1989 GALORE CREEK PROJECT

Introduction

The report which follows describes the geochemical, geophysical and trenching program carried out by Mingold Resources Inc. personnel from July 15 to August 7 and September 1-10, 1989. The report combines assessment for all 291 two-post claims which are divided into three groups (Galore Creek Group I, II and III). The assessment for each group is further subdivided into claims with anniversary dates of September through November (1989 assessment) and April through August (1990 assessment). All work done after September 1, 1989 is being applied toward 1990 assessment on the April August claims. Refer to the "Claims & Ownership" section for clarification of the above.

The 1989 program on Galore Creek consisted of two separate phases of work. The first phase was mainly a reconnaissance geochemical evaluation of the Galore Creek property targeted at locating higher grade gold mineralization within the porphyry copper environment. During this phase a total of 126 rocks, 150 silts and 266 soils were collected and 4.88 km of VLF-EM surveying was carried out. The second phase of the program consisted mainly of follow up of anomalies obtained in the first phase. During this phase a total of 84 rocks, 7 silts and 463 soils were collected and 6.55 km of VLF-EM surveying was carried out. This information is broken down in Table 1 below:

Table 1: Breakdown of Geochem and Geophysics

Year Assess. Applied For	Group II	ROCKS		Silts	Soils	VLF-EM (km)
		Chips	Channels			
1989	I	48	0	67	12	0.30
	II	36	0	51	107	2.75
	III	30	12	32	147	1.83
1990	I	21	33	6	153	4.30
	II	0	0	1	106	0
	III	9	21	0	204	2.25

In addition, four man days of trenching (Gp III) were done in the first phase and two man days (1-Gp I, 1 - Gp III) in the second phase.

Location, Access & Climate

The Galore Creek property of Stikine Copper Ltd. is situated in a basin at the headwaters of Galore Creek, a tributary of the Scud River, in the northwestern part of British Columbia. The property is centred at latitude 57° 07' 30" N and longitude 131° 27' W (see Fig. GC-89-1). The claims occur within the Liard Mining Division and extend across the boundary between N.T.S. mapsheets 104 G/3 and 104 G/4.

The property is approximately 355 kilometres northwest of Smithers, B.C. which is the major supply centre for the area. Central Mountain Air in 1989 operated a schedule fixed-wing service form Smithers to the Bronson Airstrip which is 55 kilometres southeast of the property. In addition, a turbine-equipped Otter aircraft made trips to the Galore Creek Airstrip when warranted. In 1989, helicopters were available on a casual basis from Bronson Airstrip (55 km), Telegraph Creek (90 km) and for a limited period at Galore Creek itself.

A private road was constructed by Stikine Copper Ltd. from the Scud Airstrip, at the junction of the Scud and Stikine Rivers, to the Galore Creek camp in the early 1960's. At that time, it was anticipated that production from the Galore Creek copper deposits was imminent. As it turned out, the only use of the road was for transporting several pieces of heavy duty equipment (primarily used for constructing the road). With years of lack of use, the road has overgrown with alders and the bridges have collapsed.

In 1989, the old road between the Galore Creek (Portal) Airstrip and the camp was upgraded to a useable condition for four-wheel drive vehicles. This permitted the transport of passengers and supplies by truck instead of by helicopter to and from camp.

The camp is located on the eastern side of the Galore creek valley at an elevation of approximately 760 meters above sea level. Elevations within the property boundary vary from a low of 550 meters in Galore Creek to over 1800 meters on the slopes of Saddlehorn Mountain.

Snow pack in the area is unusually heavy for northern B.C. with peak levels of 5 meters or more being typical. Snow-free conditions below the 1200 meter elevation are restricted to mid-June to late-September with air temperatures remaining relatively cool throughout the summer.

Vegetation is generally quite dense within the Galore Creek valley, consisting of mature stands of pine, spruce and cottonwood at lower elevations and passes into scrub evergreens up to treeline at 1200 meters. Underbrush of alder, willow and devil's club is extremely thick and in combination with the deeply incised creek gullies makes traversing arduous.

Claims & Ownership

The Galore Creek property consists of 252 claims and 39 fractions for a total of 291 two-post claims. These claims are wholly owned by Stikine Copper Ltd. which is controlled by Kennco (Stikine) Mining Ltd. (59%), Hudson Bay Mining and Smelting Co. Ltd. (36%) and Cominco Ltd. (5%). In 1989, Mingold Resources Ltd. entered into an option agreement with Hudson Bay Mining to explore the gold potential of the Galore Creek area.

For assessment purposes, the claims have been divided into three groups, Galore Creek Group I, II and III, consisting of 99, 92 and 100 claims respectively. Each group has been further subdivided into two sets depending on whether the claim anniversary date is before or after September 1 of the current calendar year. All claims with anniversary dates after September 1 can have assessment applied for the current year (1989) while those with anniversary dates before September 1 have to be filed for the following year (1990). A complete listing of the claims under each group subdivided into the year for which assessment is being applied is shown in Table 2.

History

Copper deposits were first discovered in the Galore Creek valley in 1955 by prospectors working for Hudson Bay Exploration and Development Co. Ltd. Staking and sampling was completed in the same year. In 1956, mapping, trenching and diamond drilling were carried out. Due to the remoteness of the area and higher priorities for expenditures elsewhere, no further work was undertaken and all but 16 claims were allowed to lapse.

In 1959, Kennco Exploration sampled the creeks in the area as part of a reconnaissance stream silt survey. Kennco began staking the resulting highly anomalous copper in the headwaters of Galore Creek in 1960. The claims surrounded the remaining H.B.E.D. ground as well as four claims which had been optioned by Cominco from one of the original prospectors. In 1962, the three companies agreed to jointly develop the property and subsequently in 1963 Stikine Copper Ltd. was formed.

Kennco was the operator of the exploration programs until early 1967. Work included 53,164 meters of diamond drilling in 235 holes and 807 meters of tunnelling in two adits. The Central Zone which occupies the valley bottom of Galore Creek became the main focus of exploration. No exploration work was carried out from 1968 to 1972.

In 1972, Hudson Bay Mining and Smelting became operator of the property and in 1972 and 1973 an additional 25,352 meters of diamond drilling was completed in 111 holes. This work focused exclusively on blocking out reserves on the Central and North Junction Zones.

In 1974, Wright Engineers undertook a feasibility study on the Galore Creek property and came out with a mining plan for the property.

Hudson Bay continued fill-in drilling in 1976, completing an additional 5,310 meters of diamond drilling in 24 holes.

Due to the enormous costs involved in bringing a deposit in this area into production the project has remained on hold until the present.

In 1989, Mingold Resources Inc. took an option on the property with the purpose of investigating the gold potential associated with the porphyry system. Although it was previously known that the gold content in the Galore Creek copper deposits was unusually high for a porphyry, the main focus of previous exploration was to delineate the copper reserves. Mingold, on the other hand, was interested in developing high grade gold deposits within or peripheral to the copper mineralization. The work carried out in this regard is embodied in this report.

Geology

The Galore Creek deposits are situated on the western margin of the Intermontane Belt, just east of the Coast Plutonic Complex. The area contains three major lithologic units: Palaeozoic and Middle Triassic metamorphic rocks; Upper Triassic volcanic and sedimentary rocks; and intrusive rocks of various ages and types. The later two units are of prime concern in the vicinity of the copper deposits. (see GC-89-3)

The Upper Triassic rocks, within the Galore Creek valley, are primarily volcanics with sediments only forming a minor component. The volcanics include pyroclastic and intrusive breccias, trachyte flows, lithic tuff, crystal tuff and pyroxene andesites. Most of the rocks have undergone moderate to intense contact metamorphism from later syenitic intrusive events. The effects of this metamorphism have been "skarnification" and "hornfelsing" of many of the rocks to an extent where the original lithologies are often uncertain. In addition, at the contacts with the intrusive rock, considerable assimilation and granitization of the volcanics has occurred resulting in hybrid porphyritic rocks which are difficult to distinguish as either volcanic or intrusive in origin. Nomenclature of the rocks has therefore been based upon the minerals present and their relative amounts.

The intrusive rocks vary considerably in composition, texture, color and age. Syenitic intrusive rocks are the most important, both volumetrically and economically. These rocks have been divided into four main rock types which in order of introduction are dark syenite porphyry, garnet syenite megaporphyry, fine-grained syenite porphyry and epidote syenite porphyry. On the detailed level, many subdivisions of each type are possible however in order to allow some form of geological interpretation on a property basis these major divisions have been adopted. The age of the intrusive rocks varies from Upper Triassic to Lower Cretaceous with the syenites being Upper Triassic to Lower Jurassic.

Known copper mineralization occurs in ten incompletely defined deposits as well as numerous erratic high-grade pods and low-grade showings. The deposits occur largely within feldspathized and biotite altered volcanic rocks and pipe-like breccias associated with alkalic (viz. syenitic) intrusive dykes and stocks. The deposits are tabular to manto-shaped and most have a north to northeast orientation parallel to the syenite contacts and structural trend of the area. Gold is generally associated with the higher grade copper mineralization although many areas of high copper lack appreciable gold. Because earlier exploration treated gold (and silver) as only by-product credits to the copper mineralization, assays were done by compositing the pulps within selected sections (0.4% Cu) of the drill holes. This approach resulted in gross representation of the gold distribution within the copper zones but failed to property evaluate the higher grade gold potential of the area.

Ore reserves estimates taken from the latest HBMS reports (Freberg, 1974, Walker, 1977) are as follows:

0 5 10K.

Central Zone (0.4% Cu cutoff) 159.7 million tonnes of 0.93% Cu, 0.38 g/mt. Au

North Junction Zone (1% Cu cutoff) 4.8 million tonnes of 2.00% Cu, 0.75 g/mt. Au

The satellite deposits have had too little work to calculate a satisfactory reserve figure.

Geochemistry

Geochemical sampling, in the form of stream silts, soils and rocks, formed the bulk of the 1989 work program at Galore Creek. Total samples collected amounted to 1,030 samples which break down as follows: 210 rocks, 157 silts and 729 soils. Each sample type is covered separately in the appropriate sections below.

The location of all the silt and rock chip samples are shown on Fig. GC-89-4. The location of the soil and trench channel samples are shown on detailed maps referred to on this same figure.

Sample Preparation and Analytical Technique

The field sampling technique is unique to each type of sample involved and is described under the respective sections below. The sample preparation described under this section pertains only to Coastech Lab's handling of the samples once they are received from the field.

All soil and silt samples are dried at 90°C and then screened to -80 mesh and mixed. Rock samples are dried at 105°C, crushed to 1/8" (5 mm) size and split in a Gilson riffle to a 250 gram sample. This portion is then pulverized to -100 mesh in a ring grinder and mixed. The prepared soil, silt and rock samples are then assayed using two different analytical techniques – one for gold and the other for all other elements.

The analytical technique for all gold assays involved fusing a 30 gram sample with a PbO flux. The resulting cupelled beads are parted with HNO_3. If less than 0.35 mg of gold is present the separated bead is put into an aqua regia solution and analyzed by A.A. If more than 0.35 mg. of gold is present then the separated bead is weighed by conventional gravimetric methods. A control and blank sample are run with each fusion.

For elements other than gold, a 0.5 gram sample is digested with 5 ml. of $HN0_3$ on a hot water bath for one hour. 10 ml of HCl is then added and digestion continues for another two hours. The solution is then allowed to cool, diluted to 25 ml with distilled water and analyzed on a standard ICP unit. Each run contains a known control sample.

Silt Sampling

Silt samples were taken systematically down all the major creeks within the Galore Creek Valley. Lack of silt in some of the steeper areas hindered sampling although generally an adequate sample density was maintained to properly evaluate the area. Sufficient silt was collected from the active part of the stream to fill a gussetted Kraft bag. The samples were then air-dried in camp and then sent to Coastech Labs in Vancouver for analysis.

A total of 157 silts were taken in 1989 and are shown as circles on Figures GC-89-4, 5 and 6. A breakdown of these into the various claim groups and assessment periods is as follows:

	1989 Assessment	1990 Assessment
Group I	67	6
Group II	51	1
Group III	32	0
TOTAL	**150**	**7**

On the sample maps the assessment periods are shown as an open circle for 1989 and a solid circle for 1990.

Soil Sampling

Soil sample grids were set up in areas where rock sampling indicated anomalous gold values or where insufficient streams were present to adequately evaluate an area (eg. Southwest Zone Grid). The area of these soil grids is indicated on the main sample location map (Fig. GC-89-4). A detailed (1:5000) sample location map indicates the sample numbers of each soil series for the respective soil grid. The grids include the North Rim - DDH 128 Grid (Fig. GC-89-7,8,9), the Southwest Zone Grid (Fig. GC-89-10, 11, 12), the Camp IP Soils (Fig. GC-89-13, 14, 15), the Saddle Creek soils (Fig. GC-89-16, 17, 18) and the Steep Creek Soils (Fig. GC-89-19, 20, 21).

Soils were taken concurrently with establishing the grid lines. Lines were put in using compass and hip-chain with no correction for slope (ie; the reason for variable spacing on the sample stations). In some areas, such as the North Rim – DDH 128 Grid, sufficient magnetite was present in the rocks to significantly affect the compass resulting in diverging and converging lines. Stations were usually put in every 25 meters however in the North Rim – DDH 128 area some 12.5 meters stations were used. Soils were collected from the "B" horizon, where available, using a grubhoe. Sample depths varied from 15 to 30 cm being typically 20 cm.

The soil was placed into a gussetted Kraft bag and then air-dried in camp. Samples were then sent to Coastech Labs in Vancouver for analysis.

A total of 729 soils were collected in 1989. A breakdown of these into the various groups and assessment periods involved is shown below:

	1989 Assessment	1990 Assessment
Group I	12	153
Group II	107	106
Group III	147	204
TOTAL	**266**	**463**

Soils are shown on the maps as a small open circle for 1989 assessment and a small solid circle for 1990 assessment.

Rock Sampling

Rock samples for plotting purposes were divided into three types: rock samples from outcrop, rock samples from float and channel samples from trenches. Rock samples from outcrop and float are shown as triangles and squares respectively on the reconnaissance maps (GC-89-4,5 and 6). The channel samples are described below under "Channel Sampling".

The reconnaissance rocks were either random chip samples or grabs. The random chip samples are taken by randomly breaking off small, equal-sized chips of rock and placing them into a plastic sample bag. They were usually taken where we wanted to check an area of more or less homogeneous rock for mineralization. Grab samples, on the other hand, were taken where interesting mineralization was observed and we wanted to see if it carried significant gold (or copper). A grab sample consisted of a single specimen of rock which was either representative of most of the mineralized rock (representative grab) or focused only on the (presumed) higher grade mineralization (select grab).

A total of 144 reconn. rocks (excludes channels) were collected during the 1989 program. A breakdown of these into the various claim groups and assessment periods is as follows:

	1989 Assessment	1990 Assessment
Group I	48	21
Group II	36	0
Group III	30	9
TOTAL	**114**	**30**

On the sample maps the rocks for 1989 assessment are shown as open triangles or squares while 1990 assessment rocks are solid.

Channel Sampling

Channel samples were taken in the hand-trenches that were put in crosscutting the presumed strike of significant mineralization. Three separate areas of trenching were done; the North Rim Trenches (Fig. GC-89-22), the DDH 128 Trenches (Fig. GC-89-23, 24, 25) and the Saddle Zone Trenches (Fig. GC-89-26). The location of all these trenches is shown on the main sample location map (GC-89-4) and, in the case of the North Rim and DDH 128 trenches, on the 1:5000 soil sample location map (GC-89-7).

Channel samples were taken by continuously chipping out samples of rock along a line such that the width and depth of the resulting channels were equal. The channel was typically 2.5 cm wide by 2.5 cm deep by 1.52 meters long. The length of the channels were sometimes adjusted for changes in lithology but not for assumed grade of mineralization. Samples were placed in large plastic sample bags, tagged and sent to Coastech Labs in Vancouver for analysis.

A total of 66* channel samples were collected in 1989 with the breakdown into claim groups and assessment periods shown below:

	1989 Assessment	1990 Assessment
Group I	0	33
Group II	0	0
Group III	12	21
TOTAL	**12**	**54**

A description of the individual rock samples is included as Appendix IV at the end of the report.

Discussion of Results

Reconnaissance (Fig. GC-89-4,5,6)

The reconnaissance silt sampling was very effective at locating the known copper zones. Using 500 ppm copper as anomalous, virtually all the major zones show up that were sampled. These include the Butte, the Southwest, the Junction, the North Junction, the South 110, the West Rim and West Fork Glacier zones. The only one which was not detected was the Saddle Zone however several samples ran 300

ppm. Several additional areas were also highlighted and in each case could be traced to in-situ copper mineralization.

Using 100 ppb gold as anomalous in silts yields a similar picture to the copper. We already know that many of the copper deposits carry low grade gold values so this result is no surprise. If we boost our anomalous level up to 300 ppb gold however many of the zone related anomalies disappear. What we are left with is ten anomalies, several of which are on the same creek drainage. M033X (874 ppb) and 34X (516 ppb) both are on Steep Creek where a showing carrying 18.77 g/tonne (0.55 oz/t) was taken in a reconn. rock sample (M005R). Attempts to reproduce this value in follow up sampling were unsuccessful. It appears that gold values are very spotty in this area with considerable nugget effect occurring. C077X (1850 ppb) is a short distance downstream from the North Rim trenches (NRT - 1 to 4) where several samples over 7.00 g/tonne (0.20 oz/t) were obtained (see Fig. GC-89-22). T031X (2570 ppb) occurs southwest of DDH 128 and follow up of the creek located copper mineralization with 1.23 g/tonne gold. A retake of the T031X sample, T147X, gave <5 ppb gold suggesting that placering or nugget effect is occurring in this area as well. C116X (650 ppb) and M070X (740 ppb) are both on Left Creek with, as yet, no source located by follow up sampling/prospecting. This area has fair talus and overburden cover locally so the source could be buried. T018X (447 ppb) near Camp Creek has also not been traced to its source again due to significant talus and overburden cover. M044X (416 ppb) and T069X (430 ppb) are both downstream from the South 110 deposit where low-grade gold was known to occur in old trenches. As well rock sample M036R taken from float upstream from these silts carried 1.39 g/tonne (0.04 oz/ton). Sample M030X (1000 ppb) was taken on a tributary of Drop Creek in the Anuk River area. follow up of this area located no mineralization of significance and a re-sample of the silt (M189X) gave <5 ppb gold.

The reconnaissance rocks confirmed the presence of gold mineralization in the areas targeted by the silts (where source exposed). In addition, they located several small low-grade copper-gold showings which, thus far, do not appear to be significant. Most importantly, however, was that they also located significant gold mineralization in three areas not picked up by the silt-sampling. Samples Y015R (8200 ppb) and Y016R (18,970 ppb) detected probable economic levels of gold within the Saddle Zone copper mineralization (previous samples ran 1-2 gm/tonne in the same area). M024R (22,135 ppb) was taken from pyritic quartz float in the area of the Camp IP soil line. Unfortunately due to a delay in receiving the lab result for this sample it was not followed up during our 1989 program. M095R (6067 ppb) led to our work on the DDH128 trenches which thus far have outlined similar grade mineralization over mineable widths. These trench results are elaborated on further under the discussion of channel sampling results below. All in all, the combination of silt and rock sampling on the reconnaissance level has proven to be an effective exploration tool in this area.

Soil sampling was done in areas of known gold mineralization, either from past work or from our 1989 silt and rock sampling results. Only three areas of gold mineralization have had extensive soil sampling done on them. These were the North Rim, the DDH 128 and the Southwest Zone areas. The other areas (Camp IP, Saddle Creek and Steep Creek) involved only reconnaissance level soils along a

single line. Soil sampling, as a whole, worked quite well at outlining the overall pattern of gold (and copper) mineralization. With closer inspection, however, some problems are evident. In the North Rim area, for instance, the soils show fairly extensive gold anomalies (100 ppb) however a sample taken right next to the best grade gold in the trenches ran <5 ppb (C266). This suggests that significant overburden, locally, is suppressing the geochemical response. Even the copper value in the same soils was only 248 ppm which is almost a background value in this area. The trench samples ran over 2% copper over considerable widths so values in the order of 5000 ppm would be more the magnitude expected. The same is true for the DDH 128 trench area although snow prevented complete sample coverage. This indicates, therefore, that drilling on soil anomalies alone may not be wise. Thorough prospecting/rock sampling of an area must be done before the drill is brought in. Anomalous level for gold in soils appears to be about 100 ppb and above while for copper it is probably about 800 ppm. A statistical evaluation of the results was attempted however, because we sampled what is overall an anomalous area, high values significantly skew the population. We are in essence trying to find an anomaly within an anomaly and normal statistical methods are not adequate for this purpose. Anomalous levels have, therefore, been chosen by inspection.

Hand-trenching of the main gold anomalies was completed where feasible. Channel sampling of the trenches are shown on Figures GC-89-22 to GC-89-26 inclusive. On the North Rim Zone, trenches NRT-1 and 2 crossed the strike of mineralization and sampling outlined a 10.4 meter section which averaged 5.59 g/tonne gold. This includes 7.0 meters of 9.26 g/tonne gold with most of the remaining lower grade material being barren dyke. The overlying metavolcanics are essentially barren although minor higher grade pods occur locally. The DDH 128 trenches were put in to cross a volcanic-intrusive contact zone which trends about 170°. Two of the trenches, 128T-1 and T-2, intersected gold mineralization in excess of 3 g/tonne with a 3.0 meter section in 128T-2 averaging 9.75 g/tonne.

The intersection in the two trenches indicate that the strike of the gold zone may be closer to 195° than the 170° assumed from alignment of fractures. The trenching on the Saddle Zone was done in an old Kennco trench which had sloughed in considerably. The trench, ST-2 crosses what is believed to be a breccia pipe with magnetite healing intrusive fragments. Sampling of the trench began 16.75 meters from the north western end of the old trench and proceeded southeasterly (1.5 meter intervals) to 48.62 meters. From 22.86 meters to 48.62 meters (25.76m) averaged 7.89 g/tonne with a high grade section from 22.86 meters to 30.48 meters (7.62m) running 12.69 g/tonne. The high gold values are associated with high copper mineralization (up to 5.4%) although not necessarily at a consistent ratio. Heavy rubble in the other two trenches prevented sampling them in 1989. Detailed mapping and sampling of the area is necessary before the limits of the mineralization (on surface) are known.

Trenching (Physical Work)

Physical work was submitted for the labour involved with cleaning out the trenches described above. The trenches are shown on figures GC-89-22 to GC-89-26 inclusive. A total of 105 meters of trenching was completed in 6 man days. The breakdown into trenches on each zone was as follows: Saddle Zone - 34 meters; North Rim Zone - 17 meters and DDH 128 Zone - 54 meters. A breakdown by claim group and assessment period is shown below:

	1989 Assessment		1990 Assessment	
	Man Days	Meters	Man Days	Meters
Group I	0	0	1	54
Group II	0	0	0	0
Group III	4	17	1	34
TOTAL	**4**	**17**	**2**	**88**

Geophysics

The only geophysics done in 1989 was VLF-EM surveys using a Geonics EM-16 unit. The operation of this instrument is well documented in the literature and will therefore not be reiterated in this report.

For the VLF-EM surveys on the Galore Creek property, two different transmitting stations were used depending on the orientation of the grid lines. The station used for all the lines trending north to northwesterly was Cutler, Maine (NAA-17.8 Hz) and the operator consistently faced southerly when taking readings. For lines trending westerly to southwesterly Seattle, Washington (NLK-24.8Hz) was used and the operator faced easterly when taking readings.

The VLF-EM utilized the same stations (25 m interval) established during the soil sampling with the exception of the east-west (grid) lines on the North Rim - DDH 128 Grid (GC-89-28). Due to the strong magnetics in this area, the east-west stations would have been too distorted to properly interpret the results. Two lines were therefore run with compass and hip-chain for this survey. Tie-ins were made with the existing cross-lines permitting an accurate representation of the actual station locations in the field.

All results were Fraser-filtered and the results are shown on Figures GC-89-27, 28, 29 and 30. Contours are at 0, 10 and 20 units. Raw data is included as Appendix V.

The total VLF-EM surveying carried out in 1989 was 11.43 kilometres. A breakdown into the amount for each claim group and assessment period is shown below:

	1989 Assessment	1990 Assessment
Group I	0.30 km	4.30 km
Group II	2.75 km	0
Group III	1.83 km	2.25 km
TOTAL	**4.88 km**	**6.55 km**

Discussion of Results

North Rim - DDH 128 Grid (Fig. GC-89-27, 28)

As detailed mapping of this area has not been done, it is difficult to know the likely source of the VLF-EM anomalies in all cases. We know from our mapping of the North Rim trenches that copper mineralization is strongest adjacent to the contact between the Upper Triassic volcanics and the underlying epidote syenite intrusive rocks. It appears that the long northeasterly trending anomaly which roughly follows the 0+00 baseline is likely tracing out this contact. The anomaly broadens out to the northeast probably because the topography in this area more or less parallels the dip of the contact. The copper mineralization is generally disseminated in the rocks and therefore would likely not show up as an EM conductor.

The strong anomaly southeast of DDH 128, by its strength, is likely a major fault. This entire area is covered in glacial till and scree so trenching or drilling would be required to determine its true source.

The anomaly in the southwestern corner of the grid is somewhat complex and may be due to a combination of rock type changes and faulting.

The two east-west (grid) lines suggest some cross-faulting is occurring however the survey in this direction is neither extensive enough nor sufficiently detailed to permit a more thorough interpretation.

Southwest Zone Grid (Fig. GC-89-29)

The EM survey of the Southwest Zone was done at a 200 meter line spacing which results in a strong east-west bias to the contouring. Despite this bias, there does appear to be a strong conductor trending roughly east-west just south of 0+00N. This coincides fairly closely with the projected trend of the Southwest Zone from drilling. The entire zone is overburden covered so the exact trend of the mineralization is not know. The EM, again, is probably not responding to the disseminated copper mineralization but rather to a major controlling structure (fault?) associated with it.

The two anomalies to the north of this are basically single line anomalies so no defined trend can be determined. The intensity of them is probably too strong to result from lithologic contacts which leads to the next most likely cause - faulting.

More detailed surveying may indicate that the middle anomaly ties in with the +16/+18 readings on line 2+00E and trends east-west. Additional lines both between the existing lines and to the east and west are necessary to properly delineate these anomalies.

Saddle Creek Grid (Fig. GC-89-30)

VLF-EM was run along this single contour line mainly to see if any of the soil gold anomalies had associated structures. Although EM anomalies were detected, they are all considerably southwest of the anomalous gold values. The only exception might be a very weak anomaly between soils C252S and C253S.

Core Sampling

A total of ten core samples were taken of DDH 88 from 100 - 200 feet (30.5-61.0 m). Samples were 1/4 split for reassay from previously split core. The section was reassayed to check the gold assays on 3 meter intervals within the previous 100 ft (30.5 m) composite which ran 0.005 oz/t gold (0.17 g/tonne). The results of this sampling are as follows:

Sample No.	Interval (m)	Width (m)	Au (ppb)	Cu (ppm)
32401	30.5-33.5	3.0	<5	1940
32402	33.5-36.6	3.1	23	697
32403	36.6-39.6	3.0	46	554
32404	39.6-42.7	3.1	<5	1019
32405	42.7-45.7	3.0	343	1478
32406	45.7-48.8	3.1	607	1479
32407	48.8-51.8	3.0	<5	1197
32408	51.8-54.9	3.1	57	1384
32409	54.9-57.9	3.0	70	1535
32410	57.9-61.0	3.1	63	732
TOTAL	**30.5-61.0**	**30.5**	**Avg. 121**	**Avg. 1202**

The core was all from epidote syenite porphyry with only trace chalcopyrite observed while splitting.

Summary and Conclusions

The 1989 exploration program at Galore Creek was successful at locating three significant zones of gold mineralization: the North Rim Zone, the DDH 128 Zone and the Saddle Zone. All these areas had previously been known for their copper mineralization however sampling for gold either was not done or was done by compositing of copper rich samples. Our sampling has only been of a preliminary nature with more extensive work required to adequately evaluate the potential of each zone.

The reconnaissance silt and rock sampling led to the rediscovery of each zone for its gold mineralization in addition to copper. Follow up trench sampling indicated significant grades of gold (and copper) mineralization over mineable widths.

Soil sampling has outlined several other areas of potential which include the Southwest Zone, the Camp IP area and the Saddle Creek area. Due to extensive overburden or incomplete follow up, additional work will be required to locate the source of these anomalies.

The VLF-EM survey has delineated several areas of likely faulting and lithologic contacts which may prove to be controlling features for the gold mineralization.

Although no "gold-only" targets were located, the 1989 program has gone a long way in developing significant gold-copper targets in the Galore Creek area. Further work is definitely warranted and is expected to be continued in the 1990 field season.

YG10464 3R (509)	ANUK RIVER	Random chip		Andesite		Pyrite.	Bleached		
YG10464 4R (#510)	ANUK RIVER	Float	-	QTZ. VEIN		Chalcopyrite Pyrite			
YG10464 6R (#511)	ANUK RIVER	Random chip		Andesite		Pyrite 5-10%			

MINGOLD RESOURCES INC.

GEOCHEMICAL DATA SHEET – ROCK SAMPLING

Sampler: E.W. Yarrow
Date: July - September 1989
Project:
Property: Galore Creek.
NTS: 104 G/3 & 4
Location Ref:
Air Photo No.:

SAMPLE No.	LOCATION	SAMPLE TYPE	SAMPLE WIDTH	DESCRIPTION			ADDITIONAL OBSERVATIONS	ASSAYS				
				Rock Type	Alteration	Mineralization		Ag	Au			
YG10464 7R (#512)	ANUK RIVER	Contin. chip	2 m	Andesite	Fe stain.	Pyrite						
YG10464 8R (#513)	ANUK RIVER	Random Chip		Silicif Volc.	Silicif.	Pyrite - 3-5%						
YG10464 9R (#514)	Headwts. of Anuk R.	Random Chip		Andesite	Qtz. -carbonate		Shear zone - 3cm. wide.					
YG10464 10R (#515)	"	Contin. chip	1.0m	Argillite	-	Pyrite	Qtz. veins in arg. (2cm wide)					
YG10464 11R (#516)	"	"	2.5m	"	Fe stain, Qtz -carb.	Pyrite blebs	Qtz. veinlets - 2-4cm.					
YG10464 12R (#0002)	Steep Creek	Contin. chip	3.0m	Syenite	Epidote	Pyrite -5-10%	Samp. along dip slope - Steep Ck. Zone.					
YG10464 13R (0003)	"	Grab	-	"	Epidote	Pyrite						
YG10463 13R (126)	SADDLE ZONE AREA	Grab	-	Intrusive	Fe carbonate		brown weathering, narrow qtz. stringers observed					
YG10463 14R (#127)	SADDLE ZONE AREA	Random chip	2m² area	Magnetite bt. - intrus.		magnetite	Malachite, qtz. veinlets
