SUMMARY GEOLOGY (lithology, age, structure, alteration, mineralization, size, and attitude):

The property is underlain by Jurassic and Tertiary acid intrusive rocks transected by large scale regional faults. Clay altered shear zones are common. Narrow quartz veins contain anomalous levels of gold and silver.

SUMMARY AND CONCLUSIONS

The WH property comprises 12 claims (181 units) in the Similkameen Mining Division, located 57 kilometres southeast of Merritt, B.C. The claims, staked during 1988, 1989 and 1990, are owned 100 percent by Fairfield Minerals Ltd. The 1990 program was funded by Placer Dome Inc. under the terms of an option agreement. The exploration target was a structurally controlled lode gold deposit.

Logging roads provide excellent access to all parts of the property. The terrain consists of rolling forested hills and scattered clear cut logged area.

Previous exploration near the property has included mapping, soil sampling, magnetometer surveys, trenching, diamond drilling, limited underground drifting and small scale placer mining. The best drill intercept was five feet of 0.43 oz/ton gold, 5.67 oz/ton silver and 0.23% copper from a showing 1.0 km east of the WH claims. Within the property area a narrow quartz vein/alteration zone yielded 15,900 ppb (0.46 oz/ton) gold and 1100.9 ppm (32.1 oz/ton) silver across 10 cm.

During 1988-89 the WH 1-8 claims were soil sampled and minor trenching was conducted. The 1990 program consisted of detailed follow-up soil sampling, minor trenching and staking of sixty claim units on the south side of the property.

The claims are underlain by coarse granite of the Coast Intrusions injected by a stock and abundant dykes of porphyritic granite of the Otter Intrusions. Clay alteration, with local disseminated pyrite, occurs along some shears. Sericite, chlorite, carbonate and silica alteration are also developed locally. Major lineaments, as well as fractures and shears exhibit predominant northeast and northwest trends. Small quartz veins have been observed locally with minor pyrite, occasional chalcopyrite or galena and some gold and silver values.

A total of 1337 follow-up soil samples were collected to help define gold anomalies on the WH 5, 6, 7 and 8 claims. In addition, 670 pulps from 1989 soil samples were reanalyzed for gold using a wet chemical extraction process to compare with the results of the originals derived using fire assay extraction.

The gold geochemical analyses confirmed three anomalous areas defined by 1989 results but failed to confirm the two largest target areas on the north part of the grid. It is suspected that the fire assay extraction technique may have provided some false anomalies due to a higher gold extraction level and that there is a strong variability in gold results due to the inhomogeneous distribution of gold in the glacial soils.

Auger sampling at 48 sites in one of the anomalous areas showed that there was no significant increase in gold values at depth compared to surface soil samples, and confirmed the high variability of gold values by comparing analyses from two cuts of the same material.

Two trenches totalling 269 metres were excavated on the north end of the property to test for gold mineralization in areas of anomalous geochemistry, VLF-EM conductors and topographic lineaments, which may represent major fault structures. Locally sheared, clay altered, granitic batholith rocks were exposed in contact with bodies of the younger quartz-feldspar porphyry intrusions. The sheared, clayey zones coincided well with the interpreted geophysical conductors. Minor disseminated pyrite and one narrow quartz vein were observed. Extensive rock chip sampling was undertaken. All gold values were low.

Soil profile samples collected from the trench walls returned only one significant value near the overburden surface, 1.5 m above bedrock. It appears that the anomalous gold values in surface soil samples came from a source outside of the trenched areas.

It is concluded from the results of the 1990 exploration program that there are several strong gold geochemical anomalies on the WH property which require further follow-up evaluation. These targets all have potential for the discovery of gold-bearing vein systems of economic tenor.

Trenches and test pits failed to explain the sources of anomalous gold in the soil except to indicate that the gold has been transported for unknown distances.

2.0

R E C O M M E N D A T I O N S

1. Establish a geochemical grid (200m x 50m) over the 60 new claim units to the south. Analyze all soils for gold.
2. Follow-up soil anomalies on the new grid, and some requiring fill-in on the old grid, with samples at 50m by 50m spacings.
3. Prospect and geologically map areas of significant gold anomalies.
4. Conduct magnetometer and VLF-EM surveys on 100m by 12.5m spacings over selected targets.
5. Utilize an overburden drill to collect soil profile samples to bedrock in areas of significant geochemical and geophysical anomalies.
6. Trench to bedrock in prospective areas outlined by overburden drilling. Clean, map and chip sample trenches.

Respectfully submitted

I N T R O D U C T I O N

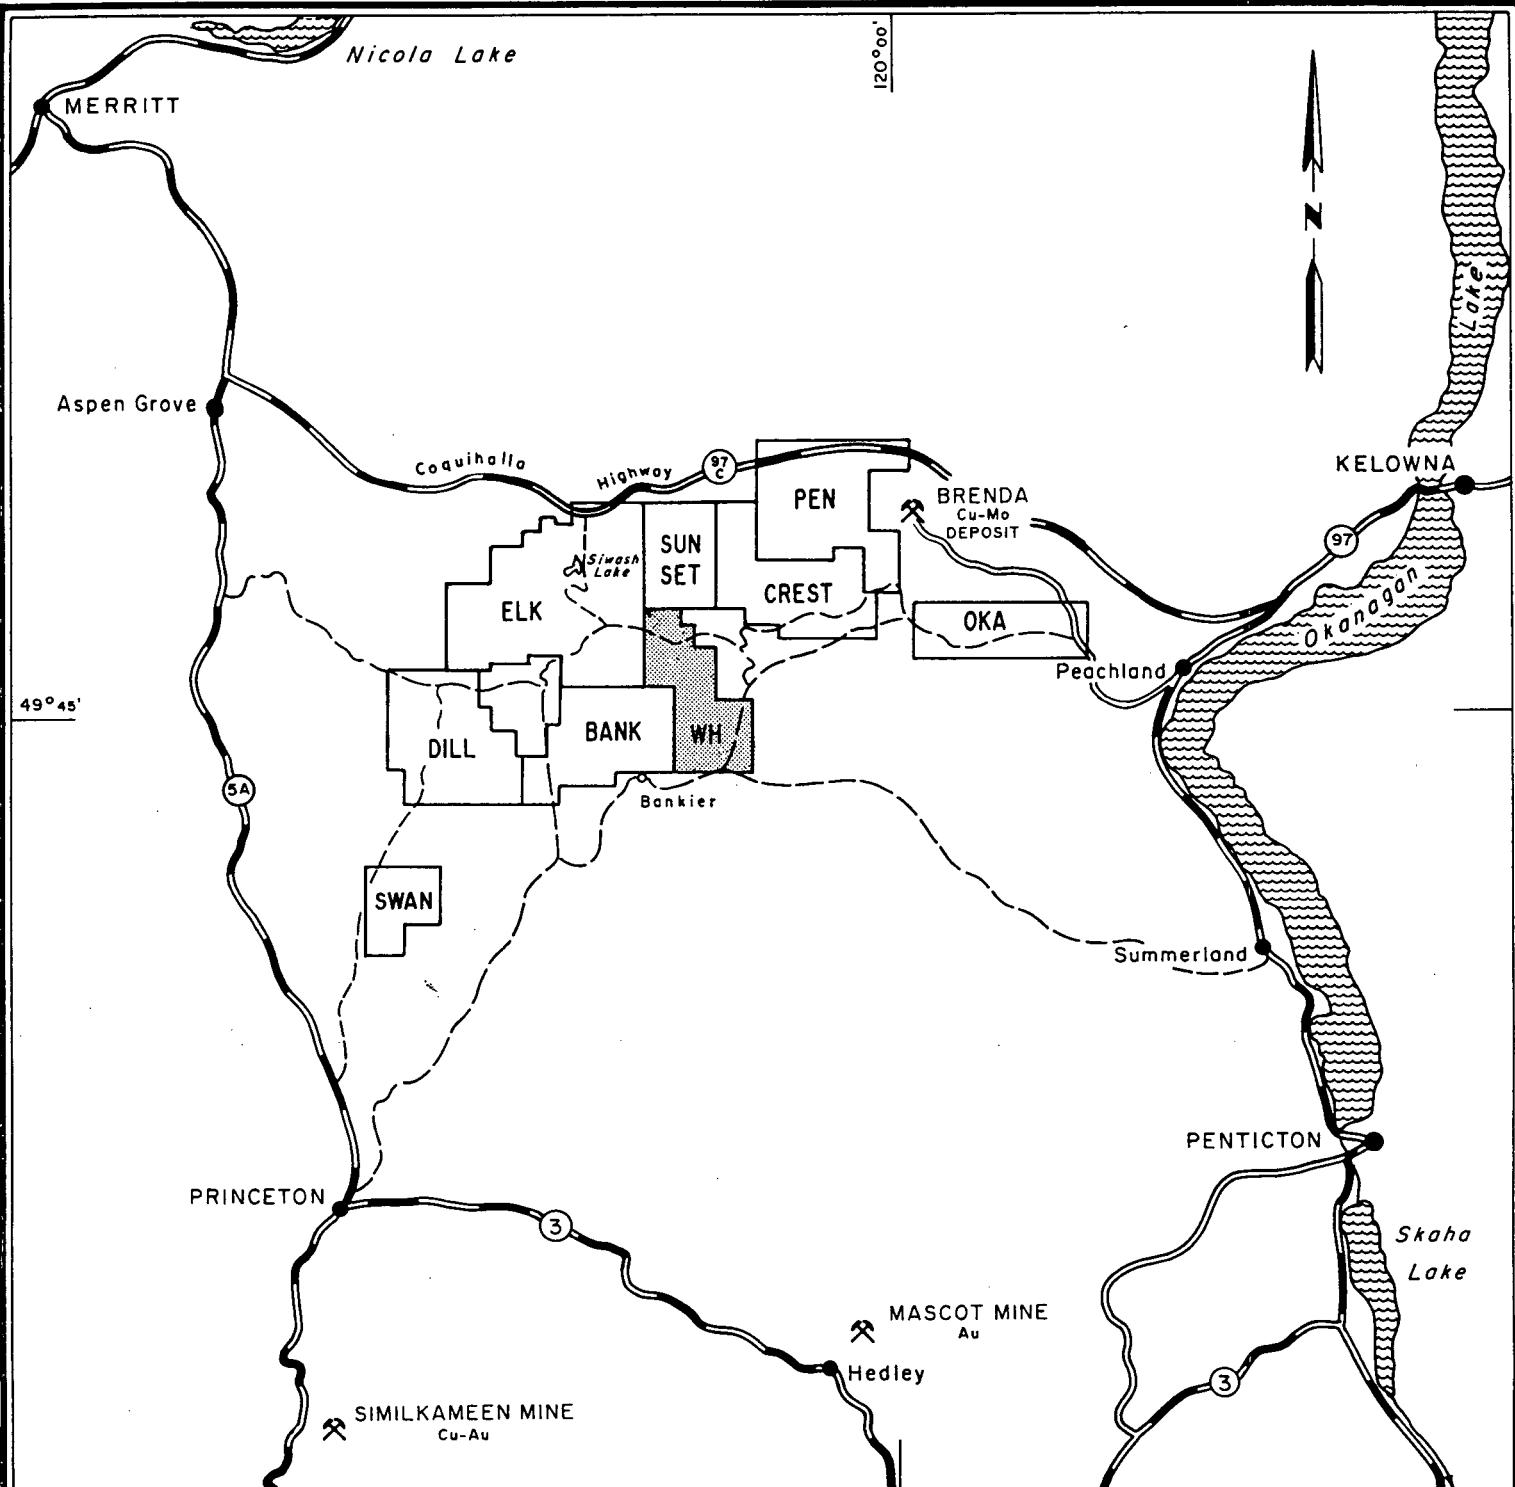

3.1 LOCATION AND PHYSIOGRAPHY (Figures 1 and 2)

The WH property is located 32 kilometres west of Peachland and 57 kilometres southeast of Merritt in south-central British Columbia (Figure 1). The property is centered on latitude 49 degrees 46'N and longitude 120 degrees 11'W within NTS map areas 92H/9E + 16E. Good gravel roads extend to the area from Peachland and from the Princeton-Merritt highway. Several logging roads traverse the claims providing excellent access.

The claims cover an area of approximately 45 square kilometres in rolling, hilly terrain on a broad uplands plateau. Elevations range from 1150m to 1550m above sea level. The east side of the property drops down steeply to Trout Creek, a two to four metre wide stream flowing to the south. Spring Creek follows a northeast trending depression across the central part of the property and North Trout Creek cuts south and east across the northern claims. Whitehead Lake, measuring 800 metres by 400 metres lies on the plateau in the east-central part of the claim group. A dam on the lake has caused a tributary creek to back up forming a long swampy zone to the southwest. Outcrop exposures are scarce with till cover ranging from less than one metre to greater than four metres. Mature stands of spruce, balsam, fir and pine have been logged from several scattered plots. Annual temperatures range from -20 degrees C to 30 degrees C and precipitation is low to moderate. The area is basically snow-free from late June through October.

3.2 CLAIM DATA (Figure 2)

The current status of the WH claims is indicated in Table 1, and their locations are shown on Figure 2. The claims, located in the Similkameen Mining Division, were staked in September and October 1988, May and July 1989 and August 1990 and are 100 percent owned by Fairfield Minerals Ltd.

HISTORY

Areas to the east and southeast of the WH claims have been previously explored. In the Spring Creek area, from 1972 to 1985 various companies conducted mapping, soil sampling, a magnetometer survey, trenching and limited diamond drilling in search of copper, molybdenum, lead, zinc and silver, with little success. Along North Trout Creek, a small, intermittent placer mining operation has recovered small amounts of gold. During 1988 and 1989 a large area east of WH was explored for gold by soil sampling, magnetometer and VLF-EM surveys, mapping, prospecting and trenching.

Directly southeast of the WH 4 claim a gold, silver, copper showing has been explored by diamond drilling, trenching, a magnetometer survey and soil sampling between 1973 and 1987. A 64 metre adit is reported to have been excavated in 1988. The best drill intercept was 5 feet of 0.43 oz/ton gold, 5.67 oz/ton silver and 0.23% copper within a 15 foot section averaging 0.30 oz/ton gold.

Prospecting of the area near Whitehead Lake in 1988 by Fairfield Minerals Ltd. located a narrow quartz vein/alteration zone in granite which yielded 15,900 ppb (0.46 oz/ton) gold, 1100.9 ppm (32.1 oz/ton) silver across 10 cm. This initiated the staking of the WH claims.

During 1988 and 1989 the WH 1-8 claims were soil sampled on 50m by 200m spaced grid lines. Fill-in samples were collected around some of the anomalous stations. One short trench and three pits were excavated in the Spring Creek area but failed to expose any significant gold mineralization.

3.4 1990 EXPLORATION PROGRAM

The 1990 program consisted of detailed follow-up soil sampling in areas of previously defined gold anomalies and excavation of two trenches and three pits to explore for sources of anomalous gold geochemistry.

The soil sampling largely failed to extend, or even duplicate, the gold anomalies indicated by the 1989 program. It appears that a different analytical technique used for the 1989 samples yielded higher background values, possibly due to a more complete gold extraction and hence some of the previous anomaly targets have been eliminated.

The trenches exposed areas of altered, sheared intrusive rocks but sampling did not yield any significant gold values.

Sixty claim units were added to the property on the south sides of WH 3 and 4 claims during August 1990. No work was conducted on these new claims.

4.0

G E O L O G Y

4.1 REGIONAL GEOLOGY (Figure 3)

The WH regional geology is shown on the northeast part of GSC Map 888A, Princeton, by H.M.A.Rice, 1939-1944 and condensed on Figure 3. The area is underlain by an Upper Cretaceous to Tertiary stock of porphyritic granite in contact with Upper Jurassic Coast intrusive granitic rocks to the west, north and south.

4.2 PROPERTY GEOLOGY AND MINERALIZATION

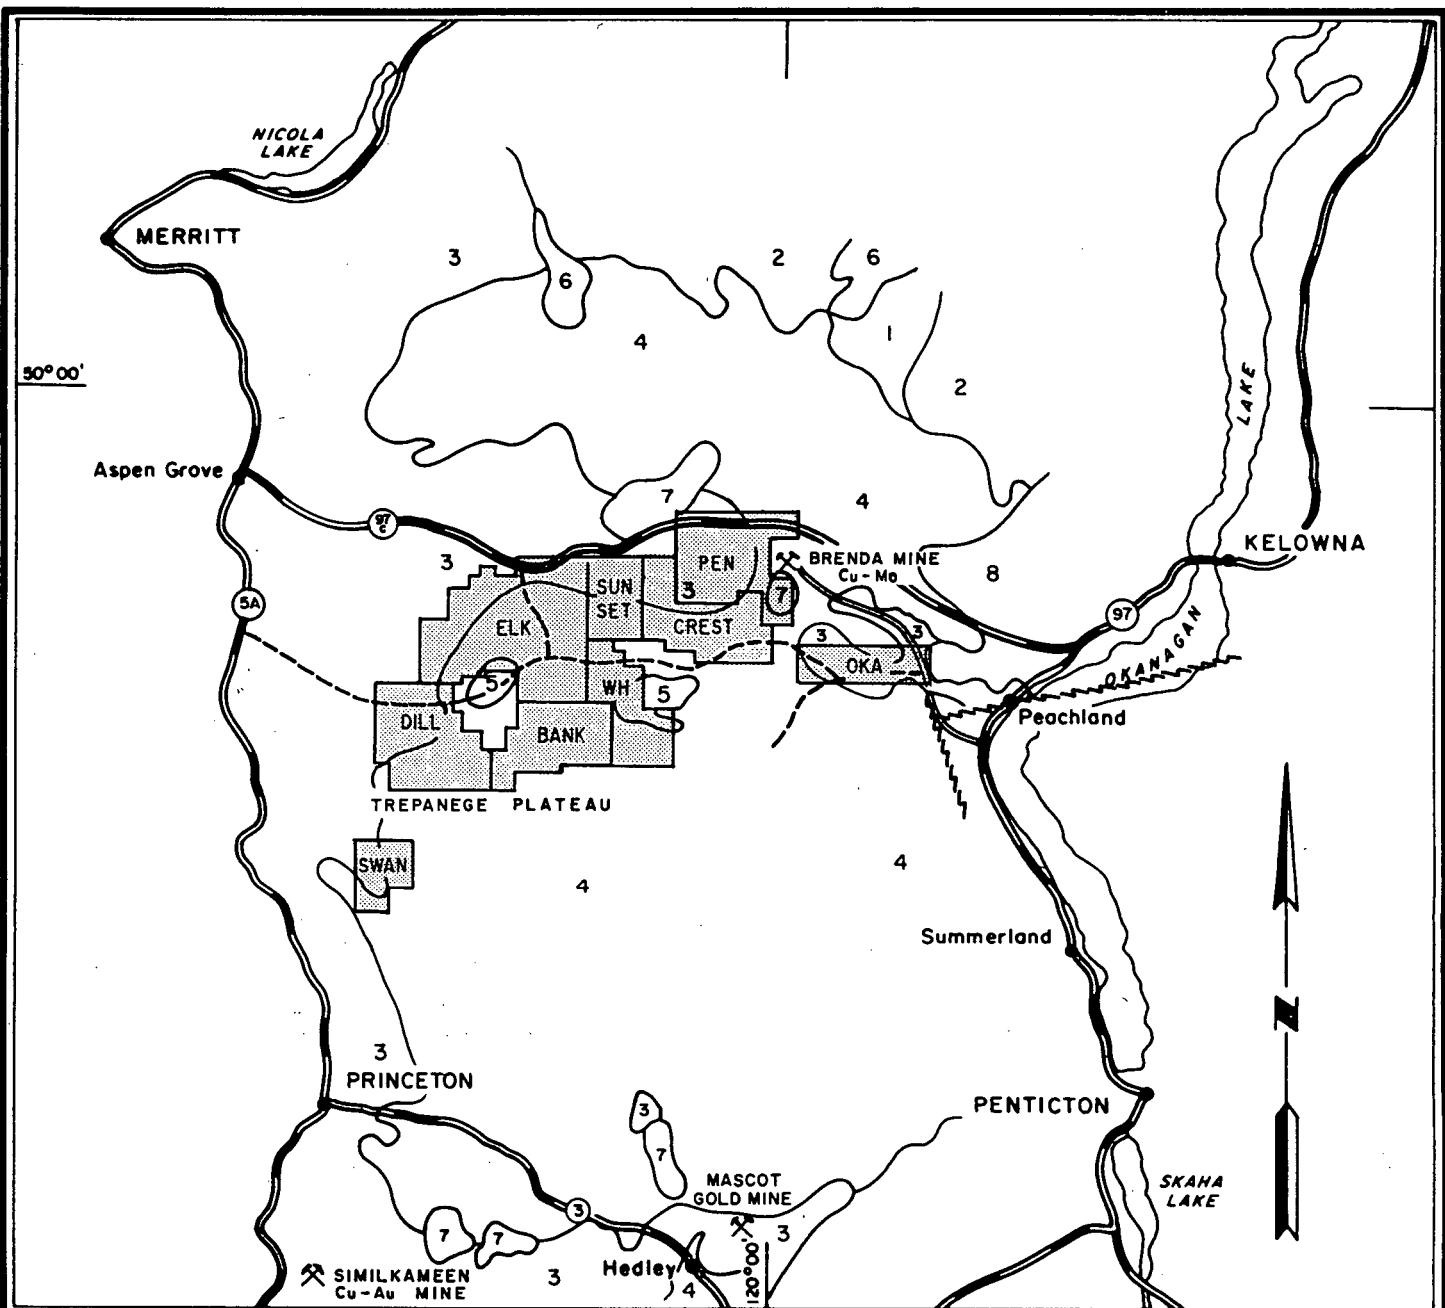

Outcrop is sparse on the property, confined predominantly to creek banks, ridges and road cuts.

The central and eastern portions of the property are underlain by a stock of quartz-feldspar porphyry of Upper Cretaceous to Tertiary age. Quartz eyes are common, reaching up to 1.5 centimetres in diameter and feldspar phenocrysts are up to 4 centimetres in length. The composition is generally granite to monzonite with local diorite sections, often near contact zones. Dykes and small stocks of similar rock were observed on the northernmost claims. Clay alteration of matrix minerals to chalky white material is common, with local weathered pyrite imparting a rusty yellow colour.

Coarse, equigranular, pink granite of the Jurassic batholithic unit dominates on the northern claims and scattered outcrops occur on the southern parts of WH 3 and 4 claims. Contacts with the porphyry stock are irregular.

Pendants of gneissic rock of possible Paleozoic age are present in both porphyry and granite as rafted inclusions. These were observed on WH 3 and 4 claims. The gneiss is fine grained, dark grey to black and weakly to moderately foliated.

In a few exposures fine-grained andesitic dykes have been noted cutting both the granite and quartz-feldspar porphyry units. These dykes may be late stage members of the porphyry intrusions.

Major lineaments on the property, which probably reflect large fault structures, trend dominantly 070 and 150 degrees. Local fracturing and shearing also exhibit similar trends.

Intense clay alteration is locally developed in some shear zones, usually less than one metre in width. Sericite alteration is prevalent in the granite and quartz-feldspar porphyry units. Low levels of silicification, chloritization and carbonatization are also locally evident.

Disseminated pyrite has been noted in quartz veinlets and in some argillically altered or silicified zones. Locally, minor chalcopyrite or galena accompany the pyrite and some anomalous gold and silver values have been returned. A 10 cm chip sample collected in 1988 from a quartz veinlet cutting altered granite on WH 1 claim returned 15,900 ppb (0.46 oz/ton) gold and 1100.9 ppm (32.1 oz/ton) silver. A 1.5 m chip sample collected in 1989 from silicified quartz diorite in a trench exposure on WH 2 claim yielded 33.5 ppm (0.98 oz/ton) silver and 30 ppb gold. The two 1990 trenches failed to reveal any significant mineralization and sample results were all low. These trenches are described in more detail in Section 6.0.

5.0

G E O C H E M I S T R Y

5.1

SAMPLING PROCEDURE

Soil samples from the 1989, 200m by 50m grid which returned values of 20 ppb Au or greater were followed up by detailed sampling at 50m by 50m, or in some cases 100m by 50m spacings. A total of 1221 fill-in soils were collected during June 1990 on the WH 5, 6, 7 and 8 claims.

Fill-in sample lines were established by measuring from existing stations with hip chain and compass. Lines were oriented north-south and stations were marked with grid numbered, water proof Tyvek tags and orange and blue flagging.

Samples were collected from the "B" soil horizon with mattocks and placed in kraft paper bags numbered with the appropriate grid coordinates. The samples were sent to Acme Analytical Laboratories Ltd. in Vancouver, where they were dried, sieved and the -80 mesh material collected. Gold content was analyzed by atomic absorption following aqua regia digestion and MIBK extraction from a 10 gram sample.

In addition, 116 soils were collected from selected 1989 sample sites and 670 pulps from 1989 samples were removed from storage at Eco-Tech Laboratories Ltd. in Kamloops, B.C. where they were originally analyzed. All these samples were sent to Acme where the gold contents were determined by the procedure described above.

In one area several existing 50m by 50m grid sites were resampled using a soil auger to test for possible masking of gold values at surface by a locally thick organic layer. A total of 48 samples were collected at depths ranging from 10 to 100 cm. The material was mixed by hand and divided into two equal portions which were sent to two different labs for gold analysis. Both labs analyzed the samples by the same MIBK/AA procedure, which is outlined above. The minimum gold detection limit reported by Acme was 1 ppb and by Eco-Tech was 5 ppb.

Sixteen reconnaissance rock and three soil samples were collected from various sites on the northern part of the property. Rocks were analyzed by Acme for gold by MIBK/AA on a 20 gram portion of -100 mesh pulverized material.

5.2 RESULTS (Plate 1, Figures 2 and 4)

Gold values for 1990 fill-in soils and resamples as well as reanalyses of 1989 pulps are illustrated on Plate 1. Analytical certificates are appended in Section 11.0. Figure 2 shows the position of the geochemical grid on the property as well as locations for reconnaissance rock and soil samples. Figure 4 is a plot comparing analytical results of auger samples conducted by two different labs.

Results from fill-in samples collected around 1989 samples believed to contain anomalous levels of gold did not confirm the higher values in many instances. It was suspected that the analytical procedure used in 1989 which consisted of fire assay followed by AA analysis of the dore bead may have given a more complete gold extraction, and hence, higher background values than the alternate MIBK/AA gold analysis.

As a check of the original results a number of sample pulps, as well as some resamples from original sites, were reanalyzed using the MIBK/AA method. Very few of the check results confirmed higher gold numbers obtained in 1989. Several significant values, up to 230 ppb Au, were obtained however from other sites, and some anomalous trends were defined.

On Plate 1 the gold results are illustrated by increasing sized symbols which represent ranges of values of from 1 to 10 ppb (background), 11 to 20 ppb (weakly anomalous), 21 to 50 ppb (moderately anomalous) and greater than 50 ppb (strongly anomalous). Squares represent samples collected in 1990 and triangles are for 1989 pulps which were re-analyzed in 1990.

An area of clustered anomalous stations was defined between 6350N and 6550N from 1500E to 2150E. No distinct linear trends were indicated, however the high values may be scattered along east to northeast trending structures represented by conductors outlined in a 1989 VLF-EM survey. Three significant gold values at approximately 7050N, between 2700E and 2900E define a northeast trending anomaly. A test pit was excavated beside the middle station, which returned 230 ppb Au, but it failed to reach bedrock (see Section 6.0).

Both of the areas described above were shown to contain several above-background gold values by the 1989 sample analyses, however, resampling and reanalyses conducted in 1990 showed a poor correlation of results for individual samples. This suggests that there are gold sources in these areas but the erratic distribution of gold in the soil causes highly variable analytical results.

Another 1989 anomaly confirmed by the 1990 fill-in sampling extends northeasterly across lines 1400E to 2200E from 4000N to 4350N. This area requires further fill-in sampling at 50 m spacings to better define targets.

Two large anomalous areas on the north part of the grid outlined by the 1989 program were only partially confirmed by the 1990 analyses. The original values are suspect, possibly due to the type of gold analysis which was performed on the samples.

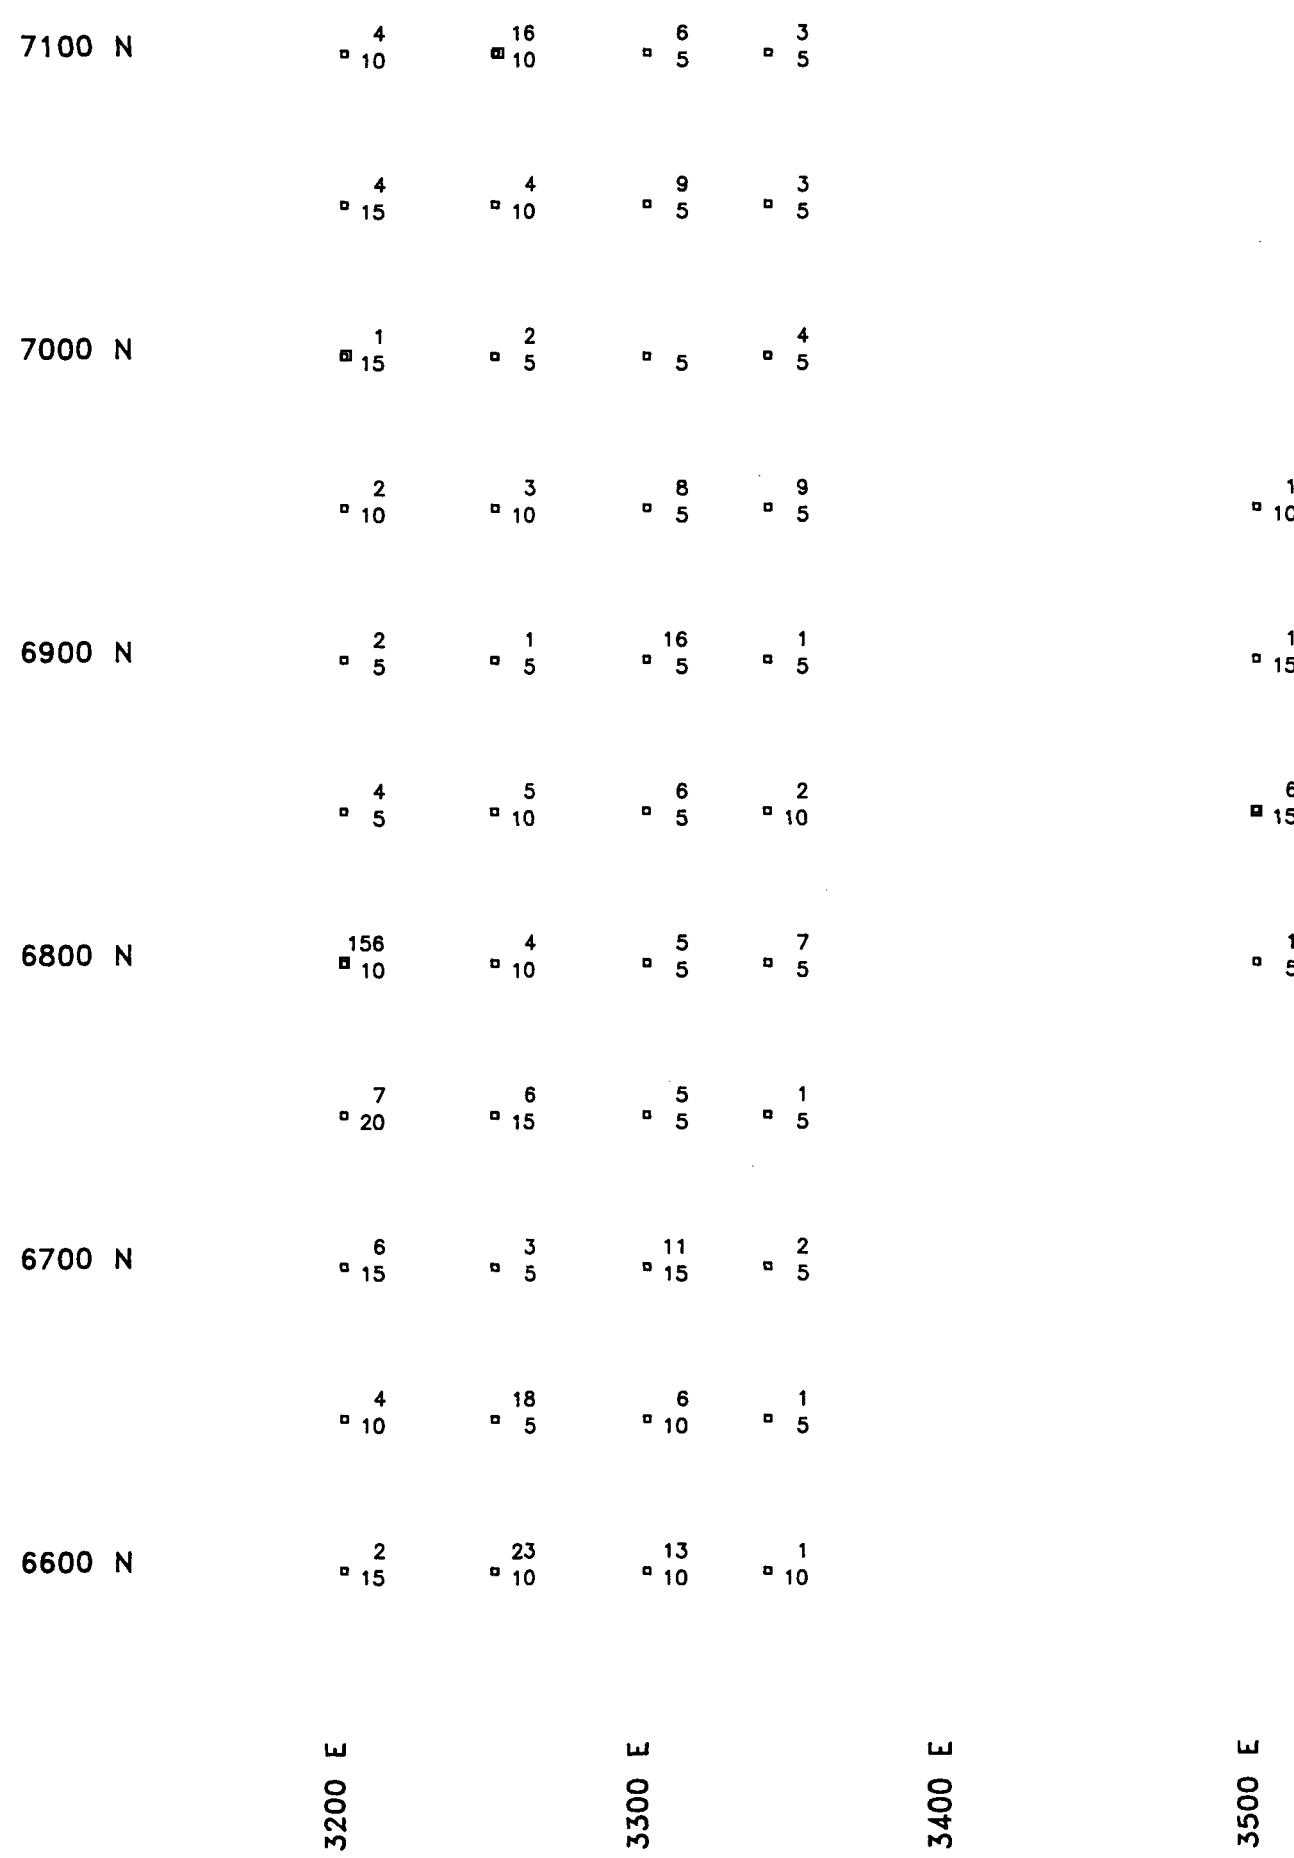

Figure 4 illustrates a poor correlation of gold values derived by two different labs from cuts of the same samples. From the 48 auger soil samples Acme determined 5 values greater than 15 ppb Au up to a high of 156 ppb, for which corresponding analyses at Eco-Tech gave 5 to 10 ppb. Only one Eco-Tech value of greater than 15 ppb was returned, a 20 ppb result corresponding to 7 ppb from Acme.

Comparing the auger sample values to those for mattock-collected samples at the same sites (see Plate 1) show no significant increase in gold values at greater depth in the overburden. It appears that the local presence of an upper organic layer in the soil has negligible effect on the gold values if samples are collected properly with a mattock. Variability of results is much more strongly influenced by the nugget effect of gold distribution in the soil. These observations are also substantiated by the results of profile soil sampling in trench WH 901 (see Section 6.2).

Reconnaissance rock samples described in Table 2 were all selected grabs from altered granitic rock or quartz vein float. Gold values are all low except for 143 ppb Au from WH 90-R10, a sample of strongly altered granite rubble cut by quartz-ankerite stringers. The angular rubble appears to have a nearby source. Three reconnaissance soil samples in the immediate area all had low gold values.

Table 2 RECONNAISSANCE ROCK SAMPLES

SAMPLE #	GRID LOCATION	DESCRIPTION (all grab-type samples)	Au-ppb	Aq-ppm
WH90-R1	6917N-3292E	Drusy, hematitic quartz vn float (3-4cm)	5

6.1 PROCEDURE (Figures 2, 5 and 6)

Two trenches totalling 269 metres and three test pits were excavated on the WH 8 and WH 6 claims to test soil geochemical anomalies and structural lineaments (Figure 2). The excavation was performed by Wiltech Developments of Kelowna, B.C., during October 1990.

The Cat 215 excavator utilized a toothed bucket in clayey compacted overburden and a smooth-edged bucket for scraping clean the bedrock surface. A 100 cc Honda pump was used to dewater sections of the trenches and to wash the exposed bedrock.

The trenches were surveyed, mapped at 1:100 scale, rock sampled and overburden soil sampled. Surveying was done with a Brunton compass and a 50 metre steel measuring tape. Geochemical grid stations were tied in to the trench location. Mapping defined geological contacts, structures and sample locations. The two trenches are illustrated at 1:500 scale on Figs.5 and 6.

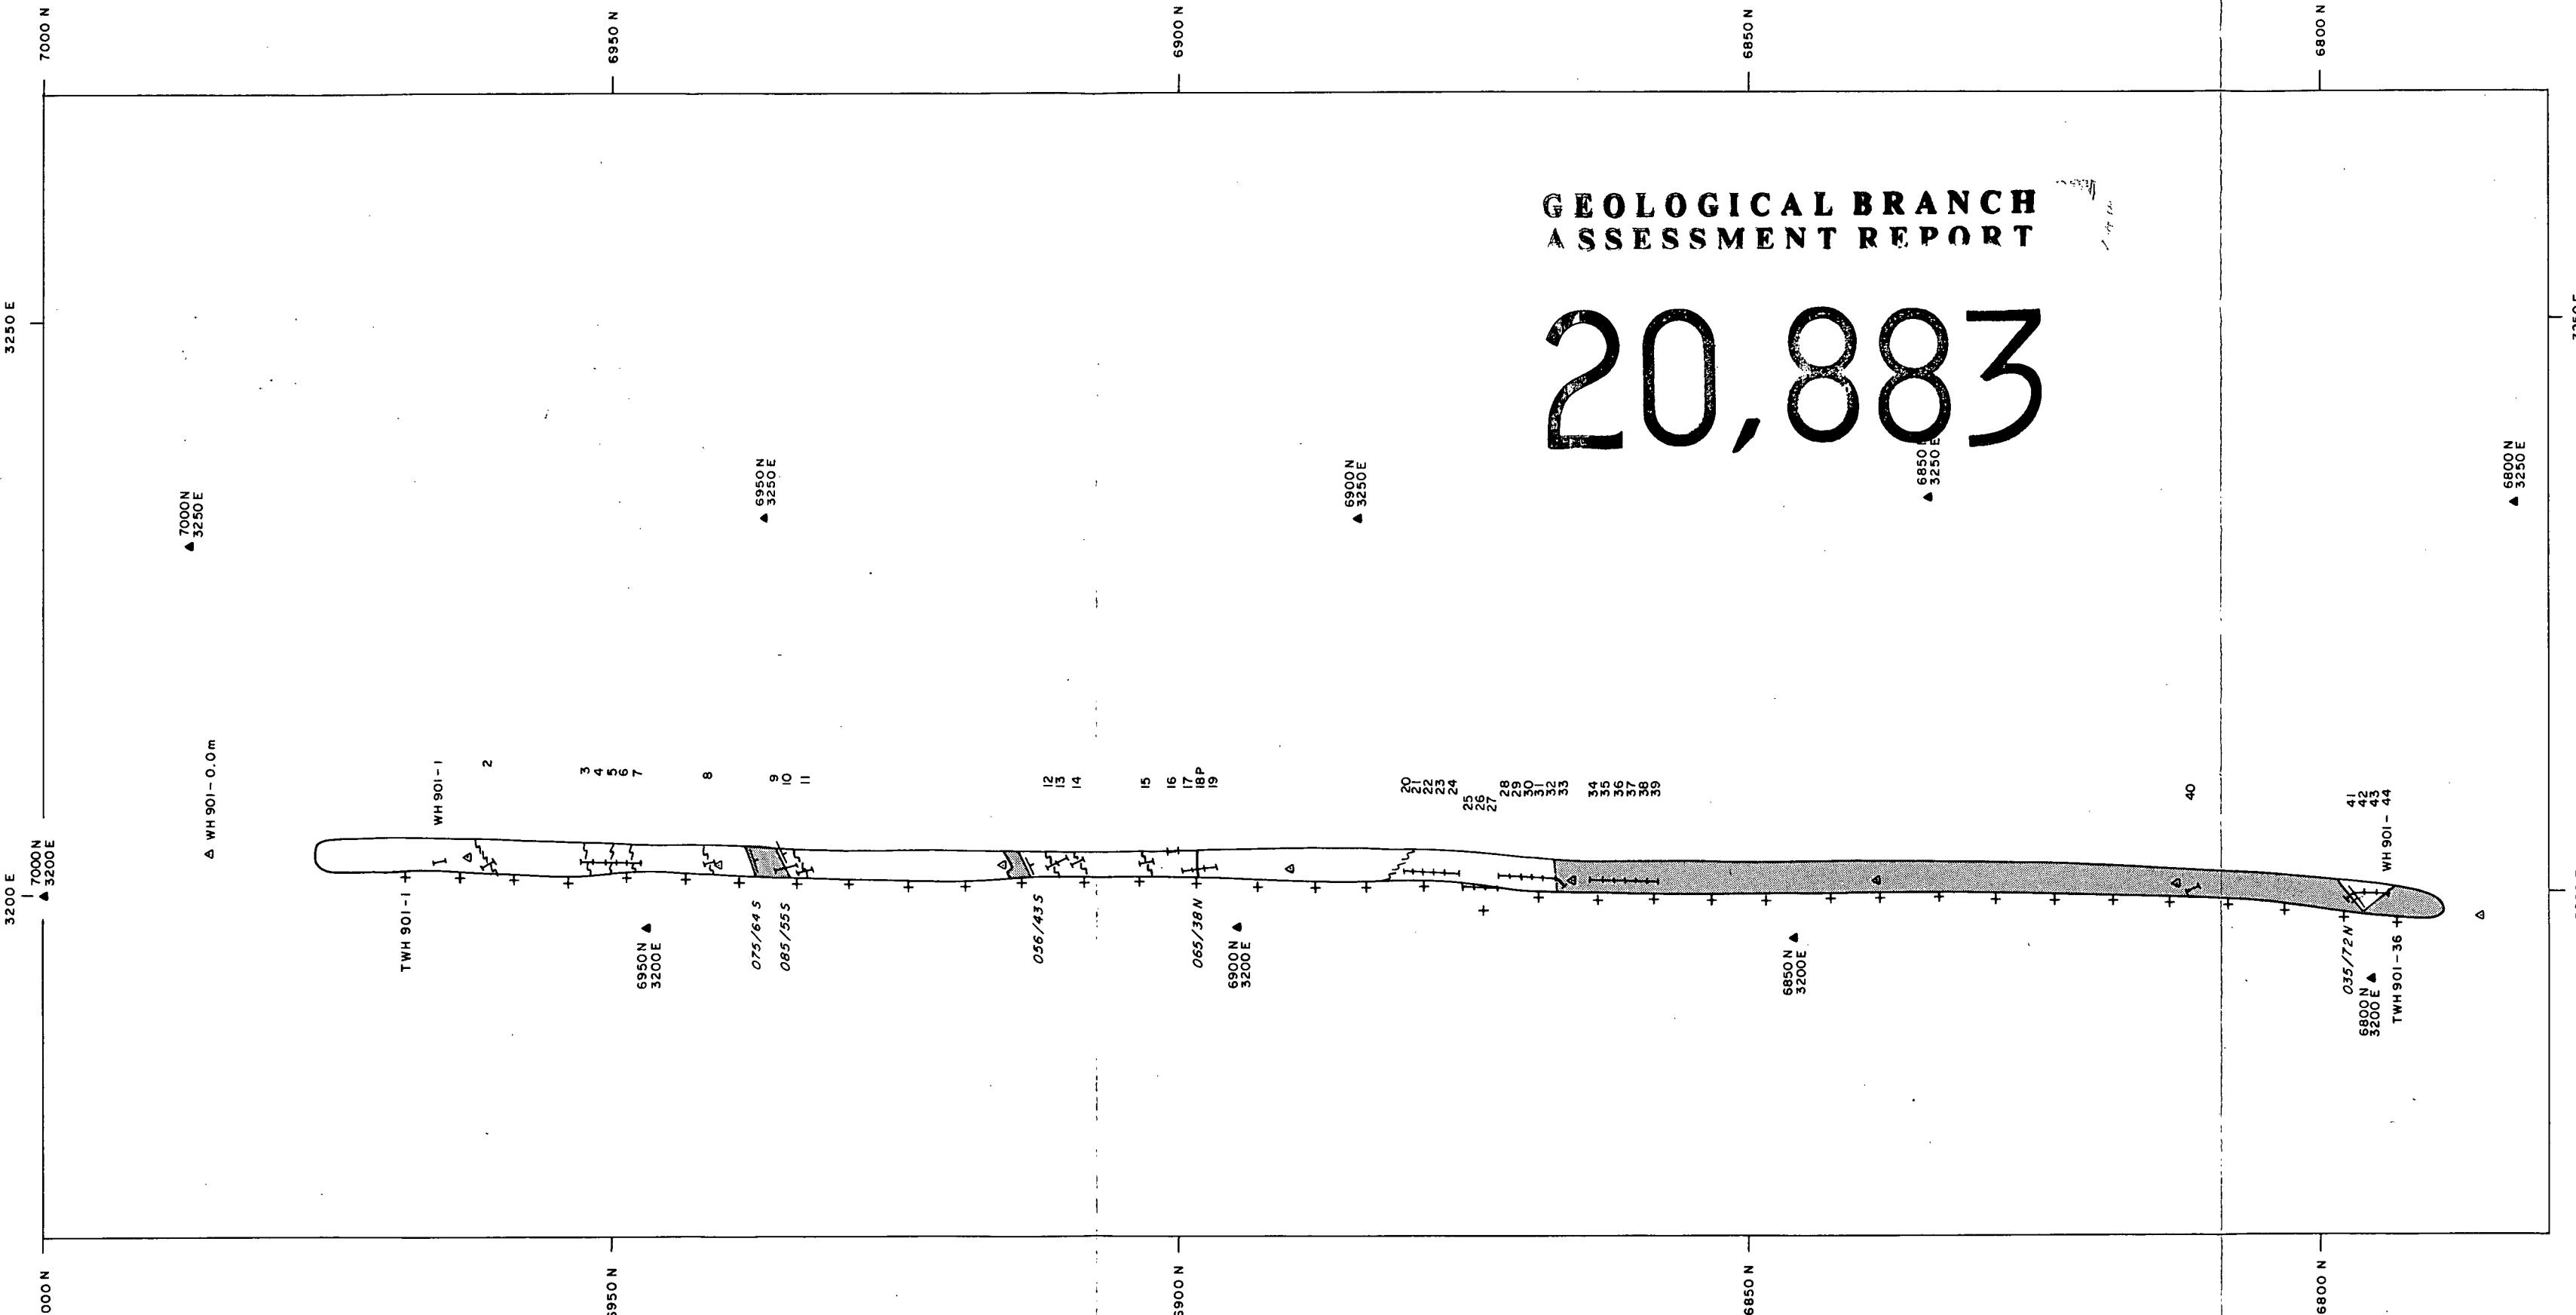

Basal soil samples were collected at 5m intervals along one trench wall at the bedrock-overburden interface. In trench WH 901 soil profile samples were also collected every 10 metres at 50 cm increments up the trench wall to surface. Basal soil samples were numbered consecutively from the trench zero point starting with number one (eg. TWH 901-1). Profile samples have the same numbering system but with a letter suffix denoting the level, with A at 50 cm above bedrock, B at 100 cm, etc. (eg. TWH 901-1A). Totals of 101 soils from trench WH 901 and 15 soils from trench WH 902 were collected and analyzed for gold by the same method described for soils in section 5.1.

Three test pits excavated near anomalous soil stations failed to reach bedrock at depths of about 4 metres. Soil samples were collected from the pit walls at depths ranging from 2.5 to 4 metres and they were immediately backfilled.

Totals of 44 rock samples from trench WH 901 and 11 from trench WH 902 were collected. These continuous chip samples were taken over 0.7 to 1.4 m lengths (most 1.0 m) in areas of altered or favourable looking bedrock and oriented perpendicular to structures, where possible. They consisted of 5 to 10 kg of rock chips broken from a 7-10 cm wide channel using a hammer and chisel.

Sample 18P from trench WH 901 was a panel consisting of continuous chips over a 0.5 m by 0.5 m area to a depth of 3-5 cm, weighing about 15 kg. This sample tested a 2 cm quartz vein and weakly argillically altered granite wallrock. The samples were numbered consecutively from the trench zero point starting with number one (eg. WH 901-1).

Rock samples were shipped to Acme Analytical Laboratories in Vancouver for gold determinations. Most were analyzed by the following procedure: crush sample to -3/16", split out 250 gm, pulverize to -100 mesh and analyze 20 gm by MIBK/AA. Sample WH 901-18P received a metallics fire assay consisting of the following steps: crush 5 kg of sample to -1/16", split out 1 kg, pulverize to -100 mesh and sieve on 100 mesh screen, conduct fire assays on 1 AT of fine material and entire coarse fraction, combine weighted results for gold content. The samples on each side of 18P had regular fire assays which resemble the above method but exclude the sieving and assay of coarse material.

Upon receipt of results the trenches were backfilled, groomed and grass seeded. The zero point of each trench is marked by an orange-painted post with attached aluminum label.

6.2 RESULTS (Figures 2, 5 and 6)

Trench sample locations are shown on Figures 5 and 6 and results are listed in Table 3. Test pit locations are plotted on Figure 2.

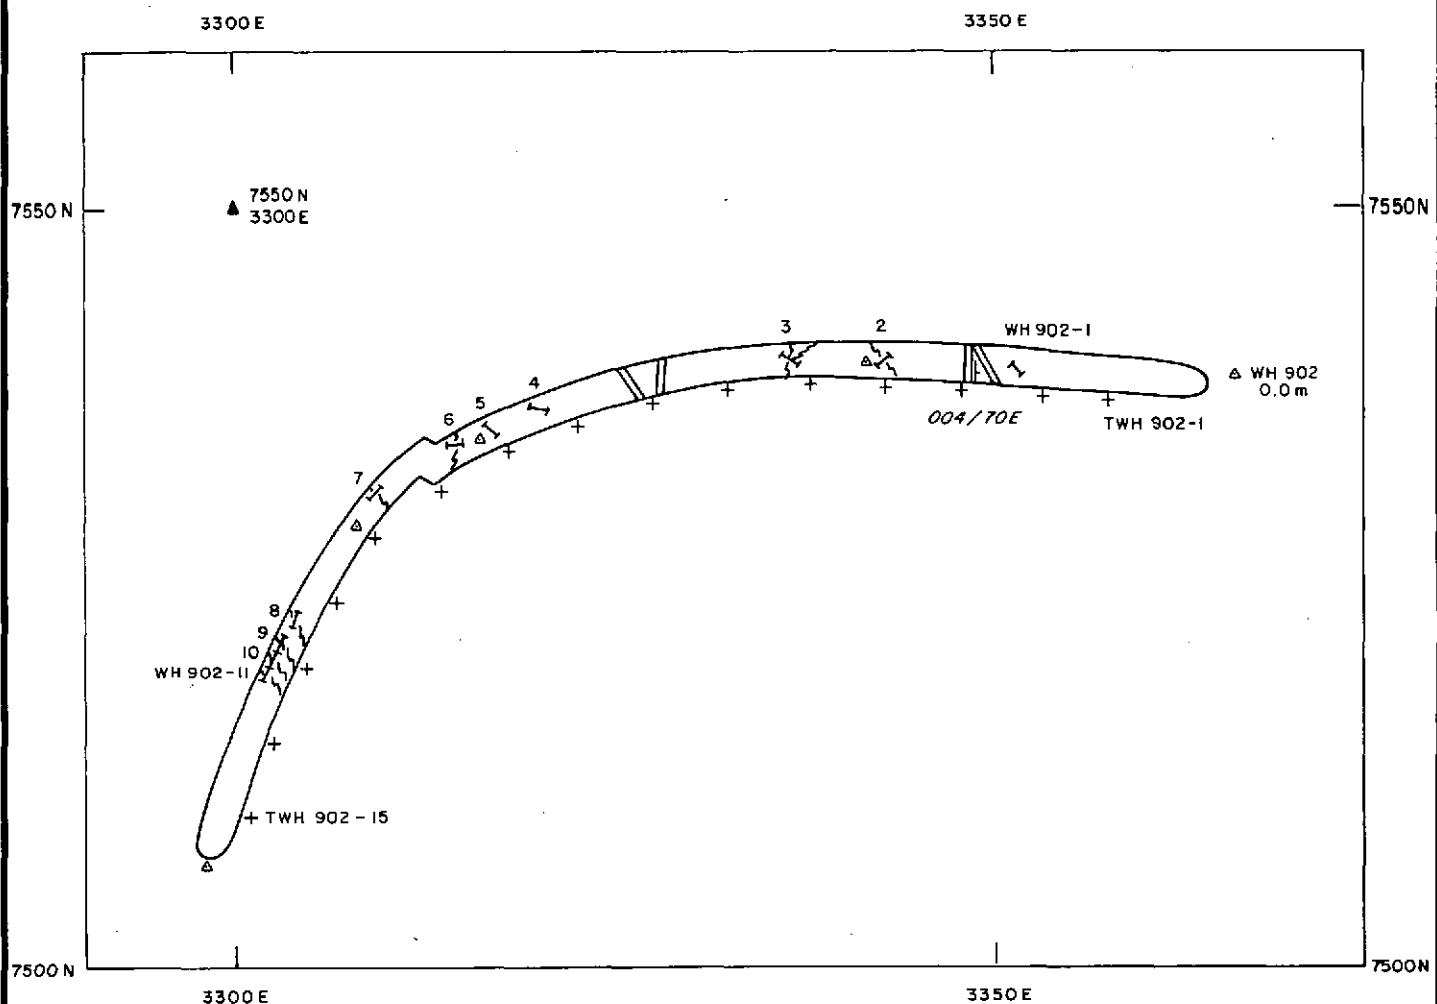

The trench and test pit soil samples returned only one value of significance, 67 ppb Au from TWH 901-3C. This sample is from near the surface of overburden consisting of sandy to clayey till. Underlying samples 3A and 3B had low gold values. It appears that the gold in the sample has been transported from a source outside of the trench area.

Rock chip samples from the two trenches all had values of 0.001 oz/ton Au or less. Strongly clay altered shears, limonitic fractures and one narrow quartz vein were observed and sampled in the trenches. The geological setting is favourable for hosting gold-bearing quartz veins however the potential in the trench area appears to be poor based on geochemical results.

Trench WH 901 was dug south along line 3200E for 187 metres to test soil geochemical values of 79 and 156 ppb Au as well as two parallel linear depressions trending 105 degrees and two easterly trending VLF-EM conductors. Overburden ranged from one to 3.5 metres thick. The southern third of the trench was underlain by coarse feldspar porphyry of the Otter intrusions and the northern part was dominated by quartz monzonite of the Jurassic batholith. Two northeast striking porphyry dykes were exposed cutting the quartz monzonite. Several northeast trending, argillically altered shears were mapped, predominantly within the quartz monzonite. Clay material was locally rusty orange coloured but no pyrite or other sulphide minerals were seen. A 2 cm quartz vein was observed trending 065/38NW surrounded by a zone of weak argillic alteration at 6898N.

See text for sample results.

Trench WH 902 was dug west and south along a road ditch for 82 metres to test an area of siliceous altered granitic float with a nearby soil anomaly of 70 ppb Au. Overburden was less than one metre thick. Bedrock consisted of biotite-rich granodiorite cut by a few narrow, north trending quartz monzonite dykes. Rocks were fresh except for narrow zones of weak argillic alteration along several 2 cm. north to northwest trending shears. Minor pyrite was observed disseminated in the granodiorite. No quartz veins were seen.
