SUMMARY

A fieldwork program of VLF-EM and magnetometer surveys completed on the Grizzly Lake Lead-Zinc Property during 1993 has delineated conductor (alteration) bedrock patterns which require core drill testing. The drilling program would be undertaken in a fashion so as to render the following information.

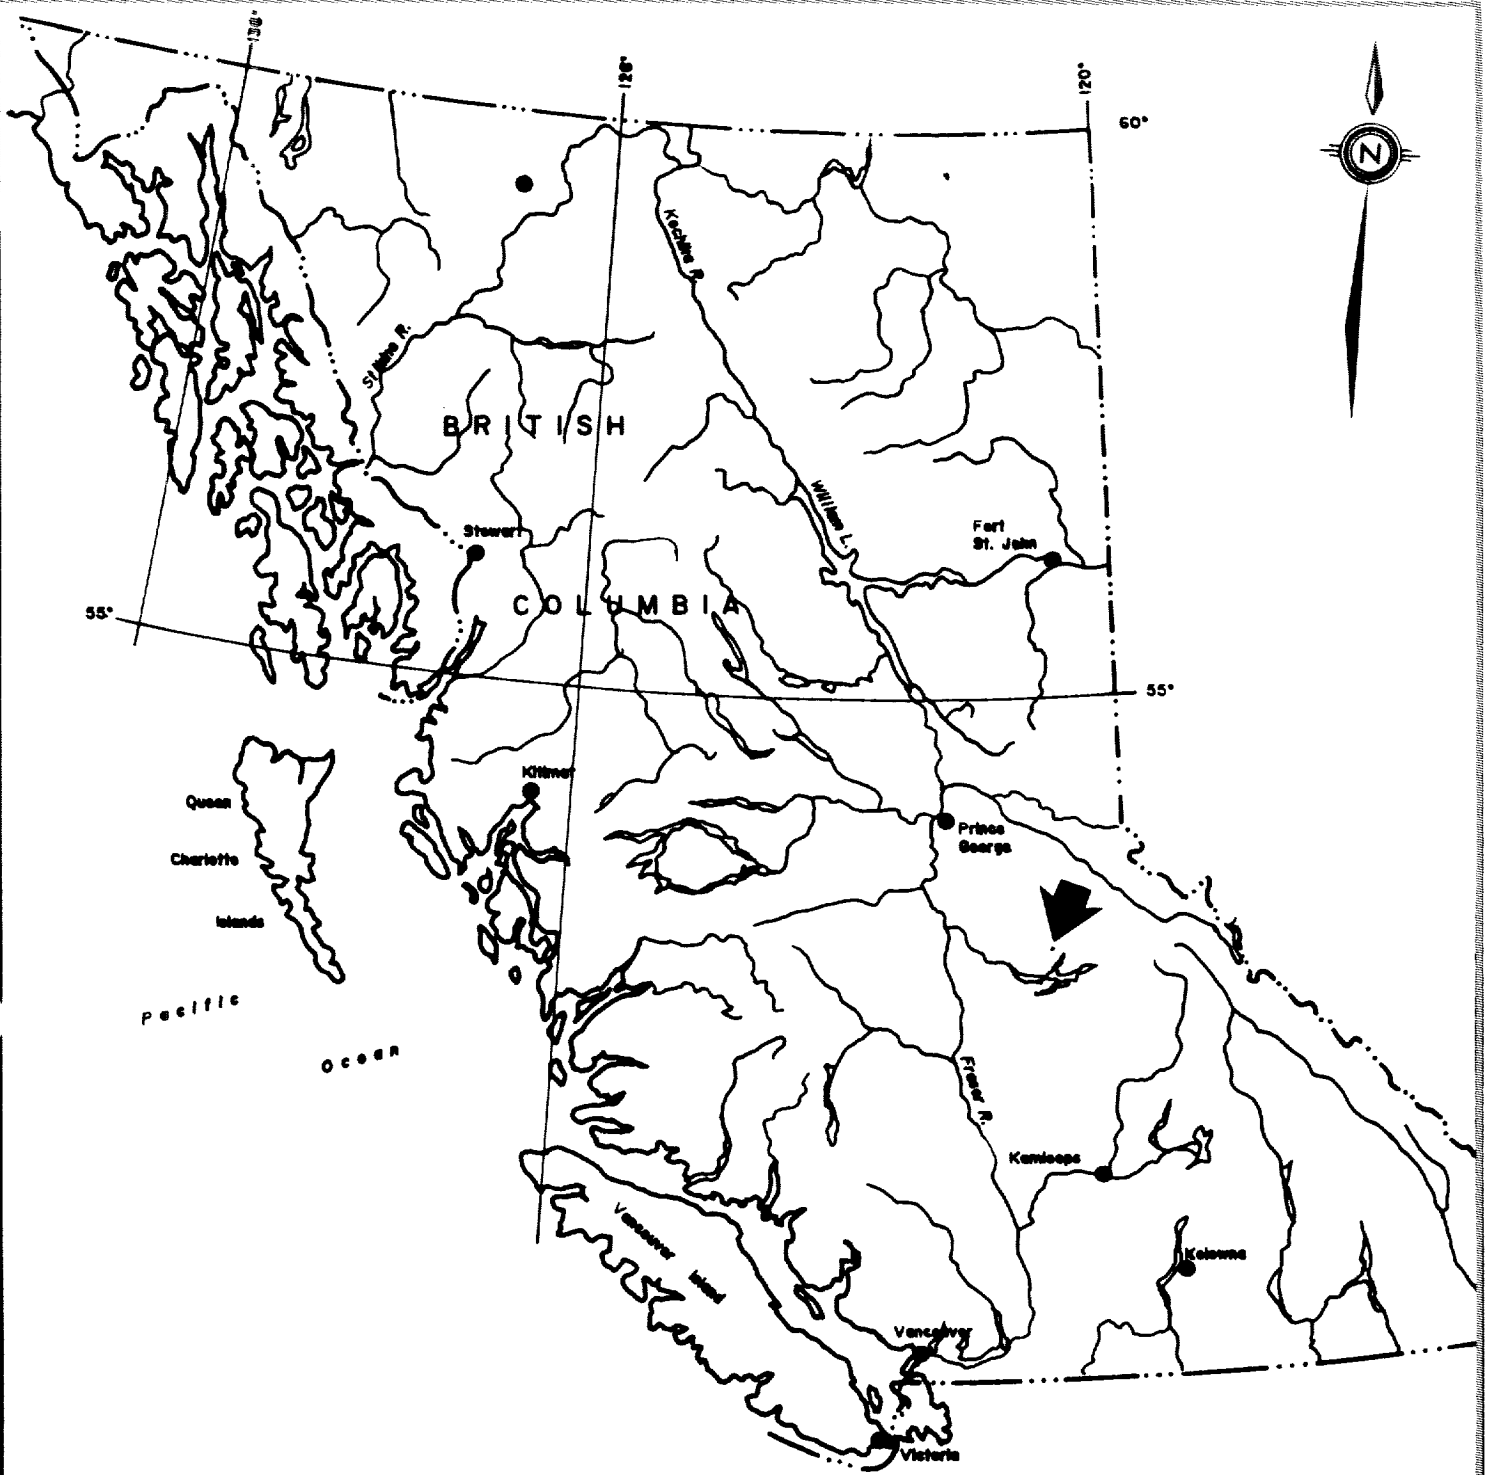

- a) Economic mineralization associated with the indicated structures.
- b) The host rock units for the mineralization and their attitude.
- c) Indication of further target areas to be tested.
- d) Test material for future core or rock chip analyses or the need for other test methods to be used, for example, down-the-hole geophysics.

The completion of the recommended work program, with emphasis on core drilling, if successful, will allow for a supplementary drill program to be initiated to determine the size and grade of the economic mineral occurrences encountered.

The above outlined program is expected to take four months to complete at an estimated cost of \$370,500.

INTRODUCTION

During the period August 5 - September 29, 1993 the writer supervised an exploration program on the Grizzly Lake Lead-Zinc Property herein referred to as the Grizzly Lake property. The fieldwork included VLF electromagnetic (VLF-EM) and magnetometer (MAG) surveys, rock

exposure mapping and sampling and a preliminary environmental assessment survey.

The area of interest covered by the present program is underlain by a northwesterly trending sequence of metasedimentary (mainly carbonate and dolomite) rocks covering an area of approximately 2 km by 9 km in the Maeford Lake area, Cariboo Mining Division, British Columbia.

The program was conducted on behalf of Golden Kootenay Resources Inc. of Vancouver, British Columbia.

LOCATION AND ACCESS

The Grizzly Lake Property is located 65 airmiles (105 km) east-southeast of Quesnel, B.C. and northeast of Williams Lake, B.C., respectively. The claim area may be located at latitude 52° 48 minutes north and longitude 120° and 58 minutes west (U.T.M. Grid Coordinates approx. 5855000N, 637000E) on NTS maps 93A/14E, 15W.

Access to the claims is provided by travelling to the northeast of the Town of Likely, B.C. for 39 miles (65 km) on a good gravel surfaced logging road (Weldwood 8400 Road) which also provides access to the historical mining towns of Barkerville and Wells, British Columbia.

The entire property is afforded road access from the main 8400 road by travelling 8 km east and 3 km west on mining property roads. During the present fieldwork program, access was provided by a Four Trac and several motorbikes.

PROPERTY AND OWNERSHIP

The Grizzly Lake property consists of 9 contiguous lode mineral claims comprising a total of 138 units which are listed as follows:

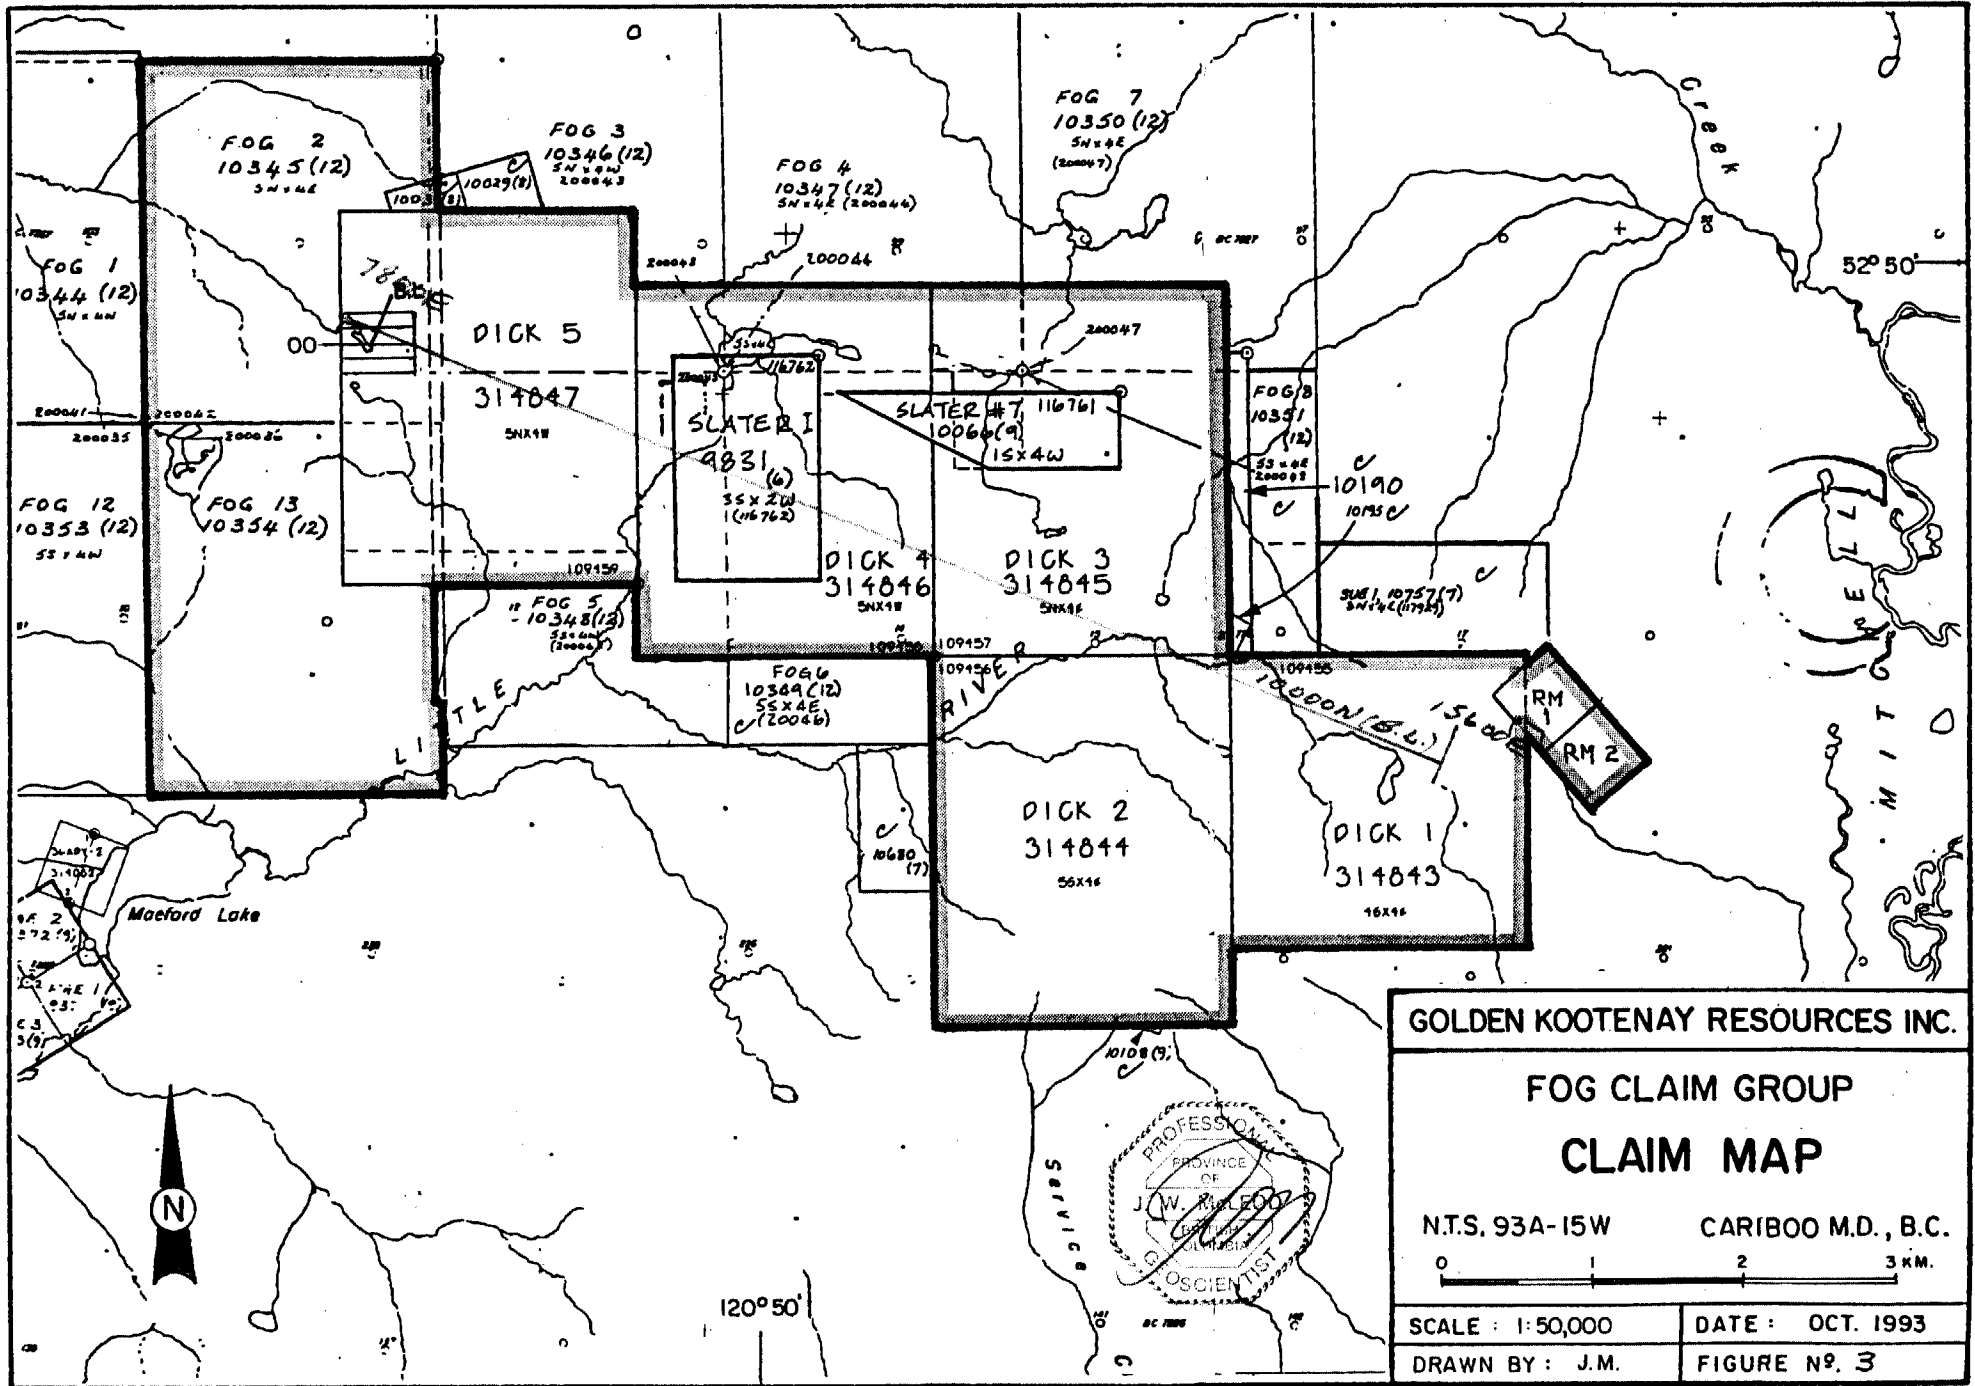

<u>Claim Name</u>	<u>No. of Units</u>	<u>Record No.</u>	<u>Anniversary Date</u>
Fog 2	20	206699	December 12
Fog 13	20	206670	December 12
Dick 1	16	314843	November 13
Dick 2	20	314844	November 14
Dick 3	20	314845	November 14
Dick 4	20	314846	November 14
Dick 5	20	314847	November 13
RM 1	1	320919	September 10
RM 2	<u>1</u>	320920	September 10
Total	138 units		

The claim area totals approximately 8,625 acres (3,450 hectares).

The claims are owned by Robert E. Mickle of Likely, B.C. Mr. Mickle optioned the claims to Cariboo Highland Metals Inc. of Vancouver, B.C. Golden Kootenay Resources and Cariboo Highland Metals subsequently entered into a joint venture agreement whereby Golden Kootenay can earn a 51% interest in the property which under certain circumstances can be increased to a 95% direct ownership position.

TOPOGRAPHICAL AND PHYSICAL ENVIRONMENT

The property lies in the sub-alpine biotic zone in the Quesnel Highlands on the eastside of the

Interior Plateau. The claim area is open, sparse conifer covered by spruce and pine with much of the open areas covered by buck brush and some grasses. The property may be described as more of a mountainous plateau lying above and to the northwest of the north-arm of Quesnel Lake. The property lies in moderately steep mountainous terrain and ranges in elevation from 4,200 to 6,000 feet (1,280 to 1,830 metres) mean sea level.

The property area generally experiences a cool, wet climate with approximately 90 cm (35 inches) of annual precipitation of which 30 to 40% may occur as snow.

HISTORY

The Grizzly Lake property historical exploration events are listed as follows:

<u>Year</u>	<u>Company</u>	<u>Work Performed and Results</u>
1969	Canex Aerial Explorations Ltd. (now Placer Dome)	Silting creek on eastside of property renders Pb-Zn anomalous samples, follow-up soil sampling reveals anomalous zone, but EM testing fails to indicate mineralization relationship.
1972	Canadian Superior Explorations	Extends Canex work to west and outlines several I.P., EM and soil anomalies and the occurrence of some high grade Pb-Zn float and vein-type mineralization. A drill is helicoptered in - three holes totalling 1,157 feet (353 m) are completed. Two holes test soil anomalies, one cuts 60 feet of 0.6% Zn and 400 ppm Pb. The third hole tests and I.P. anomaly near soil anomaly of Canex, but only weak Zn-Pb mineralization is encountered in pyrite-pyrrhotite in shaley (phyllitic?) or argillaceous rocks.
1969-1972	Cream Silver and	Performed some geochemistry and hand trenching of Pb-Zn mineralization in DeBasher Lake area.
(1971)	Morocco Mines?	Drilled 4 holes totalling 1,968 feet (600 m) near Flipper Creek (central portion of present property), scattered remnant core appears to be largely phyllite or argillaceous carbonates.

1989	R.E. Mickle	Prospecting and "Zinc-Zap" testing reveals 8-10 kilometre long, northwest-trending carbonate-hosted zinc trend. The area is seen to contain in excess of 65 separate mineral occurrences, some of which display considerable areal extent as revealed by surface stripping. Galena is found to be present in many locations throughout the property.
1989	James J. McDougall, P.Eng.	Recognized pervasive and widespread Zn mineralization. Arranges Winston Management - Mickle option. Winston Management - T.S.A. Explorations Ltd. option transfer.
1989-1990	T.S.A.-Teck Corp. joint venture on R. Mickle claims	Teck assumes initial management and funding and undertakes large soil and rock geochemistry program, rock trenching and stripping program, geological mapping, limited VLF-EM and four shallow Winkie drill holes and completes a reclamation program.
1990	R. Lonsdale as Cariboo Highland Metals (CHM)	Option on former Canadian Superior ground where shallow trenching reveals numerous mineral (Zn-Pb) occurrences.
1992-1993	CHM - Golden Kootenay Resources Inc. joint venture	Present land position acquired and VLF-EM orientation survey undertaken. Present detailed geophysical program undertaken.

The present option and joint venture agreement covers, for the first time the total (known to date) mineralized carbonate belt which encompasses an area of approximately 10 km by 3 km. Within this belt at least 65 separate Zn-Pb showings have been recorded even though overburden cover is widespread albeit thin in many locations.

REGIONAL GEOLOGY

The regional geological setting in which the Grizzly Lake property occurs has been described by a number of parties (see References). The general central and eastern area is underlain by northwesterly trending stratified rocks of Hadrynian (upper Proterozoic) to Cambrian age which are referred to as Cariboo Terrane. In the western area of the property the bedrock apparently trends northeasterly and dips to the northwest. In this area, the Cariboo Terrane is comprised of

two formations, the younger Cunningham and the older Isaac. These units are in places intruded by small granodiorite and quartz monzonite stocks of Jurassic and/or Upper Triassic age which are termed the Little River intrusions.

The Cunningham Formation is characterized by carbonate units which are comprised of thin bedded grey-white limestone, massive grey to pink coloured limestone and white dolomitic limestone.

The Isaac Formation is generally observed as thin, 10 m. to 100 m. wide beds of light brown coloured impure calcite marble and calcareous schist and phyllites.

The carbonate-dolomite sequence, with which we are most concerned, is of considerable size, with a consistency of trend, but variations in metamorphic development and/or structural preparation offer a regional belt with significant potential to host economic occurrences of "Mississippi Valley Type" (MVT) Zn-Pb mineralization. The following quote is from McDougall, 1992 "*Several important lead-zinc occurrences are known within this carbonate sequence such as Pend Orielle-Salmo on the United States and British Columbia sides of the border, the Kootenay Lake trend in B.C., and north of Grizzly, the Williston Lake prospects of Cominco.*" Examination of a geological map of this area reveals a belt of potentially favourable setting which may run the full length of the province and beyond. McDougall, 1992 also makes a suggestion that the typical large bulbous or stratiform mineralized masses of the MVT related to solution cavity fillings, etc. may not necessarily be required to afford Zn-Pb occurrences of economic significance. He recognizes similarities with the Grizzly Lake Zn-Pb occurrences and the "Irish Model" (IM) which appear to be controlled by the intersection of fault structures and favourable sedimentary units, for example the Lisheen Deposit in Ireland.

PROPERTY GEOLOGY

The Grizzly Lake property has been described by others as being underlain by Precambrian and later "Cariboo Terrane" which is locally represented by schists and phyllites of the Isaac Formation and the overlying carbonates comprised of limestones and dolomites assigned to the Cunningham Formation. Small stocks of granodiorite composition are observed on the northside of the mineralized carbonate units along the 8400 road and the writer observed one small outcropping of similar material on the northend of L14900E. The Grizzly Lake property has been geologically mapped in some detail, 1:10,000 scale, mainly after Lormand and Alford, 1989-90 and summarized by Murrell, 1991 for Teck Corp. The aerial extent of bedrock exposures on the Grizzly Lake property is low i.e. <5%, but after completion of the current fieldwork program the overburden cover on the property, although widespread can most often be expected to be thin. Soil development throughout the property is variable with podzolization observed in many locations to be early or incomplete while in other locations it appears to be well developed. Near some of the small lakes or wetter, poorly drained areas of the property a 1 to 2 foot humus, highly carbonaceous layer occurs immediately below the surface which may render pick or maddock retrieved soil samples unreliable. Examination of some of the previously sampled sites leads the writer to cautiously accept some of the old soil geochemistry results and the broad (200 m. x 50 m. grid) soil contours are probably over extended and "spot" highs should be treated as such. There are well covered areas adjacent to sometimes extensive mineralized areas, thus offering considerable potential to expand known mineralized zones. The current geophysical results indicate that overburden may mask more bedrock-surface alteration and mineralization than has been found to date.

Alteration observed on the property is pervasive and widespread dolomitized portions of the exposed limestone (Cunningham Formation?), some local weak to strong silicification and/or brecciation of the dolomites, much free quartz in places (in both the carbonates and schists) and reported jasperoid occurrences in some of the early trenches, i.e. the Main Zone (Lormand and Alford, 1989-90) and some limonite and ankerite alteration in the brecciated dolomite. Ankerite

may be very pervasive in the highly altered (and mineralized) zones. The very fine grained, greenish-grey phyllites and schists or metamorphosed siltstones (Isaac Formation) weather to a rusty brown colour. There are a number of occurrences of the carbonates of zinc and lead, smithsonite ($ZnCO_3$) and limited cerrusite ($PbCO_3$), respectively which may be due to alteration of the primary sulphides sphalerite (ZnS) and galena (PbS). Barite has been observed in veinlets in the Flipper Creek area.

Mineralization observed on the property occurs mainly as sphalerite which varies from dark brown/black to light cream coloured indicating a variation from high iron content to low iron content, respectively, but the light coloured variety is far more abundant. Other minerals present are galena, minor pyrite, some pyrrhotite, smithsonite and cerrusite. There are in excess of 65 Zn-Pb mineral occurrences found within the structurally controlled, NE or NW trending, altered, stratabound carbonate sequence which underlies the property.

The general structural trend as described by Murrell, 1991 is as follows: *"Bedding trends about 240° dipping NW on the northwestern portion of the property and 310° dipping NE on the southeastern portion so that it appears a huge warp, with axis trending NE, dominates the structure. Bedding dips 50° or less but locally can be much steeper due to local folding. Gently open, large scale folding can be seen on the ridge north of DeBasher Lake."*

A major SW-NE fault is recorded as traversing diagonally across the property (see Figure 4) which has been suggested to be a "scissor fault" resulting in an upward displacement of the eastern portion of the property. The "Little River" fault winds sinuously from the western boundary of the property through the central part to the south-central boundary of the property. At the DeBasher zone it is suggested to be a thrust fault. Air photo linears in the southeastern portion of the property are seen to have a northerly trend. Current geophysical results confirm some of these structures with some modification of attitude, but in addition has indicated a multitude of others which change some of the previously suggested patterns of bedrock, alteration and mineralization.

The writer observes a strong contact relationship between the chemically tight phyllites and possibly argillites and the limestone-dolomites, both brecciated and massive, which are thought to have undergone considerable structural preparation where mineralization occurs. This idea is suggested by the four strong conductive zones thus far indicated by the current geophysical program taking particular note of the location of the phyllite-dolomite? contact. One example is at sample location L14500E - 10013N which occurs in a rusty, siliceous, vuggy, altered zone and is anomalous in cadmium and zinc. This particular sample comes from a zone appearing sub-parallel to and possibly as an extension of the west end of the East Grid - Anomaly B conductive zone. Extension of the sample grid to the north (approx. 500 m.) in this and other locations may reveal further conductive zones. It is the writer's feeling that further investigations (drilling, etc.) of these zones will reveal massive sulphide zones, in addition to the previously known widespread occurrence of lead-zinc carbonates and sulphides.

PRESENT WORK PROGRAM

During the period August 5 to September 29, 1993 grid controlled VLF-EM and magnetometer surveys, rock exposure mapping and sampling and a preliminary environmental assessment were conducted on the Grizzly Lake property.

The grid was established utilizing where possible the old, 1989-90 Teck grid. The baseline was flagged and blazed and marked every 100 metres over a total length of 8.56 km. The grid lines were installed every 100 metres and generally extended N-S for 1 km or in the far eastside of the east grid for 1,500 metres. A global positioning system (GPS) by Micrologic was used in conjunction with the 1:10,000 scale topographical base map to fix station locations. The total length of the grid lines installed is 50.24 line kilometres.

The gridded area underwent two station, Annapolis, MD and Seattle, WA., very low frequency electromagnetic (VLF-EM) and magnetometer surveys. The magnetometer survey was

augmented with continuous one minute base station readings at a fixed station at the base camp at Maeford Lake. The particulars of the geophysical surveys, including methodology, instrumentation, field readings, maps, results, conclusions and recommendations are included in Appendix I - Geophysical Report on the Grizzly Lake Project by F.J.R. Syberg, Geophysicist, November, 1993.

A total of nine rock samples were analyzed by induction coupled plasma (ICP) and/or lead, zinc, silver and gold by wet chemical analyses and/or fire assays and subsequent atomic absorption (AA) analyses (see Appendix II). The samples generally represent areas of mineral occurrences not previously reported.

A preliminary environmental assessment field study was carried out September 18 to 20, 1993, inclusive by Smith and Company of North Vancouver, B.C. A description of the fieldwork and results is included in this report as Appendix III - Report on the Grizzly Lake Property, by Geoffrey M. Smith, Environmental Biologist.

CONCLUSIONS

The current fieldwork program has revealed a number of very interesting features about the Grizzly Lake property which add considerably to an understanding of why some of the mineralized zones occur where they do and more importantly how this information can be used to locate additional mineralized zones. The economic significance of these areas of interest must then be determined by more detailed work.

The significance of rock contacts and structural preparation was recognized by the Teck workers, 1989-91 and later by McDougall, 1992 and summarized by Murrell, 1991, i.e. *"it appears mineralizing fluids migrated up along the contacts or a combination of contacts and faulting. It precipitated out of solution at structural traps usually formed by warping of the phyllite-*

carbonate contacts, or by open space provided by tectonic separation." The writer believes that the current geophysical programs confirm these observations as well as outlining a structural pattern in underlying bedrock which may indicate wall rock alteration, rock contacts and post mineralization faulting.

Four strong conductive zones are outlined, two in the Centre Grid area and two in the East Grid area which range from 250 m. to 450 m. in length, with one of the zones in each area, open along strike in one direction while the other two are closed off by apparent faulting. There may be continuity between several of these zones which have been closed off by post emplacement faulting. Further extension of the surveys in these two areas could verify this possibility. The possible alteration patterns exhibited in Figures 5 and 6 seem to indicate post alteration faulting. The problem with these suggestions are that they do not necessarily reflect economic mineralization, but they do offer suggestions of mineralization by analogy. The significance of these anomalies can only be determined by drill testing. An underlying "feeder" system which afforded pervasive and widespread Zn-Pb mineralization is indicated. A continuation of the surveys to the north in certain areas and between the existing grids would help clarify the overall picture. There are also a number of other isolated, untested mineralized areas within the apparent underlying phyllite-carbonate contact area on the property which require further exploration.

The writer has estimated the locations of three Morocco Mines, 1971 diamond drill holes (of four); one Canadian Superior, 1972 drill hole (of three) and four Teck, 1990 short Winkie holes and it is apparent that from these locations, the uncorrelatable core available (Morocco) and lack of core recovery (Teck), the following opinion can be formulated:

- (i) the Morocco holes (3 of 4) were collared in phyllites and did not test current area of interest. The remnant core tends to confirm this, therefore the conductor indicated in this area, i.e. "Flipper" Creek, has not been drill tested. The area has exhibited in past sampling programs an abundance of Zn-Pb mineralization.

- (ii) The "Main" area tested with two short Winkie diamond drill holes in 1990 are apparently too short to test a moderate conductor and in fact both may have been collared in a fault offset zone. This area has not been adequately drill tested.
- (iii) The "Peanut Lake" area drilled (3 holes) in 1972 by Canadian Superior only revealed one drill location, i.e. DDH 1972-1 at L15100E - 9720N and it was collared in a location lacking geophysical conductor or indicated alteration expression. There is a moderate magnetic high at this location and it may be reflected in the reported pyrite-pyrrhotite mineralized shaley-phyllite intersection. Several hundred metres north of this drill collar a moderate conductor-alteration zone is indicated. The general area exhibits an abundance of Zn-Pb carbonate mineralization. This area requires more drill testing.
- (iv) The "Gunn" zone two-hole drill test by Teck, 1990 using the Winkie which reportedly rendered low core recovery, did not test this area which also lacks geophysical conductors or alteration expressions. Zones A,C and D in Figure 6 in this general area require drill testing.

In consideration of past information compiled on the Grizzly Lake property and the current geophysical results, and rock exposure mapping and sampling, the writer feels the following target areas (from highest to lowest priority) which should be drill tested are listed as follows:

- i) North Peanut Lake Conductor just north of the 10000N baseline between lines 14900E to 15300E, appears to be near the contact between the phyllites and brecciated carbonates. The anomaly appears to be closed on the east and west ends by north-south faulting, but the occurrence of an anomalous, 0.04% cadmium and >2% zinc sample at 10013N (baseline) and L14500E, which has a northeasterly trend, may be the western extension of the above anomaly. Also a limey, schistose carbonate sample which assayed 0.21% zinc and 0.04% lead

occurs at 10284N and L15600E and may in fact be near an eastern expression of the same priority anomalous zone.

Another consideration is a possible north-south fault along the eastside of Peanut Lake which may have offset this priority conductor anomaly to the south and its eastern extension may be expressed by the surface showing and high grade "Pear" sample (see Appendix II) which ran 43.60% lead, 5.74% zinc, 1.78 oz/st silver and 0.005 oz/st gold. This area would require a minimum of six, 300' to 500' holes to test essentially three zones about Peanut Lake (see Figure 29). Another criteria in choosing this zone as the highest priority is the apparent lack of an underlying magnetic response which suggests low iron content (or at least low pyrrhotite) in the conductive zone, although the spacing and lateral extent of the magnetic survey may not be sufficiently close or large, respectively to make this assumptions. The logistics of drilling this area are excellent as property road access is available to Peanut Lake and the east end of the conductor.

ii) Gunn-Oue Road Conductor

The writer rates this zone as the next highest priority on the basis of known geology, i.e. brecciated dolomites near the phyllite-dolomite contacts; proximity to surface galena-sphalerite showings, i.e. assays 0.5 oz/st silver and greater than 2% lead and 2% zinc and in fact in the general eastern extension, much high grade lead and zinc assays are available. An underlying magnetic high is apparently lacking, i.e. is there more possibility of the conductor being related to a lead-zinc massive sulphide, low in pyrrhotite?. The logistics of drill testing this area are excellent as the property road traverses this zone.

iii) North Main Conductor (Centre Grid)

This strong conductor occurs in an area which lacks bedrock definition because of low occurrence of rock exposures. The area appears that it may be underlain by rocks which reflect facies change, hence Alford, Lormand and Murrell suggest an underlying area of mixed phyllites and dolomites. The writer feels that the emphasis placed on previous geochemistry patterns in zinc and lead which appears to be sub-parallel to what is thought to be a northwesterly strike of the underlying strata is confusing. The bedrock strike trend near the "B" conductor, Centre Grid, strikes northeasterly in this area. The conductor appears terminated on the west end by a northerly trending fault between L12200E and L12300E and may continue into the small lake (Key Lake) at the north end of L12500E. This iii) priority area includes what is referred to as the 'Main Zone Showing', a large surface exposure of zinc and lead sulphides and their carbonates which underwent testing by two short (poor core recovery) Winkie drill holes in 1990. Examination of this surface showing at/or near 10000N (Baseline) and L12550E reveals an altered dolomite occurrence with phyllitic particles which may be due to brecciation (near a northeast trending fault - shear zone). McDougall makes the point that this impressive surface showing does not occur to depth (the writer is not convinced of this point), or as he is quoted, "*In the writer's view (McDougall's), if no 'roofs' are present, a case may be made that this showing is related to a low angle 'thrust fault' as yet unrecognized, but suspected in this immediate vicinity.*"

It is the writer's belief that the main conductor "B" (see Figure 5) in this general area should be drill tested first. This zone test could, if results warrant it, continue into zones "D" and "E" (Figure 5). Access and overall logistics in this area are excellent.

iv) Flipper Creek Showing

The Flipper Creek showing is a priority conductor (anomaly), situated between L11000E and L11900E in the range of 10500N (plus) to 10300N which can be visualized by examining Figure 5 (west half). An underlying magnetic expression near the "A" anomaly indicates pyrrhotite in its make-up but this is a point to be determined by future drilling. The writer's "guesstimate" of three of four old 1971 Morocco Mines drill holes appear to have been collared in phyllite. One narrow core section in one of the holes(?) revealed a brecciated, altered (sparry) dolomite which exhibited veinlet-styled luminescent zones. This area has or is in close proximity to widespread zinc and lead sulphide surface occurrences, as well as a number of occurrences of barite veinlets.

This area is logistically the easiest to drill test, i.e. close to the main 8400 road, available water, etc. Examination of the geology and geophysical interpretation maps, Figures 29 and 30, reveals detailed complexity to what has been generalized as a relatively simple northwesterly (in Centre and East Grid areas) trending carbonate package. The current geophysical program, while exhibiting abundant fault-shear-contact-conductor patterns, also clarifies to some extent, the writer feels, the underlying bedrock and possible Zn-Pb mineralization "feeder" system.

A relatively detailed reconnaissance core drilling program is required to test the above outlined features and theory and the following recommendations are designed to do that.

RECOMMENDATIONS

The geological picture which has evolved from past fieldwork and which is augmented by the current geophysical surveys indicate target areas of high priority. The main conductor-contact

areas of interest should undergo systematic core drilling which in the future may require a reverse circulation drilling program be undertaken after certain stratigraphic knowledge is gained. It has been suggested by Manns, F.T., 1993 in personal communication that luminescence of drill chips, particularly white sparry dolomite, may be useful in mapping proximity to ore (see "References"). This method deserves a try on future drill core sections. If the method has merit, it will be used as the location of ore is the reason for undertaking the program and the most efficient and economically methods will be used. Concurrently with the initial drilling program, the completion of the VLF-EM and magnetometer surveys between the currently completed areas and the northward extension of the grid to cover current areas of interest should be completed.

The recommended program is expected to take several months to complete at an estimated cost of \$370,500.

COST ESTIMATE

Phase I

Geology and supervision - including core logging and sampling	\$ 15,000
Core preparation and sampling	7,500
Grid installation - 2 men for 15 days @ \$300/day	4,500
Operators - 1 man for 10 days @ \$350/day	3,500
Geophysical maps and report	2,000
Transportation, including 4x4's and backhoe for road repair, drill site preparation, property and camp use, plus fuel and oil	8,000
Camp and board for 200 mandays @ \$80/manday	16,000
Equipment rental - IGS-2 and base-mag, 4 Trac, etc.	3,500
Maps and reports	3,000

Environmental impact bond (refundable)	5,000
Insurance and Workers' Compensation	3,000
Field supplies	3,000
Unemployment insurance, CPP, and holiday pay	3,000
Diamond core drilling - 2,000 metres @ \$130/metre, all inclusive	260,000
Assays and luminescence tests	3,500
Contingency @ approximately 9%	<u>30,000</u>
TOTAL	\$ <u>370,500</u>

Respectfully submitted,

James W. McLeod, P. Geo.

STATEMENT OF COSTS

Geology and supervision	\$ 7,500
Geophysicist	5,345
Preliminary environmental assessment tests and reports	1,700
Line installation	5,480
Geophysical equipment rental - IGS-2 and base mag recorder	3,500
Camp and board, 150 mandays @ \$80/manday	12,000
Transportation:	
a) 1-ton truck @ \$25/day and \$0.20 per kilometre - 6,000 km	1,950
b) Trailer @ \$20/day for 10 days	200
c) 2 trail bikes @ \$30/day for 30 days	900
d) 4 Trac @ \$17/day for 30 days	510
Expediting	500
Equipment rental, including generator, chainsaw, Toshiba computer and printer, etc.	2,000
Fuel and oil, etc. for vehicles, camp and office	1,575
Office rental	400
Field supplies, including axes, flagging, radio telephone, first aid and fire safety equipment	700
Assays	137
License and fees, including Workers' Compensation	3,770
Reports and maps	<u>1,750</u>
TOTAL	\$ <u>49,917</u>

CERTIFICATE

I, **JAMES W. McLEOD**, of the Municipality of Delta, Province of British Columbia, hereby certify as follows:

1. I am an Consulting Geologist with an office at #207, 1318 - 56th Street, Delta, B.C. V4L 2A4.
2. I am a Professional Geoscientist registered in the Province of British Columbia and a Fellow of the Geological Association of Canada.
3. I graduated with a degree of Bachelor of Science, Major in Geology, from the University of British Columbia in 1969.
4. I have practised my profession since 1969.
5. I am the President and a Director of Golden Kootenay Resources Inc. which is currently the managing partner of a joint venture agreement to explore and develop the Grizzly Lake Zn-Pb property.
6. The above report is based on personal field experience gained by myself in the general area over the past 24 years and in particular since supervising the current exploration program. Further available data was researched and personal communications were undertaken with other parties familiar with the area.

DATED at Delta, Province of British Columbia this 20th day of December, 1993.

James W. McLeod, P. Geo.
Consulting Geologist

The seal is a circular emblem with a scalloped border. The text inside the seal reads: 'PROFESSIONAL' at the top, 'PROVINCE OF' in the center, 'J. W. McLEOD' in the middle, 'BRITISH COLUMBIA' at the bottom, and 'GEOLOGICAL ASSOCIATION OF CANADA' at the very bottom.

SUMMARY

A total of 50.24 line km. of geophysical surveying has been conducted on behalf of Golden Kootenay Resources Inc. in the Grizzly Lake Area easterly of Likely, B.C.

The geophysical surveys consisted of measuring the total magnetic field and the VLF-EM responses due to the transmitter stations located at Seattle, WA, and Annapolis, MD.

The interpretation of the survey results suggest the detection of 4 conductor anomalies and 15 fault/shear zone type anomalies for a cumulative strike length of 5.8 km. on two out of three survey grids, the EAST and CENTER grids.

INTRODUCTION

During September, 1993, geophysical surveys were carried out on behalf of Golden Kootenay Resources Inc. in the vicinity of Grizzly Lake northeasterly of Likely, B.C.

Previous exploration in the area has been carried out by several companies, including Teck Corp. and Cominco Ltd., over the past three decades. Previous exploration work has consisted of geochemical soil sampling, geological mapping, outcrop sampling and exploratory core drilling. In addition, very limited VLF-EM geophysical surveys were conducted.

Previous survey grids have covered a baseline strike length of about 8-1/2 km with a survey line separation of 200 meters. Considerable prospecting has been carried out in the area. This has included stripping to bedrock, trenching and the use of "zinc zap" to indicate the location of zinc mineralization.

The geology in the survey area consists of limestone sequences typical of the Cariboo Mountains of British Columbia. These have locally been intruded by igneous rocks. The principal metals explored for in the survey area are lead and zinc. Bedrock exposed in the survey area included mineralization consisting of galena, smithsonite and yellow to green sphalerite. Analysis of some samples indicate the presence of silver and occasionally gold.

A baseline was established over the 8-1/2 km strike length of

the known areas of mineralization and three areas along the baseline were selected for detailed geophysical surveys. The survey line separation was 100 meters and the station interval along the survey lines was set to 25 meters. The survey methods consisted of measuring the total magnetic field and induced electromagnetics, VLF-EM using the transmitters located at Seattle, WA, and Annapolis, MD. The VLF-EM field measurements consisted of the secondary vertical in-phase and out-phase magnetic fields as a percentage of the primary electromagnetic field, and the horizontal field strength. The survey instrumentation consisted of a Scintrex IGS-2 field unit capable of measuring the total magnetic field and the responses due to a maximum of three VLF-EM transmitter stations, and a Scintrex IGS-2 magnetic basestation recorder. Both units are microprocessors designed to make the appropriate measurements and store the measurements in its digital memory. At the end of each survey day each unit was connected to a computer and the data procured during field operations transferred to the computer and saved in disk files. Apart from the measurement of geophysical responses the field data included survey line labels, station labels and the time of measurement. The basestation data consisted of the total magnetic field measured every 60 seconds.

The purposes of the geophysical surveys and the selected survey grids were to test the usefulness of reasonably detailed survey applications supported by state-of-the-art

computer applications in arriving at the interpretation of anomalous geophysical responses. The reason for using two VLF-EM transmitter stations was to measure responses due to geological structures paralleling the broader geological trends and those crossing these trends. The general geological trend in the survey area is approximately N60°W. The three survey grids have been labelled the West, Center and East grids. The distances surveyed are as follows:

WEST GRID	-	13.23 line km.
CENTER GRID	-	20.63 line km.
EAST GRID	-	16.38 line km.
Total		50.24 line km.

FIELD PROCEDURES

The internal digital clocks of the two IGS-2 units were synchronized at the beginning of each survey day. The basestation occupied the same location throughout the entire survey.

The total magnetic field measurements were made with the operator facing North. The VLF-EM measurements were made facing in a direction directly at the transmitter stations. The direction towards the Annapolis transmitter was approximately in the direction of the baseline and the direction towards the Seattle transmitter was in the direction of the survey lines.

The IGS-2 units include an LCD display which shows the current reading and the previous reading. Whenever

sufficiently large changes were encountered one or several check measurements were made.

DATA PROCESSING AND PRESENTATION

All field data files transferred from the IGS-2 units consisted of ASCII format characters. The files were edited to suit the input requirements of subsequent computer applications.

The total magnetic field measurements were corrected for diurnal variations and the VLF-EM vertical in-phase and out-phase measurements used to compute the dip angle and quadrature of the secondary responses. The methods for these computations are detailed in the instrument manuals published by Scintrex Ltd.

The relative x and y coordinates of diagnostic points along each survey line were entered into the data files so as to reflect the estimated departures of the survey lines from an idealized grid. A computer application was used to interpolate the x and y coordinates of the intervening station between the diagnostic station locations.

In preparation to digital contouring and computer applications aimed at aiding the interpretation of the secondary geophysical responses a 12.5 by 12.5 meter regular grid was superimposed on the survey areas. For each geophysical observation, corrected magnetics and the calculated VLF-EM measurements, a grid matrix was interpolated using the field measurements surrounding each

matrix node. The subsequent grid matrices were filtered to smooth out erratic characteristics which might complicate interpretational objectives. The total magnetic field grid matrices were continued upward 25 meters. This application simulates the situation where the total magnetic field measurements had been made at an elevation 25 meters above ground surface. This procedure suppresses magnetic responses due to near surface sources which have no continuity between the survey lines and reduces problems with being specific about the exact location of the measurements.

The VLF-EM grid matrices were subjected to an analytical method, Syberg, 1993, thereby specify a data adaptive and directional variably low-pass filter. The object of these filters were to suppress chaotic contributions to the field measurements which could not assist interpretational objectives.

Filter applications, such as Fraser filtering of VLF-EM dip angles, were applied to the grid matrix. For the Annapolis transmitter this was done along matrix rows, e.g. parallel to the survey lines. For the Seattle transmitter it was done along matrix rows, perpendicular to the survey lines. In the latter respect it is to be reminded that this can result in closed contour lines in between survey lines. Where the closed contours of the Fraser filtered Seattle dip angles form a relative high it is to be noted that this indicates a dip angle cross-over, occasionally relative to a bias, for which reason reference must be made to the dip angle contour

plans.

INTERPRETATIONS AND DISCUSSION

CENTER GRID: The interpretations of the geophysical survey data is illustrated in Figure 5.

The dip angle cross-over anomalies are of two types. The conductor type, anomalies A and B, coincide with quadrature signatures typical of conductive vein/dyke type anomalies, or relatively massive sulphides. The fault/shear zone type, anomalies C to K, coincide with quadrature responses typical of conductivity contrasts such as faults. They may be gradational as in a contact alteration or shear zone.

The interpretation of shear/alteration zones is based on anomaly width of Fraser filter dip angle responses. Such estimates relate to geological characteristics as opposed the existence of economic mineralization. The above anomalies trend E-W to northwesterly.

The northeasterly trending interpreted faults are the result of an echelon off-set seen in the contour patterns of VLF-EM responses.

The conductor anomaly, denoted B, is indicated by both VLF-EM transmitter stations.

Based on dip angle and quadrature responses due to the Seattle transmitter the interpretational features shown as "fault/shear zone - Seattle" are thought to be simple breaks. In the vicinity of the baseline, line 10000-N, and survey lines 12500-N and 12600-N prospecting and stripping has

revealed a large bedrock exposure containing significant amounts of smithsonite. This location coincides with an intermediate to weak dip angle response which terminates at line 12700-N along its strike.

All the anomalies, denoted A to K, are considered target areas for further exploration.

EAST GRID: The Annapolis VLF-EM survey indicates structures striking approximately westerly to northwesterly. These are indicated in Figure 6.

Anomalies A and B are of the traditional conductor type as discussed above. Anomalies C to H have been denoted fault/shear zone anomalies also discussed above.

The northeasterly striking Seattle dip angle cross-overs are, as discussed earlier, thought to coincide with an echelon type faulting.

The anomalies denoted A through to H are regarded target areas for further detailed exploration.

WEST GRID: The interpretation of geophysical responses are illustrated in Figure 7. All responses are weak and from a point of geophysics no further detailed exploration appear required in this area.

The anomalous VLF-EM responses detected throughout the CENTER and EAST grids are for the most part open ended structural trends. Subject to the results of further exploration work

done in the vicinity of the above anomalies the VLF-EM survey coverage should be expanded. The gap between the two grids should be surveyed. Also, the surveys should be extended to at least 11000-N, and in such additional directions where anomalous responses may be open.

Respectfully submitted,

A handwritten signature in cursive script, reading "F.J.R. Syberg". The signature is written in black ink and is positioned above the typed name.

F.J.R. Syberg, Geophysicist.

CERTIFICATE OF QUALIFICATION

I, F.J.R. Syberg, 2228 Franklin Street, Vancouver, B.C.,
hereby certify that:

- 1) I graduated from the University of British Columbia in 1967 having obtained a B.Sc. degree majoring in geophysics and geology.
- 2) I have been engaged in mining exploration and production since 1956.
- 3) I am responsible for all computer programs used to process the field data.
- 4) I have no interest whatsoever in the property described herein or the securities of Golden Kootenay Resources Inc.
- 6) I grant Golden Kootenay Resources Inc. permission to use all data and information contained in this report as the company may see fit.

Dated at Vancouver, B.C. this 6 day of December, 1993.

Fred J.R. Syberg, Geophysicist

**Grizzly Lake Property -
Preliminary Environmental Assessment Report
by G.M. Smith, Environmental Biologist,
December, 1993**

AQUATIC ENVIRONMENTAL RESOURCES

AT THE GRIZZLY CLAIM GROUP

Prepared for:

GOLDEN KOOTENAY RESOURCES INC.

#207 1318 56th Street

Delta, B.C.

Prepared by:

Geoffrey M. Smith

Senior Environmental Biologist

SMITH AND COMPANY

December 22, 1993

1.0 INTRODUCTION

This report on fish resource and habitat values in the vicinity of the Grizzly claim group northwest of Likely B.C. summarizes existing aquatic environmental information for the area and includes the results of a field reconnaissance carried out on September 19 and 20, 1993. The data are discussed in terms of potential effects of mineral resource development work.

1.1 BACKGROUND

The property was described by Jones (1990),¹ and more recently in documentation prepared by Mr. Jim McLeod, to which this report is appended. Of particular significance is the location of the claim group in the headwaters of river drainages tributary to the Fraser River. Drainage descriptions, channel lengths, and related terrain features are included in Section 3.0 Results.

Environmental documentation pertaining to fish resources in streams and lakes in the area was lacking; therefore Golden Kootenay Resources Inc. (GKR) hired Smith and Company to carry out reconnaissance and sampling work to investigate fish habitat values and the presence and abundance of fish populations at the property.

1.2 APPROACH

Resource development on the claim group to date remains at the exploration stage. Recognizing the complexity of surface drainage at the property, and potential implications for aquatic environmental effects of future exploratory or mine development work, elected to include in the fall 1993 geophysical assessment program an evaluation of potential risks to fish and fish habitat.

In view of the use of electromagnetic sensing equipment, and the lack of any drilling or excavation work, it was elected to limit the environmental program to assessment of aquatic habitat, with cursory examination of characteristics relating to other environmental issues, including biogeoclimatic features, terrain, vegetation, birds, mammals, and socio-economic considerations. Only aquatic resource related issues

¹ Jones, Harold M. 1990. A report on the Grizzly Lake property, Maeford Lake, Quesnel Lake area, B.C. Cariboo Mining Division. Consultant report to TSA Exp;orations Ltd. Vancouver, B.C.

are reported here. More complete environmental documentation would be prepared as any mine development at the property proceeds to Prospectus or Stage I report levels.

2.0 METHODS

The work was carried out in four steps:

- 1) review of topographic characteristics (NTS MAP 93A/15, scale 1:50000), and previous site descriptive information (Jones, 1990).
- 2) reconnaissance of stream channels and other surface drainage features in accessible areas of the claim group, using a "Four-Tract" on B.C. Forest Service Road No. 8400 and trails running east to the "Lookout" above Quesnel Lake.
- 3) aquatic habitat evaluation, relying on observations of lakes and stream channel biophysical characteristics, cursory examination of instream invertebrate species presence and abundance, and spot-electrofishing in channel sections containing habitat elements most likely to support fish.
- 4) meetings and follow-up conversations with Ministry of Environment, Lands and Parks (MELP) personnel in Williams Lake to request available population data for fish species and other significant environmental resources (e.g. caribou, waterfowl, recreational values).

3.0 RESULTS

Information in this section is presented under three headings: Watershed Descriptions, Aquatic Habitat Values, and Fish Populations. As noted previously, data compiled on other environmental issues area not included in this report, in view of the priority at this time to focus on more potentially susceptible environmental values, namely fish and fish habitat, relative to prospective development activities.

3.1 Watershed Descriptions

All surface drainage within and in the immediate area of the claim group ultimately flows to Quesnel River, which empties to the Fraser River at the Town of Quesnel, approximately 100 km to the west. The primary drainage on the property is the Little River drainage. Of the total claim group area of approximately 35.5 km², 27.5 km² lie in the headwaters of the Little River, which drains generally to the south and west. The remainder of the area is comprised of an 8 km² area

that drains north and east to Cameron Creek and the Mitchell River drainage.

The Little River drainage includes 16.5 km² that drain generally west and south, flowing from Peanut Lake, Summit Lake and Grizzly Lake, into Maeford Lake, then west to Cariboo Lake, plus 10 km² of tributary drainage that originates in the Debasher Lake area and flows west to join the Little River mainstem approximately 20 km upstream of Cariboo Lake.

3.2 Aquatic Habitat Values

3.2.1 Overview

For mainstem drainages downstream of the tributaries arising at the claim group, it is understood that highly important populations of trout and char are present, and that large runs of coho, chinook, sockeye and pink salmon occur in the Quesnel River system. Recreational fishing is an important mainstay of the local economy (comprehensive documentation of socio-economic values will be prepared if necessary for successive stages of permit application.)

The most prominent river systems in the claim group area are the Matthew, Mitchell, and Little River drainages. In river reaches down slope of the property, lakes known to support significant fisheries include Quesnel Lake (North Arm), Cariboo Lake and Maeford Lake.

3.2.2 Habitat Capability in the Area of the Claim Group

Within the property per se, five lakes lie in the Little River drainage, and two lakes drain to the Mitchell River. The most significant is Grizzly Lake, which connects via a 3 km long channel named here as for convenience as Grizzly Creek, to Little River, approximately 3.5 km upstream from its outlet to Maeford Lake.

Grizzly Creek and Little River are the only significant watercourses in the claim group. All others are ephemeral (intermittent), and have no contribution to local habitat resource values except in lower gradient sections near their outlets when they are flowing. The following information, therefore, pertains entirely to Little River and Grizzly Creek.

As noted previously, total Little River drainage area (including the Grizzly Creek drainage) within the claim group is approximately 27.5 km. From its source, Little River exhibits an ephemeral (intermittent) flow regime downstream to within 1 km of the Grizzly Creek confluence. Grizzly Creek

begins in low gradient marsh terrain around Grizzly Lake, then steepens approximately (7 %) for 0.5 km to approximately 1.5 km below the road 8400 bridge. Substrate in the steeper sections of both streams is mainly cobble and boulder with almost no gravel for spawning and little pool riffle alternation required to support fish.

From 1.5 km below the 8400 road bridge, the Grizzly Creek channel down to Little River, then the Little River channel to Maeford Lake, follows a lesser gradient of approximately 2%, and the channels develop specific biophysical elements characteristic of spawning and rearing habitat for salmonids (sinuous meanders, overhanging cut-banks stabilized by riparian root complexes, deep pools and backeddies, well developed overhanging vegetation, and gravel riffles).

Grizzly Creek and Little River are markedly different in that Little River is clear with no colour, while Grizzly Creek is slightly tea-coloured, as is typical for stream draining marshy terrain. Another observed difference is a greater diversity and abundance of aquatic flora and fauna in Grizzly Creek. Several algal species were observed, and in spot kick samples aquatic invertebrate species were numerous and abundant.

3.2.3 Fish Populations

Information available from MELP in Williams Lake on known fish species presence in the vicinity of the claim group, indicates that Maeford Lake supports important populations of cutthroat trout (*Oncorhynchus clarki*) and Dolly Varden charr (*Salvelinus malma*). No data were available for Grizzly Lake or any stream channel on the property.

Electrofishing results indicated that no fish are present in Grizzly Creek or Little River. During field reconnaissance in September, 1993, efforts to locate fish in specific habitat features of the creek channels did not result in any fish being collected. It is unlikely, therefore, that resident fish populations are present in the Grizzly Creek/Little River watershed. There may be some use of the lower reaches of Little River near Maeford Lake, by trout spawners in the spring (April) and charr spawners in the fall (September).

4.0 CONCLUSIONS AND RECOMMENDATIONS

The claim group is drained largely by one drainage, the mainstem and tributaries of Little River. Only the northeastern and southeastern corners drain to other systems. All drainages ultimately flow to the Quesnel River. Very

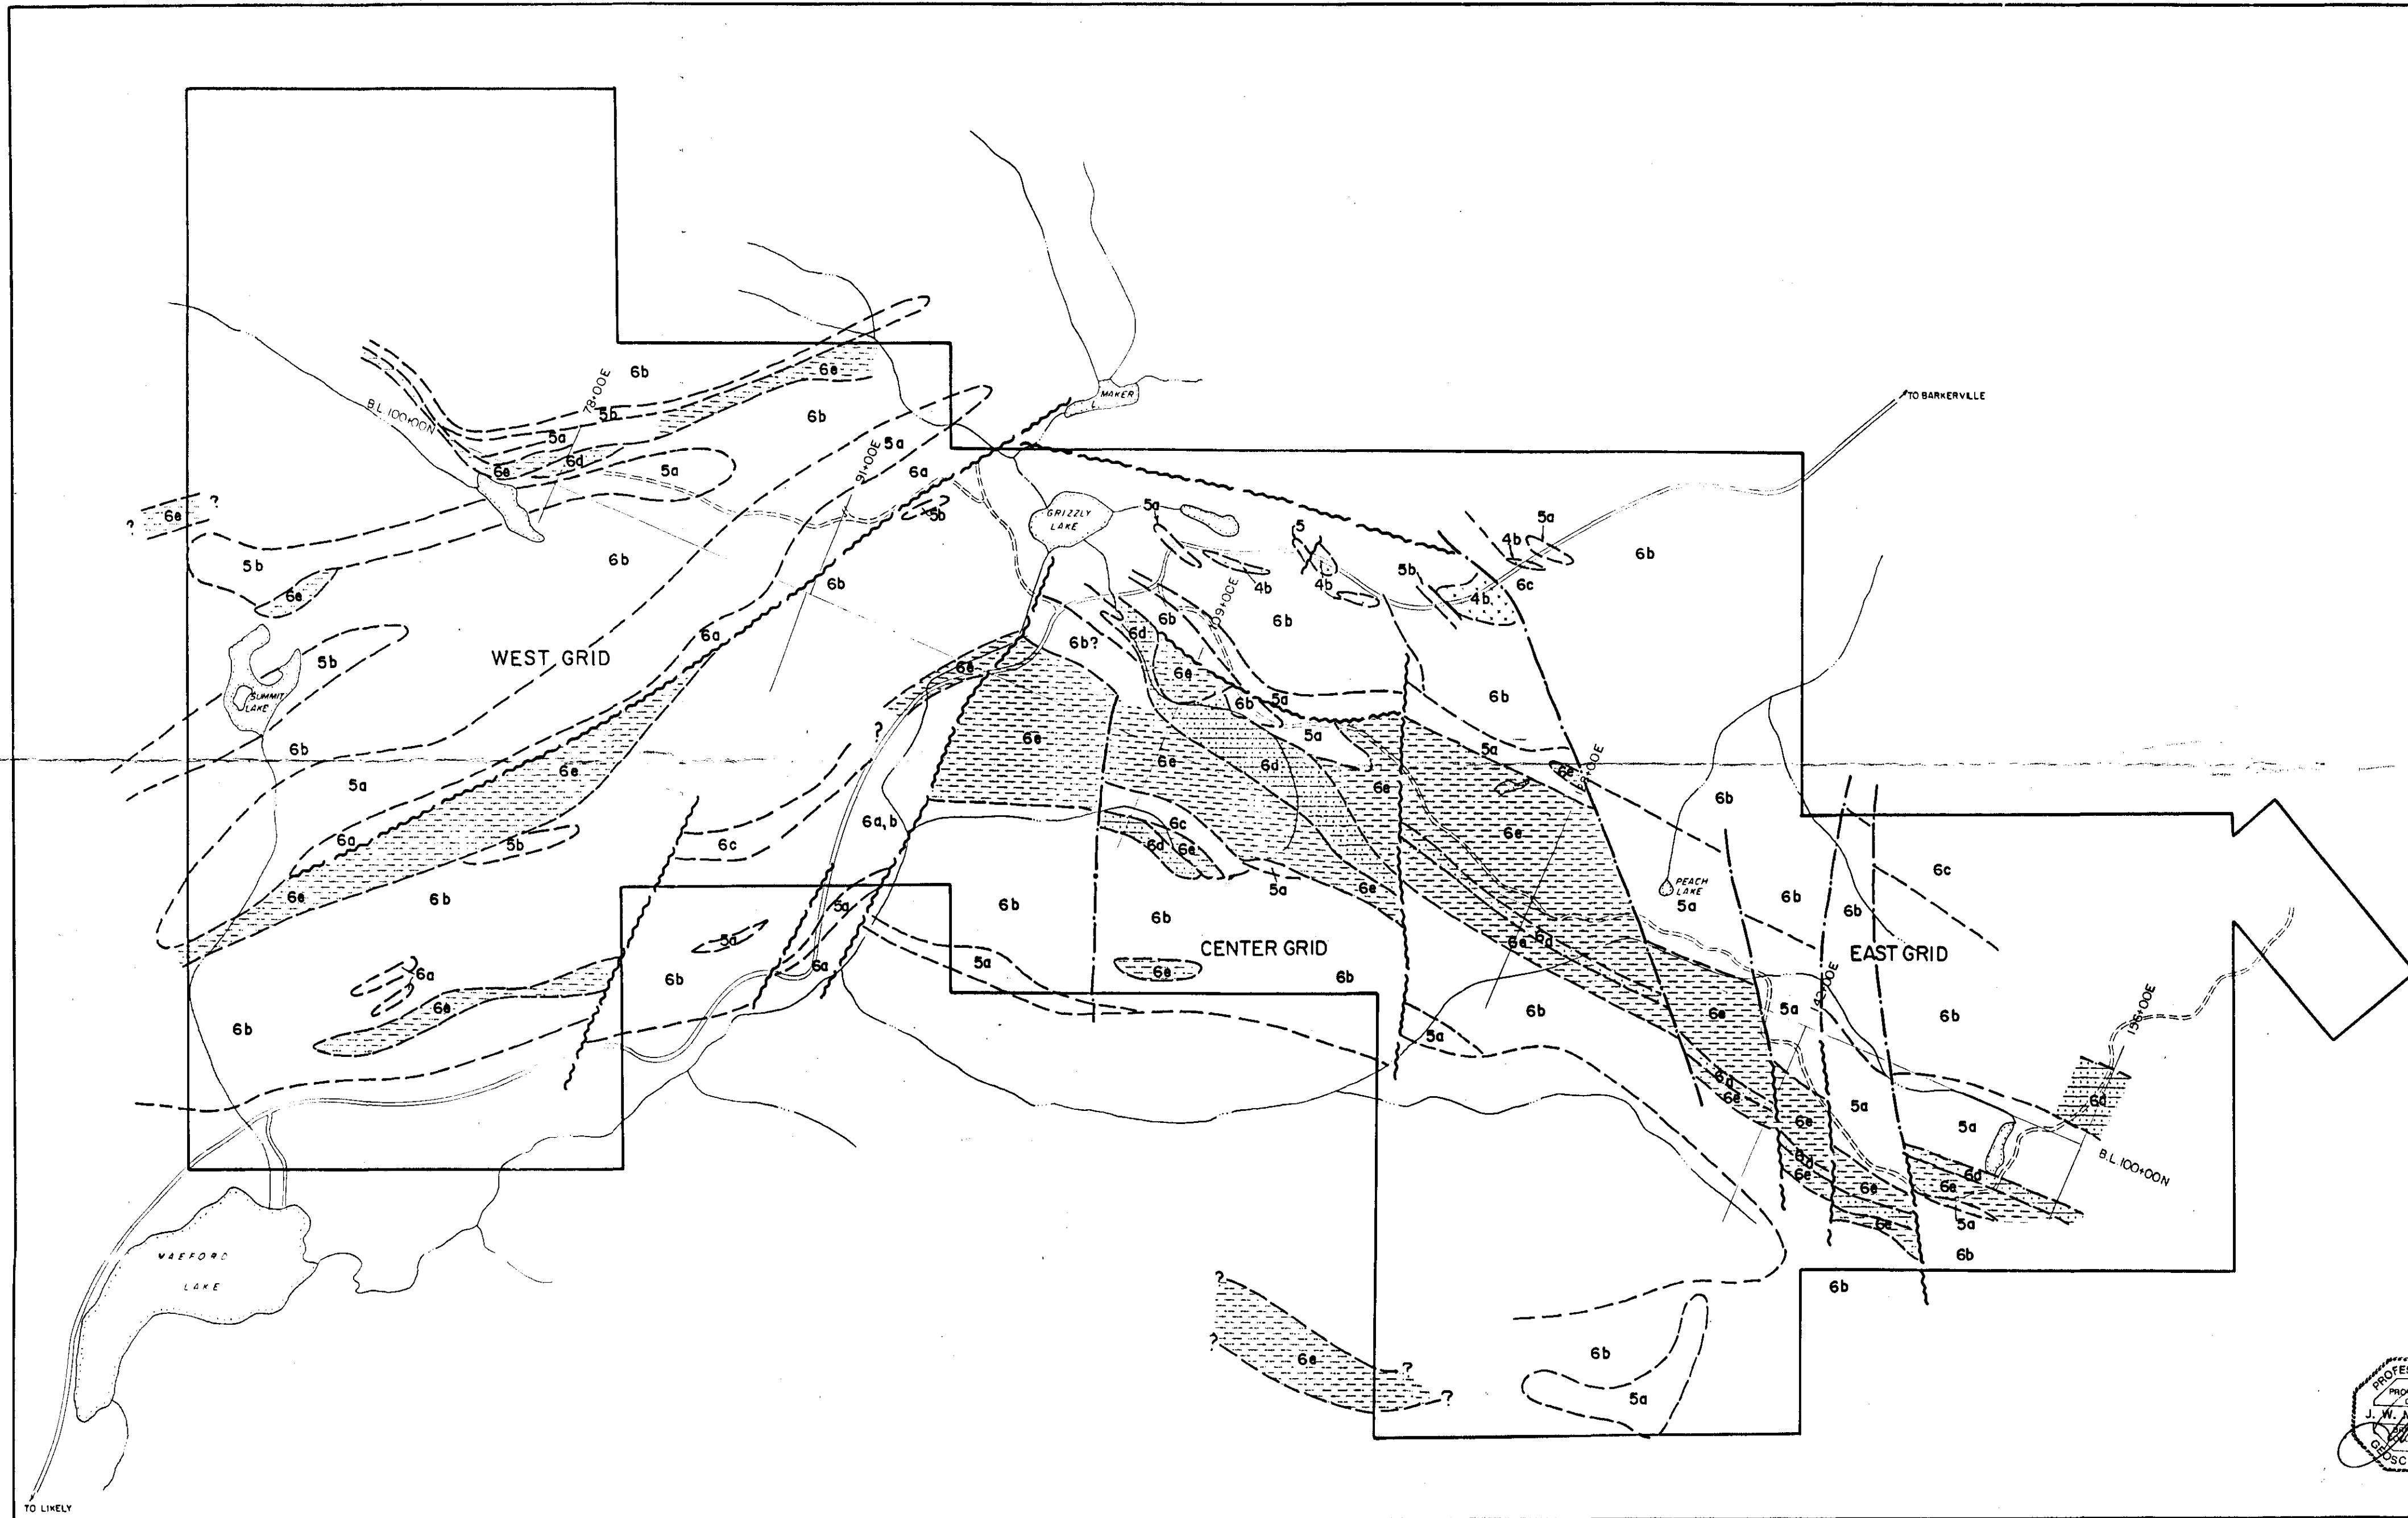

important fisheries resources exist in the lakes and rivers of the Quesnel River system.

Reconnaissance results indicated that habitat capability in Grizzly Creek and Little River is good, however no resident fish populations utilize the habitat available. Populations of cutthroat trout and Dolly Varden charr are present in Maeford Lake, and spawning might take place in the lower reaches of Little River where it enters Maeford Lake.

No data were available on water quality in the area. In view of the presence of important fisheries resources in Maeford Lake, as well as in other lakes and rivers down slope of the property, it is recommended that water quality monitoring be included in any mineral exploration program that could affect water quality. Drilling, trenching, or other mining related activity should be planned to prevent effects on surface runoff. For exploration or mine development/operation activities that cannot avoid affecting surface drainage, it is recommended that project activities be isolated from surface flows, and process water be retained and recycled (closed loop).

In the event that any significant mineral extraction project is planned for the property, substantial additional information will be required on other environmental and socio-economic issues. Documentation of these issues would be included in any filed Prospectus or Stage I Report for the property.
