**SUMMARY**

The LC 5 claim is situated within the Kamloops Mining Division of British Columbia at the junction of Deadman River and Criss Creek.

Regional geology consists of basement rocks of Triassic Nicola volcanics and Palaeozoic gneisses. Major faults such as the Deadman River fault have block faulted Eocene volcanic rocks into graben like structures. Small Triassic alkaline intrusions and Tertiary (Miocene) intermediate intrusions are spatially related to these faults. Miocene plateau basalts form topographic highs capping all other units. Northwest trending faults of Tertiary age bisect the property. These structures control major drainages such as Sabiston Creek and Carabine Creek.

Mercury deposits are prevalent in the area occurring in a 14 km wide, 39 km long belt extending from Tunkwa/Dominic Lakes in the south to Criss Creek in the north. Mercury occurs as cinnabar with associated stibnite, galena, tetrahedrite, malachite, azurite, chalcopyrite, pyrite, and gold. Placer gold occurs in Criss Creek.

Work on the LC 5 claim in 1990 was concentrated in the area of the Split Rock breccia pipe and along the lahar cliffs on the pipe's western flank. The strong argillic alteration, localised propylitic and carbonate alteration, and chalcedonic veining may be indicative of hydrothermal activity in this area.

## 1.0 INTRODUCTION

### **1.1 General**

This report describes the results of soil geochemical sampling on the LC 5 claim between June 15, 1990 and July 15, 1990. The claim is 20 units in size and located 18 km north-northwest of the western end of Kamloops Lake at the junction of Criss Creek and Deadman River.

### **1.2 Property Location and Access**

The LC 5 claim is situated within the Kamloops Mining Division of British Columbia, and is centred at Latitude 50° 54' North, and Longitude 120° 57' West on NTS map sheet 92I/1S (Figure 1).

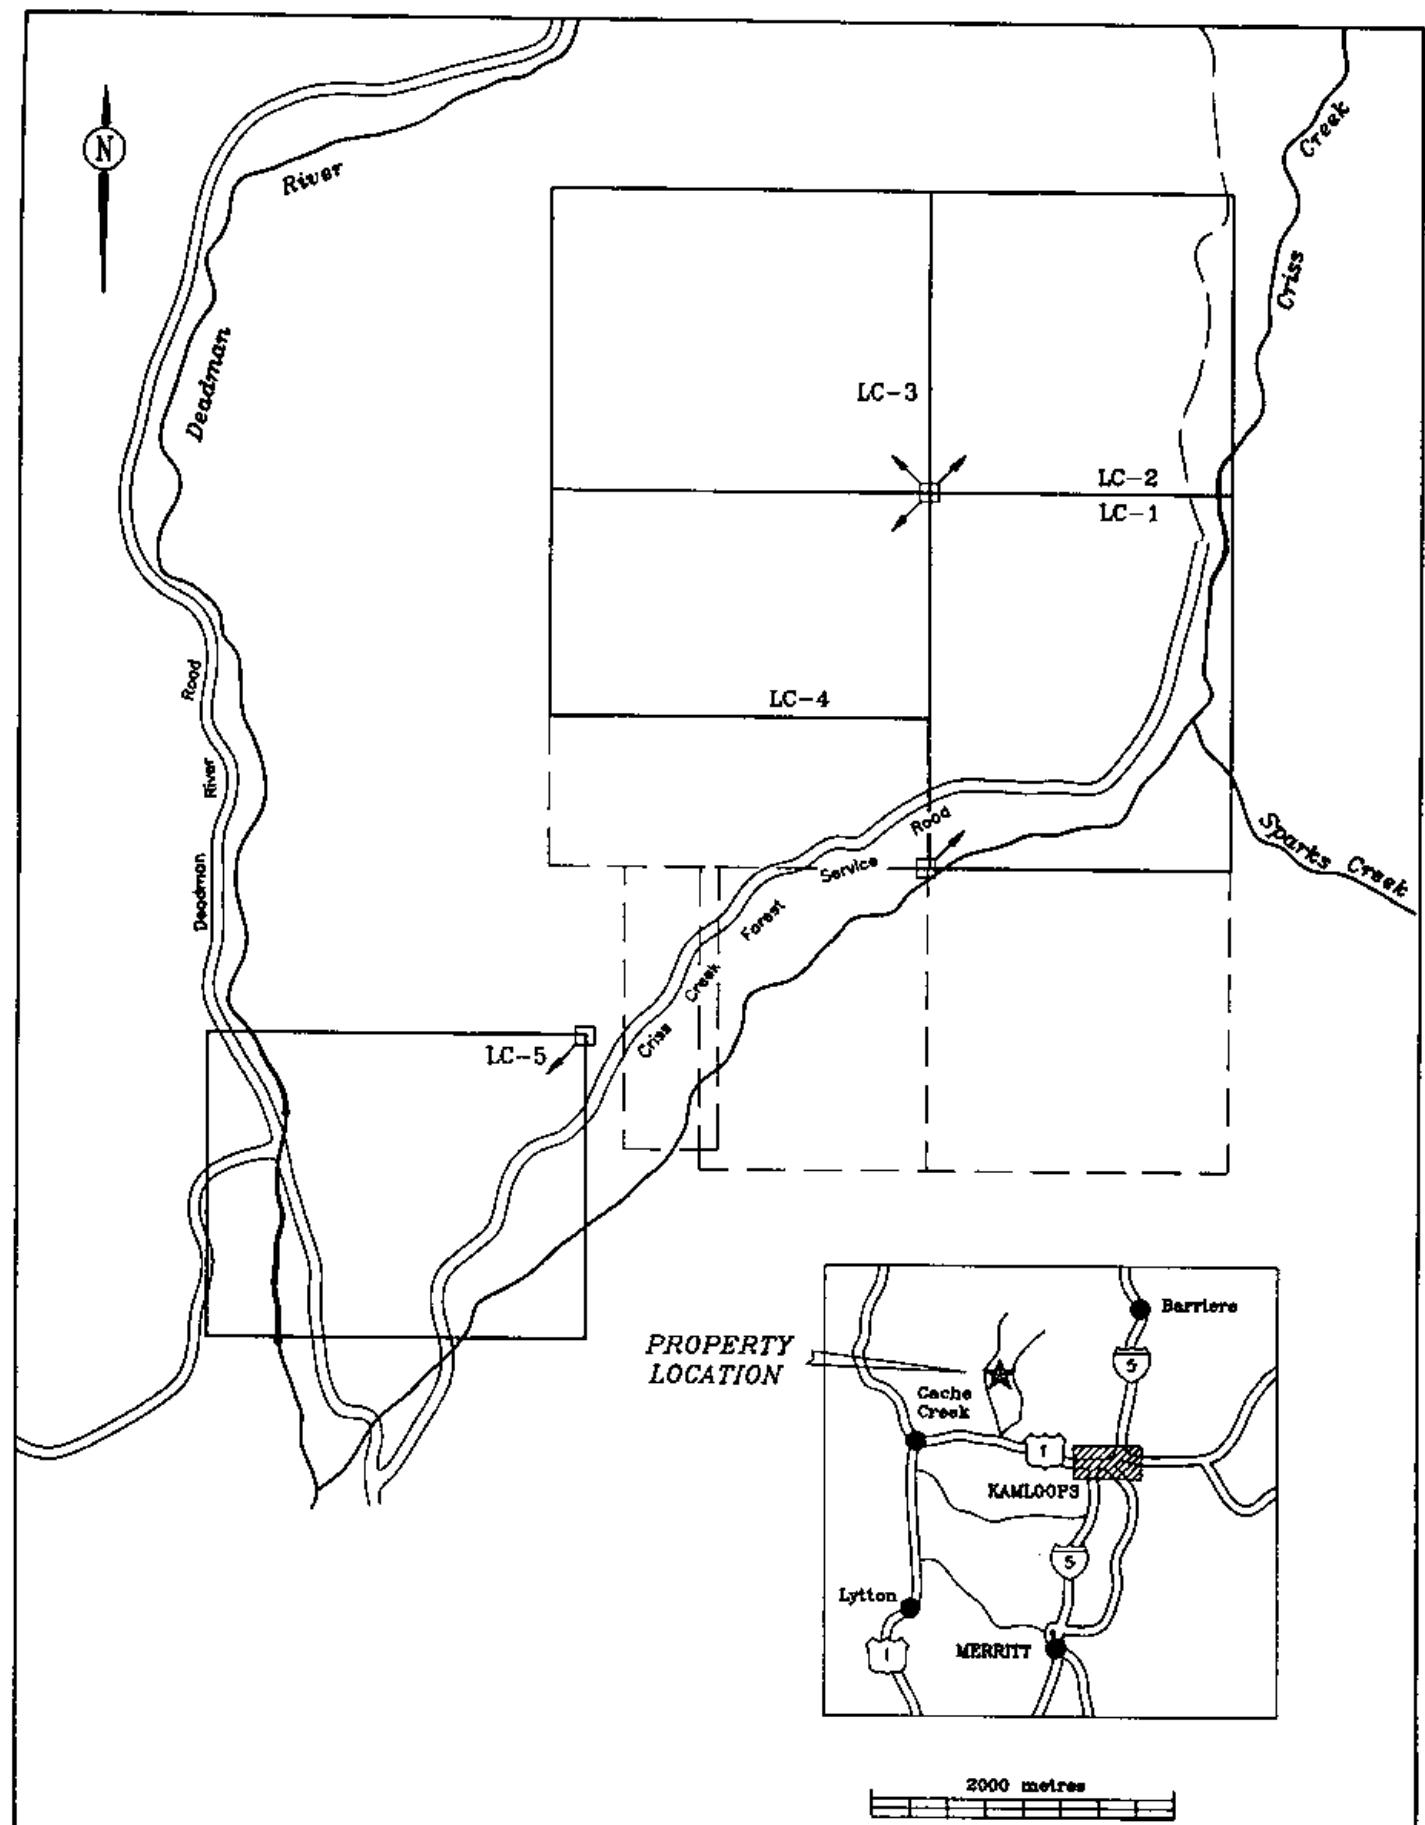

Access is gained via the Trans Canada Highway west from Savona, B.C. to the Deadman River turnoff, and then north for 15 kilometres along the Deadman River road to its junction with the Criss Creek logging road.

### **1.3 Topography, Vegetation, and Climate**

The LC 5 claim is located just above the Deadman Valley on its eastern side. Elevations range from 700 to 900 metres. Precipitation is minimal and seasonal fluctuations in temperature are severe, ranging from -40°C to +40°C. Ranching and hay cultivation are the primary activities in the valley while logging in the hill is extensive.

### **1.4 Property and Ownership**

The LC 5 claim consists of 20 units 100% owned and operated by Minnova Inc. The record number is 6944, expiring February 27, 1993 assuming acceptance of this report. Claim configuration is shown in Figure 1.

LAST CHANCE PROPERTY  
PROPERTY LOCATION &  
CLAIM CONFIGURATION

## **1.5 Property History**

Placer mining of Criss Creek occurred during the early 1900's. B.P.-Selco previously held the ground in the Deadman Valley as the DM claims. The geology and geochemistry of the Hoodoo grid, which covered much of the LC 5 area, is described by D. Gamble in assessment report #9729. This report describes a complex Tertiary history with sediments, rhyolites, basalts and the mafic breccia pipe known as "Split Rock".

## **1.6 Summary of 1990 Assessment Work - LC5 Claim**

<b>Linecutting</b>	-	7.575 line kilometres
<b>Soil Geochemistry</b>	-	346 grid and contour soil samples analyzed for Ag, As, Ba, Cu, Pb, Sb, Zn, Hg, and Au.

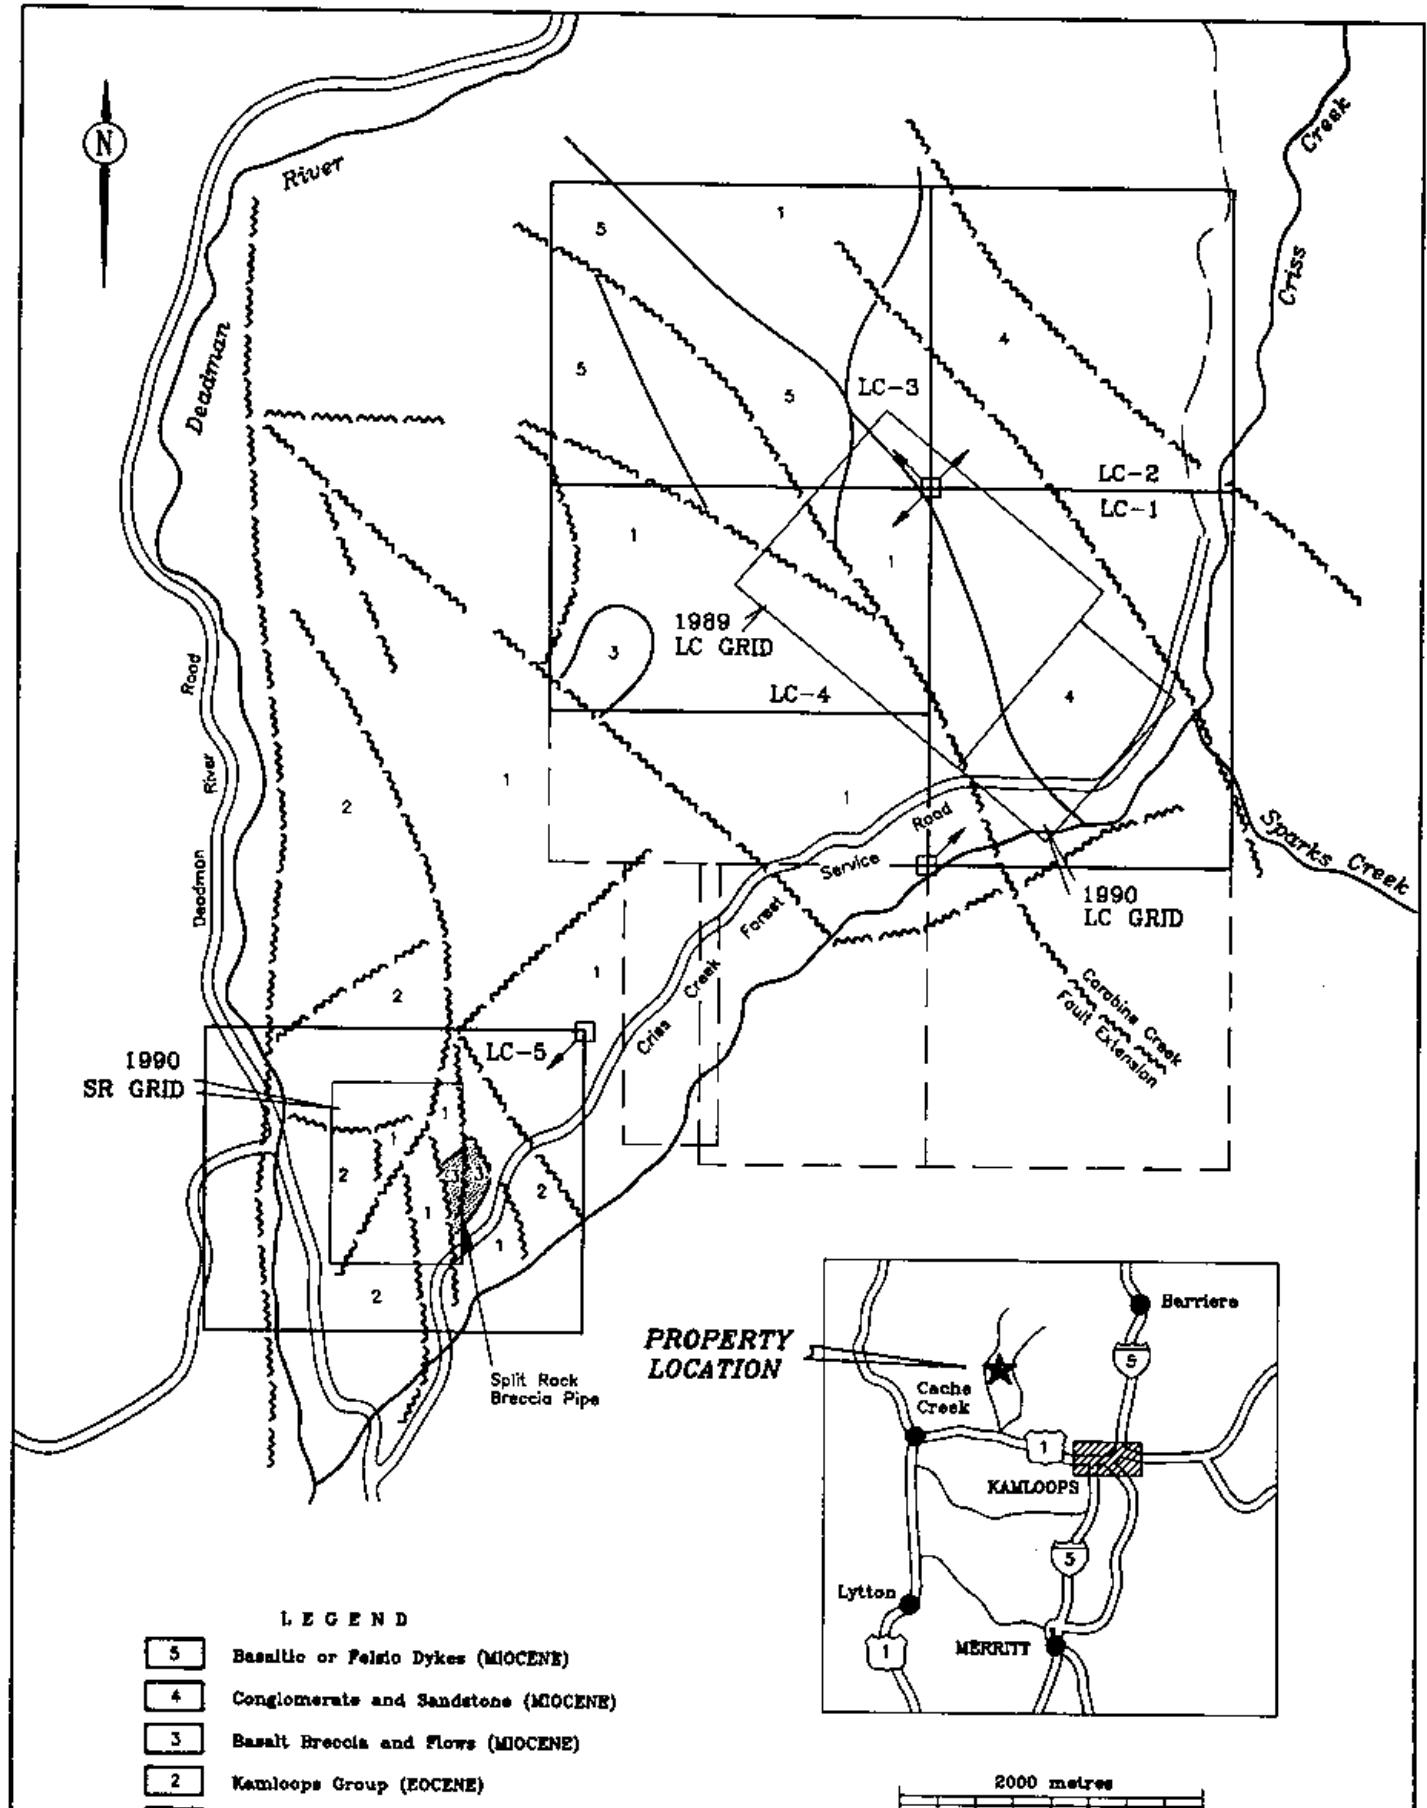

## **2.0 GEOLOGY**

### **2.1 Regional Geology**

Regionally, the LC 5 claim is underlain by basement rocks of Triassic Nicola volcanics and Palaeozoic gneisses. Major faults in the area, such as the Deadman River fault, have strike lengths upwards of 64 km and have block faulted Eocene volcanic rocks into graben like structures. Chert pebble conglomerate in the area is most probably Jurassic in age belonging to the Ashcroft Formation. Small Triassic alkaline intrusions and Tertiary (Miocene) intermediate intrusions are spatially related to northwest trending faults of Tertiary age which bisect the property. These structures appear to control major drainages such as Sabiston Creek and Carabine Creek. Miocene plateau basalts form topographic highs capping all other units.

### **2.2 Property Geology and Structure**

Geology underlying the LC 5 claim consists, briefly, of Eocene Kamloops Group basalt trachytic lahars and flows, occasional

Miocene sediments (siltstone and argillite), the Miocene "Split Rock" breccia pipe, and Miocene or younger pyroxene basalt dykes (Figure 2). Numerous faults cross cut the area in various orientations.

#### **Alteration and Mineralization**

Lahar cliffs visible from the Deadman River road form the western flank of the breccia pipe. These cliffs vary in colour from a dark ochre, to maroon, to light grey and have been subjected to strong argillic alteration. Localised areas along these cliffs show propylitic and carbonate alteration. The breccia pipe itself contains veined chalcedony (chrysoprase) which generally occurs in shear zones within the pipe. Chalcedony also occurs in the matrix of the breccia.

### **3.0 RESULTS OF 1990 FIELD WORK**

#### **3.1 Line Cutting**

Field work between June 15 and July 15, 1990 consisted of 7.575 kilometres of linecutting along the western flank of the breccia pipe followed by soil sampling of the grid. Grid lines were oriented in an east-west direction at 100 metre intervals with 25 metre station spacings. Hand tools were used for blazing trees and trimming branches.

#### **3.2 Soil Geochemistry**

A total of 346 soil samples were taken along grid lines and contour sampling lines.

In all cases an attempt was made to sample well developed 'B' horizon soil. Sample depths ranged from 5 cm to 25 cm averaging approximately 10 cm. Samples collected were placed in kraft sample bags and allowed to dry before shipping. Sampling personnel were instructed to note soil parameters such as sample depth, soil

colour, soil moisture content, soil texture, and slope direction.

Soil samples were sent to Min-En Labs of North Vancouver for ICP analysis using aqua regia total digestion. The samples were analyzed for Ag, As, Ba, Cu, Pb, Sb, Zn, and Hg. Gold was determined by atomic absorption.

Copies of analytical certificates are contained in Appendix III. Table I lists normal and log-transformed statistics for each element. Statistics were calculated using the Probplot statistical program. Histograms and statistical results for normal and log-transformed distributions are contained in Appendix IV. An anomalous response is defined as a response greater than threshold for more than two adjacent or subsequent samples. Sample locations are plotted on Figure 3; results for Cu, Pb, and Zn are plotted on Figure 4, and Ag, Au, and Hg on Figure 5.

Threshold values were chosen from histograms to be within the 97th cumulative percentile. Gold and As results show no common distribution pattern and threshold values are therefore not given. Values for these elements may be visually estimated.

Threshold	95 ppm		430 ppb		N/A	

In general, soil geochemical response was poor for the particular horizon sampled. Sporadic elevated results did not indicate any geochemical trends. No truly anomalous zones were defined by this geochemical method. The high clay content of much of the soils may suppress elemental movement in the soils.

#### 4.0 CONCLUSIONS AND RECOMMENDATIONS

The LC 5 claim is situated between the eastern edge of the Deadman River fault and the Sabiston Creek fault further east. Indications of an epithermal system and hydrothermal activity exist in the form of a large (500m x 500m) homogeneous breccia pipe containing chalcedonic veining and chalcedonic breccia infillings, extreme argillic alteration extending for several kilometres northward along the eastern side of the Deadman River valley, and localised areas of propylitic and carbonate alteration.

Despite evidence for an epithermal system, precious metal mineralization on the claim remains elusive. Soil sampling of the SR grid failed to produce any significant geochemical trends or anomalous results traceable to a source area. Two possibilities exist to explain this. The current erosional level exposed may be in the upper levels of the system. The presence of Miocene plateau basalts nearby suggest the erosional level may be close to the Miocene paleosurface. Mafic dykes cutting the Split Rock breccia pipe may have been feeders for the overlying basalts. A possible mineralized system may therefore exist at a deeper level and soil geochemical response may be masked by the extent of argillic (clay) alteration. An alternate possibility is the breccia pipe may be a volcanic vent with the intense argillic alteration of the surrounding area resulting from "flashing" of surface waters to steam, rather than from the presence of a hydrothermal system.

A detail rock sampling program should be completed over the Split Rock breccia pipe and surrounding area. Emphasis should be placed on mapping of alteration assemblages to determine any alteration "hot spots" in the area of the pipe, and areas proximal to the pipe. If any significant "hot spots" are outlined, a short drilling program of two or three holes should be able to determine

whether economic mineralization is present at depth. Should the results of a drill program on the LC 5 claim prove to be barren, no further work on the property would be warranted or recommended.

## **Appendix V**

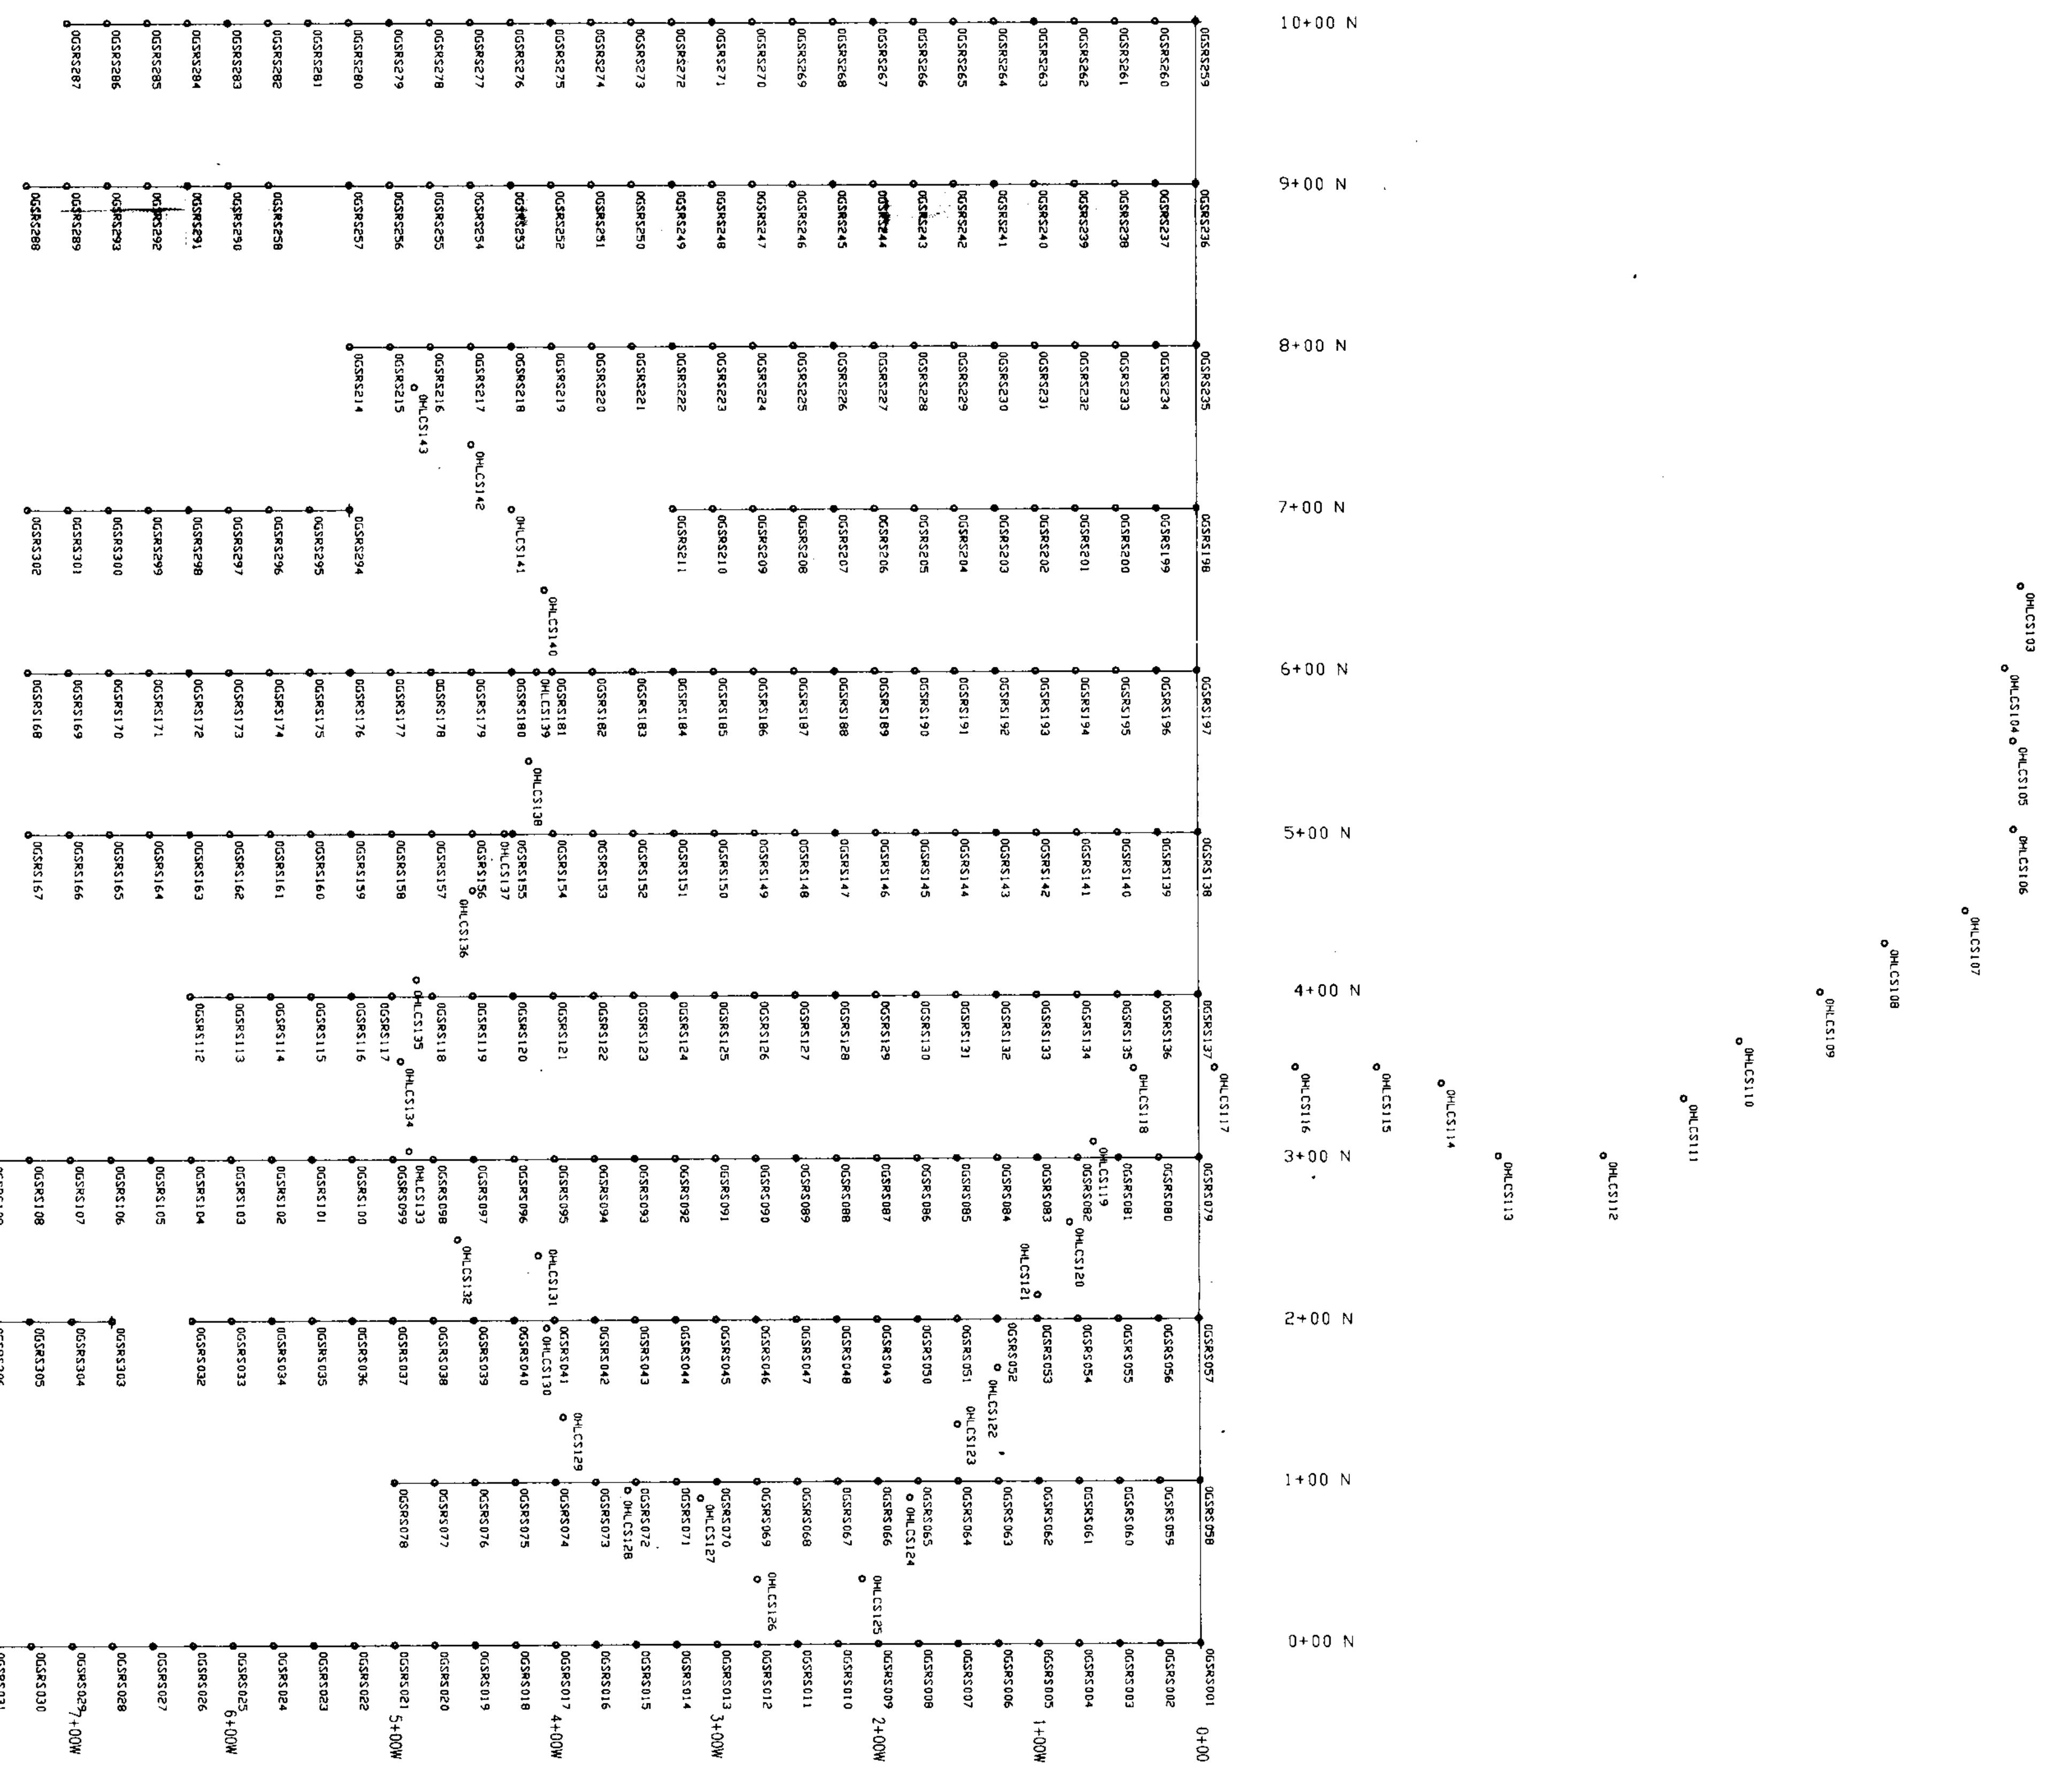

**STATEMENT OF QUALIFICATIONS**

I, Cameron J. Clayton, of 2882 Masefield Road, North Vancouver, B.C. do hereby certify that:

1. I am a graduate of Queen's University, Kingston, Ontario with a B.Sc. in Geological Engineering.
2. I have practised my profession for four years.
3. I am a contract geologist currently employed by Minnova, Inc.
4. I personally supervised work conducted on the LC 5 claim during 1990 and have personally reviewed all analytical results presented in this report.

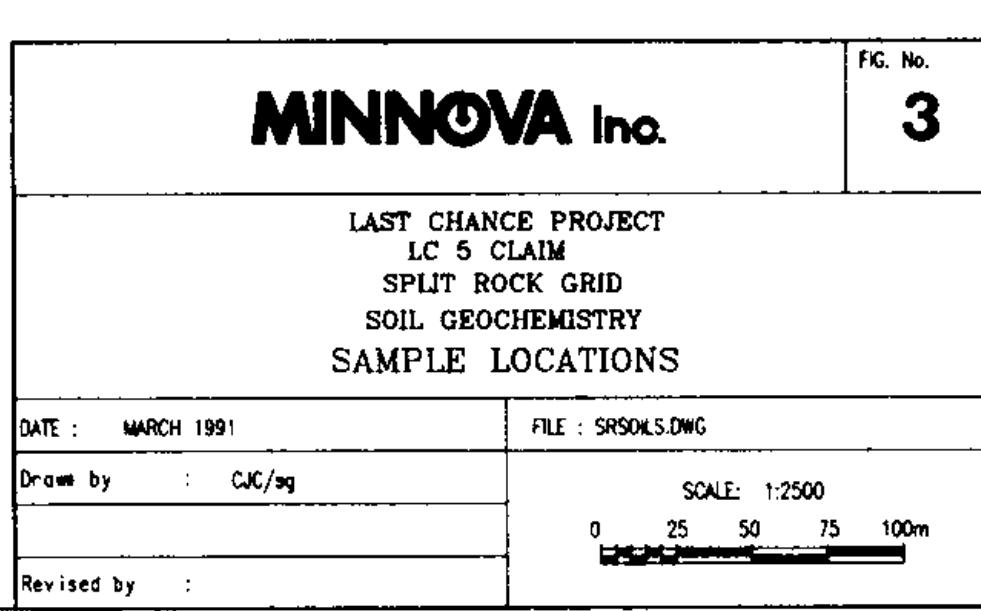

Date: May 21 1991
