APPENDICES

APPENDIX 1	ASSAY CERTIFICATES	
APPENDIX 2	REPORT OF THE MINISTER OF MINES 1898	
	p. 1013	

INTRODUCTION

Ed Frost controls the Prospectors Dream Group consisting of three reverted Crown Grants and 7 two-post mineral claims. This claim block is situated approximately 19 kilometers southwest of Cranbrook, British Columbia (Figure 1).

During October 1991 a program of trenching, utilizing a 225 Caterpillar excavator in backhoe configuration, was carried out on the area of the reverted Crown Grants PROSPECTOR'S DREAM and OLD ABE. A total of twelve trenches were excavated. The overburden was removed and, with the aid of the ripper tooth on the backhoe bucket, the trenches were dug into bedrock to depths ranging from one meter to three meters.

Figure 5, at a scale of 1:1000 over approximately 60 hectares, is a plan of the trenching. The twelve trenches were geologically mapped in detail at a scale of 1:100. All shear zones exposed in the trenches were sampled, as well as the quartz veins situated within the shear zones. The 32 samples were sent to Acme Analytical Laboratories Ltd. in Vancouver for gold analysis by fire assay. In addition, two of these samples were then analysed by I.C.P. method.

PROPERTY

The property consists of three reverted Crown Grants and the KEN two-post mineral claims:

Reverted Crown Grants	Record #	Lot #
PROSPECTOR'S DREAM	2786	3772
BEND'OR	2787	3773
OLD ABE	2788	3774

Two-Post Claims	Record #
KEN 2	1145
KEN 3	1146
KEN 4	1147
KEN 5	1148
KEN 6	1149
KEN 7	1150
KEN 8	1151

The property, hereafter referred to as the PROSPECTORS DREAM Group (Figure 4), is owned and operated by Ed Frost of Fort Steele, British Columbia. This group is also known as the Ken Group.

LOCATION & ACCESS

The Prospectors Dream Group is located in the Purcell Mountains approximately 13 kilometers southwest of Cranbrook, B.C. (Figure 2). Elevations range from 1676 meters (5500 feet) to 1800 meters (5900 feet) above sea level.

The claims are situated on the drainage of an unnamed tributary of Weaver Creek which is a tributary of the Moyie River.

Access to the property from Cranbrook, B.C. is by proceeding south from Cranbrook on Highway 93 a distance of 12 kilometers to where the Lumberton forest access road branches to the west. Proceed west on the Lumberton Road a distance of 10.3 kilometers to the Noke Creek Road. (The Noke Creek Road is not marked and could easily be missed.) Then by proceeding north on the Noke Creek Road a distance of 3.7 kilometers the road forks and is followed on the left fork a distance of 3.6 kilometers. At this point the road again forks and the initial post of two-post claim KEN 2 is situated on the north edge of the road. Also, this location is near the south boundary of reverted Crown Grant BEND'OR (Lot 3773).

HISTORY

The Prospectors Dream property is referred to in the Report of the Minister of Mines 1898 (Appendix 2). Therefore, the two declines, two shafts and numerous hand trenches were excavated prior to 1898.

Ed Frost, the present owner, acquired the property in 1978. During 1979 Mr. Frost had a branch road put into the property by bulldozer from an existing logging road to the mineralized showings. In addition, some of the old workings were exposed by bulldozer in that year.

During 1983 the property was optioned to William Inverarity who in turn optioned it to Fenway Resources. The property then formed part of the Weaver claim group most of which is situated adjacent to and immediately west of the current Prospectors Dream group. The Weaver claim group was explored during 1983 and 1984, however, no work was conducted on the area underlying the Prospectors Dream group.

The Prospectors Dream group was returned to Ed Frost in 1988. During 1989 Ed Frost retained Frank O'Grady, P.Eng. to conduct a program of geological mapping and sampling on the area of the old workings situated on reverted Crown Grants BEND'OR (lot 3773), PROSPECTOR'S DREAM (lot 3772), and OLD ABE (lot 3774). An assessment report on this work was submitted to the Minister of Mines January 26, 1990.

AREA GEOLOGY

Geological Survey of Canada Open File 820 (1981) of the Grassy Mountain Map Sheet exhibits the general geology of the area. The mapping was carried out by J.E. Reesor of the Geological Survey of Canada during 1980 and 1981. A portion of the map and the accompanying legend form Figure 3 of this report.

The aforementioned map shows the area of the Prospectors Dream group underlain by Middle Aldridge sediment and massive intrusive. Detailed mapping by the author confirmed these two rock types on the mapped area.

The Geological Notes that accompany Open File 820 state: "Commonly major valleys are drift covered, as well as the zone between 5500 and 6500 feet elevation."

The Prospectors Dream Group lies between 5500 feet (1676 meters) and 5900 feet (1800 meters). It is, with the exception of the showing area, drift covered.

GEOLOGICAL DESCRIPTION & VALUATION

Two principal rock types underly the Prospectors Dream claim group. The northern portion of the showing area is underlain by Middle Aldridge sediments of argillite and quartzite composition. These sediments are in beds of 10 centimeters to 70 centimeters thick. They strike approximately 15 degrees east of north and dip 45 degrees to the west. The southern portion of the showing is underlain by diorite of the Moyie sills.

As a result of the mapping program conducted in 1989 by Frank O'Grady, P. Eng. a decision was made to carry out a program of trenching, detailed mapping and sampling on five areas on reverted Crown Grants PROSPECTOR'S DREAM and OLD ABE.

The five areas selected were:

- 1) Shaft Area - situated on the north end of PROSPECTOR'S DREAM
- 2) Decline Area - situated on the north end of OLD ABE
- 3) Quartz vein in the diorite area - immediately east of Area 2
- 4) "Bush trench" area
- 5) Trench 91-8

The purpose of the trenching in Areas 1 and 2 is to determine if the gold bearing quartz veins in these areas can be extended by trenching. The purpose of the trenching in Area 3 is to determine if there is gold of economic significance in the quartz vein. The purpose of the trenching in Areas 4 and 5 is to determine if quartz veins containing economic gold values are present.

Figure 5 of this report is the plan of the trenching. The boundaries were located by topographic map. The trenches, including sample locations and values, are mapped in Figures 6-15, 17 and 18. Figure 16 is the Old North Shaft.

Appendix 1 of this report contains the assay certificate and sample locations information. The rock samples were analysed by Acme Analytical Laboratories Ltd. in Vancouver using the fire assay method for 32 samples. In addition, they then analysed two of the samples by I.C.P. method, the process for which is explained on the assay certificate.

1) Shaft Area

This area is underlain by Middle Aldridge sediments of quartzite composition. Mapping in 1989 outlined a quartz vein .3 meters wide with an accompanying shear zone exposed in the old shafts in this area (figure 16). In 1989 grab samples from the vein assayed at 1.34 oz/ton gold and .85 oz/ton gold.

A total of six trenches were excavated in this area approximately along the projected strike of this vein. In addition, one trench was excavated to examine the contact between the sediments and intrusive.

Trenches 91-1 to 91-4 inclusive, on the north projection of the shear zone-quartz vein structure, encountered minor shears containing minor amounts of quartz. The assays (appendix 1) from these zones indicate gold is not present in economic values within the shear exposed in these trenches. Detailed mapping and assay values form figure 6 to figure 9 inclusive.

Trench 91-5 was excavated between the old north shaft and the old south shaft (see figure 5). This trench encountered a shear zone 1.0 meter wide containing a quartz vein .33 meters wide on the footwall side of the shear. A chip sample across the vein exposed in this trench assayed .277 oz/ton gold (figure 10).

Trench 91-6 was excavated on the southern projection of the shear zone-quartz vein structure exposed in the old shafts situated 20 meters and 45 meters to the north (see figure 5). Three minor shears and accompanying quartz were encountered in trench 91-6. The material from two of the three shears assayed at .024 and .046 oz/ton gold (figure 11). These values are not of economic significance but are geochemically interesting as it could indicate these minor shears are conjugate shears from the main shear situated to the north which does contain economic values.

Evaluation of the mapping and sampling of this area indicated gold values of economic interest occur in the old north shaft, the old south shaft, and in trench 91-5 situated between the shafts. The location of the shear zone-quartz vein structure in these three sites also indicates that this structure is near the nose of a fold in this structure. This fold could be from folding of the sediments resulting from the intrusion of the nearby Moyie sill or from orogenic folding.

As a result of the 1981 program, a future program of trenching in this area will concentrate on the area east of the north-south projection of the shear zone-quartz vein structure exposed in the old north shaft, the old south shaft, and trench 91-5. The objective of the trenching will be to determine if the shear zone-quartz vein structure strikes from where it is exposed in a northeasterly and southeasterly direction.

Trench 91-7 (figure 12) was excavated to examine the contact between the sediments and the Moyie intrusive. No rock type of economic significance was encountered and, consequently, no sample was taken for assay.

2) Decline Area

This area is underlain by material of the Moyie sill of diorite composition. Mapping in 1989 revealed a shear zone approximately 1 meter wide containing a quartz vein of varying thickness. A grab sample of the material from this area assayed at 2.13 oz/ton gold in 1989.

Trench 91-11 was excavated along the shear zone-quartz vein structure. Eight assays were taken at 3 meter intervals along the shear zone-quartz vein structure. Figure 17 exhibits the assay results and sampled widths.

Examination of the decline driven to the east on the shear zone-quartz vein structure indicates the zone pinching down to a narrow width to the east within a few meters. Three of the four samples taken at 3 meter intervals on the southernmost end of the trench returned assays of economic value (figure 17).

The shear zone-quartz vein structure ends abruptly to the south and it appears to be cut off by a possible fault. The zone pinches out to the north as it approaches the Aldridge sediments.

It is difficult to interpret if the shear zone-quartz vein structure is a vein-type deposit or if it is a pod-like structure derived from the enclosing parent magma.

A further program in this area will require diamond drilling. The drilling will be designed to determine if the shear zone-quartz structure continues to the east and to determine if the pod-like structure containing the values in this area could be one of several "stacked up" pods within the Moyie intrusive.

3) Quartz Vein Diorite Area

During the course of the fieldwork on this program a quartz vein was encountered in the Moyie sill material immediately east of the south decline area.

Trench 91-9 (figure 14) was excavated to better expose this vein and to get an attitude on it. The vein was sampled and found not to be of economic significance.

Trench 91-10 (figure 15) was excavated a few meters north of trench 91-9 to determine if there was any veining or shearing in the sediment adjacent to the intrusive. This trench revealed only bedded sediments.

4) Bush Trench Area

During the course of prospecting and examination of the area by owner Ed Frost before 1989, he encountered an old sloughed in trench and an accompanying "high grade pile" near the west central boundary of the PROSPECTOR'S DREAM reverted Crown Grant. A grab sample from the high grade pile taken by Frank O'Grady, P.Eng. during the 1989 mapping program assayed 1.09 oz/ton gold.

Trench 91-12 (figure 18) was excavated along the outline of this old "bush trench". No vein or shear zone was encountered in this trench. It has been concluded that high grade float was encountered in this area during the 1890's and so a trench was dug. Then the accompanying "high grade pile" was derived from float encountered during the digging of this trench in the 1890's.

5) Trench 91-8

During the course of fieldwork Ed Frost, owner of the property, encountered quartz in the road cut. Trench 91-8 (figure 13) was excavated to determine the extent of quartz material in this area.

A shear zone 1.0 meter wide with accompanying quartz and some iron oxide coated pyrite was encountered in trench 91-8. A sample taken across the shear assayed at .004 oz/ton gold. This result is not of economic significance but may be considered a geochemical indicator of higher values along the strike of the shear.

It is not possible to determine if the shear zone exposed in trench 91-8 is the same shear zone-quartz vein system exposed in the northern Shaft Area.

CONCLUSION

Trenching in the Shaft Area and the Decline Area has encountered material of economic grade in mineable widths. However, sufficient volume of mineable material has not been encountered as of yet.

Further trenching is required in the Shaft Area to determine if the shear zone-quartz vein structure continues in a northeasterly and southeasterly direction. After that, diamond drilling will be required to test for the structure at depth.

In the Decline Area diamond drilling is required to test for more pod-like structures at depth and to determine the easterly extent of the gold bearing structure.

The remainder of the Prospectors Dream group should be examined to determine if there are more shear zone-quartz vein structures present under the overburden.

The I.C.P. analysis of sample 84053 from trench 91-5 and sample 84068 from trench 11 indicate anomalous values in lead and zinc associated with the gold bearing zones. Therefore, a program of geochemical sampling over the claim group may indicate more areas to investigate by trenching.

To the west of Weaver Creek and at the base of the hills forming the divide between it and Perry Creek, quite a number of mineral locations have been made and a considerable amount of work done. The claim best known and most developed is the *Prospector's Dream*, around which are grouped the *Old Abe*, *Last Chance*, *Annie*, *Ben d'Or*, *Parker*, *Lennie*, and the *Pauper's Dream Fraction*. How these claims lay I could not exactly determine, so much re-staking had been done, as many as twelve posts being found within a radius of as many feet, and nothing short of an actual survey would untangle the claims. The same general conditions, however, apply to each, and I was able to identify certain works as belonging to certain of the claims.

Owned by J. C. Green *et al*, Fort Steele. The country rock, seemingly, is entirely of igneous origin, probably a syenite or diorite. A quartz vein has been exposed, outcropping nearly horizontally along the hillside, and dipping into the hill N. 30' E. at an angle of 15'. This has been developed by a 20-foot open cut leading to a 40-foot inclined tunnel, both on the vein.

In the open cut the quartz was very much broken, but nearer the mouth of the tunnel the vein was more solid and showed a width of 5 feet of solid quartz. Following the tunnel down, the width of quartz seems to gradually diminish, until at 40 feet in, the vein has only a width of some 6 inches. About 15 tons of quartz, of a rusty nature, was piled on the dump, which is said to run \$10.00 in gold to the ton. The vein-matter will show free gold in the pan almost anywhere, but not indicating high values. The apparent pinching out of the vein in this one tunnel has discouraged for a while, deeper prospecting and the continuity of the vein to the dip remains to be proven.

Whether the gold obtained is the result of the weathering of iron sulphides carrying gold, or whether it will continue to a depth as free gold, has not yet been determined.

I am informed that one or more shafts have been sunk on this property on another vein, but these shafts I was unable to find, being filled, doubtless, with water. In these the vein showing is said to be nearly vertical and to carry a width of some 5 feet of quartz with gold values.

Old Abe, owned by Steve Young *et al*, of Fort Steele, is practically an extension of the claim just mentioned.

Located by Nitzel and Johnson, is supposed to lie between *Old Abe* and the *Prospector's Dream*, some 100 feet east of the workings on the latter. The area of this fraction is uncertain, until the prior claims have been surveyed. There has been some work done on the property, consisting of an open cut and two tunnels, 10 and 8 feet respectively. The fraction was evidently located to catch that portion of the *Prospector's Dream* lead which may not be covered by the main claims.

The *Last Chance*, owned by Wm. Haupt *et al*; War Eagle, Hy. Kershaw *et al*; Annie, Wm. Thompson *et al*; Ben d'Or, J. C. Green *et al*; Parker, Gus Theiss, and Lennie. J. S. Parker, all of Fort Steele, are all locations in the same vicinity, but with only slight development work done on them that I could find. The limits of these claims I was unable to distinguish without a survey, in the absence of the owners to point out the true lines.
