**GEOPHYSICAL REPORT
ON AN UTEM SURVEY
ON THE ESTELLA PROPERTY
FORT STEELE M.D., B.C.**

- ASSESSMENT REPORT -

INTRODUCTION

The Estella Property is underlain by rocks of the Fort Steele (oldest), Aldridge, and Creston (youngest) Formations. The Estella Mine occurs as a vein deposit in the Aldridge Formation sediments near a felsite (or quartz monzonite) plug. The mine produced approx. 118,000 tons roughly estimated to average 1.6 oz. Ag, 8% Zn and 3.5% Pb.

A geophysical program consisting of UTEM surveying was carried out directly over and peripheral to the Estella Mine. The purpose was to test for a large conductor below the mineralized vein.

UTEM surveying totalled 45 kms and was carried out both on grid lines and in a reconnaissance mode. This work was performed by Cominco Ltd. personnel under the direction of geophysicists, I. Jackisch and J.G. Parkinson.

This report discusses the operation of the deep penetrating UTEM system and presents the results.

LOCATION AND ACCESS

The Estella Property is located 28 km east-northeast of Kimberley, B.C. and 17 km north of Ft. Steele, B.C. It is in the front range of the Rocky Mtns., 2 km north of Mt. Bill Nye (2,429 m).

The Estella Mine site can be reached by dirt road from Wasa, B.C., which is on the Kootenay River, 17 km north-northwest of Ft. Steele, B.C. This road roughly follows Lewis Creek up into the mountains. The numerous switchbacks provided adequate access to a large portion of the survey lines. Helicopter support was not used, but resulted in very slow progress on the more unaccessible reconnaissance lines.

The vegetation varies from very thick to open (in talus areas) and the topography is steep everywhere, and treacherous on the slope to the west and south of the mine site. Elevations over the survey area vary from 1,300 m to 2,400 m.

DESCRIPTION OF UTEM SYSTEM

UTEM is an acronym for "University of Toronto ElectroMagnetometer". The system was developed by Dr. Y. Lamontagne (1975) while he was a graduate student of that University.

The field procedure consists of first laying out a large loop of single strand insulated wire and energizing it with current from a transmitter which is powered by a 1.7 kW motor generator. The loop is generally square shaped, wherever possible, with sides between 500 metres and 1,500 metres long. In this survey, the loop dimension was 1,000 m x 600 m. Survey lines are generally oriented perpendicular to one side of the loop and surveying can be performed both inside and outside the loop. The field procedure is similar to Turam, a better known electromagnetic surveying method.

The transmitter loop is energized with a precise triangular current waveform at a carefully controlled frequency (30.9 Hz for this survey). The receiver system includes a sensor coil and backpack portable receiver module which has a digital recording facility on cassette magnetic tape. The time synchronization between transmitter and receiver is achieved through quartz crystal clocks in both units which must be accurate to about one second in 50 years.

The receiver sensor coil measures the vertical magnetic component of the electromagnetic field and responds to its time derivative. Since the transmitter current waveform is triangular, the receiver coil will sense a perfect square wave in the absence of geologic conductors. Deviations from a perfect square wave are caused by electrical conductors which may be geologic or cultural in origin. The receiver stacks any pre-set number of cycles in order to increase the signal to noise ratio.

The UTEM receiver gathers and records 9 channels of data at each station. The higher number channels (7-8-9) correspond to short time or high frequency while the lower number channels (1-2-3) correspond to long time or low frequency. Therefore, poor or weak conductors will respond on channels 9, 8, 7 and 6. Progressively better conductors will give responses on progressively lower number channels as well. For example, massive, highly conducting sulphides or graphite will produce a response on all nine channels.

The UTEM receiver records data digitally on a cassette. This tape is played back into a computer at the base camp. The mini computer processes the data and controls the plotting on a small (11" x 15") graphics plotter. Data are portrayed as profiles of each of the nine channels, shown for each survey line of each transmitter loop. These profiles and an interpretive plan are appended to this report.

The magnetic field amplitudes from both the transmitter loop (primary field) and from the electric currents induced in the ground (secondary field) vary considerably from the beginning of a line (near the transmitter loop) to the end of the survey line (far away from the transmitter loop). In order to present such data, a normalizing scheme must be used. In this survey, the primary field from the loop is used for normalizing and presenting the data in two ways.

1. Continuously normalized plots.

This is the standard normalization scheme.

a) For Channel 1:

$$\% \text{ Ch.1 anomaly} = \frac{\text{Ch.1} - P}{P} \times 100$$

where P is the primary field from the loop at the station and Ch.1 is the observed amplitude for Channel 1.

b) For the remaining channels ($n=2$ to 9)

$$\% \text{ Ch.}n \text{ anomaly} = \frac{\text{Ch.}n - \text{Ch.1}}{\text{Ch.1}} \times 100$$

where Ch. n is the observed amplitude of Channel n (2 to 9).

2. Point normalized plots.

These plots display an arrow at the top of the section indicating the station to which all data on the line are normalized. The purpose of point normalized plots is to display only the relative amplitude variation of the secondary field along the line, that is, only that magnetic field from the currents induced in the ground.

a) For Channel 1:

$$\% \text{ Ch.1 anomaly} = \frac{\text{Ch.1} - \text{Ppn}}{\text{Ppn}} \times 100$$

where Ppn is the primary field from the loop at the point norm station and Ch.1 is the observed amplitude for Channel 1.

- b) The remaining channels ($n=2$ to 9) are Channel 1 reduced and Channel 1 normalized:

$$\% \text{ Ch.}n \text{ anomaly} = \frac{\text{Ch.}n - \text{Ch.}1pn}{\text{Ch.}1pn} \times 100$$

where $\text{Ch.}n$ is the observed amplitude of Channel n and $\text{Ch.}1pn$ is the observed Channel 1 amplitude at the point norm station

Point normalized plots are usually produced on data sections containing anomalies in order to help interpretation by providing a different perspective to the data. In this survey, all the Data Section numbers containing a "p" are point normalized plots.

The above normalizing procedures result in chaining errors displayed in Channel 1 only, since all other channels are normalized to Channel 1.

SURVEY GRID, RECONNAISSANCE LINES, AND LOGISTICS

The plotted grid lines on Plate 368-89-2 show good agreement with creek and road intersections. The only exception is Line 1800S where Tracy Creek is out by 100 m. The grid over the mine site (Loops 1,2,3) is correctly tied in to the Tracy Creek grid (Loops 4 and 6) as shown on the map.

The loop fronts to Loops 1, 2 and 3 are fairly accurately known because they follow a cut baseline or tie line. The sides and backs to these loops were laid out by bush-wacking and climbing wherever it was possible to maneuver, and are only roughly located.

Grid stations are 50 m apart horizontally. Slope corrections were made using an inclinometer and were measured in by compass and nylon chain, not topo chain.

The reconnaissance lines used the same loops as the grid lines, but were surveyed starting from the side or back of the loop. Line locations are estimated from topography, compass direction, creeks, direction of distant peaks, etc. Station locations were recorded for direction (compass), for distance (topo chain), and change in elevation (inclinometer). These lines were put in by the UTEM receiver operator and his assistant, concurrent with the UTEM survey. Line direction and distance between stations were changed occasionally to avoid difficult terrain.

One assistant was always present at the transmitter site. This was to prevent theft from passing vehicles, to provide assistance in the event of an accident on the cliffy terrain, and to disconnect the loop from the transmitter in case of lightning activity (which was frequent).

INTERPRETATION

Plate 368-89-2 shows the UTEM crossovers and contact responses along with the survey grid and claim map.

CONCLUSIONS

45 kms of UTEM surveying was completed on the Estella Property in the time period from August 23rd to October 6th, 1989. Several crossover and contact responses were detected which need to be followed up by geological mapping.
