainly epiclastics & basalt.

- 12 Andesitic lapilli tuff, locally crystal rich
- 11 Andesitic greywacke
- 10 Andesitic conglomerate, sometime with limestone clasts
- 9 Limestone
- 8 Well-bedded, graded andesitic greywacke - conglomerate
- 7 Basaltic mudstone
- 6 Basalt flows 6a pillowed, amygdaloidal; 6b non-pillowed porphyritic &/or vesicular

UNCONFORMITY

GROUP ONE (Upper to Late Triassic) Mainly andesitic country rocks intruded by monzonite.

- 5 Andesitic lahar. Contains clasts of Unit 2, 3 & 4
  - 5a lahar with Unit 2 clasts only & with minor interbeds of andesitic pyroclastics. Intruded by andesite dyes labelled as 2c
- 4 K-spar megacrystic andesite with trachytic flow texture
  - 4a plug
  - 4b flows
  - 4c dykes
- 3 Monzonitic intrusive (K-Ar date = Late Triassic) - undifferentiated monzonite
  - 3a lower dyke latite porphyry
  - 3b upper dyke monzonite porphyry
  - 3c ridge dyke monzonite porphyry
- 2 Andesite - either pyroclastic or flow
  - 2a pyroclastics
  - 2b flows
  - 2c dykes
- 1 Sedimentary rocks
  - 1a black siliceous argillite
  - 1b brown well-bedded siltstone with Norian (Upper Triassic) fossils

Attitudes (inclined, vertical) of :
- Bedding
- Joint
- Cleavage
- Shearing
- Lineation
- Primary flow structures in igneous rocks
- Dyke
- Vein (indicating gangue & width)

- Outcrop boundary
- Fault (observed or topographic trace). Dip indicated.
- Geological contact (inferred)
- Flow contact
- Soil sample site
- Stream sediment sample site
- Rock sample site
- Rock sampling line (random chips)
- Diamond drill hole projection
