INTRODUCTION

The Pilldolla 1 - 7 mineral claims were staked for Aquaterre Mineral Developments Ltd. in August, 1993 during a regional reconnaissance exploration program. This acquisition stemmed from a comprehensive research and evaluation of known literature covering this area of Britannia Roof Pendant geology.

Initial interest in the property area arose in August, 1993 while prospecting crews carried out traverses covering noticeably different coloured gossans. Well mineralized till and talus rock specimens returned highly anomalous results in gold - silver - copper values with local concentrations of lead and zinc were obtained. Subsequent follow-up examination involved continued prospecting, geological mapping and detailed sampling.

The mineralized area occurs within a one kilometre wide roof pendant of Gambier Group interbedded sediments and volcanics bounded to the west and east by Coast Range Complex intrusive.

Work to date on the Pilldolla project has delineated an extensive area of well mineralized till and talus boulders several hundred metres in length. Although spectacular gossans occur immediately uphill from this material, the same grade of mineralization as seen in the boulder material has not been located in outcrop. This area is characterized by extremely steep cliffs and as such makes traversing possible only by trained mountain climbers.

Samples from the area have produced 16 values over 1,000 ppb Au with the highest

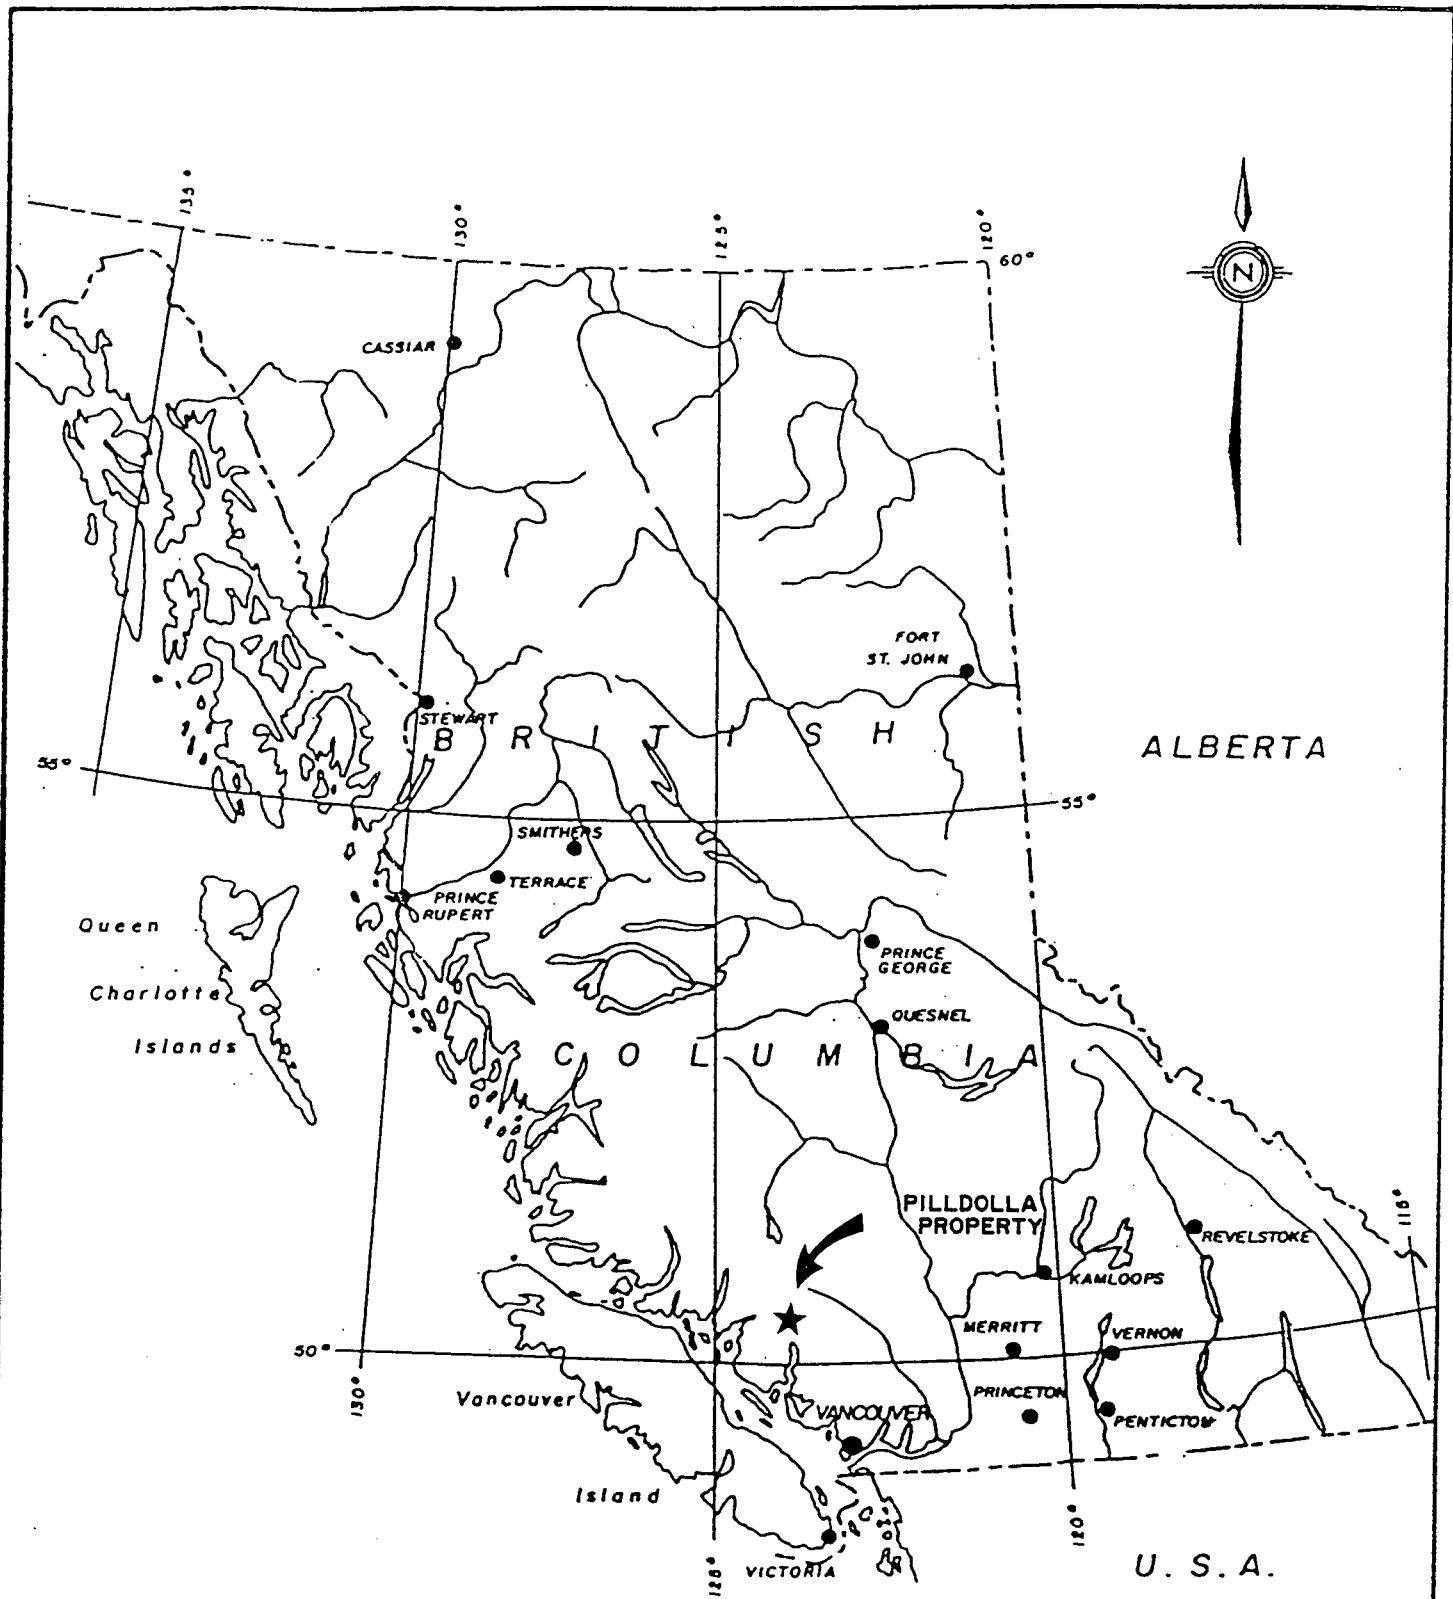

being 0.369 and 0.595 oz/ton Au, 8.73 and 16.00 oz/ton Ag, 2.15 % Cu and 1.34 and 10.25 % Pb. Anomalous sample values taken from outcrop range up to 775 ppb Au across 0.65 metre and 933 ppm across 1.0 metre.

Considering this an exciting new gold discovery within the Gambier Group, it is recommended that an aggressive evaluation program be carried out in 1994. This work would include detailed geological mapping, prospecting and sampling by experienced mountain climbers followed by diamond drill testing.

2.0 LIST OF CLAIMS

Records of the British Columbia Ministry of Energy, Mines and Petroleum Resources indicate that the Pilldolla 1 - 7 mineral claims are owned by John R. Kerr, and held in trust for Aquaterre Mineral Development Ltd. (Figure 2).

3.0 LOCATION, ACCESS AND GEOGRAPHY

The Pilldolla property is located approximately 125 kilometres northwest of Vancouver, B.C. and 85 kilometres east-northeast of Campbell River, B.C. on Vancouver Island (Figure 1). The small village of Egmont on the Sunshine Coast lies 60 kilometres to the south. Princess Royal Reach at the head of Jervis Inlet is 10 kilometres to the southeast. Pilldolla Creek runs east - west along the south end of the property draining into Skwawka River near the head of Jervis Inlet. The highest mountain peaks in the immediate claims area reach elevations of 1970 metres. Coordinates of the claims area are 124° 07' west longitude and 50° 18' north latitude, and the property falls under the jurisdiction of the Vancouver Mining Division.

Access to the property is via helicopter which was based in Egmont during the time of the program. Flight time one way is approximately 25 minutes. Barging service is to a well maintained logging camp at the head of Jervis Inlet. Westward from there new logging roads following the north side of Pilldolla Creek to within one kilometre of the claims.

Physiographically, the claims area is steep especially when in major drainages such as Pilldolla Creek. Elsewhere, topography is moderately steep. Vegetation consists of spruce and cedar trees with thick underbrush of slide alder and locally thorn bushes.

Precipitation in the area consists of heavy rainfall during the spring and fall months and snow accumulations of several feet between December and May. The

property should be easily workable between May and November and could probably be worked year-round with some additional attention to overcome winter conditions.

4.0 AREA HISTORY

No known recorded information is available pertaining to the subject claims and no signs of previous work are evident in the field. The mineralization found during the course of the 1993 season is considered to be a new discovery.

The Britannia Mine and occurrences such as the Mt. Diadem prospect are located in similar Gambier Group rocks. The Mt. Diadem property is located 30 kilometres to the south of the Pilldolla property. Mineralization at the Lower Adit Zone consists of pods and lenses of massive sphalerite, chalcopyrite, pyrrhotite, galena and arsenopyrite developed within steeply dipping shears. At the Upper Adit Zone, three en echelon, stratabound stringer sulphide zones up to 30 metres wide occur on surface. Drill holes intersected stringers, veinlets, blebs, pods and minor disseminations of pyrrhotite, chalcopyrite, sphalerite, galena, tetrahedrite and arsenopyrite.

The Britannia Mine is located 100 kilometres to the southeast of the Pilldolla claims. Historically, 52.7 million tonnes of ore were produced from several deposits averaging 1.1% Cu, 0.65 % Zn, 6.8 grams per tonne Ag and 0.6 grams per tonne Au. Ten different deposits were defined within the Britannia Shear Zone. All mineralization occurred near the top of a dacite pyroclastic unit beneath overlying argillites.

5.0 REGIONAL GEOLOGY

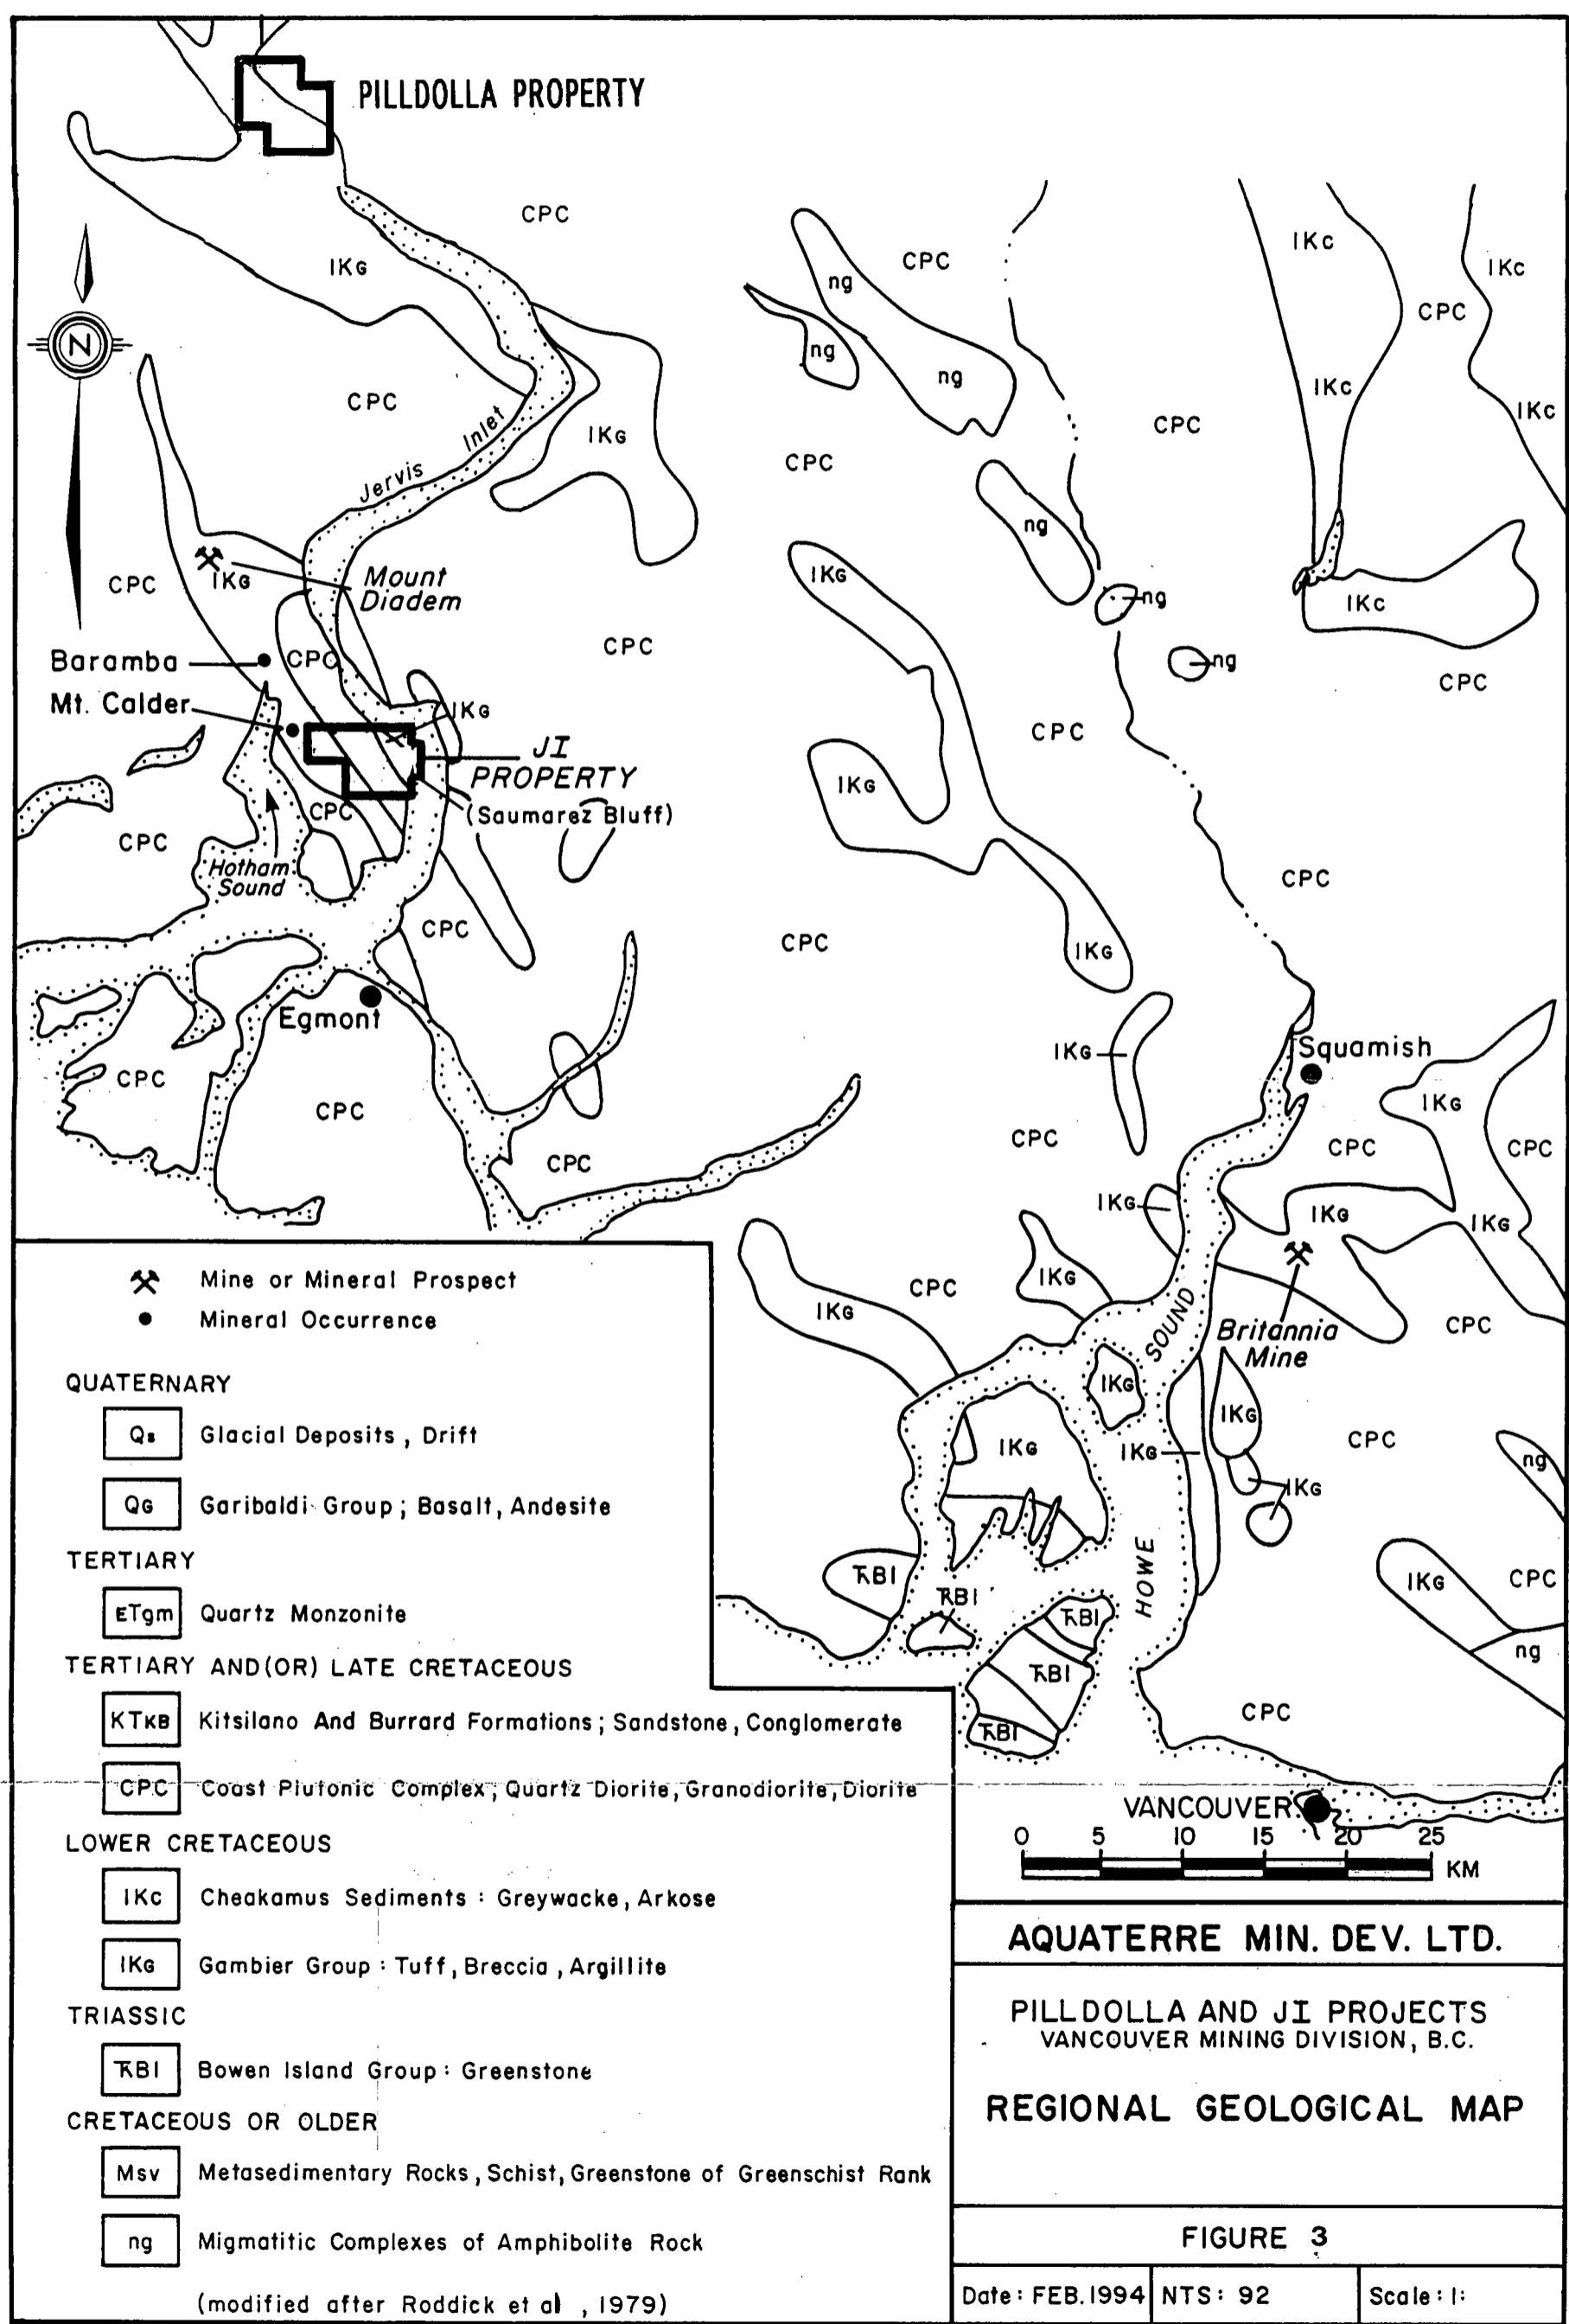

The Britannia belt is a series of northwest trending volcanic and sedimentary roof pendants surrounded by the Tertiary - Cretaceous Coast Plutonic Complex. The roof pendants consist of several different ages of rocks which have in simple terms been divided into pre-Jurassic metamorphosed volcanics and sediments and Lower Cretaceous Gambier Group volcanics and sedimentary rocks (Figure 3).

Metamorphic rocks, generally upper green schist to amphibolite facies, consist of amphibolite, gneiss, schist and quartzite.

Gambier Group rocks consist of volcanic andesite, dacite and rhyolite flows, tuffs and breccias and argillite, siltstone and limestone sedimentary rocks.

In the area of Pilldolla Creek, Roddick (1977) in GSC Open File 480 has included this area in Belt 5 of their mapping exercise. He describes the location as being the north end of a pendant beginning some 18 kilometres to the south at Mt. Alice. Midway along this same pendant lies Mt. Alfred, where Aquaterre also holds the Alf 1 & 2 mineral claims which cover favourable geology. Roddick indicates rocks in the Pilldolla Creek area to consist of marble, schist and metavolcanic rocks, differing considerably from the Mt. Alfred area where shale, slate, argillite, schist, conglomerate and andesitic flows and breccias occur. The conglomerate consists predominantly of dacitic clasts commonly 10 cm in size but locally are up to 2 metres.

Marble beds in the Pilldolla area are up to 3 metres thick with intercalated

rhyolite and schist. The metavolcanic rocks are dominant in some areas and consist of rhyodacite, andesitic volcanic breccia and chlorite schist. The siliceous volcanic rocks are commonly pyritiferous and rusty weathering. On the east side of Pilldolla Creek near its headwaters, a complex relationship between the metavolcanics and diorite exists.

6.0 1993 WORK PROGRAM

During the 1993 field season, 39 man days were spent preparing and carrying out work on the Pilldolla project. Field programs totalling \$41,742.72 were undertaken between July 31 - August 21 and September 27 - October 6. A total of 236 rock samples, 42 soil samples and 21 silt samples was collected from the claims. The majority of work was directed to a strongly gossanous cliff area on the Pilldolla 1 claim where a significant number of well mineralized boulders were discovered early in the program.

Geological mapping, prospecting, soil sampling and rock saw channel sampling were incorporated into the program. Trained mountain climbers were employed during the project to map and sample the extremely steep cliff areas.

7.0 PROPERTY GEOLOGY

Geological mapping on the Pilldolla claims indicates that several lithologies occur within this roof pendant which lies along trend to the northwest from the

Britannia pendant. Quartz-mica schist, quartz-chlorite-schist, marble, limestone, metavolcanic and metasedimentary rocks occur on the property (Figure 4).

QUARTZ-MICA SCHIST

This unit outcrops extensively along the east side of the pendant in close proximity to the Coast Range granodiorite. The rocks are pervasively oxidized on surface and ubiquitously pyritized. Fresh surfaces are medium to dark grey, fine to medium grained and have coarse crystals and clots of quartz enclosed by fine undulating bands of biotite. The unit has a well developed foliation.

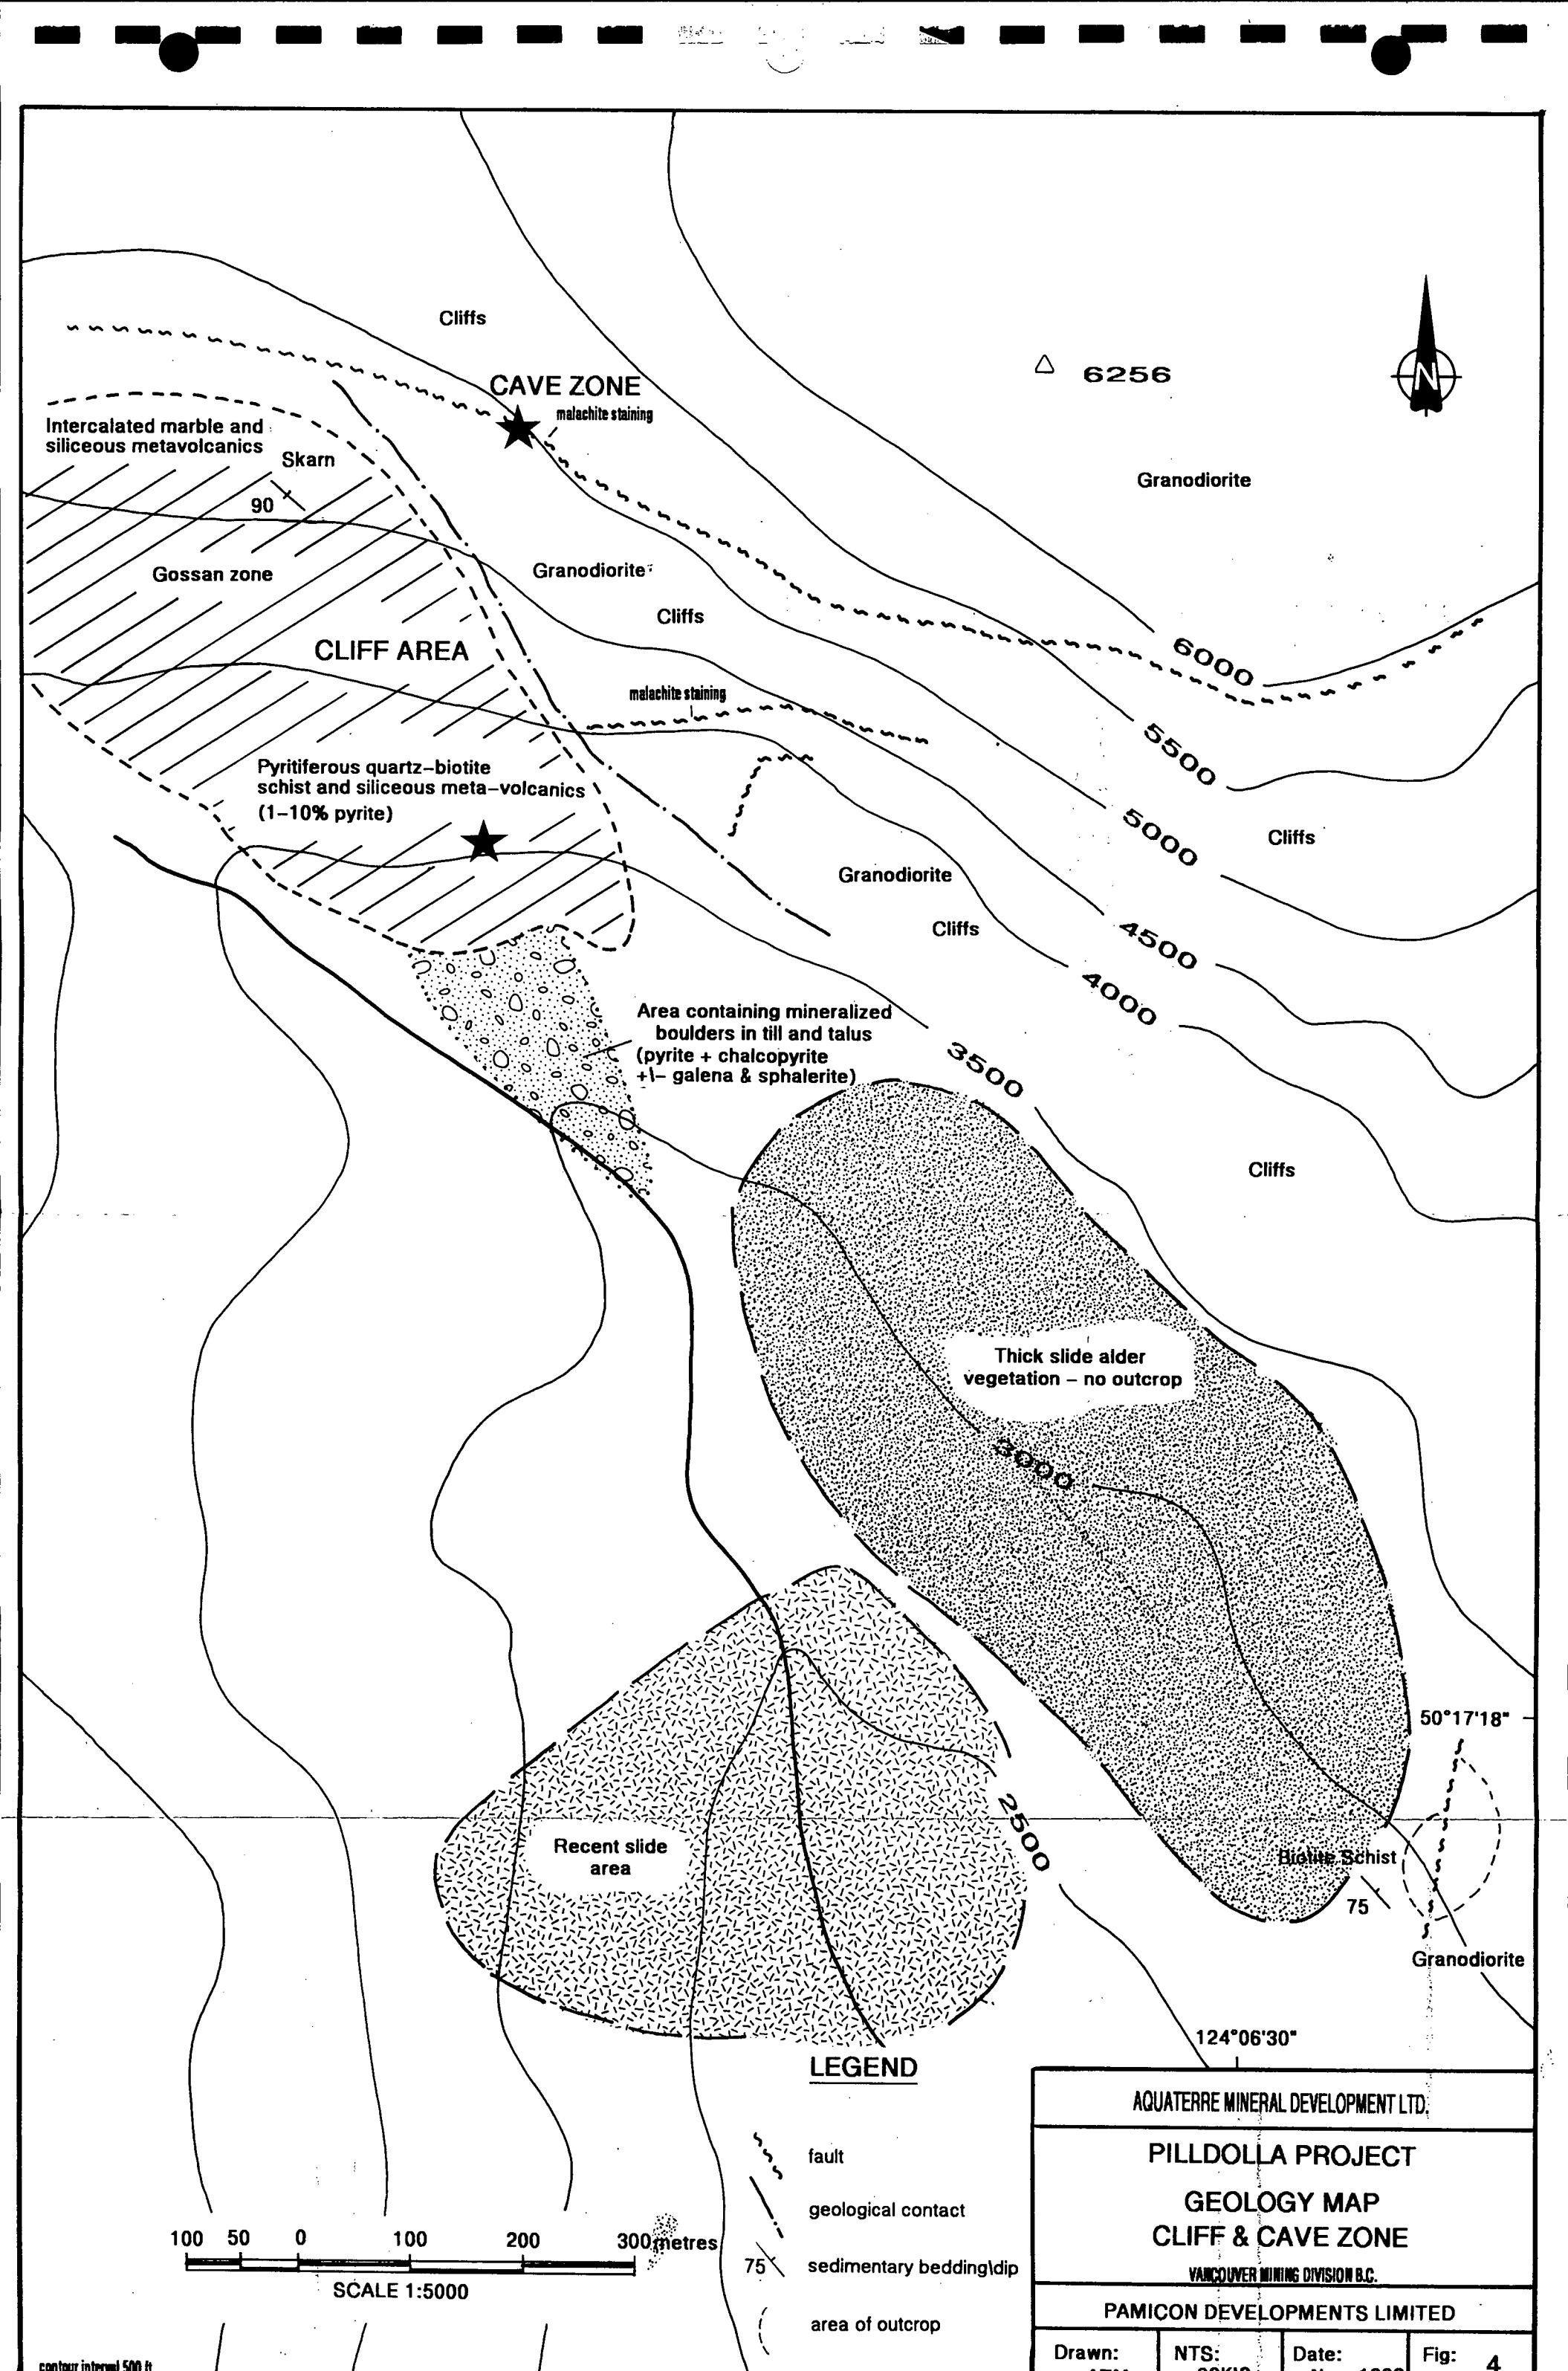

Pyrite is the most common sulphide and is seen throughout the unit as stringers, veinlets, blebs and disseminations. Cubes are up to 1 cm in size and often tarnished on weathered surfaces. Chalcopyrite is less common and occurs as blebs and disseminations often intimately associated with pyrite. Massive pyrrhotite, galena and veins/veinlets of magnetite were seen in boulders and have not yet been located in place.

Fracture orientations measured appear to indicate two fracture sets. One trends N-S to NW-SE (186/58W, 172/38E) and the second trending NE-SW (210/50W, 227/65NW, 219/20NW).

Some small shear zones that were noted trend 213/90 and 186/58W.

QUARTZ-CHLORITE SCHIST

Narrow bands of quartz-chlorite schist occur within the quartz-mica schist. They

are green-grey in colour and fine to medium grained. A strong schistosity is developed by the alternating segregated bands of fine grained chlorite, quartz and biotite. Rocks of this composition were also mapped at higher elevations on the west side of the headwaters of Pilldolla Creek.

Sulphides do not appear to be present as was the case in the quartz-mica schist. The most predominant fractures measured trend 313/18SW.

BIOTITE SCHIST

This unit outcrops near the head of a new logging road in the southwest corner of the claims. The biotite schist is fine grained, medium grey to black weathering, brown coloured and rusty. Muscovite and chlorite occur locally. Quartz is often present as veinlets likely due to sweating during metamorphism. Sparse pyrite occurs as both fine grained disseminations and narrow stringers.

METAVOLCANIC AND METASEDIMENTARY ROCKS

Intercalated within the quartz-mica schist are bands of siliceous metavolcanic and metasedimentary rocks that Roddick (1977) has suggested are rhyolitic in composition. Locally, these rocks appear to be hornfelsed. Near the headwaters of Pilldolla Creek on its east side and extending east these rocks are generally strongly gossanous and ubiquitously pyritized with 3 - 8 % disseminated fine grained pyrite.

LIMESTONE/MARBLE

An extensive area at higher elevations east of the headwaters of Pilldolla Creek is underlain with predominantly by white marble and light grey limestone. Narrow

bands of siliceous metavolcanic and metasedimentary rocks are intercalated within the carbonates.

Weak skarning occurs within this unit adjacent to the Coast Range granodiorite. Epidote, garnet, diopside and local magnetite and chalcopyrite were noted.

GRANODIORITE

Coast Range Complex intrusive rocks of granodiorite to quartz monzonite composition bound the roof pendant rocks. Fresh surfaces are light grey in colour, equigranular and medium to coarse grained.

Near the pendant contacts, the granodiorite is occasionally strongly silicified and/or argillically altered with up to 10% fine grained disseminated pyrite. Small irregular quartz sweats occur locally with varying coarse grained pyrite.

STRUCTURE

The most prominent structural feature observed to date on the Pilldolla claims is a west-northwesterly trending moderately dipping shear in the centre of the Pilldolla 1 claim. The shear separates an expansive limestone/marble/siliceous metavolcanic assemblage to the north from strongly gossanous quartz mica schists/siliceous metavolcanics in the Cliff Area. Several hundred metres to the east, the structure passes from Gambier Group rocks into Coast Range intrusive into the Cave Zone.

8.0 SOIL GEOCHEMICAL SURVEYS

Due to steep topographic conditions, contour soil lines were employed instead of grid survey lines (Figures 5 & 10). Samples were generally collected from soil holes averaging 15 - 30 cm in depth. The sample material varied from well developed soil to talus fines. The samples were placed in numbered kraft bags corresponding to flagged and marked survey stations which were chained with the use of topo-fill instruments. Analytical procedures are summarized in Appendix II.

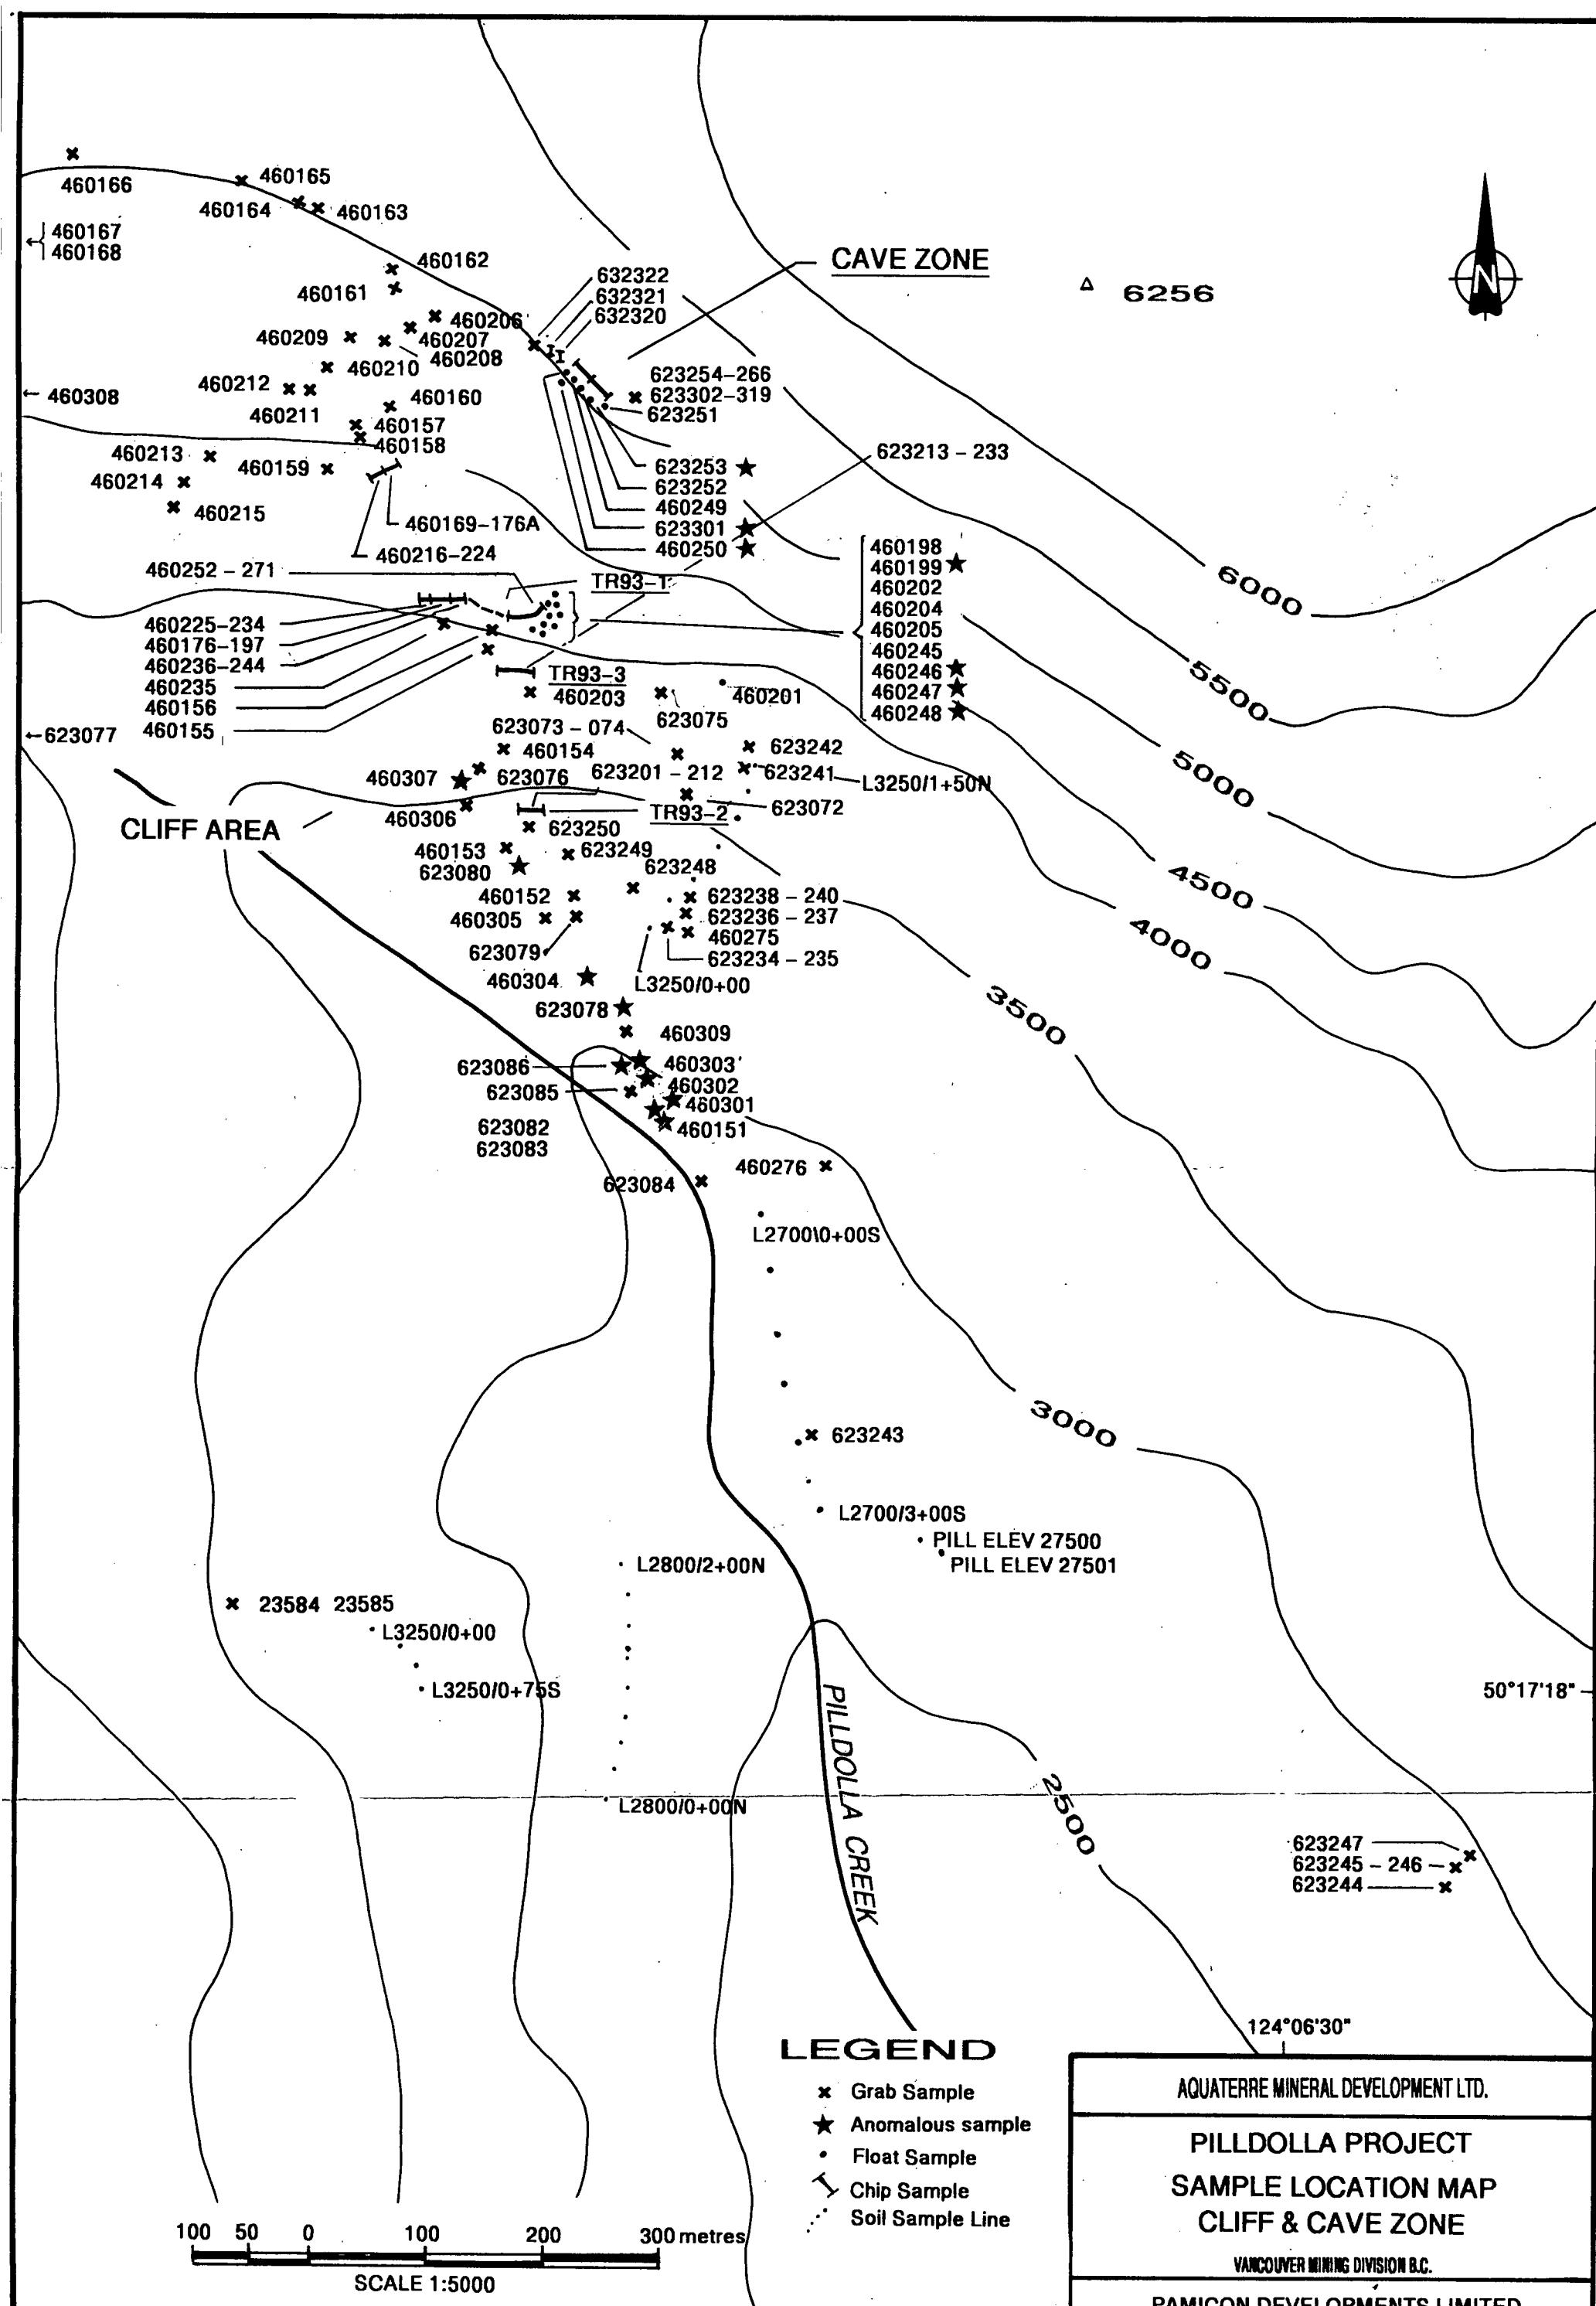

No statistical analyses of the geochemical results was attempted because it was considered that the limited number of samples taken would not be a meaningful representation of the entire area.

Individual contour soil lines that were sampled in various parts of the property are plotted at a scale of 1:10,000 on Figure 10 and 1:5,000 on Figure 5. Assay certificates corresponding to the soil line data are listed in Appendix III of this report.

From the limited sampling carried out to date, no areas of anomalous values have been identified on the Pilldolla claims.

9.0 STREAM GEOCHEMICAL SURVEY

Two areas of the Pilldolla claims were surveyed utilizing silt and heavy sediment

sampling. Near the headwaters of Pilldolla Creek, the main creek and its tributaries were sampled to investigate the potential for mineralization upstream in extensively gossanous cliff area (Figure 5). Subsequent prospecting in this area discovered abundant gold-silver-copper-lead till and talus boulders. A second area along the north side of Pilldolla Creek towards the south end of the property was also sampled (Figure 10). A recently built east-west trending logging road along the valley provided control. Streams were sampled that crossed the road.

Analytical procedures are summarized in Appendix III while assay certificates for individual samples are listed in Appendix IV.

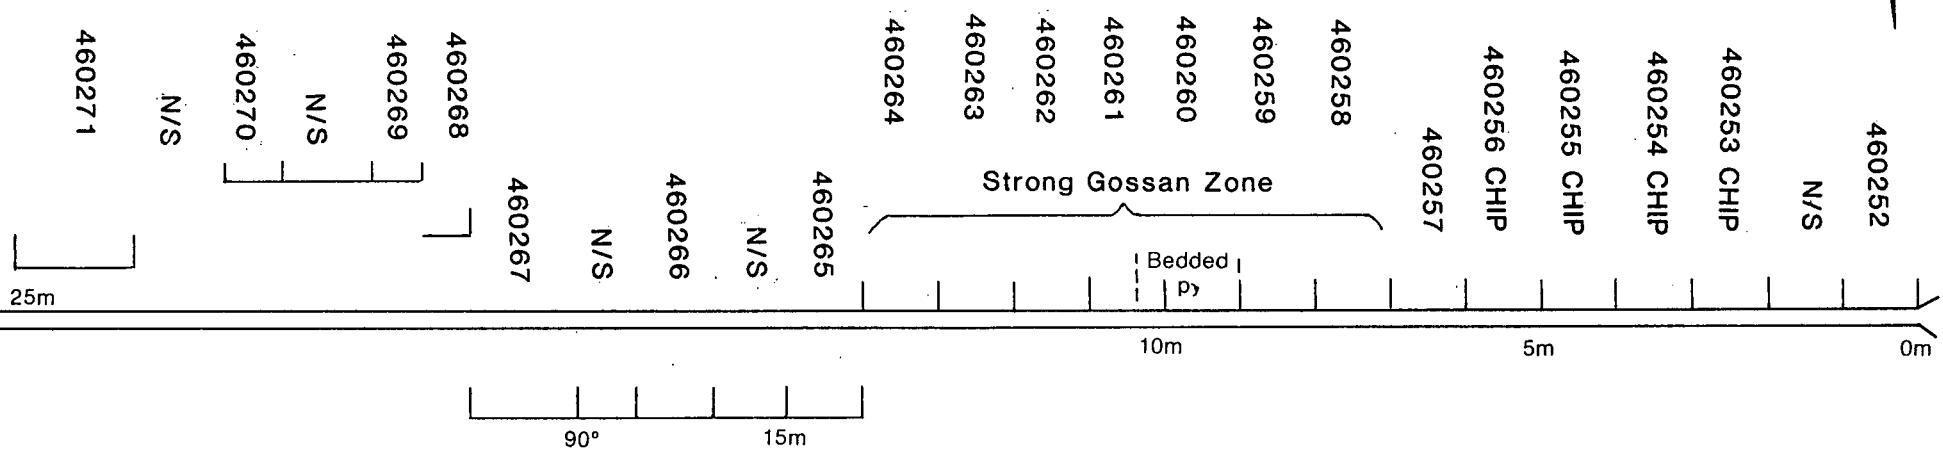

No anomalous samples were reported including the sites directly below the mineralized till and talus field in the Cliff Area and Cave Zone on the east side of Pilldolla Creek near its headwaters.

10.0 MINERALIZATION

Work carried out during 1993 on the Pilldolla project has discovered one primary target for ongoing evaluation at the Cliff Area and Cave Zone. A west-northwest trending shear extends for over one kilometre as observed to date on the east side of the headwaters of Pilldolla Creek. This shear cross-cuts both Gambier Group rocks and Coast Range intrusive and lies uphill to the north from a train of numerous sub-angular to sub-rounded well mineralized boulders. Fine to coarse grained pyrite is common with chalcopyrite as disseminations and blebs appearing

to be intimately associated with gold mineralization. Less commonly galena, pyrrhotite and sphalerite occur. Rock sample locations are plotted at a scale of 1:5,000 on Figure 5.

Experienced mountain climber geologists utilizing climbing ropes and other technical equipment carried out select sampling and mapping traverses over different areas of the Cliff Area and Cave Zone gossans in attempts to locate the source of the mineralized boulders. Rock saw channel sampling of three areas was done in addition across more accessible parts of the cliffs (Figures 6 - 8).

Mineralization at the Cave Zone consists of fine to coarse grained pyrite within a west-northwesterly trending moderately dipping shear which varies from 1.0 metre wide at its west end to 3.0 metres at the east end where worked. Rocks hosting this structure at the Cave Zone are Coast Range granodiorite. Although the climbers utilized ropes during the sampling of this area, time did not permit a complete and thorough examination of the entire cliff area. Noticeable sulphide mineralization seen in overhanging cliff walls was not sampled during this program. Continuous chip sampling over varying widths of the shear along it's strike produced values ranging up to 755 ppb Au across 65 cm (623302) (Figure 9). The highest values obtained from the Cave Zone area were from one piece of float (623253) directly below the mineralization seen in the overhanging cliff. This sample assayed 0.369 oz/ton Au, 3.15 oz/ton Ag and 2.15 % Cu. Anomalous results from the Cave Zone are listed below:

<u>Sample Number</u>	<u>Type</u>	<u>Au (ppb)</u>	<u>Ag (ppm)</u>	<u>Cu (ppm)</u>	<u>Pb (ppm)</u>

From the base of the cliffs near the bottom of the Cliff Area and Cave Zone, 12 samples of mineralized schist have returned values greater than 1,000 ppb Au. Copper values range up to 9,111 ppm Cu. One select grab of mineralization from a single boulder assayed 0.595 oz/ton Au, 16.00 oz/ton Ag and 10.25 % Pb.

A summary of results typical of the mineralized talus boulders found at the base of the cliffs below the Cliff Area is tabulated below:

<u>Sample Number</u>	<u>Type</u>	<u>Au (ppb)</u>	<u>Ag (ppm)</u>	<u>Cu (ppm)</u>	<u>Pb (ppm)</u>

11.0 CONCLUSION

The Pilldolla property is located 125 kilometres northwest of Vancouver, B.C. and 85 kilometres east-northeast of Campbell River, B.C. Recently constructed logging roads pass through the southern portion of the claim block and allow for excellent access to the claims area from tide water.

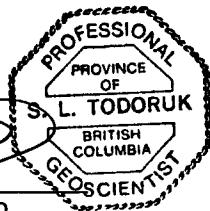

Field exploration work carried out during the 1993 season has discovered an extensive train of well mineralized boulders below a spectacular gossanous cliff. Highly anomalous values in gold are reported associated with copper and locally lead and silver. Assay values up to 0.369 and 0.595 oz/ton Au, 8.73 and 16.00 oz/ton Ag, 2.15% Cu and 1.34 and 10.25% Pb have been obtained from sampling. The source of these encouraging mineralized boulders remains unexplained at this time although a prominent west-northwesterly trending shear extending for over one kilometre in strike length passes up hill above the boulder train and continues on to the east through the Cave Zone.

Traverses carried out in selected areas of the steep terrain were unable to duplicate gold results obtained from numerous boulders at the cliff base although anomalous values were produced in one area which warrants detailed follow-up work.

In light of the significant number of anomalous samples with very encouraging assay results, continued evaluation of the Pilldolla property is recommended.

Respectfully submitted,

Steve L. Todoruk, P.Geo.

Mr. Steve Todoruk
Aquaterre Mineral Development
#711-675 W. Hastings St.
Vancouver, B.C.

Fax: 684-0279

Dear Steve:

Please find below our techniques for sample preparation and analytical determinations for Aquaterre samples in 1993.

Sample Preparation

Rock and Drill Core

1. All field material submitted was dried when required and reduced to -10 mesh using Jaw and Cone Crushers.
2. A 250 g representative split of the -10 mesh material was obtained using a Jones Riffle Splitter.
3. The representative split was pulverized to -150 mesh using a ring and puck pulverizer.
4. The pulverized material was homogenized, bagged and labelled.

Soil and Sediment Samples

1. All field material was dried at 60 °C.
2. The dried sample was screened for the -80 mesh particle fraction, unless an alternative fraction was requested.
3. The -80 mesh fraction was homogenized, bagged and labelled.

Au determination - Fire Assay Preconcentration finished by Atomic Absorption Spectroscopy

A thirty gram sample is weighed into a fire assay crucible. The fire assay preconcentration consists of a standard litharge fusion followed by cupellation of the lead button to obtain the precious metals concentrated into a tiny (about 3 mg) silver prill. Bondar-Clegg has adopted this technique as our primary method for the preconcentration of gold and other precious metals because of its proven track record and sensitivity. The silver prill is dissolved in aqua regia and the diluted solution is then aspirated into the AAS flame for measurement of the gold concentration.

The ICP procedure consists of taking a sample that has been put into an aqueous solution after an acid digestion and is aspirated into the plasma of the instrument for measurement of the concentration of the elements of interest. When the elements from the sample solution reach the high energy plasma, the intense heat of the plasma causes them to emit their characteristic wavelengths of light. The spectrometer isolates the light of the different elements and measures the amount of light at the specific wavelength for each element to be determined. This emission intensity is compared with that obtained from solutions of known element concentrations in order to calculate the concentrations of the elements in the sample.

The Hg was determined using a HNO₃/HCl extraction-Cold Vapour, Flow Injection/Atomic Absorption, detection level of 0.010 ppm.

Major and Minor Oxides on Selected Samples

The following major and minor oxides were determined on selected samples using a lithium metaborate fusion, Inductively Coupled Plasma Emission measurement:

<u>Element</u>	<u>Detection Level</u>	<u>Element</u>	<u>Detection Level</u>
SiO ₂	0.01%	Al ₂ O ₃	0.01%
Fe ₂ O ₃	0.01%	CaO	0.01%
MgO	0.01%	K ₂ O	0.01%
Na ₂ O	0.01%	TiO ₂	0.01%
P ₂ O ₅	0.01%	MnO	0.01%
BaO	0.01%	Cr ₂ O ₃	0.01%

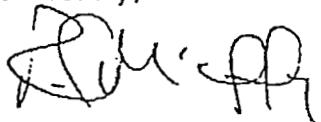

0.1 g of sample material is fused at 1050 °C for 15 minutes. The molten "jelly" is then dissolved in a HNO₃ acid solution. The solution is diluted and the major and minor oxides are then measured using an ICP-Atomic Emission Spectrometer.

Loss on Ignition

Loss on ignition is performed at a temperature of 850 °C for 4 hours. A 1 g test sample weight is used and a detection level of 0.05 % is achieved. Other LOI temperatures and times are available on request. All weights are down-loaded electronically into the Bondar-Clegg computer data base. All LOI calculations are performed by the computer after data acquisition is complete.

Should you need additional information, please contact me at (604) 985-0681.

Sincerely,

Rick McCaffrey
Manager, Geochem Department

Pilldolls
- from a traverse
along Creek of
Greiss zone
up strike
to South.

Pilldolls
- a traverse ~ 600 m to South of 623234-242
up another creek along strike.

Pilldolls - near base of cliff in talus field at bottom
of Greiss Zone where galena has been found.

623308-322
Andrew/Willie's?

APPENDIX VI
STATEMENTS OF QUALIFICATIONS

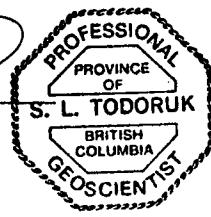

STATEMENT OF QUALIFICATIONS

I, STEVE L. TODORUK, of 6441 Samron Road, West Sechelt, in the Province of British Columbia, DO HEREBY CERTIFY:

1. THAT I am a Geologist in the employment of Pamicon Developments Limited, with offices at Suite 711, 675 West Hastings Street, Vancouver, British Columbia.
2. THAT I am a graduate of the University of British Columbia with a Bachelor of Science Degree in Geology.
3. THAT my primary employment since 1979 has been in the field of mineral exploration.
4. THAT my experience has encompassed a wide range of geologic environments and has allowed considerable familiarization with prospecting, geophysical, geochemical and exploration drilling techniques.
5. THAT this report is based on data and information collected by the authors of this report.
6. THAT I have an indirect interest in the property described herein and the securities of the company.

DATED at Vancouver, B.C., this 22 day of December, 1993.

Steve L. Todoruk, P.Geo.

STATEMENT OF QUALIFICATIONS

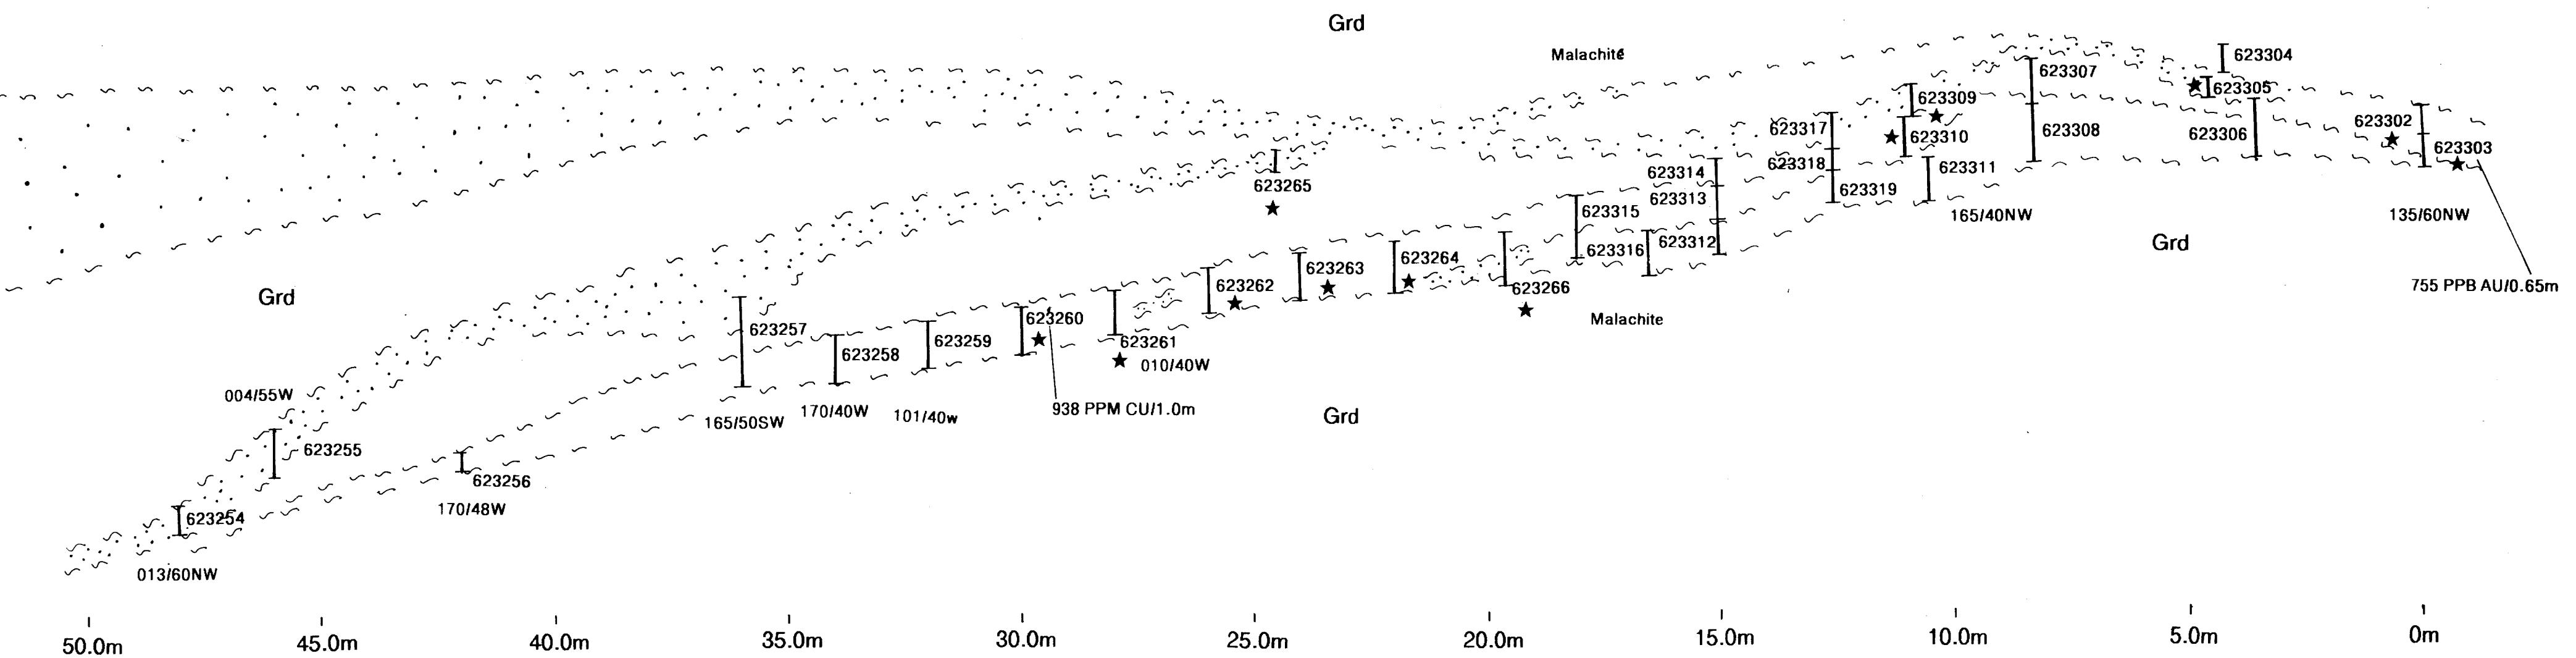

I, MYRA G. SCHATTEN, of 629 Riverbend Drive, Calgary, in the Province of Alberta,
DO HEREBY CERTIFY:

1. THAT I am a Contract Geologist currently employed by Aquaterre Mineral Development Ltd., with offices at Suite 1003, 470 Granville Street, Vancouver, British Columbia.
2. THAT I was actively involved as a field geologist on the Pilldolla Project during the 1993 field program and assisted in the collection of the data referred to in this report.
3. THAT I graduated from the University of Alberta, Edmonton, Alberta, B.Sc. Geology. I have been actively involved in mineral exploration since 1987.

DATED at Vancouver, B.C., this 12 day of JANUARY, 1993.

M.G. Schatten, Geologist
