## **SUMMARY**

The Porphyry Creek project covers a 75 km<sup>2</sup> area, 23 km south of Johanson Lake, B.C., in an area of moderately rugged mountains. Regional exploration in 1990 and 1991 has relied on geologic mapping and prospecting, and on the collection of soils and talus fines on contour traverses around the steep mountain slopes. A total of 2034 soil and talus fine samples comprise the survey for both years and an additional 159 soil samples were taken on a grid basis in Bloom Cirque.

The geochemical survey is of high quality, and as a consequence eight major anomalies for one or more of the elements: Au, Cu, Ag, Pb, Zn, Cd, Mo, W, and Co have been defined. Anomalous zones tend to exhibit a high degree of contrast with background, and are very large, having dimensions typically in the 1 to 2 km across range. Four anomalies have been followed up by grid soil sampling and three (two at Porphyry Creek, one at Raven Creek) are the subject of independent reports. An outstanding anomaly centers on Bloom Cirque where cobalt bloom accompanies high values of Cu. The North Fork and East Emer Ridge anomalies are striking in their distribution of Pb and alteration element indicators, as is the Granite Basin anomaly. Anomalous zones are associated with gossanized Takla volcanic bedrock in proximity to diorite intrusions. Additional regional traverses and soil grids have been recommended to evaluate these zones, as well as a relatively untested area in South Sarah Cirque.

Followup is highly recommended. It should be staged, proceeding via additional regional and grid soil surveys where appropriate; ground magnetic surveys and where topography is favourable, IP surveys. Prospecting and geological mapping needs to accompany all work. Emphasis is being placed on continuous chip sampling of outcrop suspected of being the source for soil anomalies at 5 m intervals, assisted by hand trenching where necessary to achieve continuous sections. Drill targets likely can be defined once results of the preliminary program are in hand. Continued followup is highly recommended.

## RECOMMENDATIONS

1. Continued regional exploration of still untested mountainside is recommended. Effort allocated to this endeavour should amount to no more than 10% of the 1992 budget.
2. Detailed evaluation of the five geochemical anomalies not described in companion reports is warranted on a high priority basis.
3. Grid soil sampling employing a line spacing of 100 m and a sample interval of 25 m is recommended where overburden is thought to be thin (i.e. near or in the mountains). Sampling east-southeast of the Raven Grid can be undertaken using a 50 m sample interval, in view of the deeper overburden conditions. Grid surveys, including ground magnetics and possibly IP surveys are recommended below:
  - (a) North Fork anomaly : 1 km<sup>2</sup>, 400 samples (25 m interval)
  - (b) East Raven Creek anomaly : 1.5 km<sup>2</sup>, 400 samples (25-50 m interval)
  - (c) East Emer Ridge anomaly : 0.5 km<sup>2</sup>, 200 samples (25 m interval)
  - (d) West, North Sarah Cirque : 0.8 km<sup>2</sup>, 350 samples (25 m interval)
  - (e) West, Granite Basin anomaly: Potential target 0.5 km<sup>2</sup>, 200 samples (25 m interval)
4. Geological mapping and prospecting should accompany evaluation of all targets. The objective is to identify mineral occurrences, alteration and structure which would assist in priority rating of targets.
5. Rock chip sampling at a 5 m sample interval along contour traverses at or upslope of soil anomalies is recommended to proceed diamond drilling. Chip sections should extend into background areas to define halos and alteration patterns. Sample size should be about 5 kg and all samples should be analyzed by multielement methods.

6. Rock chip sampling at 3 m intervals of bedrock exposed in gullies along cirque headwalls would provide information perpendicular to the trenches described in (5) above and is appropriate to followup overburden anomalies located downslope. Such a program would provide information on grade similar to a drill program, albeit sample quality would not be as high.
7. Completion of the program as planned would involve collection of up to 1600 soil samples on soil grids, 350 samples on reconnaissance sampling, and sampling of up to 8 km of trenches (1600 samples at a 5 m interval).
8. All samples would be analyzed at the same laboratory as conducted work for the previous two seasons (Rossbacher Laboratories, Vancouver, B.C.) using the same preparation and analytical procedures.
9. Completion of recommendations (1) through (6) should produce diamond drill targets. Soil anomalies in the east Raven Creek area worthy of followup would need close evaluation of overburden conditions prior to diamond drilling.
10. All drill core should be split and subject to a geochemical Au determination plus a multielement analysis on a routine basis.

## INTRODUCTION

Purpose of the exploration program in 1991 was to continue an evaluation of the base and precious metal potential of the Porphyry Creek area begun in 1990. Emphasis was placed on porphyry style copper and gold mineralization. The exploration was conducted between July 10, 1991 and September 9th, 1991 and involved mapping at 1:10,000 scale, prospecting and contour soil/talus fine sampling. A soil grid was positioned over the Porphyry Creek and Bloom Cirque areas. Soil samples were collected on grids at 25 m intervals along lines 100 m apart. Results and recommendations for the Porphyry Creek grid program can be found in Part B (Hoffman, 1992). This report describes results of the Porphyry Creek and Bloom Cirque geochemical reconnaissance.

## LANDSCAPE, TOPOGRAPHY, VEGETATION AND GLACIATION

The area is underlain by rugged ridges flanked by steep talus slopes. Broad Cirque and wide main valley floors are also characteristic of the landscape. Alpine vegetation covers more gentle slopes and higher portions of the valleys. Scrub willow, alder and forests of spruce thrive at lower elevations. Treeline is about 1500 m a.s.l. Property elevations range from 1130 to 2300 m a.s.l. A number of small alpine lakes are scattered over the property.

Most of the region was covered by a Pleistocene ice sheet and later modified by alpine glaciation. Ice movement was from southwest to northeast. Glacial till is restricted to the floors of valleys and cirques, extending roughly to treeline. Thickness varies from greater than 15 m in valley bottoms to less than 1 m on the upper slopes.

## GEOCHEMICAL SURVEY

### Sample Collection and Analysis

The Porphyry Creek project area covers approximately 75 km<sup>2</sup> area. Priority rating of areas of interest is mandatory if exploration is to proceed in a cost effective fashion. The survey area is mountainous, and a geochemical program was conceived to evaluate the ground using contour soil and talus fine sampling, complimented by chip sampling of the

talus blocks and outcrop. These latter two media are not considered in this report. Sampling was conducted at a 50 m interval, and sample locations are shown on Fig. 15.

A total of 1367 soil and talus fine samples collected in 1990 were augmented by an additional 677 samples collected in 1991. One hundred and fifty-nine (159) samples were taken along the base of Bloom Cirque. Two thousand four hundred and one (2401) samples were taken at Porphyry Creek. All sample stations were marked with an orange flag on which was affixed the sample number. Field notes were recorded at each station.

Approximately 500 gm of material were collected in a wet strength Kraft paper envelope and labelled on site. Samples were shipped to Vancouver, B.C., where they were oven dried, sieved to minus 80-mesh and analyzed for Au on a 10 gm split using a fire assay preconcentration technique and for a suite of 32 aqua regia leachable elements on a second 0.5 gm split. Analytical data are reported in Appendix 1 and analytical procedures are reported in Appendix 2.

#### **Method of Data Evaluation**

Geochemical data are summarized on histograms, labelled Fig. 16. Method of interpretation of the histograms is given in Appendix 3. The interpretation permits assignment of different size-coded dots or diamonds to represent the data in map form. The geochemical maps use these selected intervals to represent the results.

Appreciation of multielement surveys demands that maps be no larger than page size, in this case 39 cm by 26 cm. Porphyry Creek soil grid results as well as cirque headwall reconnaissance data are shown on Fig. 17 at a 1:10,000 scale.

#### **Description of Results**

##### **1. Gold (Fig. 6A, 7A, 8A)**

Au backgrounds in the steep mountain environment are high, with an anomaly threshold established at 90 ppb and maximum values are in the 200 to 2000 ppb

range. Anomalous zones tend to have dimensions in the 250 m to 500 m across, full dimensions uncertain in view of the sampling plan.

The Porphyry Creek drainage is associated with extensive zones of Au enhancement, both to the west and to the north of the creek, mostly in areas underlain by diorite to quartz monzonite (Fig. 6A). Weaker and more heterogeneous zones of Au enhancement lie to the east-southeast of the Porphyry Creek Cirque. Au anomalies described above are on the opposite side of the mountain range associated with the SOUP claims Au-bearing skarn.

Gold anomalies, from Porphyry Creek in the southwest, trend approximately 8 km northeastward within a zone 2 to 3 km wide. Au enhancement is prominent on the north and west side of Bloom Cirque. Despite conducting the grid soil survey within Bloom Cirque in 1991, Au anomalies are not fully delineated (Fig. 8A) particularly in the north and east. The anomalous zone is at least 800 m wide by 1500 m long, associated with diorite intruding volcanics. Strongest Au enrichment lies along the east side of the grid, near the base of talus slopes, suggesting the Au source lies upslope. Au has also accumulated north of Bloom Cirque, to the west of North Sarah Cirque. Au enhancement is seen in the headwalls of South Sarah Cirque where sampling follows a more open plan. Both latter anomalous areas are underlain by volcanics (Fig. 7A).

Sampling at Raven Creek (Fig. 7A) has defined an anomalous zone exceeding 40 ppb having dimensions of 600 m X 900 m associated with and peripheral to dioritic intrusions at the northern limit of the Raven prospect. Detailed sampling at Raven has been described in a companion report (Hoffman, 1990).

Au enhancement to levels comparable to Raven characterize East Emer Ridge. Somewhat higher anomalous Au levels are seen near the entrance to Granite Basin

over a lateral distance of almost 2 km. Background Au contents are typically less than 20 ppb.

2. **Copper** (Fig. 6B, 7B, 8B)

Cu contents of soils are substantially lower than average contents of talus fines (150 ppm versus 450 ppm, respectively. This is typical, reflecting Cu leaching from soils. Cu data have consequently been normalized to upgrade the significance of anomalous soil values. The regional surveys highlights the Bloom Cirque and vicinity as the most outstanding Cu anomaly of the program (Fig. 6B). The zone of anomalous Cu begins near East Croydon Creek in the west, and extends at least 2.0 km eastward. North-south dimensions are in the order of 1.5 to 2.5 km. Maximum values are in the 2000 to 4000 ppm range.

Cu contents within Bloom Cirque are outstanding, with almost all values exceeding 350 ppm, except over the southernmost entrance to the cirque (Fig. 8B). Maximum values are seen in regional sampling along the western and northern cirque walls. Values are lower in the east, but many exceed 1000 ppm and high values are found along a regional traverse some 300 to 500 m to the east of the grid (Fig 7B). The character of the Cu distribution on the cirque floor suggests Cu mineralization will be found within the cirque as well as at upper elevations.

Porphyry Creek (Fig. 6B) is associated with weak Cu enhancement, in narrow zones which typically correlate with Au or Ag-rich samples. Surprisingly, Raven Creek (Fig. 7B) is not reflected by an outstanding Cu anomaly, despite the fact that a prominent Cu anomaly has been defined by detailed grid work. Anomalous conditions at Raven are reflected by Cu values exceeding 450 ppm in talus fines or 150 ppm in soils. The case history at Raven is important in determining methodologies which will allow identification of significant anomalies elsewhere in the region. Reconnaissance sampling east of 1990 work has indicated

substantial Cu accumulation in the lowlands in the east in addition to Cu enrichment along Raven Creek which may represent an alluvially transported feature.

Sampling along East Emer Ridge has identified several anomalous zones which lie downslope of Au and Ag anomalies and correlate somewhat with enhanced As geochemistry. The strength of anomalous conditions suggests sampling should extend into the lowlands. Cu anomalies tend to be independent of the location of Au-rich zones.

Cu values vary homogeneously over the southeast corner of the survey, with elevated values in Granite Basin and in the two cirque headwalls to the south. Enhanced values are also seen along Kliyul Creek (at upper elevations) and along the south headwall of South Sarah Cirque.

### 3. Silver (Fig. 6C, 7C, 8C)

Most Ag values are at detection limits. Homogeneous Ag accumulation to levels exceeding 1.0 ppm is prominent on the north and west sides of Bloom Cirque (Fig. 6C, 8C), at Raven Creek (Fig. 7C) and around Granite Basin (Fig. 7C). Anomalous Ag values reach 2 to 6 ppm and higher. Anomaly dimensions are in the 400 to 500 m range and are found in both dioritic and volcanic terrains. Significant second order anomalies are noted on East Emer Ridge (Fig. 7C), and at North Fork (Fig. 6C). Elevated backgrounds to the south of South Sarah Cirque appear to be an analytical artifact and no anomalies are outlined.

### 4. Arsenic (Fig. 6D, 7D, 8D)

As backgrounds are somewhat higher in talus fines than in soils. As levels are low in the west (Fig. 6D), typically at levels below 12 ppm, but become progressively higher in the east where backgrounds average 25 ppm. The highest contrast anomalies are associated with Raven Creek, East Emer Ridge and

Granite Basin (Fig. 7D) in a distinct northwestward regional trend. The As-rich zone in each case is much larger than the corresponding Au anomaly, having dimensions of 1000 m by 1500+ m, perhaps indicating a zoning relationship. By contrast, As anomalies in the extreme southwest do not accompany Au enrichment. Maximum As levels are 50 to 100 ppm.

Bloom Cirque is associated with minor As enhancement along the western and northern cirque walls (Fig. 8D). Au anomalies south of Bloom Cirque are marginal to a zone of elevated As. North Sarah Cirque has several As anomalies but no Au in the headwall. Correspondence is seen between Au and As at South Sarah Cirque, but the Au anomaly along the north cirque headwall has no As accompaniment.

#### 5. Antimony (Fig. 6F, 7F, 8F)

Most Sb values are at detection limits. Spotty Sb enrichment is seen in the Porphyry Creek (Fig. 6E), Bloom Cirque (Fig. 8E), Raven Creek (Fig. 7E), and East Emer Ridge (Fig. 7E) areas. More substantial enhancement is seen in the headwaters of East Croydon Creek (Fig. 6E), and south of Granite Basin (Fig. 7E). The analytical validity of the Sb data needs to be checked prior to expending large sums of money following up Sb anomalies.

#### 6. Bismuth (Fig. 6F, 7F, 8F)

Bi anomalies typically comprise single or pairs of samples which are widely distributed on the regional sampling, mostly remote from Au anomalies.

#### 7. Lead (Fig. 6G, 7G, 8G)

Pb levels are slightly higher in talus fines than in soils. Anomaly thresholds are about 35 ppm in both media, and maximum values are in the 50 to 500 ppm range. Pb levels exceeding 100 ppm should be investigated for their indication of proximity to galena occurrences.

The largest and most homogeneous anomaly is located in the far northwest (Fig. 6G). Pb concentrations often exceeding 100 ppm are found at North Fork along the headwaters of East Croydon Creek, overlying an area exceeding 3000 by 1000 m. This Pb anomaly appears associated with a dioritic intrusion into Takla group volcanics. A second zone of Pb accumulation, possibly having similar dimensions, characterizes hills around the Granite Basin area (Fig. 7G). A Pb anomaly north and northwest of Bloom Cirque lies to the west of the Au anomaly and is associated with Ag enrichment (Fig. 8G). A second Ag anomaly along the western cirque headwall is not Pb-rich. The Pb-rich zone is much larger than the Ag anomaly, extending to East Croydon Creek, and perhaps across the creek. The Pb anomaly on the east side of East Croydon Creek is 1.5 km by 1.5 km in size. By contrast, the Bloom Cirque Cu anomaly extends twice as far to the south as does the Pb feature.

Four other Pb anomalies are outlined: at Porphyry Creek (Fig. 6G), at Raven (Fig. 7G), at East Emer Ridge (Fig. 7G), and in the west of south Sarah Cirque (Fig. 7G). All have about the same dimension of 500 to 700 m and all are open. Maximum values typically exceeding 100 ppm, except the zone in the South Sarah Cirque headwall. All have at least a partial Ag association, although Ag anomalies tend to be smaller than corresponding Pb features. The Raven and East Emer Ridge anomalies lie within an As-rich environment, as does the Granite Basin area. Correlation of Pb with Cu is commonly weak, with the exception of the zone along East Emer Ridge, the Granite Basin area, and the north Bloom Cirque region.

#### 8. Zinc (Fig. 6H, 7H, 8H)

Zn contents are higher in soils compared to talus fines (185 ppm versus 150 ppm anomaly thresholds, respectively). High contrast anomalies lie in proximity to Granite Basin (Fig. 7H), on the north side of Bloom Cirque (Fig. 6H) and in the Raven Creek area (Fig. 7H). The Zn anomaly in the Granite Basin area is much

larger than the corresponding Pb feature whereas the Zn anomaly is smaller than is the corresponding Pb feature northwest of Bloom Cirque, although within the cirque patterns are almost identical (Fig. 8H). Maximum contents are in the 500 to 1500+ ppm. These high values are unusual, and suggest sphalerite occurrences are necessary to explain the soil anomalies (sphalerite has been mapped at Raven). Zn enhancement is common over much of the sampling over the east side of East Croydon Creek (Fig. 6H), suggesting a zonal relationship with Pb.

Enhanced Zn backgrounds typify East Emer Ridge and the south and west sides of South Sarah Cirque. By contrast, the Porphyry Creek area reports Zn values typically less than 100 ppm. Zn typically exhibits a zoned relationship relative to Pb, although coincidence is also noted.

9. **Cadmium** (Fig. 6I, 7I, 8I)

Cd anomalies are rare, lying in the midst of major zones of Zn enhancement at Bloom Cirque (Figs. 6I, 8I), Raven Creek (Fig. 7I), and Granite Basin (Fig. 7I). Maximum Cd values are in the 10 to 30 ppm range.

10. **Molybdenum** (Fig. 6J, 7J, 8J)

Six major Mo anomalies are defined by a regional survey which shows a slight enhancement in talus fines compared to soils (threshold of 12 ppm versus 10 ppm, respectively). The highest contrast and most homogeneous anomaly is associated with diorite and quartz monzonite along the south side of Porphyry Creek (Fig. 6J), where Mo has accumulated to the 50 to 300 ppm range. The soil anomaly reflects a known porphyry Mo deposit.

Substantial enhancement of Mo in two zones is defined in the Raven Creek area (Fig. 7J). Mo anomalies are prominent at North Fork (Fig. 6J), at the mouth of Granite Basin (Fig. 7J), and along the south headwall of South Sarah Cirque.

Anomaly dimensions tend to be in the 500 m to 750 m range, and maximum concentrations are in the 20 to 30 ppm range. Acidic intrusion into Takla volcanics is probably characteristic of anomalous areas.

Enhanced values of Mo in Bloom Cirque lie to the north and west of the cirque (Fig. 6G, 8G). In the north, Mo anomalies resemble Cu, Pb, Zn and Ag features, and to some extent correlate with Au. Pb and Zn are not enhanced in association with the western Bloom Cirque Mo anomaly which extends to Croydon Creek.

11. **Tungsten** (Fig. 6K, 7K, 8K)

The W distribution is dominated by anomalies in the Granite Basin area (Fig. 7K) and along the south side of Porphyry Creek (Fig. 6K) where maximum values are in the 20 to 40 ppm range. W-rich samples are homogeneously distributed. Elsewhere, elevated values probably reflect a higher detection limit than is reported by the laboratory (probably in the order of 5 ppm rather than the 1 ppm quoted). This would explain the line of high values on the west side of Bloom Cirque (Fig. 6K) compared to the line of detection limit values downslope. Line-related enhancement characterizes sampling to the east of South Sarah Cirque and at North Fork.

W solubility is limited in aqua regia. Occurrence of scheelite and powellite in the Porphyry Creek area, down-stream from Karen Creek may be reflected by existing data. Determination of total W is appropriate if W anomalies are important to continued exploration.

12. **Iron** (Fig. 6L, 7L, 8L)

Fe contents of soils are lower than Fe contents of talus fines (thresholds of 6.5% versus 7.0%, respectively). The largest zones of Fe accumulation are found along a northwesterly trend through Raven Creek, East Emer Ridge, and Granite

Basin in the east (Fig. 7L). Zonation is seen between Fe and Au, Cu, Pb, Zn, and Mo. Closest correspondence between elements is seen along East Emer Ridge.

An Fe-rich zone 1 km<sup>2</sup> in size characterizes the north side of Bloom Cirque (Fig. 6L, 8L). The anomaly provides an Fe-rich environment containing the Ag, Cu, Pb, Zn, and most of the As anomalies. Au appears peripherally distributed relative to Fe. Fe has accumulated along Croydon Ridge but Fe enhancement is not prominent at the Mo-rich area south of Porphyry Creek. The Croydon Ridge Fe-rich zone is associated with weak Cu, Pb, Mo, and Ag anomalies in this region. Low Fe contents of less than 4.2% characterize traverses as lower alterations along major stream channelways.

13. **Manganese** (Fig. 6M, 7M, 8M)

Mn contents are higher in talus fines than in soils (thresholds 1800 ppm versus 1600 ppm, respectively). The Mn distribution resembles that of Fe in the east but high values are commonly displaced eastward in the east (Fig. 7M). Zonation describes the Mn-Fe relationship in the west with Mn accumulating to the northwest of Bloom Cirque (Fig. 6M). Smaller anomalous conditions characterize East Emer Ridge, the Raven grid, and the west side of South Sarah Cirque. Maximum values are in the 3000 to 5000 ppm. Of all the elements, the distribution of Zn most closely resembles that of Mn, probably reflecting a scavenging relationship. The Mn distribution is homogeneous, suggesting the element is controlled by primary features in underlying bedrock. Lowest Mn contents of less than 400 ppm (soils) to 700 ppm (talus fines) are found at lower elevations of Croydon and Raven Creeks.

14. **Cobalt** (Fig. 6N, 7N, 8N)

Co contents are higher in talus fines compared to soils (thresholds of 55 ppm versus 40 ppm, respectively). A large number of Co values exceed 55 ppm, and

the name Bloom Cirque was chosen to reflect the presence of cobalt bloom in one of these anomalies (Fig. 8N). Similarly high Co values are found to the north and northwest of Bloom Cirque (Fig. 6N), following the distribution of Fe, Mo, Pb, Zn, and Cu and to some extend Ag and Au.

Comparably high Co contents are widely distributed in the Granite Basin area (Fig. 7N), following the Mn distribution. Similarly, Co accumulation on East Emer Ridge follows Mn whereas the Co anomaly at Raven is larger than the Mn feature. Co contents are not anomalous to the north of the north arm of Raven Creek where Mn accumulation is substantial. Co anomalies are much more widespread than Mn along the south side of South Sarah Cirque and 1 km to the south along the Kliyul Creek valley. Co backgrounds are much higher at upper elevations at the latter location compared to the line 300 to 400 m downslope.

Co values are lowest west of West Croydon Creek (Fig. 6M), although a number of anomalous values exceeding 100 ppm are found along the north side of Croydon Ridge. It is somewhat peculiar that backgrounds along adjacent reconnaissance lines are so different, suggesting a sampling, or more likely an analytical artifact. The difference is most notable in the southeast.

15. **Nickel** (Fig. 6O, 7O, 8O)

The Ni distribution shows an extreme range of concentrations, with higher levels in talus fines (threshold 90 ppm) compared to soils (threshold 65 ppm). Three major zones of Ni enhancement are outlined, with elevated Ni contents in the 50 to 300 ppm range. Dimensions range from 5 km east-west and 1.5 km north-south, north of Bloom Cirque (Fig. 6O), trending across East Croydon Creek and extending to the headwall of North Sarah Cirque. Contrast is extreme, as seen in the Bloom Cirque detailed survey (Fig. 8O). High contrast Ni anomalies having dimensions about 500 m across are located in the Porphyry Creek valley (Fig. 6O). Elevated Ni levels are probably reflecting andesitic or basaltic units

of the Takla volcanics. Presence or absence of high Ni is not critical to the occurrence of Au, Ag, Cu, Mo, Fe, Mn and Co anomalies, but it does appear to be exerting some control on the distributions of Pb, As and Zn.

Blocks of Ni enhancement characterize the mountain peak west of Granite Basin (Fig. 7O) and the east side of South Sarah Cirque. Ni-rich talus fines highlight the eastern limit of the regional sampling at Bloom Cirque (Fig. 7O) and the west side of South Sarah Cirque.

Low Ni contents of less than 25 to 35 ppm characterize Raven Creek East Emer Ridge and much of Bloom Cirque proper. Low Ni contents also characterizes a granitic intrusion to the southwest of Porphyry Creek and over portions of the survey in the extreme northwest.

16. **Chromium** (Fig. 6P, 7P, 8P)

The Cr distribution is very similar to that of Ni, although differences are apparent. For example, the Cr anomaly associated with Croydon Ridge (Fig. 6P) extends at least one extra km upslope of the Ni feature and is associated with a 3 km by 1.5 km block of ground. Cr levels are consistent with an underlying geology of mafic volcanics. The major Ni anomaly north of Bloom Cirque, extending from East Croydon Creek to North Sarah Cirque, is reproduced by Cr, although contrast is not as great (Fig. 6P, 7P).

The Cr anomaly extends further eastward than Ni, including East Emer Ridge (Fig. 7P). The Ni anomaly along the east side of Bloom Cirque (Fig. 7P) and west side of South Sarah Cirque is reproduced by the Cr distribution. An additional Cr-rich area lies southwest of Bloom Cirque (Fig. 6P), a feature not seen in the Ni distribution.

The Cr pattern has been adversely affected by an analytical problem which developed part way through the analysis program. This has resulted in low values being reported in the Granite Basin area where enriched conditions would have been predicted based on Ni patterns. Similarly, low Ni in the far northwest and east of the Raven grid are probably analytical artifacts.

17. **Vanadium** (Fig. 6Q, 7Q, 8Q)

The V distribution does not follow Fe, a relationship which is fairly common for soil surveys. Highest V backgrounds exceeding a threshold of 140 to 150 ppm to maxima of 200 to 250 ppm lie north of Porphyry Creek and west of Bloom Cirque (Fig. 6Q). High V is not commonly accompanied by high Au, although a sympathetic relationship is seen with Cu. Anomaly contrast is exceptional, as seen in Bloom Cirque proper (Fig. 8Q) where an east-west trend is noted. Elements such as Ag, Pb, and Mo have accumulated in V-low zones, whereas some overlap is seen between Zn and Mn and V.

Anomalous distribution of V is much more clearly defined in the east (Fig. 7Q), where zones of enhancement are seen in the Raven Creek, North Sarah Cirque, East Emer Ridge, and Granite Basin areas. Low values of less than 100 ppm are common along Kliyul Creek, from south of Bloom Cirque to south of Granite Basin. Zones of comparably low V values trend in a northwesterly direction along the north arm of Raven Creek to north of Granite Basin.

18. **Barium** (Fig. 6R, 7R, 8R)

Ba contents of talus fines and soils are about equal. Maximum Ba contents lie at North Fork (Fig. 6R) where values are in the 500 to 2000 ppm range, associated with both a dioritic intrusion and host Takla volcanic rocks. Ba correlates with Ag, Au, Pb, and Mo and lies to the north of a zone of elevated Mn, Ni, and Cr values. Somewhat similar in character but smaller in size is a Ba anomaly northwest of Bloom Cirque (Fig. 6R) overlying about a 1 km<sup>2</sup> area.

This zone contains smaller Zn, Ag, Pb, Zn, Mo, and Mn features and lies within a larger Cu and Co anomaly. Ba accumulation appears to crosscut major changes in underlying geology as indicated by patterns in the distribution of Ni and Cr.

Within Bloom Cirque (Fig. 8R), the regional anomaly in the northwest is a high contrast feature. Lower levels of Ba accumulation characterize the east side of the cirque. Anomalous Ba contents typify the quartz monzonite intrusion to the southwest of Porphyry Creek, whereas sampling along Porphyry, Croydon, and most of Kliyul Creeks report low Ba concentrations of less than 80 ppm.

Enhanced Ba, including values of 500 to 1400 ppm, lie in samples along East Emer Ridge, correlating with Au, Ag, Pb, Zn, Fe, Mn and Co and lying peripheral to As, Cu and V. Substantial Ba accumulation zones characterizes ground northeast of Raven, but these anomalies are remote from precious and base metal, and pathfinder element anomalies. Ba enrichment in the granite Basin area is also prominent, but Ba-rich zones are commonly peripheral to zones of Au, Cu, Ag, As, Pb, An, Mo, and W anomalies.

19. **Strontium** (Fig. 6S, 7S, 8S)

Sr threshold levels are significantly higher in talus fines compared to soils (thresholds of 180 ppm versus 135 ppm, respectively). The Sr distribution is homogeneous, and in view of the survey topography, Sr patterns are believed to reflect underlying geology (rather than seepage zones to be expected if relief was gentle).

Most extensive zones of Sr accumulation includes areas covering over 4 km<sup>2</sup> at North Fork (Fig. 6S), and a slightly larger area around Granite Basin in the southeast (Fig. 7S). Maximum values are in the range of 250 to 400 ppm. In both cases, Sr follows Ba, although its anomalous signature is inferior to that of Ba in the northwest and superior to that of Ba in the southeast.

An extensive zone of Sr enhancement overlying a 1.5 km wide and 800 m deep area lies south and southwest of Bloom Cirque (Fig. 6S). Maximum values are 300 to 500 ppm. Backgrounds are abruptly lower at less than 50 ppm 300 to 400 m downslope. This is possible if downslope dispersion is minimal, but the validity of the analytical results need to be checked, in view of the important implications these data have for interpretation of the genesis of geochemical anomalies elsewhere (i.e., estimate of downslope dispersion distance in steeply sloping terrain). Within Bloom Cirque proper (Fig. 8S), the eastern cirque headwall has a larger anomalous signature than in the west and the valley floor reports Sr backgrounds of less than 40 ppm.

Sr contents are only weakly enhanced in association with the Kliyul Creek Pluton in the far southwest (Fig. 6S). By contrast, Sr contents are low at less than 30 to 50 ppm associated with the Bloom Cirque Ba anomaly (Fig. 6S). Sr contents are high at Raven Creek (Fig. 7S) where Ba concentrations are low. Sr enhancement is weak along East Emer Ridge and along the southern margin of South Sarah Cirque.

20. Calcium (Fig. 6T, 7T, 8T)

Ca concentrations of talus fines are about the same as Ca contents of soils. Backgrounds are lowest in the Porphyry and Croydon Creek areas (Fig. 6T) and south and east of Raven Creek (Fig. 7T), at less than 0.3%. Highest Ca contents, exceeding 1.0% and ranging upwards to 2 to 3% are found along East Emer Ridge and within and north of Granite Basin (Fig. 7T). The Ca pattern resembles that of Sr but contrast is much stronger. Ca accumulation is characteristic at North Fork (Fig. 6T), but contrast is reduced from that seen for Sr.

The Ca distribution weakly resembles that of Sr in the west, south of Bloom Cirque. By contrast, the Kliyul Creek pluton (Fig. 6T) is not Ca-rich, only

volcanics east of the pluton show weakly elevated Ca values. Maximum Ca enhancement around Bloom Cirque is typically between 0.6% and 1%, the pattern not exhibiting as much contrast as seen for Sr. Within the cirque proper, a zone of Ca accumulation to 1 to 1.2% levels lies in the south central portion of the grid (Fig. 8T). Weak Ca enhancement follows ridges in the Raven Creek area (Fig. 7T), particularly north of Cu-Mo anomaly, whereas values are very low in sampling at lower elevations east-southeast of the Raven Creek grid.

The Ca distribution is always examined to identify a noisy character which have implications for sampling quality. The Ca distribution on this project is basically homogeneous, suggesting local bedrock conditions rather than sample composition exert the main controls on Ca levels. Some sampling peculiarities are noted, but none are particularly adversely affecting the appearance of base or pathfinder element distributions. Several samples report Ca contents near 10%, and these are believed to reflect the occurrence of carbonate minerals in bedrock nearby.

21. **Soil pH** (Fig. 6U, 7U, 8U)

Soil pH of talus fines is more alkaline than soil pH (6.5 versus 6.3, respectively, for threshold levels). The most outstanding pH feature is the distinctly alkaline soils within and north of Granite Basin and along East Emer Ridge (Fig. 7U). The pH pattern correlates closely with that of Ca. Alkaline pH is also seen along the ridge between East and West Croydon Creeks (North Fork), in the northeast (Fig. 6U). Distributions of pH and Ca correlate closely with each other.

pH in the Porphyry Creek area (Fig. 6U) and West Croydon Creeks are acidic ( $\text{pH} < 4.9$ ), correlating with areas of low Cu and Zn values. Cu anomalies in this region are commonly contained in more neutral soils. The Bloom Cirque area displays near neutral pH in the midst of the Cu anomaly on the west cirque headwall (Fig. 8U) although Cu anomalies extend to the west, into areas of more acidic soils. Within the cirque proper, much of the valley floor reports pH values

of less than 5.3. Near neutral pH lies north of Bloom Cirque (Fig. 6U) and along East Emer Ridge (Fig. 7U) apparently unrelated to Cu or Zn distributions. Zones of acidic pH lie east-southeast of the Raven Creek grid in an area reporting high Cu values (Fig. 7U).

22. **Magnesium** (Fig. 6V, 7V, 8V)

The Mg distribution is relatively homogeneous, with thresholds in talus fines higher than that in soils (2.7% versus 2.1%, respectively). Lowest values of less than 0.85% characterize the Porphyry Creek area (Fig. 6V), the Kliyul Creek pluton (Fig. 6V), and with of Raven Creek (Fig. 6V).

Mg accumulation in the range of 3 to 4% and greater typifies large blocks of ground around the hilltop west of Granite Basin (Fig 7V) and the area between East Croydon Creek to North Sarah Cirque, north of Bloom Cirque. Mg enhancement covers 3 to 4 km<sup>2</sup> areas and probably reflects Mg-rich volcanic units. At Granite Basin, Mg follows the Co and Ni distributions (Cr data here are faulty), whereas north of Bloom Cirque, Mg follows Mn, Co, Ni, and Cr patterns. Weaker Mg enhancement lies to the west of the Raven Grid (Fig. 6V) and surrounds the Mg low at Porphyry Creek (Fig. 6V).

Bloom Cirque proper (Fig. 8V) exhibits average Mg backgrounds, but a zone of low values (<1.35%) crosscuts the northern portion of the grid in a northwesterly direction. The Raven grid area (Fig. 7V) is reflected by average Mg contents, but low values lie to the east and northeast.

Au, Cu, Ag, As, Pb, An anomalies generally lie remote from Mg-rich zones, although some coincidence is seen in the Porphyry Creek area.

23. Aluminum (Fig. 6W, 7W, 8W)

Al displays a striking change from low backgrounds in the west to regionally enhanced values in the east following an approximately northwesterly trend. The Al pattern, defined by values exceeding a threshold of 4.6% in soils and 4.2% in talus fines, contains most of the Au, Ag, Pb, Zn, and Mo anomalies on the eastern mapsheet (Fig. 7W). The regional Al pattern follows As and Fe distributions, although the Al pattern is the most outstanding. Al enhancements to the 5 to 6.5% range is homogeneous in the Raven Creek area. Levels are slightly lower, in 4 to 6% range, along East Emer Ridge and are slightly greater, at 4% to 9%, north and east of Granite Basin. Bloom Cirque and Porphyry Creek anomalies (Fig. 6W) are not within an Al-rich environment; although in detail, an Al-rich (3.3% to 4.0%) zone accompanying V, Mg and Ti crosscuts the Bloom Cirque (Fig. 8U).

Al is an element which can control quality of the survey if results are heterogeneous. Survey quality here is probably not being adversely affected by erratic scavenging by clay minerals.

24. Potassium (Fig. 6X, 7X, 8X)

K contents are higher in talus fines than in soils (thresholds of 0.35% versus 0.25%, respectively). Anomalous conditions are well developed (i.e., high contrast) associated with the Mo anomaly along Porphyry Creek (Fig. 6X), with Cu zones around Bloom Cirque (Fig. 6X, 8X) and associated with Au and Cu anomalies at Raven Creek (Fig. 7X). Exceptional enhancement between West and East Croydon Creeks (North Fork) overlies at least a 4 km<sup>2</sup> area and corresponds with anomalous conditions in the distribution of Pb, Mo, Ba, Sr and Ca. Anomaly development of 0.5% to 1.0% is relatively strong compared to backgrounds of less than 0.1%. K enrichment is also typical of the Granite Basin and areas to the north of Granite Basin (Fig. 7X). The high levels of K

enhancement within anomalous zones is unusual, and if not determined to be an analytical artifact, reflects K-rich bedrock.

Low K levels of less than 0.1% are widespread. These characterize much of the West Croydon Creek valley (Fig. 6X), the Kliyul Creek valley (Fig. 6X, 7X) (except in association with the Kliyul Creek pluton in the extreme southwest), East Raven Creek (Fig. 7X), and the region between and within North and South Sarah Cirques (Fig. 7X).

25. **Titanium** (Fig. 6Y, 7Y, 8Y)

Ti backgrounds are about the same in soils as in talus fines. Two major zones of Ti enrichment some 2 km<sup>2</sup> in area, are found in the West Croydon Creek drainage (Fig. 6Y) and in North Sarah Cirque - East Raven Creek Area (Fig. 7Y). Maximum values exceed a threshold of about 0.25% to 0.5%. A similarly sized zone with a somewhat reduced contrast (maximum values in the 0.2% to 0.4% range) lies along the east end of Croydon Ridge (Fig. 6Y). Ti-rich zones are typically remote from base, precious, or pathfinder element anomalies, although in Bloom Cirque some coincidence is noted (Fig. 8Y). Low Ti backgrounds primarily lie along the banks of Kliyul Creek.

26. **Phosphorus** (Fig. 6Z, 7Z, 8Z)

P contents are higher in talus fines than in soils. Backgrounds are extremely low at less than 0.07% west of West Croydon Creek (Fig. 6Z).

P contents are exceptionally enriched south of Bloom Cirque (Fig. 6Z), following Sr. The P anomaly exhibits high contrast but is larger than the Sr feature, extending up to 1 km further eastward. Bloom Cirque proper is characterized by high P concentrations (0.13 to 0.25%) in the cirque headwalls, but low backgrounds (<0.11%) on the valley floor (Fig. 8Z).

P contents are anomalous within the midst of the Raven Creek grid area, centring on Raven Knoll (Fig. 7Z), correlating with Cu, Mo, Fe and Co. P backgrounds are exceptionally enhanced on East Emer Ridge and at lower elevations of South Sarah Cirque. The former feature covers a multielement anomaly but is much larger than base, precious and pathfinder element features whereas the latter P-rich zones is not accompanied by base or precious metal anomalies. P enrichment is common south of Granite Basin (Fig. 7Z), following Zn, Mn and Sr, but haloing anomalous conditions in the Cu, Pb, Ag, Mo, W, Fe, Co, Ni, Ba and Mo distributions. Low P concentrations, <0.055 %, occupy low ground east-southeast of Raven (Fig. 7Z).

27. **Lanthanum** (Fig. 6AA, 7AA, 8AA)

The La distribution is dominated by high backgrounds (Fig. 6AA) associated with the Kliyul Creek pluton. La levels can also be high at North Fork, associated with a dioritic intrusion (Fig. 6AA). Otherwise, most La contents report at less than 6 ppm (Fig. 7AA, 8AA).

28. **Beryllium** (Fig. 6BB, 7BB, 8BB)

Be levels appear anomalous in the midst of the Pb anomaly on the west side of Bloom Cirque (Fig. 6BB, 8BB). Values are elevated within the Porphyry Creek valley (Fig. 6BB), but many of these high concentrations may be due to a peculiarity associated with the analysis. Be backgrounds for much of the 1991 analyses are much lower than 1990 backgrounds. This artifact can be seen east-southeast of Raven (Fig. 7BB) and around Granite Basin (Fig. 7BB) where values report under 2 ppm compared to 2 to 5 ppm in 1990. Little significance is attached to the Be anomalies.

29. **Sodium** (Fig. 6CC, 7CC)

Na was not determined in 1990. Results from 1991 are dominated by an outstanding positive feature exceeding a threshold of 0.12 to 0.13% to 0.2 to

0.4% at the mouth and north of Granite Basin (Fig. 7CC). The Na anomaly is unusual for the high concentrations seen for this element which follows Ca, pH and Al in its distribution. Above detection limit Na contents were not seen in Bloom Cirque.

### **Discussion of Results**

Geochemical reconnaissance of the Porphyry Creek project, involving contour traverses around the mountainous slopes, has defined a number of outstanding precious and base metal anomalies meriting followup (Fig. 9 & 10) in a geochemically interesting environment (Fig. 11, 12). Local conditions of the overburden and an absence of erratic data suggest localization of mineralized occurrences in bedrock will be relatively straightforward. Anomalies are large, many having dimensions over 1 km across, and exhibit extreme contrast. They are described below, from west to east, and are priority rated:

1. Porphyry Creek Anomaly: The anomalous Au zone is 1.5 km long by 0.5 km wide at the headwaters of Porphyry Creek and is accompanied by smaller zones of Cu accumulation. In part, the Cu and Au anomalies appear related to the contact of the Mo porphyry in the east and the anomaly may be the eastern extension of the SOUP magnetic skarn. Most of the Au and Cu-rich zones lie remote from rocks rich in Ni and Cr. This anomaly is considered in more detail in a companion report on the Porphyry Creek grid.
2. Porphyry Creek Mo-W-K Anomaly: This known porphyry Mo deposit is haloed by Cu, Au and Pb anomalies. Many of the metal concentrations for the multielement soil/talus fine survey are low in this area which is highlighted by an outstanding Mo anomaly 2 km long and 1 km wide. The Mo anomaly is described in more detail in the Porphyry Creek report.

3. North Fork Anomaly: Only weak Au, Cu and Ag anomalous zones are defined within a very large block of ground which is associated with substantial Pb and Mo accumulation in a geological environment rich in Ba, Sr, Ca and K. The southeastern margin of the anomalous zone is marked by a striking Mn anomaly. The multielement anomaly is underlain by a diorite along the East Croydon Creek valley intruding Takla volcanics in the hills around the valley. Priority 2
4. Bloom Cirque Anomaly: The Bloom Cirque anomaly is a multielement feature comprising Cu, Au, Ag, Mo, Co, Pb, and Zn with weak As haloing the northeast corner of the zone. The Cu anomaly at 2 km by 2 km is the largest of the anomalous zones. The Au zone appears to have northeasterly and northerly components. Ag is generally anomalous to the west of the Au zone and correlates with Mo. Mo has accumulated on three zones through the centre of the anomaly whereas Co focuses on the west side of the Cu feature and Pb, Zn and Mn lie to the north.

Three centres of K enhancement lie to the north and on the east and west sides of Bloom Cirque within the Cu anomaly, but at the margins of the Au zones. A Sr-P anomaly on the southwest side of Bloom Cirque lies mainly outside the Cu anomaly but is associated with two Au zones. Sr also accompanies Au in the east of Bloom Cirque. Ba accumulation within the Cu anomaly in the northwest of Bloom Cirque lies west of the northward trending Au anomaly. The northern limit of base and precious metal anomalies overlaps a major Ni-Cr-Mg-rich zones probably reflecting mafic volcanics which characterize a 5 km long block of ground up to 1.5 km wide north of Bloom Cirque. Priority 1.

5. Raven Creek Anomaly: Au, Ag, As, Cu, Pb, Zn, Cd, Mo, Fe, Mn and Co anomalies in an environment which is dominated by high Al, with Mg-Ti enhancement to the west and Ti enhancement to the east. The Raven Creek zone marks the western end of a northwesterly Fe trend. Raven Knoll focuses K, Sr

and P anomalies which may be alteration related. The Raven Creek reconnaissance anomaly has been followed up by a detailed soil grid (Hoffman, 1990) and that work indicated how detailed sampling can materially change geochemical patterns for elements such as Cu which do not form impressive anomalies on the basis of regional results. Priority 1.

6. East Emer Ridge Anomaly: This 1 km<sup>2</sup> area is associated with anomalous concentrations of Au, Ag, As, Cu, Pb, Zn, Mn and Co. East Emer Ridge is part of the throughgoing Fe and Al northwesterly trending anomalous zone. Base and precious metal anomalies lie in P-rich environment haloed by elevated Ti values. The southern limit of the anomaly is marked by Mn-Ba accumulation whereas a weak K anomaly lies to the northern limit of sampling. Priority 1.
7. West South Sarah Cirque Anomaly: The zone is about 1 km by 1 km in size associated with very reconnaissance sampling. Elements of interest include Au, weak Cu, Pb, Zn, Mo and Co. The western limit of the anomaly is found in an As-Ni-rich environment, accompanied by Ba enhancement. Priority 2.
8. Granite Basin Anomaly: The Granite Basin area is associated with substantial enhancements in many elements. Au anomalies are located near the entrance to the Granite Basin Cirque, overlapping Cu to a limited extent. The Cu anomaly is a large, low contrast feature which includes the hilltop to the west. Much of the Cu pattern is probably rock related, associated with volcanic rock types high in Ni, Mg, (probably Cr), Co, Zn, and Ca. This portion of the anomaly is not considered to have much potential for reflecting an alkalic Cu-Au porphyry system.

The Au anomaly is accompanied by Ag, As, some Cu (as noted above), Mo, Pb, Zn, Cd, W and Co and lies within or marginal to the prominent Fe-Al northwesterly linear. The anomalous zone is flanked to the west and north by

Mg-Ba anomalies, perhaps reflecting alteration. The zone is accompanied by K, Ca, Na and Sr. Priority 1.

Geochemical anomalies as defined are major zones of metal accumulation. The mountainous terrain is normally associated with locally derived overburden comprising talus, talus fines, and colluvium at higher elevations, and valley fill comprising alluvium, thicker colluvium, and outwash deposits along the valley floors. Lateral moraines and till deposits can also be found in the valley bottom environment.

Regional patterns are identified which are probably lithologically controlled. These include:

1. Fe, Al and As: Enhancement zone trends northwestward across the eastern half of the project over about a 1 to 1.5 km width for a distance of 8+ km.
2. Ni, Cr, and Mg: Extreme contrast is seen amongst data for these elements, suggesting rock type variations. These are found north of Bloom Cirque, east of Bloom Cirque, and in the Granite Basin area.
3. Ba, Sr, La, negative V, negative Mg and negative Ca: The Kliyul Creek pluton has this distinctive geochemical signature.
4. Cr, weak Ni, V, Ti and negative P: The area north of the Porphyry Creek intrusion has this geochemical signature. The relationship between Cr and Ti is zoned.
5. Sr, Ca, K and P: A block of ground south of Bloom Cirque is distinctive in geochemical character. A similar signature is found in the Raven Creek area.

6. Zn, V, Ba, Sr, Ca, alkaline pH, K and Na: Some of this signature may be related to mineralization, but high levels of Ca, alkaline pH and Na are distinctive of the northern portions of the Granite Basin mountain range; the signature also seen in part on East Emer Ridge.

In view of the fact significant artifacts have not been introduced by the process of sampling, geochemical data can be interpreted in a relatively straightforward manner. Several observations assume fundamental importance in the interpretation process, namely:

1. The Raven Creek reconnaissance program in 1990 defined weak Cu and Ba anomalies in an area where subsequent detailed work has outlined large and strongly anomalous conditions.
2. The Porphyry Creek grid program of 1991 produced the same conclusions as seen in 1990 at Raven Creek (i.e. detailed work resulted in definition of more outstanding geochemical anomalies than was apparent in regional work).
3. The Sr anomaly south of Bloom Cirque is a high contrast feature on the upper regional traverse, but is apparently not displaced 250 m to 400 m downslope. This establishes a maximum limit for downslope mechanical dispersion, and
4. The grid soil survey in Bloom Cirque proper established that downslope dispersion probably does not extend more than 100 m, as seen by marked contrast in the distribution of elements such as Pb, Zn and Ni. The V-Al-Ti distributions which are marked by at least 2 times background linear anomalies trending east-west across Bloom Cirque, and a negative Mg-V anomaly immediately to the north, demonstrate that landsliding or colluvial action are not transporting metal much more than 100 m down to the Bloom Cirque valley (to the south).

The regional sampling program does not provide exhaustive evaluation of the Porphyry Creek project area. For example, major valley bottoms have not been sampled. With this limitation in mind, it can be assumed that the sampling program has identified major mineralized zones. Additional reconnaissance sampling is still warranted in 1992, but at a lower intensity compared to followup efforts of existing anomalies.

Elements of importance in the alkalic model and typically anomalous concentrations in overburden, synthesized from observations at Mount Milligan, QR, Cat Mountain and other alkalic porphyry prospects and properties and related to the Porphyry Creek project area include the following:

1. Cu contents in soils are in the 150 to 500 ppm range. Higher values, to the 1000 ppm and greater level, may be prominent in talus fine environments. Exceptionally high Cu ( $> 500$  ppm) and Ag contents occurring in isolated samples which are Ca-enriched are probably representative of false anomalies. These are not significant here in view of the absence of organic matter at most sites. All eight regional anomalies have a Cu association.
2. Au contents in soils are in the 40 to 100's of ppb, with the occasional value exceeding 1000 ppb. Au anomalies tend to be very large at a 40 ppb threshold. The Porphyry Creek project is associated with eight areas where Au concentrations meet these criteria.
3. As, acting as a pathfinder element, is documented at QR and appears to be acting in a similar fashion at Mount Milligan and in part at Cat Mountain. As anomalies are peripheral or lie above prospective alkalic Cu-Au targets, often occurring with peripheral vein-type mineralization (with Sb). Caution must be exercised in evaluating As anomalies, as geological units may be enriched in this element independent of Au. As spatially haloing Au and/or Cu anomalies is documented at four locations on the Porphyry Creek project.

4. Mo anomalies are documented at all alkalic Cu-Au targets, typically near the centre of mineralization. Mo enhancement probably reflects acidic intrusion accompanying the mineralization. Again, caution needs to be exercised in examining Mo results, as rock types such as argillites can contain high backgrounds of this element. Mo anomalies in soils are present in seven of the Cu-Au-rich zones.
5. Co was first noted at QR, but is prominent in soils at Mount Milligan, Cat Mountain, and at a number of other alkalic Cu-Au prospects and properties. Co can be scavenged to abnormal levels by Mn, and the distribution of the latter element needs to be examined to ensure Co anomalies are not artifacts. Enhanced Co contents on the Porphyry Creek project are not being scavenged by Mn, and are noted in association with five of the Cu-Au anomalies. Co levels at Bloom Cirque where cobalt bloom has been noted is not the highest of the survey and additional occurrences of Co mineralization are to be expected.
6. Fe and V anomalies are common at alkalic Cu-Au prospects. High Fe concentrations probably reflect large quantities of Fe sulphide or oxides, and high V contents reflects V substituting for Fe in the Fe-bearing minerals. Both Fe and V distributions can also be controlled by rock type. Fe, V and As anomalies associated or haloing Cu-Au-rich zones are found at three target locations.
7. Mn enhancement in soils is typically variable as a consequence of sampling factors. Mn content in bedrock surrounding alkalic porphyry occurrences can be quite high, and if sampling is not a factor, the Mn halo can be transferred to soils in a recognizable fashion. This is probably the case here where high Mn contents lie along the south side of Raven and East Emer Ridge, and on the north side of Bloom Cirque.

8. Pb and Zn may be present in minor amounts as galena and sphalerite with Cu-Au ore as seen at QR, West Zone, or they may be found in enhanced abundances at the margins of the Cu-Au zones. The Pb-Zn anomalies at North Fork, Granite Basin, East Emer Ridge, north of Bloom Cirque, and at South Sarah Cirque may be reflecting a halo condition. Alternatively, they may be indicating a Pb/Zn potential which could be the subject of continued exploration.
9. Enhanced Al contents, if not being controlled by overburden composition, may be indicating clay alteration associated with peripheral parts of an alkalic deposit. Al enhancement may compliment As in these cases. Al anomalies along the eastern margin of the survey area are large, exhibit outstanding contrast, and are associated with Fe and gossans in addition to accompanying As. A geological explanation is required to determine if the Al distribution is reflecting clay alteration associated with the mineralizing process.
10. K enrichment is one of the main alteration products of alkalic Cu-Au porphyry deposits, but elevated aqua regia leachable K contents are commonly seen only if the K is in the form of clay minerals or biotite. Thus K anomalies would appear as halos to mineralized zones. K anomalies may also develop in response to K-rich intrusive rocks if these are well weathered. K anomalies are prominent on the Porphyry Creek project, being found on seven of the eight targets (only South Sarah Cirque does not have a positive K signature). A geological explanation is needed for these findings.
11. Ca (and pH) and Sr can be present in carbonate altered rocks, if present in abundance, these elements are transferred to the overlying soil. Ca and Sr are also two key indicators of sample quality, and artifacts must be recognized and discounted before rock type or alteration patterns are interpreted from the data. These are not noted on the Porphyry Creek project. Sr and Ca levels can also be controlled by rock type, and in part this is probably true here. Sr/Ca reflecting

alteration is suspected at North Fork, Raven, Granite Basin and Bloom Cirque. Ca/Sr reflecting rock type, with or without Na, is likely at Granite Basin and East Emer Ridge.

Guidelines established by work at Raven Creek and Bloom Cirque suggest geochemical dispersion is limited, perhaps to under 200m. Glacial transport of material has to be suspected, particularly the occurrence of lateral moraines which indicate dispersion parallel to slope rather than down slopes. The rugged topography mitigates easy establishment of grids to control soil geochemical or ground geophysical surveys. Nevertheless, anomalies as defined represent potentially significant mineral occurrences, and followup needs to proceed. If additional reconnaissance would better delineate targets to more manageable sizes, they should be conducted early in the program in 1992. For example, two additional reconnaissance lines at 300 m intervals is suggested to extend eastward at Granite Basin. Other regional traverses are indicated on Fig. 13. Most of these lie outside current land holdings. Nevertheless, they are warranted and maybe responsible for acquisition of additional claims by staking or option.

Followup of existing anomalous conditions is described below, in the order of the numbering scheme of anomalies described at the beginning of this section (Fig. 13):

1. Porphyry Creek Au-Cu anomaly: This anomaly was followed up in 1991 by a soil grid comprising some 2401 samples. Results and findings are described in a companion report (Hoffman , 1991).
2. Porphyry Creek Mo-W-K anomaly: This anomaly was also covered by the Porphyry Creek grid in 1991. Results and findings are found in the same companion report mentioned in (1) above.
3. North Fork anomaly: This zone was discovered in 1991 and is characterized by outstanding distributions of Pb and Mo. Unfortunately, anomalous conditions for

Cu and Au are very limited in size and restricted to the southeastern and for Cu the northwestern portions of the anomalous area. The character of an anomalous element suite might be indicators of alteration, including Mn, Ba, Sr, Ca and K, or it may be related to a dioritic intrusion along the floor of North Croydon Creek.

Reconnaissance traverses are recommended to the west of the existing anomaly. A soil grid is suggested to cover the Au-Cu-Ag anomaly in the southwest. The area of interest to be covered by grid work is about a 1 km<sup>2</sup> area (Fig. 13A), with a baseline trending up and down slopes at about a 030 bearing and crosslines running approximately parallel to slopes. The entire anomalous zones merits a close geologic inspection, with prospecting for mineralization, alteration, and structure important aspects of the followup program.

4. Bloom Cirque anomaly. Bloom Cirque was evaluated in 1991 by 159 sample soil grid along the bottom of the valley. Rugged topography has mitigated additional soil or talus fine sampling of this 4 km<sup>2</sup> anomaly. Some additional regional sampling is nonetheless recommended, attempting to establish a line spacing of 200 m, particularly in the North Sarah Cirque and the mouth of Bloom Cirque (Fig. 13A). Results may suggest positioning of a grid in the headwalls of North Sarah Creek.

Topography limits sampling of overburden beyond what has been done or recommended. An outstanding anomaly exists, and logistics effectively prevent grid geochemical or geophysical surveys to continue the evaluation to identify the position of the best zones of mineralization. Physical work involving trenching is suggested to be prime followup procedure.

Substantial anomalous conditions exist for Au, Ag, Cu, Co and other elements. These need to be quantified by bedrock sampling. An extensive diamond drill

program would accomplish this objective at great cost. As an intermediate function, chip sampling to produce composite samples representing 5 m of ground should be undertaken in proximity to reconnaissance soil/talus lines where these are anomalous. Hand trenching and blasting probably are needed to provide continuous rock exposure. Each rock sample would weigh about 5 kg. Sampling would extend in a horizontal direction for the most part, although selected vertical transects are also needed, probably along creek channelways where bedrock is well exposed.

Continuous chip sampling must consider both mineralized and apparently barren country surrounding mineralized zones to establish alteration and halo anomaly indicators. Mapping geology and alteration would accompany sampling, as would identifying structures which may be controlling mineralization. Figure 13A suggests the approximate location of some of the needed trenches, although in detail their locations would be established in the field based on outcrop exposure and ease of access.

The existing grid within Bloom Cirque should be surveyed using a ground magnetometer, lines extending up the hill to the east, if possible. Mapping and prospecting of anomalous zones, in conjunction with the magnetic survey, might define drill targets.

5. Raven Creek anomaly: Followup was undertaken over the main portion of the anomaly in 1990. Recommendations for additional work were issued at that time (Hoffman, 1990; Grexton and Roberts, 1990). Several additional reconnaissance lines in 1991 suggest a 200 to 300 ppm Cu anomaly lies along the floor of the creek draining North Sarah Cirque. Sufficient interest exists in this region by virtue of acidic soils ( $\text{pH} < 4.8$ ) which should be promoting leaching of Cu from soils to encourage a grid soil survey to be positioned in conjunction with the northwestern portion of the East Emer Ridge anomaly (to be described below).

The area of interest would be about a 1.5 km<sup>2</sup> area (Fig. 13B) and a sample interval of 50 m is recommended, closing to 25 m only in proximity to East Emer Ridge. The baseline would be established at approximately 135°. Geophysical surveys would also be conducted over the soil grid.

6. East Emer Ridge anomaly: Grid soil sampling using a 25 m sample interval is recommended to cover the east and northeast side of East Emer Ridge, forming part of the soil grid described above (Fig. 13B). The grid survey would extend to the creek draining South Sarah Cirque. Geophysical surveys would include this grid extension.

In addition to soil work, it is suggested one line of rock chip sampling be undertaken. Procedures would follow those described for Bloom Cirque.

7. West of South Sarah Cirque. The area would be efficiently evaluated by a soil grid (25 m by 100 m density) of about 0.8 km<sup>2</sup> along the valley bottom of South Sarah Cirque (Fig. 13B). Additional reconnaissance sampling is warranted along the south and west cirque wall of the South Sarah Cirque, at several elevations where logistics permit such work.
8. Granite Basin: Much of Granite Basin lies outside the land-holding. Nevertheless, reconnaissance lines have been suggested to fully delineate anomalous conditions (Fig. 13B). A bedrock chip sampling line has been suggested within held lands.

The Porphyry Creek project has progressed to the point where one target, Bloom Cirque, has been established as a zone where bedrock metal values across specific widths need to be determined. Hand positioned trenches, assisted by geological mapping and prospecting are suggested preliminary to diamond drilling at the best zone thus defined. Limited but similar programs are suggested for East Emer Ridge and Granite Basin.

Three soil and geophysical grids have been recommended to cover the North Fork, Emer Ridge and South Sarah Cirque anomalies. Extension of the East Emer Ridge grid to the base of the Granite Basin mountain range awaits results of a reconnaissance traverse. Geophysical work is suggested for Bloom Cirque. Additional reconnaissance traversing is indicated in the Granite Basin area and around the South Sarah Cirque and North Fork grids. Table 1 summarizes anomalous conditions and followup recommendations. Continued exploration is highly recommended.

**Table 1**  
**Summary of Au ± Cu Anomalies,**  
**Porphyry Creek Project, 1990-1991**

Anomaly Number	Anomaly Name	Element Association	Followup Recommended
1.	Porphyry Creek Cu-Au	Cu, Au	Porphyry Creek Grid (completed 1991)
2.	Porphyry Creek Mo	Mo, Cu, Au, W, K	Porphyry Creek Grid (completed 1991)
3.	North Fork	Cu, Au, Pb, Ag, Pb, Mo, Ca, Ba, Sr, K, Mn-halo south	Soil Grid - 400 samples Reconnaissance - 5 km
4.	Bloom Cirque	Cu, Au, Co, Ag, Mo, Pb, Zn, K, Sr, P, Ba, Mn	Reconnaissance - 5 km Trenches 5.5 km
5.	Raven Creek	Au, Cu, As, Ag, Mo, Pb, Zn, Mn, Co Al, Fe, P, Mg, K, Sr	Raven Grid (completed 1990) East Raven Grid-400 samples
6.	East Emer Ridge	Au, Cu, As, Ag, Co, Pb, Zn, Mn Al, Fe, P, Ba, Ca	East-East Emer Ridge Grid - 200 samples Trenches - 1.5 km
7.	South Sarah Cirque	Cu, Au, As, Pb, Zn, Mo, Co Ba	Grid - 350 samples Reconnaissance - 3 km
8.	Granite Basin	Cu, Au, As, Ag, As, W, Pb, Zn, Co Al, Fe, Sr, Ca, Na, K halos by Mg, Ba	Reconnaissance - 7.5 km Trench - 0.75 km

### Conclusions

Regional reconnaissance of the Porphyry Creek project area in 1990 and 1991 has led to definition of eight major anomalies meriting followup. Each has Au and Cu potential, as well as being associated with one or more of Ag, Pb, Zn, Co, Mo and W anomalies. Additional work is required to outline anomalous conditions using regional and grid soil geochemical surveys, the latter complimented by ground magnetics and IP. Lithogeochemical sampling, complimented by mapping and prospecting, is given high priority to establish diamond drill targets.

# RUSSBACHER LABORATORY LTD.

## CERTIFICATE OF ANALYSIS

2225 Springer Ave., Burnaby,  
British Columbia, Can. V5B 3N1  
Ph:(604)299-6910 Fax:299-6252

To : TECK EXPLORATIONS LTD.  
# 960-175 SECOND AVE.  
KAMLOOPS, B.C.

Project: 1384

Type of Analysis: ICP

**Certificate:** 91196 A  
**Invoice:** 20339  
**Date Entered:** 91-08-01  
**File Name:** TEK91196.A  
**Page No.:** 2

# ROSSBACHER LABORATORY LTD.

## CERTIFICATE OF ANALYSIS

To : TECK EXPLORATIONS LTD.  
# 960-175 SECOND AVE.  
KAMLOOPS, B.C.

Project: 1384

Type of Analysis: ICP

2225 Springer Ave., Burnaby,  
British Columbia, Can. V5B 3N1  
Ph:(604)299-6910 Fax:299-6252

**Certificate:** 91198.1  
**Invoice:** 20347  
**Date Entered:** 91-08-09  
**File Name:** TEK91198.I  
**Page No.:** 3

# ROSSBACHER LABORATORY LTD.

## CERTIFICATE OF ANALYSIS

To : TECK EXPLORATIONS LTD.  
# 960-175 SECOND AVE.

KAMLOOPS, B.C.

Project: 1384

Type of Analysis: ICP

2225 Springer Ave., Burnaby,  
British Columbia, Can. V5B 3N1  
Ph:(604)299-6910 Fax:299-6252

**Certificate:** 91212  
**Invoice:** 20351  
**Date Entered:** 91-08-17  
**File Name:** TEK91212.I  
**Page No.:** 7

# ROSSBACHER LABORATORY LTD.

## CERTIFICATE OF ANALYSIS

2225 Springer Ave., Burnaby,  
British Columbia, Can. V5B 3N1  
Ph:(604)299-6910 Fax:299-6252

To : TECK EXPLORATIONS LTD.  
# 960-175 SECOND AVE.

KAMLOOPS, B.C.

Project: 1384

Type of Analysis: ICP

**Certificate:** 91212  
**Invoice:** 20351  
**Date Entered:** 91-08-17  
**File Name:** TEK91212.I  
**Page No.:** 10

# ROSSBACHER LABORATORY LTD.

## CERTIFICATE OF ANALYSIS

To : TECK EXPLORATIONS LTD.  
# 960-175 SECOND AVE.  
KAMLOOPS, B.C.

Project: 1384

Type of Analysis: ICP

2225 Springer Ave., Burnaby,  
British Columbia, Can. V5B 3N1  
Ph:(604)299-6910 Fax:299-6252

**Certificate:** 91225 B  
**Invoice:** 20370  
**Date Entered:** 91-08-25  
**File Name:** TEK91225.B  
**Page No.:** 4

# ROSSBACHER LABORATORY LTD.

## CERTIFICATE OF ANALYSIS

To : TECK EXPLORATIONS LTD.  
# 960-175 SECOND AVE.  
KAMLOOPS, B.C.

Project: 1384

Type of Analysis: ICP

2225 Springer Ave., Burnaby,  
British Columbia, Can. V5B 3N1  
Ph:(604)299-6910 Fax:299-6252

**Certificate:** 91225 C  
**Invoice:** 20370  
**Date Entered:** 91-08-25  
**File Name:** TEK91225.C  
**Page No.:** 2

# ROSSBACHER LABORATORY LTD.

## CERTIFICATE OF ANALYSIS

To : TECK EXPLORATIONS LTD.  
# 960-175 SECOND AVE.  
KAMLOOPS, B.C.

Project: 1384

Type of Analysis: ICP

2225 Springer Ave., Burnaby,  
British Columbia, Can. V5B 3N1  
Ph:(604)299-6910 Fax:299-6252

**Certificate:** 91225 D  
**Invoice:** 20370  
**Date Entered:** 91-08-25  
**File Name:** TEK91225.D  
**Page No.:** 2

# **ROSSBACHER LABORATORY LTD.**

## **CERTIFICATE OF ANALYSIS**

**To :** TECK EXPLORATIONS LTD.  
# 960-175 SECOND AVE.  
KAMLOOPS, B.C.

**Project:** 1384

**Type of Analysis:**

**Type of Analysis:**

2225 Springer Ave., Burnaby,  
British Columbia, Can. V5B 3N1  
Ph:(604)299-6910 Fax:299-6252

**ertificate:** 91225 D  
**Invoice:** 20370  
**Date Entered:** 91-08-25  
**File Name:** TEK91225.D  
**Page No.:** 5

# ROSSBACHER LABORATORY LTD.

## CERTIFICATE OF ANALYSIS

To : TECK EXPLORATIONS LTD.  
# 960-175 SECOND AVE.

KAMLOOPS, B.C.

Project: 1384

Type of Analysis: ICP

2225 Springer Ave., Burnaby,  
British Columbia, Can. V5B 3N1  
Ph:(604)299-6910 Fax:299-6252

**Certificate:** 91225 E  
**Invoice:** 20370  
**Date Entered:** 91-02-25  
**File Name:** TEK91225.E  
**Page No.:** 5

**APPENDIX 2**

**ANALYTICAL PROCEDURES**

Jan. 1991.

GEOCHEMICAL ANALYTICAL METHODS CURRENTLY IN USE AT  
ROSSBACHER LABORATORY LTD.

A. SAMPLE PREPARATION

1. Geochem. Soil and Silt:

Samples are dried and sifted to minus 80 Mesh,  
through stainless steel or nylon screens.

2. Geochem. Rock:

Samples are dried, crushed to minus 1/4 inch,  
split, and pulverized to minus 100 mesh.

B. METHODS OF ANALYSIS

1. Multi element: (Mo, Cu, Ni, Co, Mn, Fe, Ag, Zn, Pb, Cd, As):

0.50 Gram sample is digested for four hours with  
a 15:85 mixture of Nitric-Perchloric acid. The  
resulting extract is analyzed by Atomic Absorbtion  
spectroscopy, using Background Correction where  
appropriate.

2. Antimony:

0.50 Gram sample is fused with Ammonium Iodide and  
dissolved. The resulting solution is extracted into  
TOPO/MIBK and analyzed by Atomic Absorbtion spectro-  
scopy.

3. Arsenic: (Generation Method)

0.25 Gram sample is digested with Nitric-Perchloric  
acid. Arsenic from the solution is converted to arsine,  
which in turn reacts with silver D.D.C. The resulting  
solution is analyzed by colorimetry.

4. Barium:

0.20 Gram sample is repeatedly digested with HC1O<sub>4</sub>-  
HNO<sub>3</sub> and HF. The solution is analyzed by atomic absorbtion  
spectroscopy.

5. Biogeochemical:

Samples are dried and ashed at 550°C. The resulting  
ash analyzed as in \*1, Multielement Analysis.

6. Bismuth:

0.50 Gram sample is digested with Nitric acid. The  
The solution is analysed by Atomic absorbtion spectroscopy.

## METHODS OF ANALYSIS (CONT'D)

### 7. Chromium:

0.25 Gram sample is fused with Sodium Peroxide. The solution is analyzed by atomic absorption spectroscopy.

### 8. Fluorine:

0.50 Gram sample is fused with Carbonate Flux, and dissolved. The solution is analysed for Fluorine by use of an Ion Selective Electrode.

### 9. Gold AR/AAS:

10.0 Gram sample is roasted at 550°C and dissolved in Aqua Regia. The resulting solution is subjected to a MIBK extraction, and the extract is analyzed for Gold using Atomic Absorption spectroscopy.

### 9A Gold FA:

10.0 Gram sample is fused with appropriate fluxes, and the resulting lead button is cupelled to produce a gold/silver bead. The bead is dissolved in Aqua Regia and analyzed for gold by AAS.

### 10. Mercury:

1.00 Gram sample is digested with Nitric and Sulfuric acids. The solution is analyzed by Atomic Absorption spectroscopy, using a cold vapor generation technique.

### 11. Partial Extraction and Fe/Mn oxides:

0.50 Gram sample is extracted using one of the following: hot or cold 0.5 N. HCl, 2.5% E.D.T.A., Ammonium citrate, or other selected organic acids. The solution is analyzed by use of Atomic Absorption spectroscopy.

### 12. pH:

An aqueous suspension of soil, or silt is prepared, and its pH is measured by use of a pH meter.

### 13. Rapid Silicate Analysis:

0.10 Gram sample is fused with Lithium Metaborate, and dissolved in HNO<sub>3</sub>. The solution is analyzed by Atomic Absorption for SiO<sub>2</sub>, Al<sub>2</sub>O<sub>3</sub>, Fe<sub>2</sub>O<sub>3</sub>, MgO, CaO, Na<sub>2</sub>O, K<sub>2</sub>O, TiO<sub>2</sub>, P<sub>2</sub>O<sub>5</sub>, and MnO.

### 14. Tin:

0.50 Gram sample is sublimated by fusion with Ammonium Iodide, and dissolved. The resulting solution is extracted into TOPO/MIBK and analysed by atomic absorption spectroscopy.

**15. Tungsten:**

1.00 Gram sample is sintered with a carbonate flux, and dissolved. The resulting extract is analyzed colorimetrically, after reduction with Stannous Chloride, by use of Potassium Thiocyanate.

**16. ICP :**

0.5 Gram sample is digested with Aqua Regia, and analyzed using a JOBIN YVON MODEL JY 32 1987 ICP Emission Spectrophotometer for Ag, Al, As, Au, B, Ba, Be, Bi, Ca, Cd, Co, Cr, Cu, Fe, Hg, La, Mg, Mo, Mn, Ni, P, Pb, Sb, Si, Sr, Ti, U, V, W, Zn.

**APPENDIX 3**

**METHOD OF HISTOGRAM INTERPRETATION**

## METHOD OF HISTOGRAM INTERPRETATION

### RULES FOR CHOICE OF SIZE CODING OR CONTOURING INTERVALS

1. Examine both arithmetic and logarithmic histograms for each geochemical survey. Choose the histogram which most closely approximates a normal (or lognormal) distribution. If several populations are present on the histograms, subjectively divide the data into a series of (overlapping?) normal or lognormal distributions. Always avoid interpreting histograms which are strongly skewed. Portions of arithmetic or logarithmic histograms may be chosen over specific metal concentration intervals, if this allows for the best portrayal of the data in graphical form.
2. Choose, as two of the coding intervals, points which represent between 90% and 95%, and 95% and 97.5% of the data; two different numbers. These choices highlight from 1 in 10 to 1 in 20 samples which are considered slightly anomalous and definitely anomalous, respectively. These limits are optimistic in that the two categories are defined to be anomalous regardless of the distribution of values on the remainder of the histograms. A rigorous statistical approach would suggest that only values above the 97.5 percentile should be considered anomalous. Choice of any of the above percentiles is entirely subjective and meant to highlight the highest values of the survey.
3. Divide the remaining portion of the histogram into recognizable populations. The dividing point of each of these populations is chosen as a coding interval. Artifacts introduced as a consequence of detection limit considerations are ignored. These artificial breaks in the histograms can be recognized by referring to the laboratory reports and scanning data results.
4. For each population, choose one or two numbers which correspond to the 90% and 95% cumulative frequencies for the population (1 in 10 and 1 in 20 samples for that population). These will also be used to represent anomalous conditions for each population. Coding intervals can be no closer than 2X the detection limit for each element being considered.
5. A maximum of six numbers can be chosen to plot symbol maps. This number is dictated by the ability to present data in graphical form with sufficiently different symbol sizes for them to be easily distinguishable, particularly if maps are to be reduced. The seven defined concentration classes are normally sufficient to represent geochemical data on a map. More intervals can be chosen if data are to be contoured. Avoid choosing arithmetic intervals without considering rules (1) and (4).

6. Maps plotted using the preceding instructions might result in two areas being distinguished from each other by a relatively uniform density of symbol sizes, yet only poor contrast anomalies are indicated. Difference between the two areas, A and B, might be due to underlying geology, overburden character, soils etc. Whatever the cause, the data are not well displayed. If the underlying control distinguishing A and B can be recognized, the data can be divided and reinterpreted following steps (1) to (5). Two sets of maps can be drawn, or both sets of interpreted data can be plotted on a single map. For such superimposed geochemical maps, symbol sizes lose their absolute meaning but assume a more important stance, that of reflecting anomalous conditions regardless of the underlying control. To illustrate, consider the case where A and B are areas underlain by very different geology. Anomalous conditions for low background rock types might be concentrations which are much lower than average values for the high background rock types. Nevertheless, anomalies defined in each area are considered significant. Reliance on absolute concentrations can be misleading in such cases.

**APPENDIX 4**

**STATEMENT OF QUALIFICATIONS**

CERTIFICATE OF QUALIFICATIONS

I, Stanley J. Hoffman of 2834 West 24th Avenue, Vancouver, British Columbia, hereby certify that:

1. I am a consulting geochemist with office at 1531 West Pender Street, Vancouver, B.C., V6G 2T1;
2. I hold the degrees of Bachelor of Science in geology and geochemistry from McGill University of Montreal (1969), a Master of Science in Geochemistry from the University of British Columbia (1972) and a Doctor of Philosophy in Geochemistry from the University of British Columbia (1976);
3. I have practised the profession of geologist/geochemist continuously since 1973.
4. My list of publications include:
  - 2 - Theses (unpublished)
  - 17 - Scientific papers in referred journals (3 in the last 3 years)
  - 1 - Published Geochemical Manual (report writing)
  - 1 - Published Directory: 1990 AEG Membership Listing and Directory of Geochemical Exploration and Environmental Services
  - 1 - Unpublished Manual - Organization of a Geochemical Symposium
  - 2 - Books (Reviews in Economic Geology - Volume 3, Writing Geochemical Reports)
  - 2 - Scientific papers in unreferred journals
5. My memberships include:
  1. Member Geological Association of Canada, since 1967; Fellow since 1986
  2. Canadian Institute of Mining and Metallurgy, since 1973
  3. Association of Exploration Geochemists, since 1972
  4. American Society of Agronomy, since 1973
  5. Geochemical Society, 1983 - 1990
  6. International Association of Geochemistry and Cosmochemistry, since 1986
  7. American Chemical Society, since 1989
6. Other qualifications include:
  1. Association of Exploration Geochemists council, (1980-1986, 1988-1990), president (1987-1988), business manager (1988-1991).
  2. Lecturer, B.C. Department of Mines Prospecting Course, (1977-1991), B.C. & Yukon Chamber of Mines (1987-1990), Short Course, Prospectors and Developers Association (1990), Short Course, Calgary MEG (1989), Short Course, AIME (1988), Short Course, Northwest Mining Association (1979, 1985, 1988), Brokers Course (1984, 1985).
  3. Chairman, GOLD-81 and GEOEXPO-86 Geochemical Exploration Symposia, Vancouver, B.C.
  4. Committee for professional registration, province of British Columbia (1980-1983, 1990 and 1991).
  5. P. Geo. (B.C.) Accreditation as a professional geoscientist of British Columbia, since 1991.
7. I have no interest in claims comprising the Porphyry project, or in Teck Exploration Ltd.

Dated this 23 day of January, 1992, Vancouver, British Columbia

Stanley J. Hoffman, PhD, P.Geo.
