i) Survey Specifications

Induced Polarization (IP), resistivity and magnetic surveys on the Raven and Porphyry grids took place during the period July 16, 1991 to August 17, 1991 under the direction of Grant D. Lockhart, geophysicist. A total of 89.1 line kilometres of IP / resistivity data (25.75 km on Raven, 63.35 km on Porphyry) and 88.1 line kilometres of magnetic data (25.975 km on Raven, 62.125 km on Porphyry) were acquired. In the case of the Porphyry Grid, the IP/resistivity station spacing was not corrected for the effects of topography, while the magnetic data was collected on horizontally correct stations.

The IP/resistivity surveys were carried out using the pole - dipole array with an inter-electrode spacing of 50 meters along the slope. The moving current electrode was located to the south of the potential electrode pair. Four dipole separations ($n=1-4$) were recorded during the surveys. Total field magnetic measurements were made at horizontally correct 12.5 meter intervals on the same grid lines used for the IP/resistivity survey.

ii) Instrument Specifications

The IP / resistivity measurements were made using an EDA Model IP-6 six channel time domain receiver set to "mode 2" whereby a delay time ($TD = 120$ milliseconds) is followed by 10 measurement windows of equal width ($td = 90$ milliseconds), yielding a total integration time of 900 milliseconds. The signal used to make the measurements was provided by a Phoenix Model IPT-1 transmitter producing a 2 second on / 2 second off square wave of alternating polarities powered by a 2.0 kilowatt motor generator set. IP effects were recorded as chargeability in milliseconds while apparent resistivity values were normalized in units of ohm-meters.

A GEM Systems Model GSM-19 Overhauser magnetometer was employed to collect the total field magnetic data along the grid lines while an EDA Model PPM-375 magnetometer recorded the magnetic field at the base station. At the end of each day, the recorded base station data were combined with the field readings to correct for diurnal variations in the earth's magnetic field.

iii) Data Presentation

The IP / resistivity results are shown on the following data plots in pseudo-section format:

<u>Line</u>	<u>Electrode Interval</u>	<u>Reading Interval</u>	<u>Total Coverage</u>

Also included with this report are contoured, 1:5000 scale plan map (PLAN: MRAVIP for Raven and PLAN: MPORIP for Porphyry) presentations of the 10-point Fraser-filtered chargeability values which include the IP interpretations. The Fraser filter involves calculating an average value for each dipole separation using one n=1 value, two n=2 values, three n=3 values and four n=4 values. These intermediate results are then further averaged to yield one number which can be contoured in plan view. The strong, moderate and weak IP anomalies are indicated by bars in the manner shown on the plan map legend as well as on the pseudo-sections. These bars represent the surface projection of the anomalous zones interpreted from the transmitter and receiver locations when the anomalous values were measured. The contoured, 10-point Fraser-filtered resistivity data are illustrated on the 1:5000 scale plan maps labelled PLAN: MRAVRES and PLAN: MPORRES (Raven grid and Porphyry grid respectively). Posted, contoured total field magnetic results are illustrated by 1:5000 scale maps labelled PLAN: MRAVMAG and PLAN: MPORMAG (Raven and Porphyry respectively).

iv) Discussion of Results

Raven Grid

For this discussion, the reader is referred to the interpretive plan map labelled MRAVIP. The IP and resistivity survey data collected over the Raven Grid are thought to reflect the presence of a sulphide system which encompasses most of the present geophysical grid.

The most dominant feature observed within the system is a northwest - southeast striking zone of high chargeability measurements located in the middle - to - southern section of the survey grid. The approximate centre of this zone also coincides with moderately anomalous magnetic measurements. Generally speaking, the apparent resistivity measurements recorded within the zone are inconclusive. The depth to the top of the material responsible for the high magnitude IP effects which characterize the zone is estimated to be within 50 meters of surface. It is the authors' understanding that three diamond drillholes

collared within this feature (illustrated on plan map MRAVIP) encountered significant amounts of pyrite.

North of the zone discussed above, and parallel to it, is another more lenticular shaped feature included within the larger scale sulphide system interpreted to be present. It is typified by moderate - to - high magnitude IP effects as well as a weak, but clearly discernable, magnetic high. Again, the resistivity data collected in the area is not conclusive but it is noted that the southeastern portion of the zone is coincident with a fairly substantial decrease in magnitude of the measured resistivities. The polarizable material's depth of burial in this case is thought to be within 50 meters of surface -- similar to the larger zone located to the south.

Outside the two zones discussed above, the interpreted sulphide system manifests itself as weak - to - moderate magnitude IP effects. This data is indicative of a decrease in the amount of polarizable material present and/or an increase in its depth of burial. It should be noted that the highest magnitude magnetic values recorded during the survey are located at the northwest corner of the present grid, within an area of decreased chargeabilities.

Porphyry Grid

The IP data recorded on this grid outline a very large area of moderately anomalous to highly anomalous IP effects, which appear to indicate the presence of a large sulphide system. The interpreted extent of the source of the anomalous response, as detected to the approximately 100 meter depth limit of the 50 meter pole-dipole array data, is illustrated on Plan: PORIP. Set within this envelope, which covers much of the survey grid, are a number of more intense zones that are discussed in the following paragraphs.

Zone A1 - High magnitude IP effects constitute this feature, which is evident in the northern corner of the survey grid. Lower than background apparent resistivity values can be discerned coincident with interesting IP effects throughout most of the zone, pointing to the presence of more concentrated metallic mineralization. Depths to the top of the causative source of the geophysical response are less than 50 meters.

Zone A2 - Somewhat lower than normal apparent resistivity readings correlate with the moderately anomalous IP measurements that constitute Zone A2, possibly indicating the presence of stringerized metallic mineralization. The source of the

western part of the zone may be buried at depths in the order of 50 meters, while the extreme eastern portion does not appear to be as deeply buried. In addition, anomalous magnetic readings are noted in the vicinity of the eastern end of Zone A2.

Zone A3 - This IP Zone is the most interesting feature detected by the present survey. The high magnitude IP readings that constitute Zone A3 form a roughly circular shape, with the most anomalous values concentrated in the center region, coincident with somewhat lower than normal apparent resistivity measurements. Higher than background resistivity values form a distinct ring-like structure within the outer periphery of the IP zone. Quite anomalous magnetic readings are seen to be closely associated with the area of highly anomalous IP response. One possible source for the above geophysical signature would be disseminated metallic sulphides, and magnetite, surrounding a central core region composed of more conductive metallic mineralization, as well as magnetite.

Zone A4 - Relatively deeply buried disseminated sulphides are interpreted to underlie the eastern corner of the geophysical grid area. IP Zone A4 is formed where this sulphide material extends to within 50 meters of the surface. The most anomalous response is seen in the data acquired on Line 6100E, in the vicinity of Station 5600N, where moderately high magnitude IP readings are noted. Apparent resistivity values are at background levels throughout the area.

Zone A5 - This feature is indicated to be caused by a relatively narrow tabular body that underlies Lines 6400E and 6300E in the region of Station 5275N, at a depth of less than 50 meters. The source appears to extend to the southeast beyond the limits of the grid. A distinctive magnetic anomaly that is coincident with the IP zone, together with a resistivity pattern that suggests a somewhat resistive target, points to disseminated metallic sulphides and/or magnetite being present.

Zone A6 - Considerably lower than background apparent resistivity values are detected to be closely coincident with the very anomalous IP measurements that form this IP zone. Heavy concentrations of disseminated and/or stringerized metallic mineralization are the most likely cause of IP Zone A6. Burial depths of the IP source are indicated to be less than 50 meters throughout the zone.

Zone A7 - This zone is located between and in close proximity to IP Zone A6 and IP Zone A8. It is possible that a common source is present, with the three

separate IP zones being interpreted where the polarizable material involved lies within 50 meters of the surface. Disseminated sulphides probably give rise to the western portion of IP Zone A7, as indicated by background level apparent resistivity determinations; however, the eastern part of the trend appears to be somewhat conductive.

Zone A8 - Strongly anomalous IP effects, combined with much lower than normal apparent resistivities, point to substantial sulphide concentrations being the causative source of the southeastern two thirds of this IP zone. The northwestern part of the response, on the other hand, displays background level resistivity values, together with moderately high magnitude IP measurements. Depth to the top of the source is generally less than 50 meters.

v) Conclusions and Recommendations

Raven Grid

Induced Polarization (IP), resistivity and total field magnetic surveys carried out on the Raven Grid, Porphyry Creek Project, have returned results which are interpreted to indicate the presence of a sulphide system underlying most of the geophysical grid. Primarily, the system is characterized by anomalously high IP effects and, to a lesser degree, increased magnetic field measurements. Within this system, two large zones of substantially higher chargeabilities have been identified. The depth to the top of both zones is felt to be within 50 meters of surface.

It recommended that further IP/resistivity surveying be carried out on grid lines located both east and west of the present survey grid in order to fully outline the extent of the interpreted sulphide system. At that point, all available data (geological, geochemical and geophysical) should be reviewed in order to best design a diamond drillhole program to further test the sulphide system for the presence of copper/gold mineralization.

Porphyry Grid

The induced polarization and resistivity survey of the Porphyry Grid has also detected a large scale sulphide system that is interpreted to underlie most of the present survey grid. Set within this region of anomalous IP effects are a number of zones of even higher IP response, which, in most cases, are probably outlining areas of increased sulphide content. IP Zone A3, in particular, is of

interest due to coincident IP/Magnetic anomalies, which contain an annular high resistivity zone surrounding a central lower resistivity region.

Drill testing of IP Zone A3 is recommended due to the unique nature of this feature. All of the other zones of enhanced IP effects are possible drill targets, as well. However, it is recommended that all other information, such as geology and geochemistry, be correlated with the geophysical data prior to assigning drilling priorities.

It is also recommended that the existing geophysical survey grid be expanded towards the northwest, northeast, and southeast in order to completely define the extent of the mineralized system.
