SUMMARY

The MAID 2 mineral claim was located in 1988 to cover an area with anomalous gold values in heavy mineral samples. The anomalous samples are located in Maiden Creek and two of its southern tributaries. Follow up samples at 500 m spacing in these tributaries outlined a gold anomaly in the western part of the claim. The MAID 3 & 4 claims were located in 1990 to cover the possible western extension of this anomaly. The MAID 10 Fraction was located in 1990 to cover open ground between MAID 2 and claims to the south. These claims have been grouped to form the MAID WEST claim group.

The property covers part of the western contact of the Bonaparte Graben. It is underlain by bedded wacke and coarse pebble-cobble conglomerate in the east and massive limestone in the west. These sediments are interpreted to represent a proximal alluvial fan facies from a northern source. The conglomerate is well sorted with subrounded pebbles and cobbles. The sediments are deposited as plane beds in alluvial channels by continuous sediment transport in the Upper Flow Regime.

A geochemical soil survey was completed to locate the source of the heavy mineral gold anomaly. The 45 km MAID GRID covers the drainages of both the tributaries south of Maiden Creek. Thirty kilometres of the grid, which extends east onto MAID 1, is located inside the claim group.

Six hundred and twenty five samples were collected on 25 1.2 km lines by Discovery Consultants. The samples were analyzed for gold by fire assay with atomic absorption and for 32 additional elements by ICP. The samples returned scattered gold values of up to 445 ppb. Several small anomalies which account for 39.3% of the anomalous values (>24 ppb) are located in the northwest corner of the grid.

Two arsenic anomalies (up to 30 ppm) are located on the grid. One anomaly is associated with the gold anomalies in the northwest corner of the grid. The other is located in the centre of the grid. Spotty Be values to 2 ppm are located in the southern part of the grid. The remaining trace elements returned background values.

The sampling was completed in an area with thick glacial overburden, in excess of six feet. Locally a poorly developed A horizon overlies the glacial till. Previous anomalous gold values (up to 954 ppb) from the till/A horizon couldn't be duplicated.

The soil samples are believed to reflect the mineral distribution of the glacial till, rather than the underlying bedrock. Other techniques are required to locate the source of the heavy mineral gold anomaly.

INTRODUCTION

The MAID WEST claim group is located in the central interior of B.C. within the Kamloops Mining Division. It is composed of three modified grid claims and one fraction claim. The claim group contains 55 units and covers about 1,375 hectares.

The claims are part of a group of claims under option from A.J. MacDonald. A 15% net profits royalty is held by a Vernon group. Teck Corporation has an option to earn 70% interest in the claim by funding exploration on the property.

The property is located in the northwest part of the Bonaparte Graben. The graben is filled with Cretaceous alluvial fan sediments which might be correlated with part of the Pasayten Group. To the west, the sediments are in contact with massive limestone of the Permian to Triassic Marble Canyon Formation (Central belt of the Cache Creek Complex). To the northeast, the graben is bounded by schist of the Pennsylvanian to Triassic Eastern belt of the Cache Creek Complex. In the south and east, the sediments are in contact with volcanics of the Triassic to Jurassic Nicola Group. To the southwest, the graben borders Tertiary sediments.

Previous exploration in this extensively overburden covered area has been concentrated east and west of the Bonaparte Graben. Cominco's Maggie Porphyry Cu-Mo Deposit is located to the east, while B.C. Hydro's Hat Creek Coal Deposit is located to the south.

Sporadic exploration for gold has been done since the turn of the century. The majority of the work was done in the Maiden Creek drainage, which runs through the northern part of the claim group.

Heavy mineral sampling in the Bonaparte Graben in 1987 and 1988 by Discovery Consultants, located anomalous gold values in Maiden Creek and two of its southern tributaries. The MAID 2 mineral claim was located in 1988 to cover part of this gold anomaly. Following the option by Teck Corporation in 1990, three additional claims were located to cover a possible western and southern extension of this anomaly.

This report summarises geological and geochemical work on the claim group in 1990.

LOCATION, ACCESS, PHYSIOGRAPHY

The MAID WEST claim group is located about 90 km west of Kamloops, 220 km northeast of Vancouver and 21 km northwest of Cache Creek in south central B.C. (Figure 1). Provincial Highway 97, north from Cache Creek, runs along the valley 8 km east of the claim group. The claims cover part of the Maiden Creek drainage at latitude 50° 56' N and longitude 121° 32' W on NTS map sheet 92 I/13E.

Access from Provincial Highway 97 east across the property, is provided by a logging road along Maiden Creek and its tributaries.

The property is located in an upland plateau region with subdued topography, and an elevation ranging from 2,800 to 4,500 feet. Vegetation consists of predominantly coniferous trees ranging from mature timber to second generation growth following intermittent logging. Minor deciduous trees and sage brushes are mixed with the coniferous trees in a semi arid climate. Temperature is high in the summer and moderate in the winter, which allows for year round exploration.

CLAIM DATA

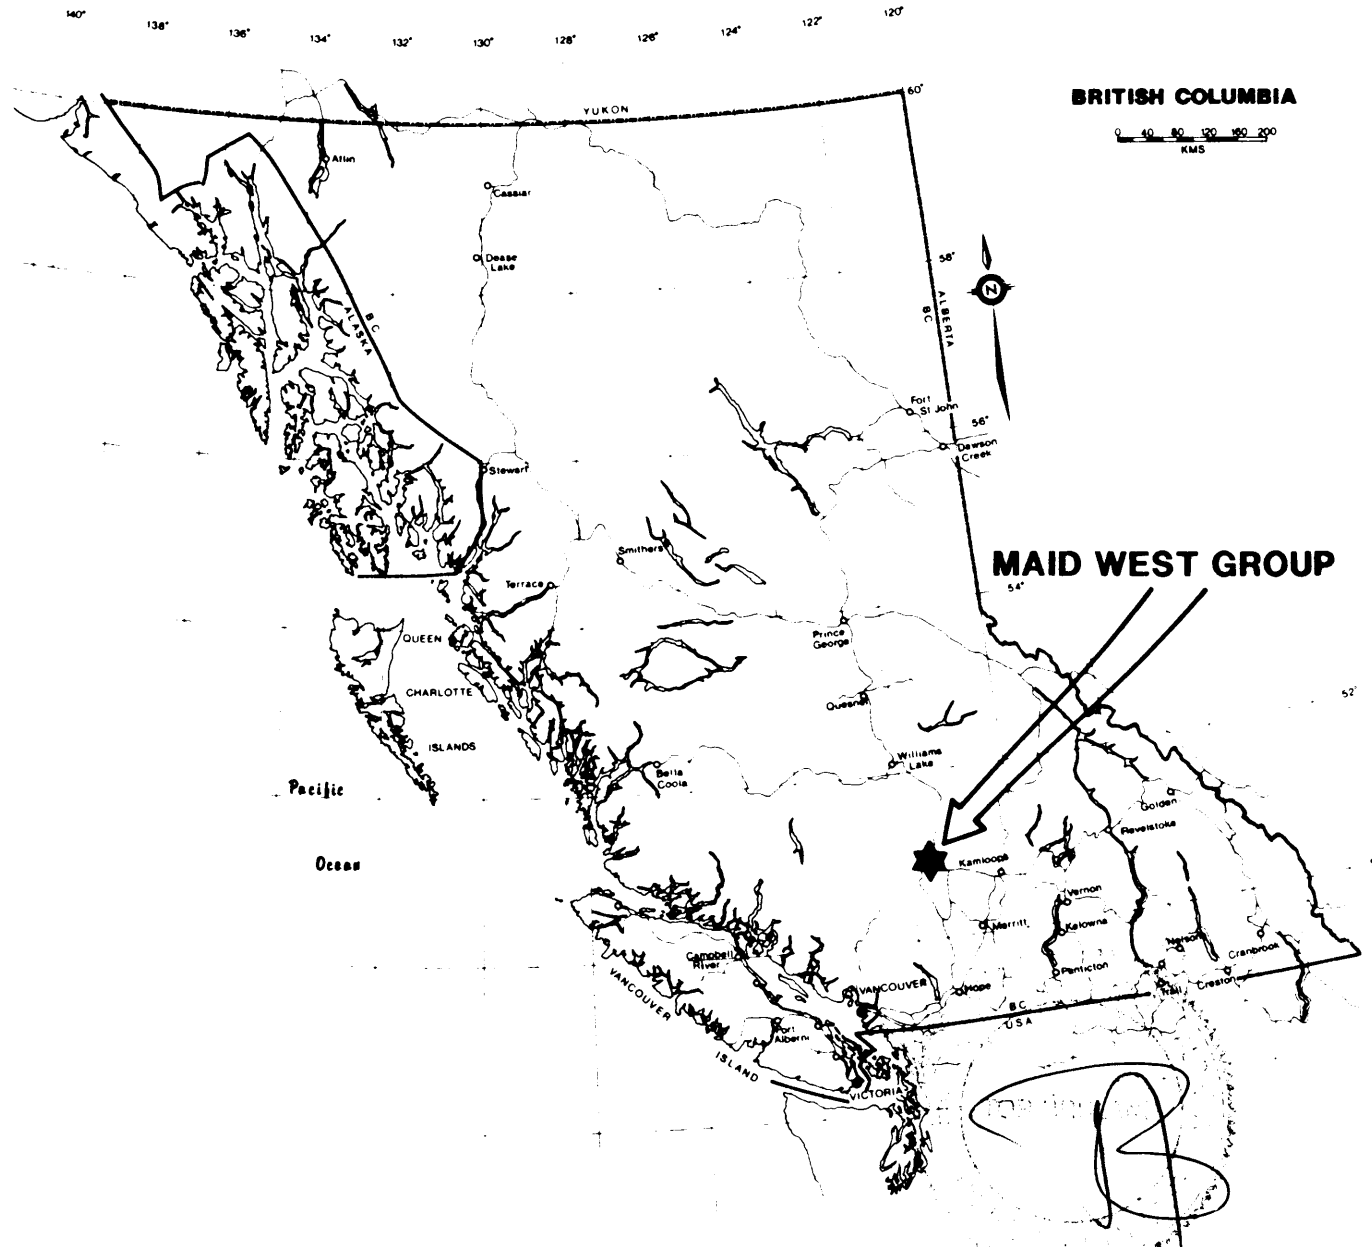

The MAID WEST claim group consists of three modified grid claims and one fraction claim (Table 1). The group which has 55 units and covers 1,375 hectares, is located in the Kamloops Mining Division, NTS 92 I/13E (Figure 2).

HISTORY

To the south B.C. Hydro conducted intense exploration for coal between 1970 and 1982. A large coal deposit estimated to contain between 10 and 15 billion tons of coal was outlined southwest of the Bonaparte Graben. A high grade section of 350 million tons of subbituminous/lignite coal has been delineated as feed for B.C. Hydro's planned thermal electrical plant. The project has been on hold since 1983, and commercial production is still pending.

FIGURE 1

Porphyry copper exploration east of the Bonaparte Graben in the 70's, located the Maggie Deposit which contains 181 million tons of .28% Cu and .029% Mo. The deposit is located adjacent to the eastern boundary of the graben.

Small amounts of placer gold have been found in the area since the turn of the century. Bedrock gold mineralization was reported in 1901. A sample of quartz conglomerate from the lower extent of Maiden Creek, east of the claim group, assayed about .19 oz/ton gold.

Most of the work since then has been done in the Maiden Creek area. In 1980 Cominco explored an area of the Bonaparte Graben about 15 km to the south of the claim group .

A regional heavy mineral program for the Bonaparte Graben was initiated in 1987 by Discovery Consultants. Minor follow up work with closer spaced sampling on selected anomalies was done in 1988 and 1989. The heavy mineral samples were separated into magnetic, para-magnetic and non-magnetic fractions. Experience has shown Discovery that the gold is located in the -150 mesh non-magnetic fraction.

Heavy mineral samples from the Maiden Creek and its southern tributaries returned 1,200 ppb (0.04 oz/ton) to 41,000 ppb (1.2 oz/ton) gold in the non-magnetic fraction. These samples are associated with anomalous As and Ba values.

The MAID 2 mineral claim was located in 1988 to cover the western part of the anomaly. In 1990 the MAID 3, MAID 4 and MAID 10 FRACTION were added to cover possible extensions of this anomaly.

OBJECTIVE OF THE CURRENT PROGRAM

The gold anomaly from the heavy mineral samples is located in the southern slope of the Maiden Creek Valley. Anomalous gold values are located in Maiden Creek itself and in two tributaries that flows north into Maiden Creek at the eastern boundary of the MAID 2 claim (A in Figure 7). In the southern tributaries the anomaly is cut off about 1.0 km upstream to the south. This indicates a possible source for the anomaly in the central part of the claim group.

To locate the source of this anomaly, a geochemical soil survey was completed. The MAID GRID with 100 m lines and 50 m stations was located in the southern slope of Maiden Creek Valley, and 30 km of the grid is located inside the claim group.

Mapping and prospecting of the limited outcrops on the claim group was done to locate mineralization in bedrock.

REGIONAL GEOLOGY

The MAID WEST claim group is located in the allochthonous Intermontane Belt (Figure 3). This is a superterrane composed of two oceanic terranes (Slide Mountain and Cache Creek), and two island arc terranes (Quesnel and Stikine). The claim group covers an area in the southeastern part of the Cache Creek Terrane close to the boundary of the Quesnel Terrane. The location is about 20 km east of the Fraser River Fault system (Figure 4).

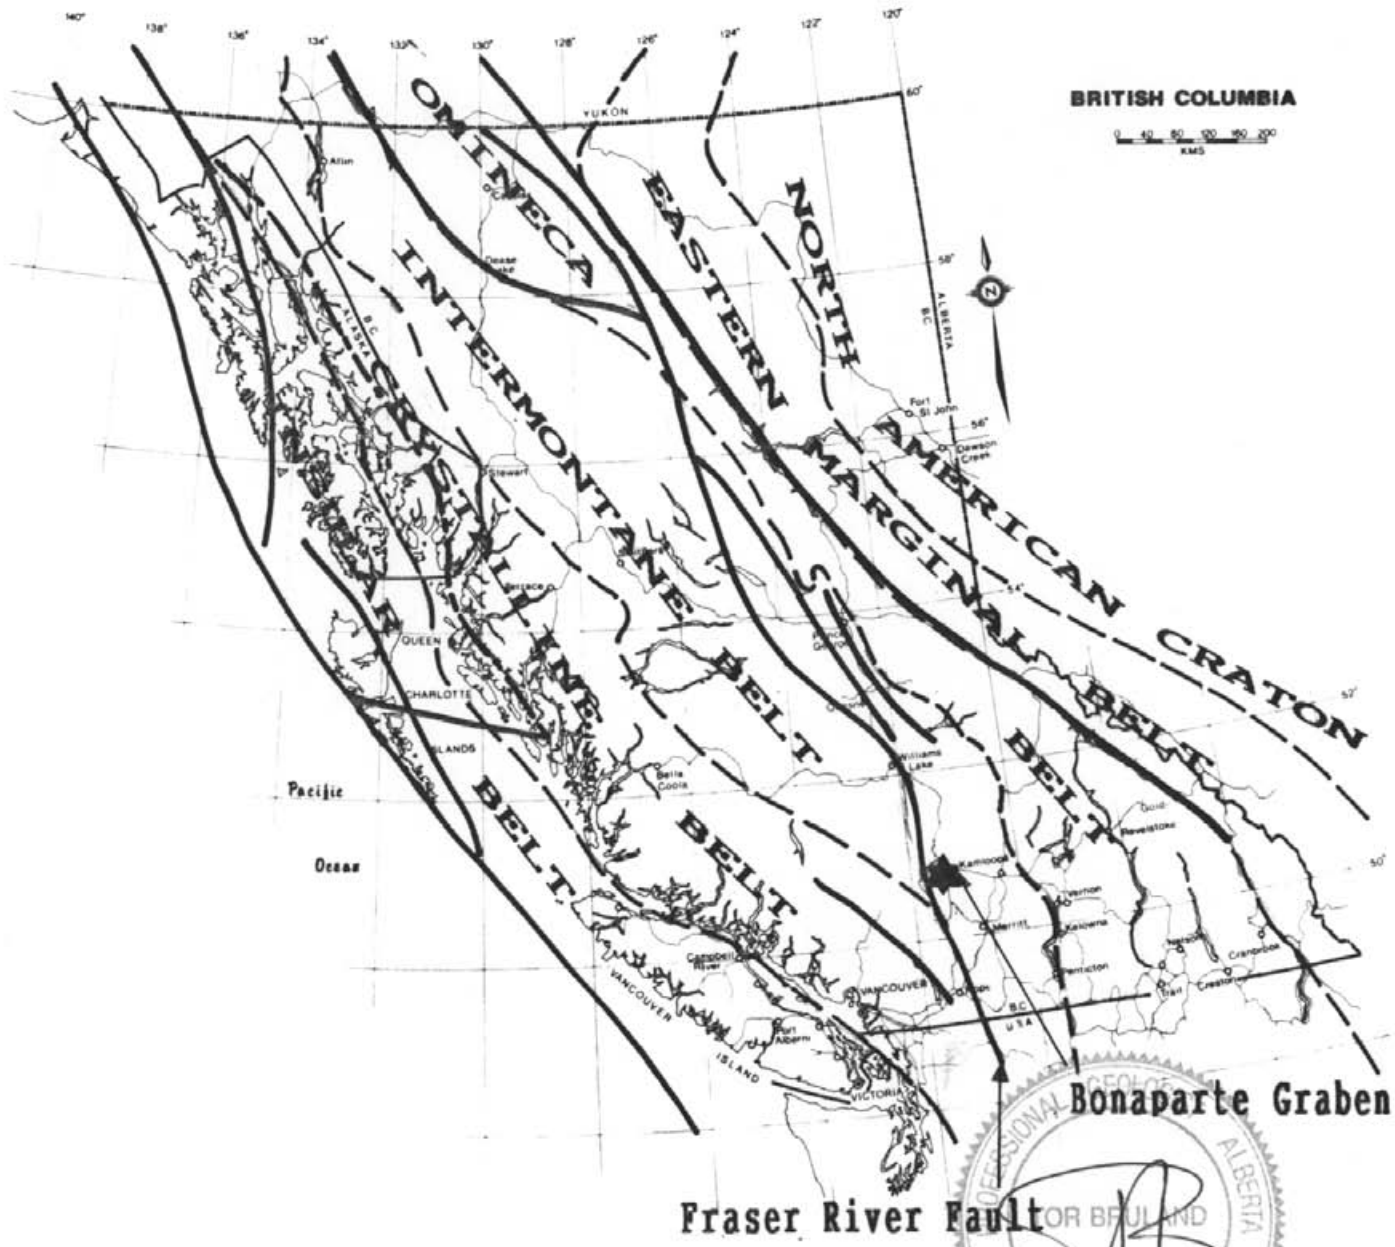

The Bonaparte Graben is part of the Cache Creek Terrane. The claim group is located over the western contact of the graben (Figures 5 & 6). It is filled by Cretaceous alluvial fan sediments of unknown thickness, which might be correlated with part of the Pasayten Group. The coarse clastic sediments are a bedded, coarsening upwards sequence. They dip to the W and E from a central core of the western volcanic facies of the late Triassic to early Jurassic Nicola Group. The Nicola Group is part of the Quesnel Terrane.

The sediments were deposited on a Triassic paleosurface of Nicola Group volcanics. There is a northern proximal fan facies (coarse cobble to boulder conglomerate), and a southern distal fan facies (wacke and fine pebble conglomerate). This indicates a northern source for the sediments. The sediments are deposited as plane beds in alluvial channels by continuous sediment transport in the Upper Flow Regime. Minor sericite and carbonate alteration of the sediments can be identified in thin sections.

The alluvial fan sediments are unconformably overlain in the southwest by an arid cobble conglomerate. This conglomerate is believed to be of mudflow or debris flow origin.

In the west the graben is bounded by the Permian to Triassic Marble Canyon Formation. Massive limestone is interbedded with minor ribbon chert, argillite, tuffs and volcanic flows. This is part of the Central Belt of the Cache Creek Complex.

To the northeast, the graben is bounded by the middle Pennsylvanian to late Triassic Eastern Belt of the Cache Creek Complex. It is composed of chert, phyllite, schist, argillite, basalts and minor carbonate. This belt host the Maggie Porphyry Cu-Mo Deposit.

TECTONIC BELTS

DRAWN: LL	DATE: APR./91
	FIG. 3

**SOUTH-CENTRAL B.C.
TERRANE DISTRIBUTION**

In the south and east, the graben is bounded by the western and central volcanic facies of the late Triassic to early Jurassic Nicola Group. These facies are composed of pyroclastics and flows of andesitic to dacitic composition, argillite and sandstone. The volcanic breccia and lapilli tuff of the lower part of the facies (possible subaerial origin) changes into fine grained volcanoclastics and massive limestone in the upper facies (possible subaqueous origin). Amygdaloidal basaltic pillow lavas in the north are believed to be part of the underlying Nicola Group.

Post sedimentation compression (possible Laramide) formed a northwest striking anticline in the graben. Subsequent erosion has exposed the Nicola Group volcanics in the core of the anticline. The presence of serpentinite along the northeastern part of this core suggest a tectonic origin of the block. The absence of other structural evidence indicates that the serpentinite in the graben could be part of an ultramafic sequence (opholite) in the Nicola Group rather than structural controlled intrusions. This fact is further supported by the present dip of the alluvial fan sediments.

In the southwest, the graben is bounded by Tertiary sediments consisting of argillite and graphite which host the Coal Deposit.

The sediments were intruded by Eocene quartz latite and rhyolite bodies ranging in size from narrow dykes to large domes or sills. These rocks have patchy argillic alteration.

Syn or post Eocene deformation formed large and small scale faults throughout the graben.

The area is covered by extensive glacial overburden from at least one episode of Pleistocene glaciation.

CLAIM GROUP GEOLOGY

The claim group covers a 4.5 km strike length of the Bonaparte Graben (Figure 5). It is underlain by the western contact which is not exposed in the area (Figure 6).

The eastern part of the claim group is underlain by bedded wacke and polymictic pebble-cobble conglomerate. Limited outcrops suggest there is about 65% wacke. The wacke is medium to coarse grained well sorted with 65% quartz and feldspar and 35% subrounded rock fragments. There are up to 2% subrounded pebbles to 15 mm in the wacke.

The conglomerate varies between pebble-cobble supported (15% matrix) and matrix supported (40% matrix). The fragments, which are quartz, tuff, siltstone and wacke, are subrounded to angular ranging in size from 5 to 100 mm. The texture and composition of the sediments suggest plane bed deposition by continuous sediment transport Upper Flow Regime in alluvial fan channels.

In the central part of the claim group there is extensive rhyolite floats/erratics indicating proximity to a bedrock source.

In the west, the claims cover the bedded impure limestone and argillite of the Marble Canyon Formation.

The property is covered by extensive glacial overburden with very poor soil development. Road cuts indicate that soil development is limited to a thin A horizon.

MINERALIZATION

Only minor disseminated pyrite and malachite have been identified in the Bonaparte Graben. The mineralization is located about 8 km to the south of the claim group. It is hosted by the western facies of the Nicola Group volcanics in the core of the anticline.

GEOCHEMICAL SURVEY

Little is known about the glacial overburden which covers the area. On Discovery Consultants's recommendation the heavy mineral anomaly was followed up by a geochemical soil survey.

An evaluation of the overburden was done by three orientation pits at previous anomalous soil sample sites. These pits indicate that the overburden is glacial sand with minor foreign subrounded cobbles. The grain size and composition of this sand is clearly different from the underlying Cretaceous wacke and conglomerate. The glacial sand is overlain by a thin, poorly developed A horizon.

Previous gold values of 416 to 954 ppb within 25 m of these pits, could not be duplicated. Results from the pits varied between <5 to 165 ppb Au with 65% of the samples <6 ppb Au. The A horizon and organic debris shows up with elevated Mn (>1,000 ppb), while the leached calcium carbonate horizon shows up with elevated Ca (>1%). The pit profiles and gold values are shown in Figures 8 A-C.

The geochemical survey was conducted on 25 E-W lines with 100 m spacing and 50 m stations (MAID GRID, Figure 9). The grid covers the southern slope of the Maiden Creek Valley east and west of the two southern tributary creeks. Elevation ranges from 3,000 to 4,000 feet. Thirty km of the grid is located on the MAID WEST group west of the two tributaries.

Six hundred and twenty four samples were collected and, and 97.0% of the samples were collected from the glacial till, 2.2% were from the A horizon and .8% from the leached Calcium carbonate horizon. All samples were sent to Chemex Labs Ltd. in North Vancouver for analysis. Each sample was dried and sieved to -80 mesh. Geochemical fire assay for gold with atomic absorption finish on a 30 gram sample was done on 99% of the samples. The remaining samples which contained <30 gram of -80 mesh material, were fire assayed on a 10 gram sample. Determination for 32 additional elements (Ag, Al, As, Ba, Be, Bi, Ca, Cd, Co, Cr, Cu, Fe, Ga, Hg, K, La, Mg, Mn, Mo, Na, Ni, P, Pb, Sb, Sc, Sr, Ti, Tl, U, V, W, and Zn) were done by nitric-aqua-regia digestion and analyzed by inductively coupled plasma spectroscopy (Appendix 2).

The samples returned gold values to 445 ppb with 16.5% of the samples >4 ppb Au. A value of twenty five ppb gold are considered to be anomalous, and 10.6% of the samples are >24 ppb Au. Of the anomalous samples 39.3% are located in a 500 by 800 m area in the northwest corner of the grid (Figure 9). The anomalous area also contain samples with low but anomalous As values (to 25 ppm). A second area with low but anomalous As values (to 30 ppm) is located in the central part of the grid. A few Be values to 2 ppm are located in the southern part of the grid.

Due to the extensive glacial overburden which is greater than six feet, it is believed that the samples reflect mineral distribution in the till. Better sampling techniques are required to located the source of the gold anomaly in the central part of the MAID WEST claim group. An evaluation of the present geochemical results can not be done before a complete assessment of the overburden is undertaken.

CONCLUSIONS AND RECOMMENDATIONS

The source of the heavy mineral gold anomaly on the claim group has not been located. Work to date indicates that it is located west of the present grid in an area with extensive rhyolite floats/erratics.

To locate the possible rhyolite a magnetometer survey will be required in the area of the rhyolite floats/erratics. This should be coordinated with additional mapping and prospecting.

An extensive orientation survey of the overburden is required to design a suitable sampling technique for a geochemical survey. The present grid should be extended to the west for both the geochemical and magnetometer surveys.

HEAVY
MINERAL
SAMPLE
LOCATIONS

SCALE 1:50,000

DATE: SEPTEMBER, 1990

DATA: T. BRULAND

FIGURE 7

DRAWN BY: P.H. L.L.

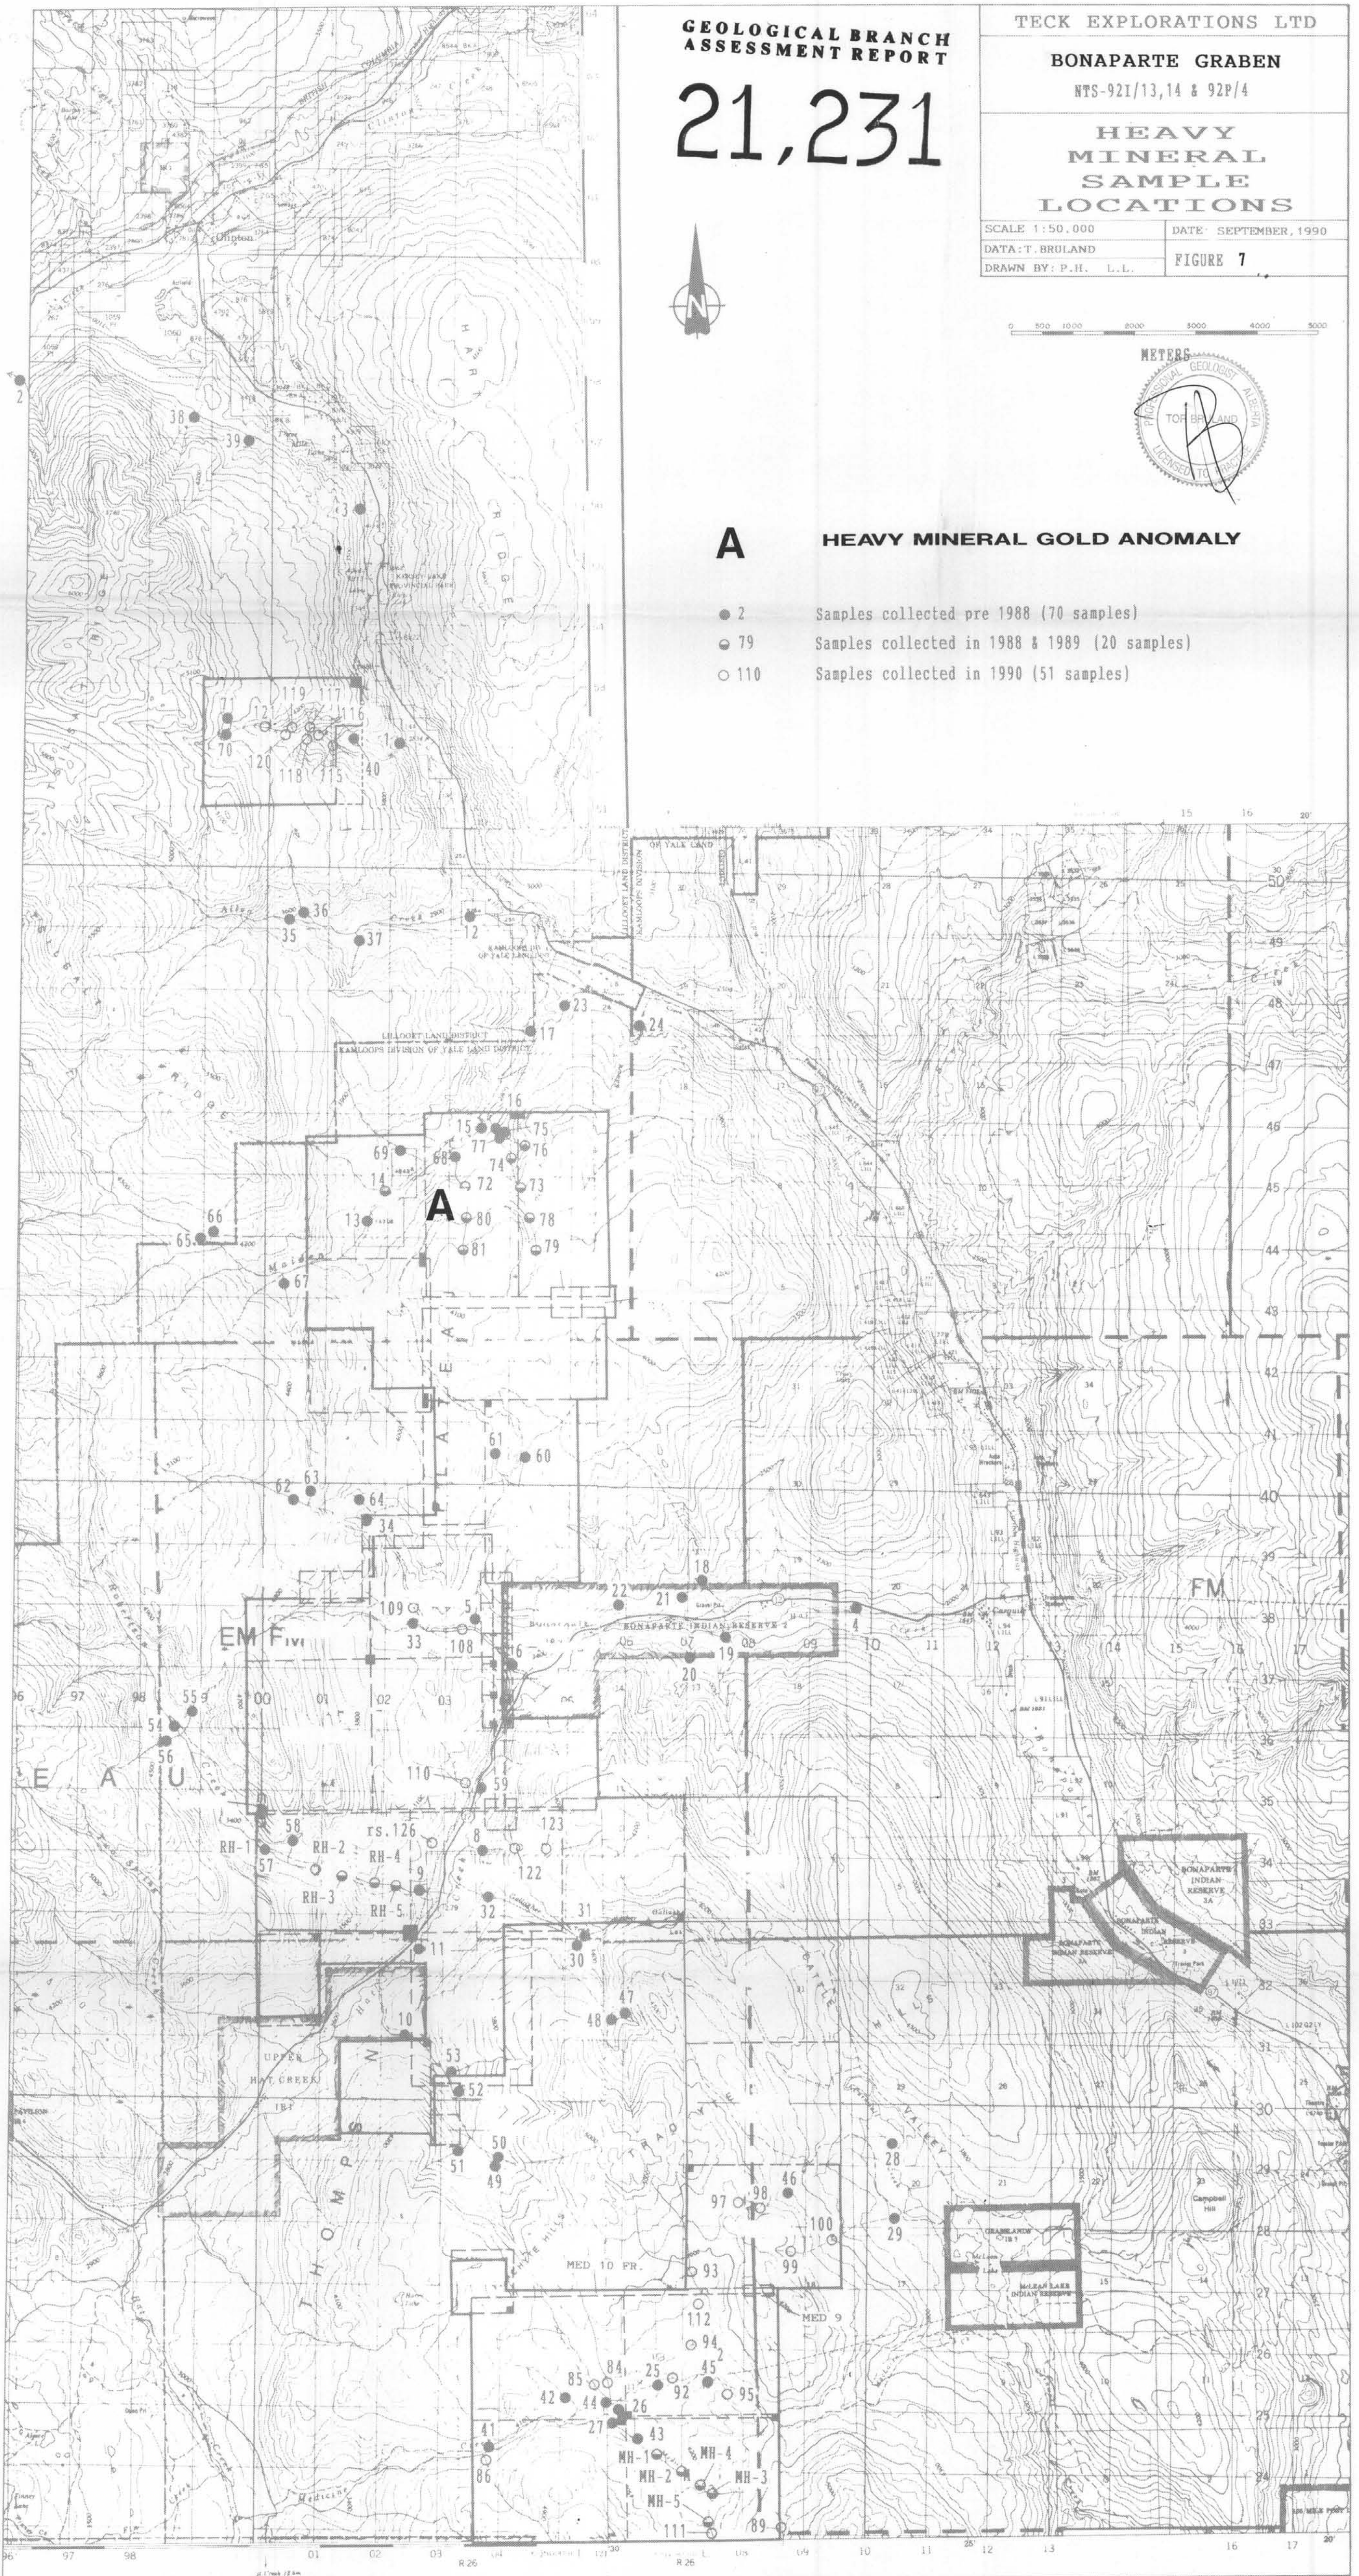

0 500 1000 2000 3000 4000 5000

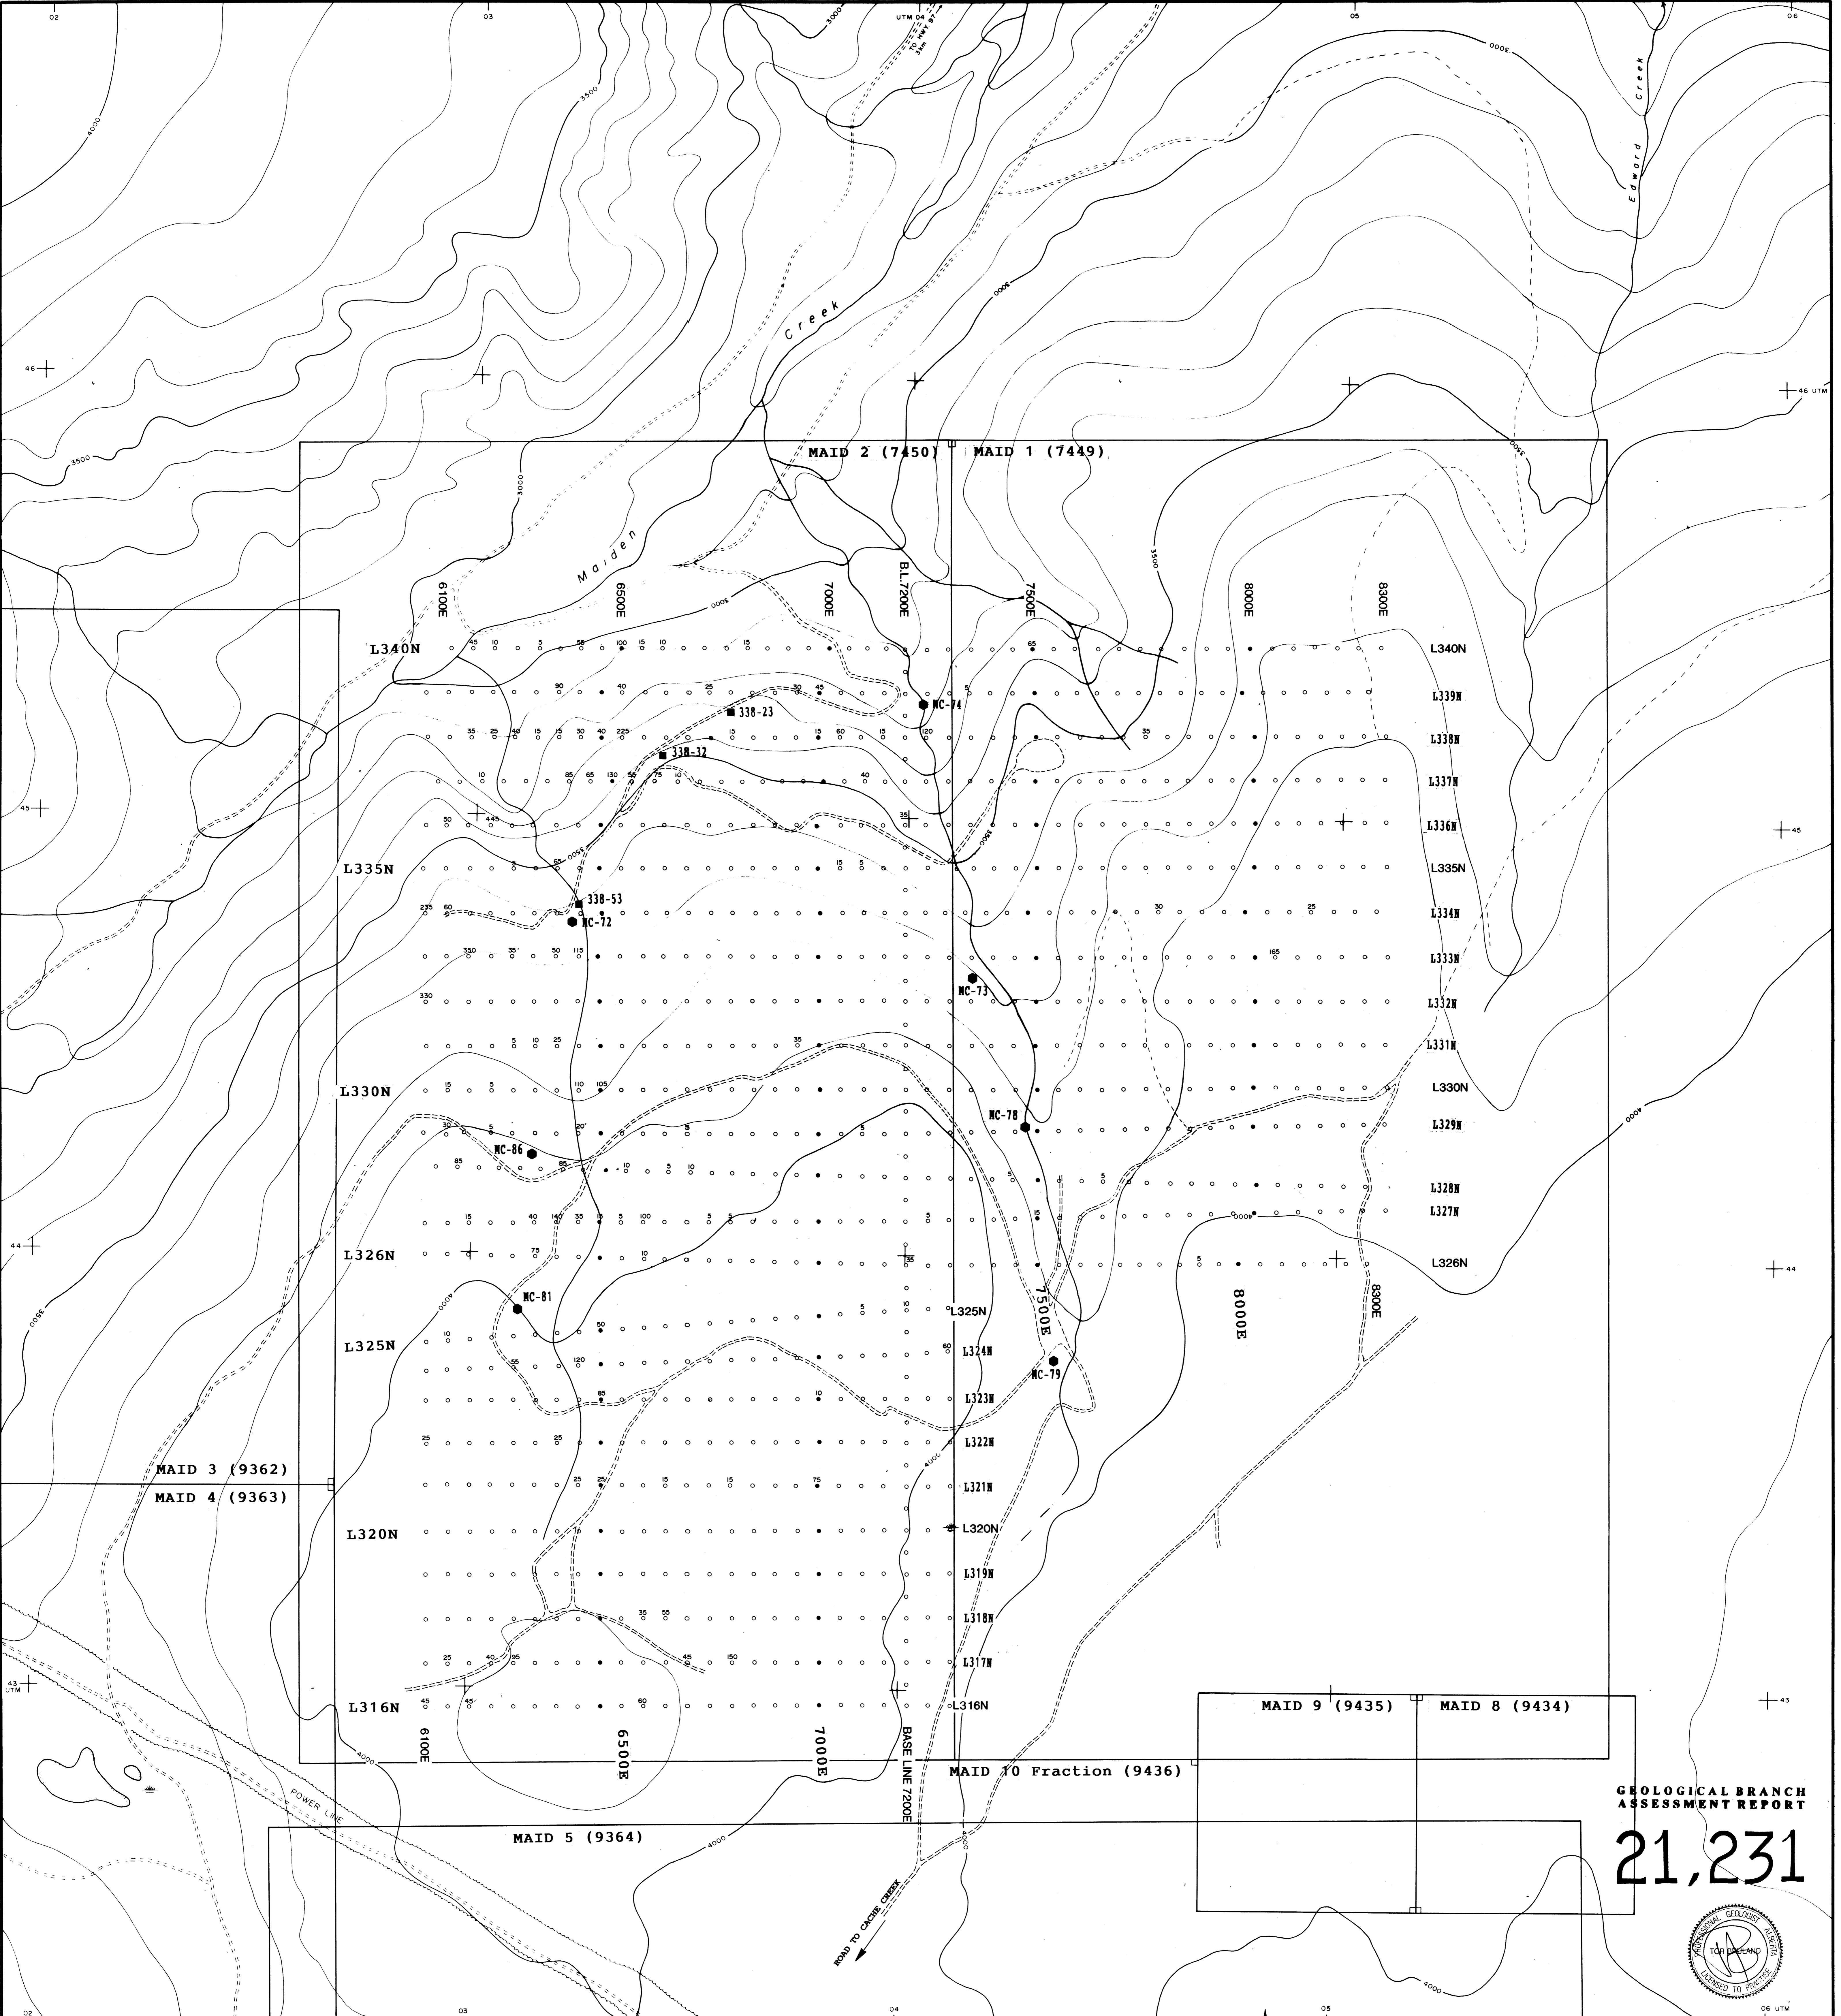

METERS

A HEAVY MINERAL GOLD ANOMALY

- 2 Samples collected pre 1988 (70 samples)
- 79 Samples collected in 1988 & 1989 (20 samples)
- 110 Samples collected in 1990 (51 samples)

LEGEND

- ○ ○ Grid soil sampling
Values shown in ppb Au (>5 ppb)
- Test pit
- Heavy mineral sample location

DRAWN JAN 29/1990
