GEOLOGICAL BRANCH
ASSESSMENT REPORT

21,420

SUMMARY AND CONCLUSIONS

The Steele property, which is located within the Duckling Creek Syenite - Hogem Batholith area, was investigated for alkalic porphyry type Au-Cu mineralization between July 5 and August 11, 1990. The property was surveyed by reconnaissance-style geological mapping, soil-rock sampling and proton mag surveying.

No significant gold values in soil or rock were encountered on the Steele property. However, the property does host several broad moderate to strong copper anomalies which are hosted within strong potassically altered syenites which may warrant follow-up as a porphyry copper target. Some of these anomalies can be traced for greater than 2300 m along strike and up to 800 meters in width. Copper values range from 300 to 4050 ppm with most values above 500 ppm.

RECOMMENDATIONS

No further work is recommended for gold exploration on the Steele property. However, the property does host several significant copper anomalies, in both soil and rock, and should therefore be further evaluated for its porphyry copper potential.

1. INTRODUCTION

The Steele property, which is located within the Duckling Creek Syenite, Germansen Landing area, B.C. was investigated for alkalic porphyry type Au-Cu mineralization during the period July 5 to August 11, 1990. The property was investigated by reconnaissance-style geological mapping, soil-rock sampling and proton mag surveying.

No significant Au values were encountered on the Steele property, however several moderate to strong widespread Cu soil anomalies were found to be associated with strong potassically altered syenites.

2. LOCATION AND ACCESS

The Steele property is located 60 kilometers to the northwest of Germansen Landing and 800 kilometers north of Vancouver, British Columbia (Figures 1 and 2). The property is located on NTS map sheet 93N/14.

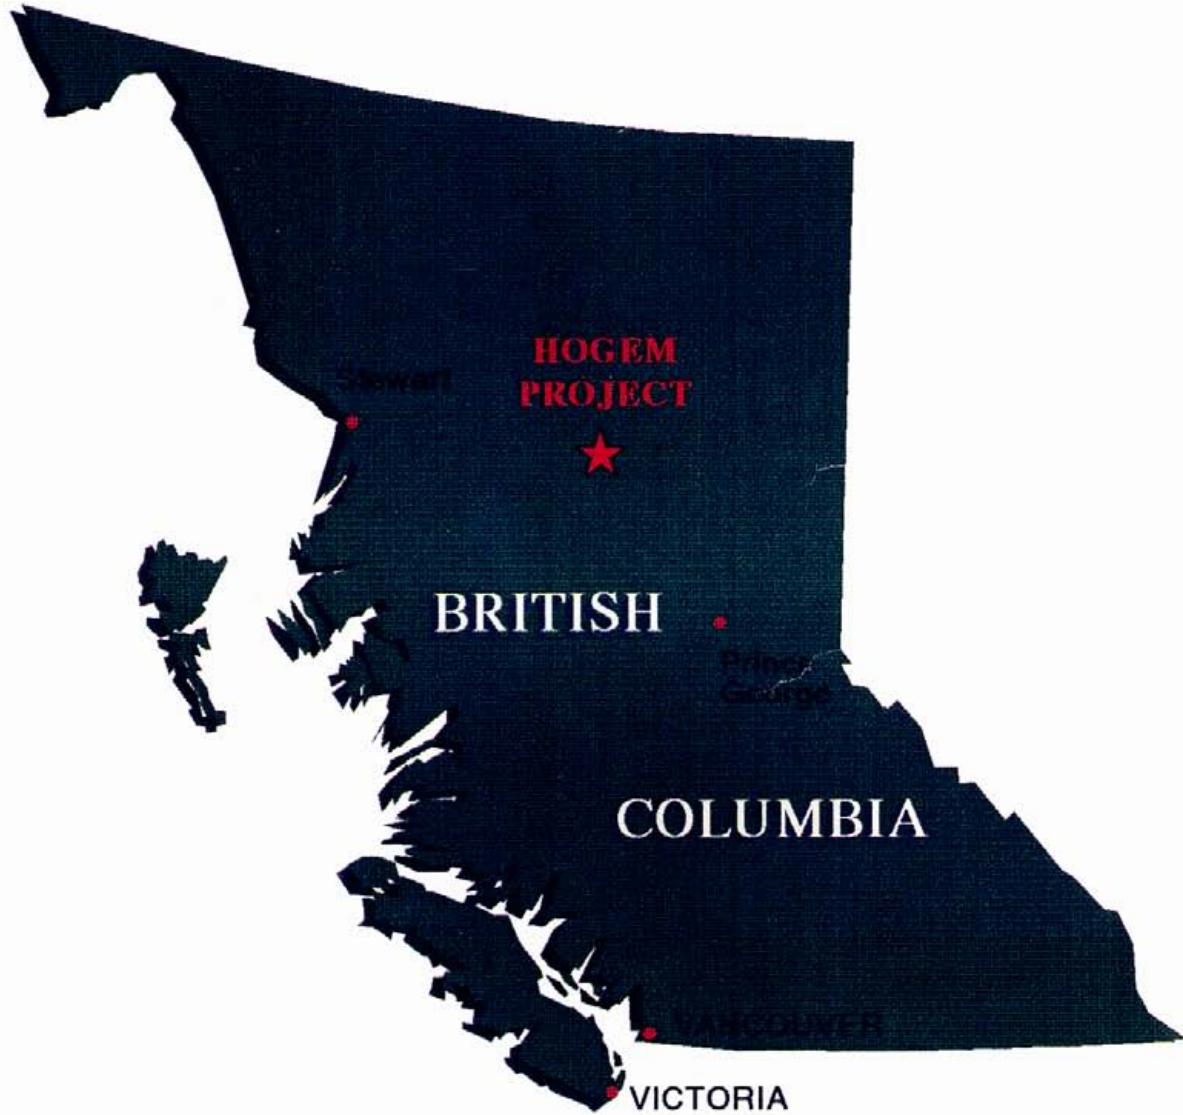

Access is by logging road from either Windy Point or Fort St. James to the Osilinka logging camp a distance of 250 kilometers and 270 kilometers, respectively. From a point near the logging camp a helicopter is then to required to access the property.

3. PHYSIOGRAPHIC SETTING

The Steele property is underlain by moderate to steep mountainous terrain. Relief varies from 1200 m to up to 1900 m above sea level. Treeline is generally along the 1600 to 1700 m contour.

Regional drainage direction is eastward towards Williston Lake. Vegetation consists of mature engleman spruce and sub alpine fir some of which is of commercial value. There is active logging being conducted within 2 kilometers of the property.

Cyprus Gold (Canada) Ltd, has a 100% undivided interest in the entire claim group (Figure 3).

5. HISTORY AND PREVIOUS WORK

During the summer of 1971 Amoco Canada conducted a reconnaissance stream sediment sampling-mapping program over the Hogem Batholith in search of porphyry Cu-Mo deposits. A total 7376 silts, water, rock, and soil samples were collected from an area of approximately 2400 square kilometers and analyzed for copper and molybdenum. Amoco did not assay for gold in any of these samples. Numerous areas with anomalous Cu and/or Mo in stream sediments were detected. Four areas were staked and worked by Amoco during 1972 to 1974. These areas were known as the Tyger, Needle, Oy and Hawk properties. Property work consisted of reconnaissance and detailed soil sampling and geological mapping.

The latter three properties have recently been in part or entirely restaked by Cyprus and named the Steele, Ten and Hawk properties, respectively.

Figure 3 - Steele Claim Map

**HOGEM PROJECT - STEELE PROPERTY
CLAIM MAP**

NTS 93N/14

Scale: 1: 50,000

0 1 2 3 Km

Several other major and junior mining companies were evaluating the Hogem Batholith for porphyry Cu-Mo during the same period of Amoco's evaluation. Numerous occurrences were located and worked during the 1970's. The majority of the Cu occurrences within the Hogem Batholith were noted to be localized with a particular intrusive phase known as Duckling Creek Syenite. The main bulk of the Duckling Creek Syenite is found in the north end of the Hogem Batholith where it trends northwest and has dimensions of approximately 32 kilometers by 6 kilometers. The main Cu occurrences are known as the Hawk (Amoco), Tam (UMEX), Misty (El Paso), Lorraine (Kennco), Dorothy (Kennco), Rondah (Tyee Lake Resources) and Duckling (Donna Mines). There are numerous smaller intrusions of syenite throughout the Hogem Batholith and adjacent volcanics which may also warrant follow-up for their porphyry Au-Cu potential.

6. REGIONAL GEOLOGICAL SETTING

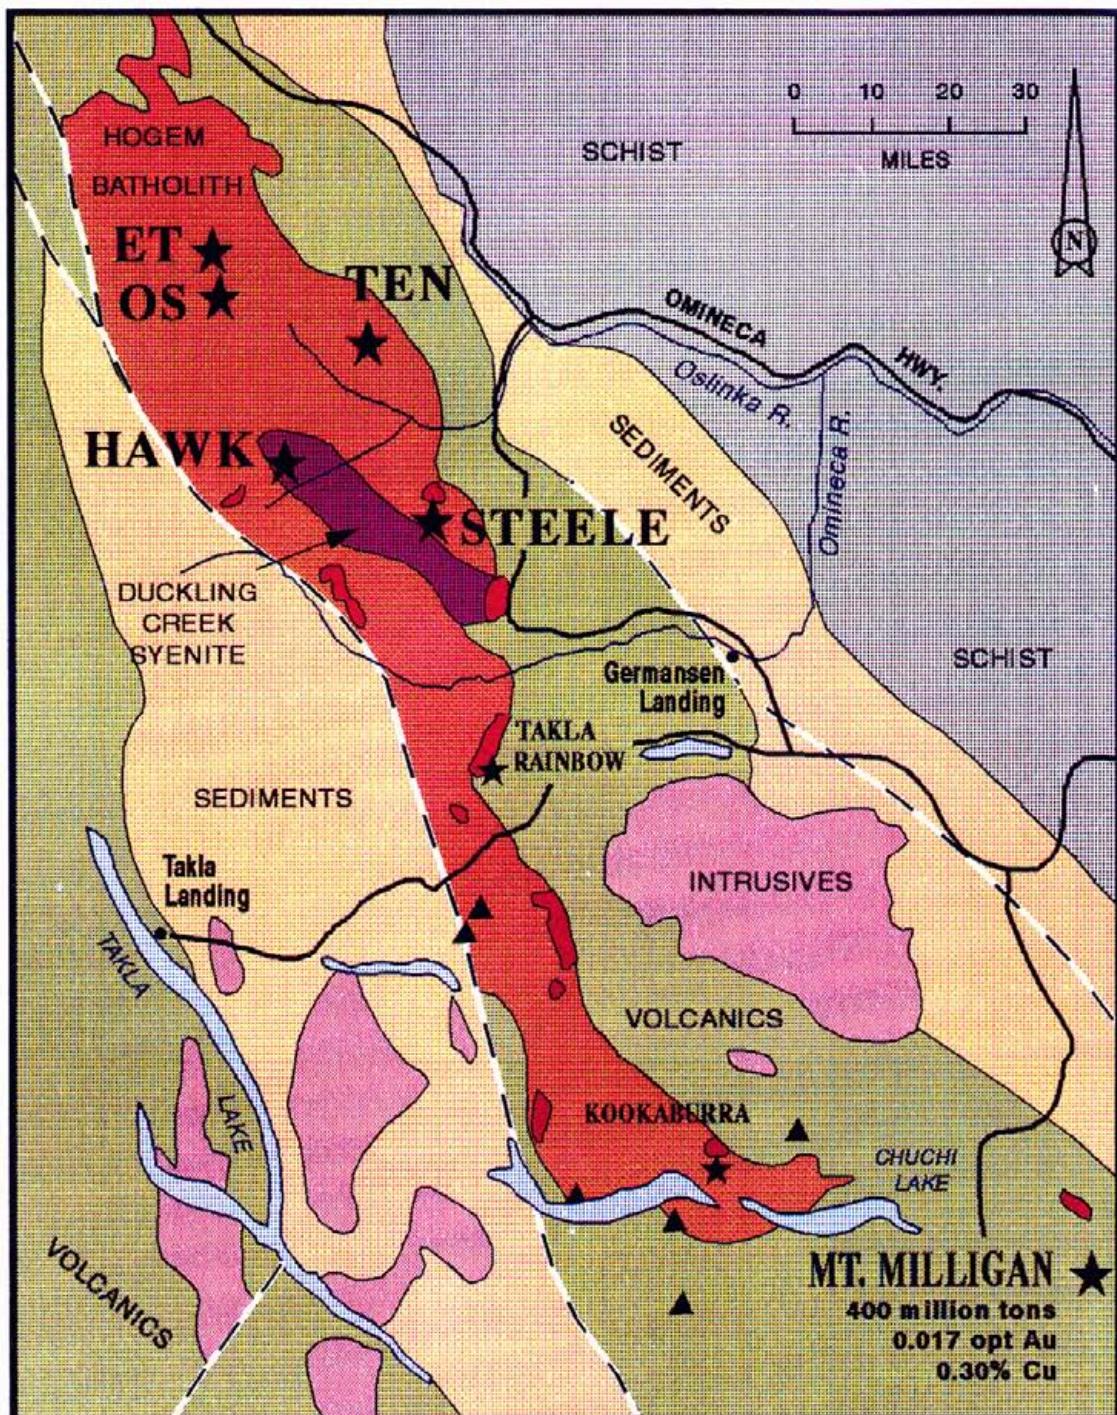

The Steele property is located within the Duckling Creek Syenite (Figure 4). The Duckling Creek Syenite is part of several calc-alkalic and alkalic intrusions comprising the Hogem Batholith. These intrusions are dominated by granites and granodiorites but most importantly by a younger suite of intrusive syenitic bodies. The Hogem Batholith is the largest of the Omineca Intrusions which forms the spine of the island arc related allochthonous Intermontane super terrane in British Columbia. This NW trending elongate batholithic body extends for 120 km from Chuchi Lake in the south to the Misilinka River in the north. It is bordered to the west by the Pinchi Fault and to the east by the Upper Triassic to Lower Jurassic Takla volcanics.

7. 1990 EXPLORATION PROGRAM

A total of 937 soils and 86 rocks were collected on the Steele property during 1990. Ninety kilometers of ground magnetic surveying was also conducted in conjunction with the soil surveying.

Where possible the "B" horizon of the soil profile was collected utilizing a grubhoe or pick. Average hole depth would be 25 centimeters. A composite

sample was then collected and placed in a 10 cm by 25 cm kraft paper envelope. Sample stations were marked on the envelope and their locations were later plotted on a 1:10,000 scale map. In talus material, which was encountered usually above treeline, a composite of the surrounding soil was sieved through a conical metal screen before placed in the kraft envelope. If the terrain permitted, soil sampling was conducted on a 250 m x 75 m grid pattern. However if the terrain was too steep contour sampling was conducted. Spacing between contour lines varied, due to topography, but in most cases did not exceed a 250 m horizontal distance. Sample spacing remained at 75 meters. Grid lines were established by hip chain and compass while contour lines were established using hip chain, compass and an altimeter. All sample stations were appropriately marked and flagged.

All soil and rock samples were analyzed for Au and Cu by wet geochemistry. A small number of samples were analyzed by ICP for Ag, As, Bi, Co, Cu, Mn, Mo, Ni, Pb, Sb, Zn and chromium. All analyses were performed at Min-En Labs located in North Vancouver, B.C. Canada. Gold and copper values have been plotted and contoured. Property geological, geochemical and geophysical maps can be found at the back of the report. Reports on analytical procedures are also found at the back of the report.

All grid and contour soil lines were also surveyed with a proton magnetometer. Readings were taken at the same stations as the soil samples. All mag data was corrected for diurnal drift. Two Scintrex MP-2 proton precession magnetometers, one for each crew of three people, were used for the surveys.

7.1 STEELE PROPERTY

7.1.1 Steele - Reconnaissance Exploration

7.1.1.1 Steele - Recon Geology

Three areas on the Steele property were investigated for their Au-Cu potential. These include the Steele Main, Steele South and Steele North grids.

The majority of the Steele North grid does not occur on Cyprus held ground. At the time the grid was put in it was not known a competitor had previously staked the ground. The results of our survey is presented nevertheless.

Six rock types were observed to be present on the Steele property. These include leucocratic syenite, mesocratic syenite, monzonite, monzodiorite, diorite and mafic volcanics.

The leucocratic syenites are fine to coarse grained to megacrystic massive to porphyritic and light to bright orange-pink in color. The syenites composition consists of primarily potassium feldspar with minor amounts (less than 20%) of biotite and hornblende. The rocks have minor limonite and chlorite alteration associated with it. Locally intense potassic alteration is present in many areas. This rock type does frequently contain minor to locally abundant disseminated pyrite, chalcopyrite, malachite, azurite and bornite. In addition minor to moderate magnetite is present throughout the leucocratic syenite.

The mesocratic syenite is very similar to the leucocratic syenite but tends to be coarser grained and dark orange-pink rather than light orange-pink. Obviously the mafic component, consisting of biotite and hornblende, is higher, generally greater than 20-30 percent. Minor epidote and chlorite alteration and minor magnetite is present. Only rare pyrite and malachite was observed.

The monzonite which is the dominant rock type on the Steele property is similar to the mesocratic syenite but is light to medium grey in color as opposed to dark orange-pink. The monzonite also tends to be invariably medium grained and contains pervasive minor disseminated magnetite. The similarities are its mafic content and its low sulphide content.

As to be expected the monzodiorites are more mafic resulting in a darker grey color. Chlorite and epidote alteration, which may be just retrograde reaction of the mafic components, is slightly stronger and more pervasive. These rocks are medium grained and contain minor to moderate amounts of magnetite.

The diorite, which occurs as two small plug-like bodies, is fine grained, massive, equigranular, dark grey-black and rich in biotite and hornblende. This rock type has a distinctive salt and pepper appearance and contains moderate to abundant magnetite.

The only volcanic rocks in the area are found on the Steele North grid. These rocks are fine grained massive dark grey to black green cherty andesites. They are not magnetic but contain abundant fine grained disseminated pyrite.

As previously indicated the monzonite is the dominant rock type on all three grids and may represent the primary intrusive event in the area. The monzonite is in contact with mafic volcanics in the east which are presumably Upper Triassic to Lower Jurassic Takla volcanics. The sequence of the other intrusive rocks is not known as few contacts were observed. The frequency of the intrusive rocks other than the monzonite, especially on the Steele Main grid, may be purely the result of topography as these rocks appear mainly along the ridge tops. In areas where monzonite is reported there is extensive overburden, therefore many more intrusive types may actually exist.

No significant structural features were observed.

7.1.1.2 Steele - Recon Rock Geochemical Results

A total of 86 rock samples have been taken on the Steele property. None of the samples returned significant gold values. The highest gold encountered is 81 ppb which is from sample number 2400 and located at the north end of grid line 500 W. However there are several samples which are anomalous in copper. These values range between 480 to 5100 ppm copper. These copper values in rock do coincide with high copper values in soil.

7.1.1.3 Steele - Recon Soil Geochemical Results

Gold results in soils are negative for the Steele property. Only random spot highs of up to 155 ppb were encountered. Most values are less than 30 ppb

gold.

Copper values however are moderate to locally strong and are quite extensive on the Steele Main grid. Most of the soil anomalies are concentrated on the ridge tops which parallel the EW trending Steele Creek. The northern anomaly which coincides with the northern ridge top is traceable for 2300 m along strike and is open to the west. Widths vary from less than 75 m to over 800 meters. Values within this anomaly range between 300 to 4050 ppm copper with the majority above 500 ppm copper.

The southern anomaly which is south of the baseline and between line 1250 W and 1000 E is traceable for 2200 m along strike and possibly beyond. Widths vary from less than 75 m to over 600 meters. Values in this anomaly range from 300 to 1350 ppm copper.

Other smaller anomalies are present on the grid but may be surficial anomalies as they occur in depressions and marshy areas.

On the Steele North grid a high of 558 ppm copper was detected. This value was part of an anomaly which is 300 m in length and up to 200 m wide. This anomaly does occur on Cyprus held ground.

At the Steele South grid three spotty copper highs were detected and one broader 2-3 line anomaly. The highest value of 1680 ppm Cu is part of a less than 75 m wide anomaly which is traceable across 300 meters. The broader anomaly is located at the base of a cirque in the south end of the grid. It measures 600 meters by 250 meters and has a high of 700 ppm copper.

7.1.1.4 Steele - Recon Ground Geophysical Results

Due to the reconnaissance nature of the mag survey only general contacts between rock types were outlined. It appears the monzonite, which is the most extensive rock type, has moderate to low magnetic relief while the series of intrusive rocks along the ridge tops have a slightly higher magnetite content and

therefore higher values. As observed in outcrop the mafic volcanics have very low magnetic content relative to other rock types on the property. The contact between the volcanics and intrusives is therefore quite obvious.

Division of Assayers Corp. Ltd.

ANALYTICAL PROCEDURE REPORT FOR ASSESSMENT WORK:

PROCEDURE FOR WET GOLD GEOCHEMICAL ANALYSIS

Samples are processed by Min-En Laboratories, at 705 West 15th Street, North Vancouver, employing the following procedures.

After drying the samples at 95 C, soil and stream sediment samples are screened by 80 mesh sieve to obtain the minus 80 mesh fraction for analysis. The rock samples are crushed by a jaw crusher and pulverized on a ring mill pulverizer.

5.00 grams of sample is weighed into porcelain crucibles and cindered @ 800 C for 3 hours. Samples are then transferred to beakers and digested using aqua regia, diluted to volume and mixed.

Further oxidation and treatment of 75% of the above solution is then extracted for gold by Methyl Iso-butyl Ketone.

The MIBK solutions are analyzed on an atomic absorption spectrometer using a suitable standard set.

ANALYTICAL PROCEDURE REPORT FOR ASSESSMENT WORK:

PROCEDURE FOR AG, CU, PB, ZN, NI, CO OR CD GEOCHEM

Samples are processed by Min-En Laboratories at 705 West 15th Street, North Vancouver, employing the following procedures.

After drying the samples at 95 C, soil and stream sediment samples are screened by 80 mesh sieve to obtain the minus 80 mesh fraction for analysis. The rock samples are crushed by jaw crusher and pulverized on a ring mill pulverizer.

0.50 gram of the sample is digested for 2 hours with an aqua regia mixture. After cooling samples are diluted to standard volume.

The solutions are analysed on atomic absorption spectrometers using the appropriate standard sets. A background correction can be applied to Ag, Pb, and Cd if requested.

ANALYTICAL PROCEDURE REPORT FOR ASSESSMENT WORK

PROCEDURE FOR AU, PT OR PD FIRE GEOCHEM

Geochemical samples for Au Pt Pd are processed by Min-En Laboratories, at 705 West 15th St., North Vancouver, B. C., laboratory employing the following procedures:

After drying the samples at 95 C, soil and stream sediment samples are screened by 80 mesh sieve to obtain the minus 80 mesh fraction for analysis. The rock samples are crushed and pulverized on a ring mill pulverizer.

A suitable sample weight; 15.00 or 30.00 grams is fire assay preconcentrated. The precious metal beads are taken into solution with aqua regia and made to volume.

For Au only, samples are aspirated on an atomic absorption spectrometer with a suitable set of standard solutions. If samples are for Au plus Pt or Pd, the sample solution is analyzed in an inductively coupled plasma spectrometer with reference to a suitable standard set.

ANALYTICAL PROCEDURE REPORT FOR ASSESSMENT WORK:

PROCEDURE FOR TRACE ELEMENT ICP

Ag, Al, As, B, Ba, Be, Bi, Ca, Cd, Co, Cu,
Fe, K, Li, Mg, Mn, Mo, Na, Ni, P, Pb, Sb,
Sr, Th, U, V, Zn, Ga, Sn, W, Cr

Samples are processed by Min-En Laboratories, at 705 West 15th Street, North Vancouver, employing the following procedures.

After drying the samples at 95°C, soil and stream sediment samples are screened by 80 mesh sieve to obtain the minus 80 mesh fraction for analysis. The rock samples are crushed by a jaw crusher and pulverized on a ring mill pulverizer.

0.50 gram of the sample is digested for 2 hours with an aqua regia mixture. After cooling samples are diluted to standard volume.

The solutions are analyzed by computer operated Jarrall Ash 9000 ICAP or Jobin Yvon 70 Type II Inductively Coupled Plasma Spectrometers.

Appendix 4 - Project Cost Breakdown

PROJECT COST BREAKDOWN
CYPRUS GOLD (CANADA) LTD.
STEELE PROPERTY
(July 5 to August 11, 1990)

Salaries.....	\$28500.00
Assays.....	\$8910.50
Field Supplies - Cookery.....	\$6994.59
Report Compilation.....	\$3750.00
Helicopter (\$9787.50 x 20%).....	\$1957.50
Drafting.....	\$1760.35
Mag Rental.....	\$1288.93
Truck Rental.....	\$1167.82
Freight.....	\$1043.35
Travel Expenses.....	<u>\$675.10</u>

Total Project Cost - \$56048.14

Appendix 5 – Statement of Qualification

STATEMENT OF QUALIFICATION

I, David B. Stevenson, of the Municipality of North Vancouver in the Province of British Columbia, certify as follows regarding the report on the Steele property, Omineca Mining Division, British Columbia.

I am a graduate of the University of New Brunswick, Fredericton, New Brunswick with a Bachelor of Science, Honours in Geology, 1981.

I have practised geology in Canada and Norway since 1981.

I am employed by Cyprus Gold (Canada) Ltd., 1810-1055 West Hastings Street, Vancouver, B.C. V6E 2E9.

I supervised and coordinated exploration activities on or adjacent to the Steele property.

I am a Fellow of the Geological Association of Canada.
