SUMMARY

The Jesse Creek Property centred on Merritt, British Columbia consists of 24 contiguous mineral claims totalling 188 units and covering approximately 4700 hectares. Much of the property is underlain by Triassic, Nicola Group (western facies) volcanics and sediments with local diorite to monzonite intrusives (Triassic or later age). A significant amount of previous exploration has taken place on the property, much of which is poorly documented. The exploration target for much of this work was Craigmont style Cu-Fe skarn deposits.

In October and November 1994, Conlon Copper Corporation conducted a diamond drilling program on the Mike skarn area. In this area a thick sequence of folded andesite to basalt flows and volcaniclastic rocks with minor sediments lie in the contact metamorphic aureole to the Jesse Creek stock (monzonite). Limy units have been converted to cal-silicate hornfels and local medium to coarse grained copper-iron mineralized skarn with local anomalous gold values. Two out of the four proposed holes were completed for a total of 192.93 metres. These encountered narrow skarn zones with at least two stages of alteration. The later stage is structurally controlled with specular hematite, epidote and chalcopyrite, and returned copper values in both holes.

1.0 INTRODUCTION

This report presents the results from a 1994 diamond drilling program on the Jesse Creek Property, Mike grid (QZ#3 claim) in the Nicola Mining Division. The object of this program was to test copper mineralized skarn zones that had been outlined during a detailed geological mapping program in 1993. These zones on the Mike grid had several (significant) geological features in common with the Craigmont Copper Iron skarn deposit located 10 kilometres to the northwest.

The drilling program took place between October 15 and November 28, 1994 and was supervised by R.C. Wells P.Geo., F.G.A.C. consulting geologist for Kamloops Geological Services. Ltd. Conlon Copper Corporation with offices located at Suite 1003-850 Burrard Street, Vancouver financed the program. The total cost of the program was $28,584.46, of which $28,000.00 is being applied to the Jesse Creek east and west claim groupings for assessment work credit.

1.1 LOCATION AND ACCESS

The Jesse Creek Property is located north and west of the town of Merritt, British Columbia (Figure 1) and is covered by the NTS map sheet 92I/2. Most of the property is easily accessed from a network of old logging and mining roads, many of these can be driven using a 4x4 vehicle. The Nicola-Mameet Indian Reserve lies immediately to the west of the property.

1.2 PROPERTY

This large property, located in the Nicola Mining Division of British Columbia, consists of twenty four mineral claims with a total of 188 units (4700 hectares). Details concerning the individual claims are available in Table 1 and Figure 2. Patrick Conlon and Lorne Mclelland, both of Merritt B.C. are the recorded owners of the claims. Conlon Copper Corporation financed all of the exploration conducted on the property in 1994. This company has an agreement with the owners to earn 100% interest in the property subject to a 2% NSR.

1.3 PHYSIOGRAPHY AND VEGETATION

The west trending Nicola Valley, with a mean elevation close to 600 metres, bisects the Jesse Creek Property (Figure 3). To the north and south, steep valley slopes with widespread talus and local cliffs rise to an undulating plateau ranging from 1000 to 1300 metres in elevation. These highlands are dry with a few small ponds and are dissected by small drainages. Jesse Creek is the largest drainage on the property and is located in the northern area. Much of the property is dominated by open coniferous woodland with some large meadows on the plateau regions. Jesse Creek Valley and the lower valley slopes on the Jean Claim are heavily wooded with much undergrowth. Large parts of the property, in particular, the north and west have been logged to varying degrees. Much of the Nicola Valley on the property is in agricultural, commercial or residential use.

1.4 HISTORY AND PREVIOUS WORK

The property area has a long exploration history, dating back to the 1880's. A wide variety of deposit types are present around Merritt; over 200 mineral occurrences have been documented. Gold-silver bearing quartz veins occur near Stump Lake (Enterprise-King William veins), polymetallic veins with combinations of copper, lead, zinc, gold and silver at Swakum Mountain, Nicola Lake (Turlight) and Iron Mountain (Leadville/Comstock), copper-iron skarns at Craigmont, Swakum Mountain and on the Jesse Creek Property (Cinderella-Chase, Mike, Val). The Craigmont deposit, located 10 kilometres northwest of the property, became the single major producing mine in the Merritt area in 1961 (discovered in 1957). Between 1957 and 1982, Craigmont produced from surface and underground workings a total of 29.3 million tonnes of ore, averaging 1.4% copper.

The property itself has a history of copper exploration dating back to the early 1900's. Until recently, the showings covered by the Jesse Creek property were held by a number of different individuals and mining companies. This is the first time that the area and all the showings have been covered by a contiguous claim group under one owner. Over thirty exploration and small development programs have been documented on the property (Table 2). Many of these programs appear to have been small. Details on the larger programs by Peele Resources/Nippon 1964-65, Newvan Resources Ltd. 1972 and Quintana Minerals Co. 1976 are sparse, especially regarding the location and results from drilling and trenching.

MINERAL SHOWINGS AND AIRBORNE ANOMALIES

KAMLOOPS GEOLOGICAL SERVICES LTD.

DATE	NTS	FIGURE
August 1993	92I/2	4

Figure 4 gives the location of the main mineral occurrences on the property. A brief description of previous exploration on each of these follows. Table 2 should be consulted for sources of reference.

1) Copper Belle (Jean Claim)

This area features several short adits and a number of rock cuts over a 300 metre strike length. Shallow dipping and generally narrow lenses of massive specular hematite, carbonate, quartz (replacements, veins) with chalcopyrite cut Nicola volcanics. Between 1908 and 1913, a number of small hand sorted shipments, including 47 tons averaging 7.15% Cu in 1913, were sent to Trail and Tacoma smelters. More recently between 1960 and 1985, there have been several geophysical and geochemical surveys of very limited coverage.

2) Anaconda (Jean and Bob Claims)

The old Anaconda workings feature a shallow pit and two caved adits. The pit has steeply dipping, fracture controlled zones of specular hematite in Nicola volcanics. There is very little information on these workings, and no work has been recorded since 1915.

3) Cinderella-Chase (Pete and Pete#2 Claims)

This northerly trending zone of limestone with associated copper skarn zones (local Pb and Zn) is over 2 kilometres long. It should be noted here, that in many publications the Chase and Cinderella mineral occurrences are shown in different locations. Minfile has the Chase north of Cinderella, McMillan (1981) has Chase to the south. For the purposes of this report, the Chase is located over the northern skarn showings, the Cinderella over the south. There has been substantial though poorly documented trenching, stripping and some drilling in a number of areas. Three shallow pits of unknown age occur at the Cinderella copper, lead, zinc occurrence. Major exploration programs were conducted on the Cinderella-Chase zone by Peele Resources in 1964 and Nippon Mining Corporation in 1965. Peele's program included trenching, soils, magnetic, geological surveys and a single drillhole. Nippon conducted significant trenching and 12 drill holes. There is very little available information on these programs and some doubt exists about how many of these holes were actually completed. Quintana Minerals Co. in 1976 conducted an exploration program over the entire zone and adjacent areas. Results from a ground magnetic survey is all that is available.

In 1979, H. Allen completed a 500 foot hole at the northern end of the limestone,skarn zone with disappointing results.

4) Mike (QZ #2 and QZ #3 Claims)

There has been significant trenching in this area, exposing a number of copper-iron skarn showings. There is also evidence on surface for a single drillhole in the trench area. None of this work is public domain. However, it is possible that this work was follow-up to a 1970 magnetic survey by Silver Key Exploration Ltd. These skarn zones were the target for the 1994 drill program.

5) Pumpkin-Val Area (QZ #2, Pete #2, Pete #4 Claims)

This area lies between, and to the north, of the Mike and Cinderella-Chase occurrences. A number of old trenches and copper showings occur in this area. Quintana's magnetic survey in 1976 covered much of this area but did not extend as far west as the western copper showings. Previous to Quintana, Newvan Resources Ltd (1972) is reported to have conducted a 17,000 foot trenching program with a total of 1650 feet of drilling in eleven holes on the old Val 5 and 6 claims. Again, there is very little available data on this program. Traverses in the area indicate that much of the drilling and trenching occurred along the main northeast magnetic trend on the QZ #2, Pete #2 and Pete #4 claims.

Recent work on the property by Conlon Copper Corporation has focused on the known showings. In 1992, a preliminary grid was installed over the Val area and parts of the Cinderella, Chase and Mike showings. This physical work was filed for assessment credit earlier in 1993. A limited amount of sampling from old trenches on the grid was conducted by Greg Ven Huizen in September 1992, and confirmed copper values in the four areas with local lead, zinc and silver.

In 1993 Conlon Copper Corporation financed geological mapping and sampling programs on the Copper Belle-Anaconda (Jean), Mike and Cinderella-Chase areas of the property. The aim of these programs was to outline copper skarn and possible porphyry style targets for further exploration.

DATE August 1993	NTS 92I/2	FIGURE 5

1.5 REGIONAL GEOLOGY

The Merritt area lies in the Intermontane Belt of the Canadian Cordillera and is part of Quesnellia Terrane. Within this section of Quesnellia, the Upper Triassic Nicola Group consisting of volcanics, sediments and associated intrusive rocks constitutes an island arc assemblage. Preto (1977) subdivided the Nicola Group between Nicola Lake and Princeton into three northerly trending fault bounded belts each containing a distinct lithologic assemblage (Figure 5). The Eastern Belt (TNe) facies, east and south of Nicola Lake, consists of mafic, augite phyric volcaniclastic rocks, minor volcanic flows and sedimentary rocks. The Central Belt (TNc) facies consists of alkaline mafic flows and pyroclastic rocks with abundant subvolcanic intrusions of diorite to syenite composition. The intrusive volcanic complexes host alkaline type Cu-Au porphyry deposits near Kamloops (Afton). The Western Belt (TNw) facies is an easterly facing succession of calc-alkaline mafic, intermediate and felsic volcanic rocks, syno-volcanic rhyolite plugs, volcaniclastic sediments and reefoid carbonates. These units are well exposed in the Promontory Hills west of Merritt and host the Craigmont Cu-Fe skarn deposit. Cogenetic calc-alkaline intrusive rocks, such as the Guichon Creek Batholith host plutonic copper molybdenum deposits in the Highland Valley area northwest of Merritt. The Craigmont skarn lies close to the southern edge of this batholith.

The Nicola Group is unconformably overlain by Jurassic Age Ashcroft Formation clastic sediments, and Tertiary (Eocene) Princeton Group intermediate volcanic flows and clastic sediments with coal seams (Coldwater Beds).

Major Tertiary structures, notably the Guichon Creek Fault and Clapperton-Coldwater Faults intersect west of Merritt and are extensional features.

1.6 PROPERTY GEOLOGY - MIKE GRID AREA

The location of the Mike grid relative to the mineral claims is shown in Figure 6. This grid covers some of the highest ground on the Jesse Creek Property, with elevations in the 1100 to 1300 metre range. A very large part of this area has been logged. The hill tops and steeper slopes are barren with large areas of outcrop and talus. In the Mike showing area (old trenches), the topography is hummocky with several overgrown gulleys and small swampy areas. On the west side of the grid a large area has been cleared for grazing. Detailed geological mapping was conducted on the Mike grid area in 1993 and is simplified in Figure 7.

(a) Lithology

During the 1993 geological mapping program, several distinct rock units were defined in the grid area. These are as follows:

LATE TRIASSIC TO CRETACEOUS
INTRUSIVE ROCKS

5 Quartz-Feldspar-Porphyry. Grey to brown, siliceous dikes with plagioclase phenocrysts and local quartz eyes.

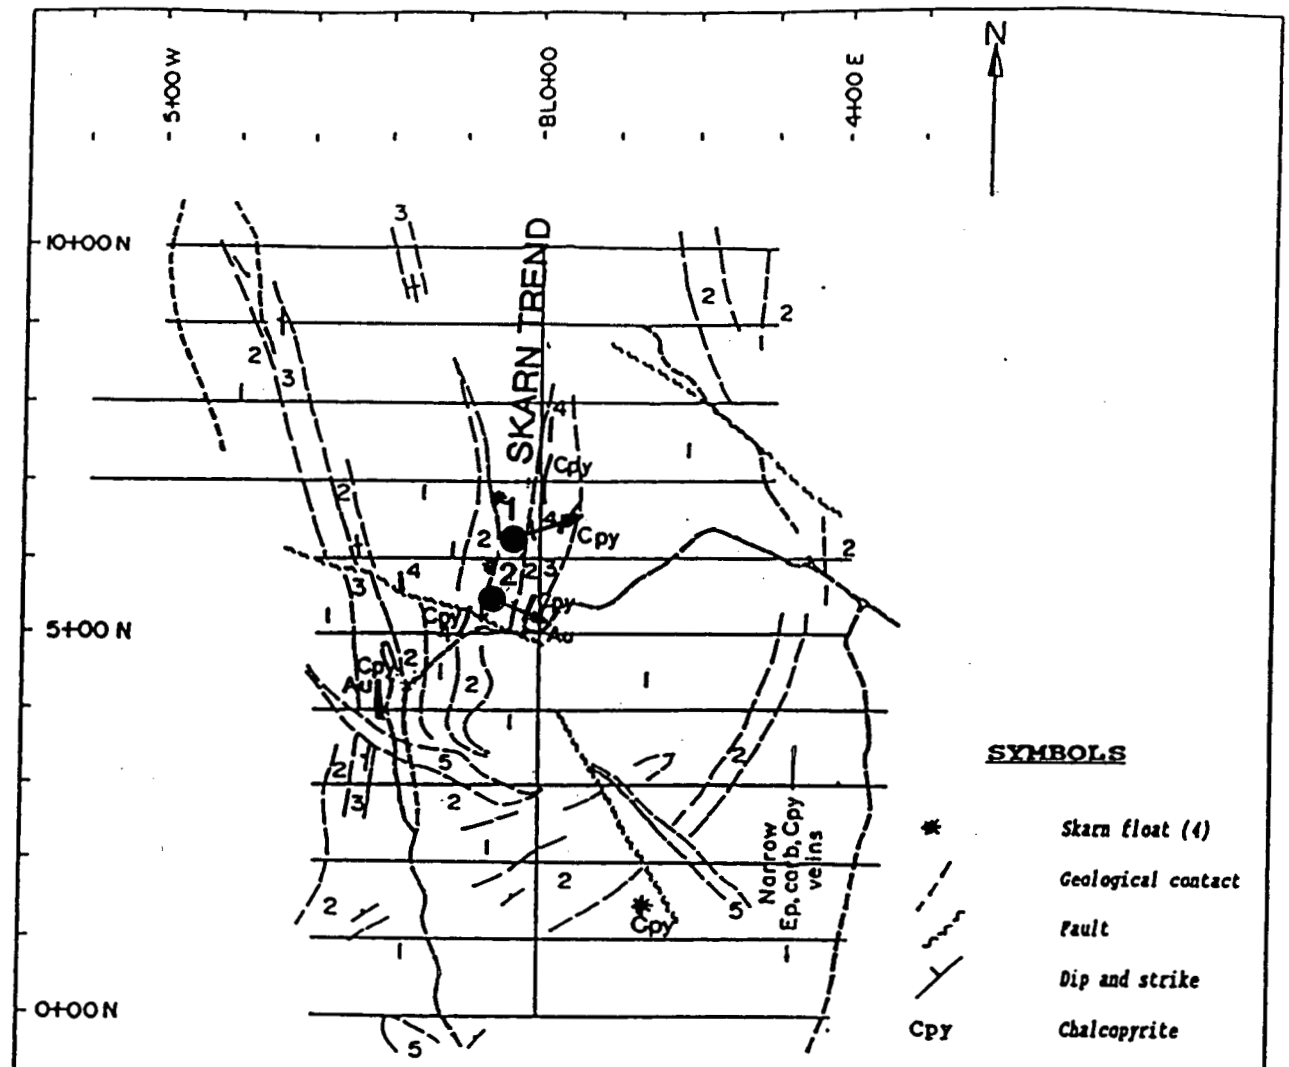
LATE TRIASSIC
NICOLA GROUP - WESTERN BELT

3 Altered limy sediments and tuffs.
3a Bleached and silicified tuffs and breccias.
3b Fine grained siliceous and calc-silicate altered sediments and tuffs.

2 Andesitic tuffs and breccias. Commonly as mixed sequences with Unit 1.
2a Undifferentiated.
2b Heterolithic to monolithic tuff, breccia, minor epiclastic units.
2c Coarse heterolithic breccias and tuffs, clasts greater than 1 cm.
2d Fine to medium grained, bedded tuffs, some cherty units.

1 Dark green to black, massive andesite to basalt flows, variably magnetic.

1a Medium to dark green andesite to basalt, sparse phenocrysts.
1b Medium green to black, commonly crowded plagioclase porphyritic andesite to basalt.
1c Light to medium green andesite, sparse phenocrysts, non magnetic.



LEGEND

LATE TRIASSIC-PRE TERTIARY INTRUSIVE ROCKS

5 — *Quartz Feldspar porphyry*

LATE TRIASSIC NICOLA GROUP - WESTERN BELT

4 — *Skarn altered units*

3 — *Calc silicate altered tuffs, sediments*

2 — *Andesitic tuffs and breccias*

1 — *Massive to porphyritic andesite to basalt flows*

ALTERATION

4 Skarn: several medium to coarse grained mineral assemblages including magnetite, specularite, actinolite, epidote, calcite and K-feldspar. Disseminated chalcopyrite, local pyrite, pyrrhotite.

Moderate to strongly magnetic Nicola volcanics predominate in the grid area (Unit 1). These are massive to plagioclase porphyritic (locally augite) flows and breccias with fine disseminated and local fracture controlled (vein) magnetite. The volcanic assemblage includes intercalations of volcaniclastic rock and minor sediments which range from a few metres to many tens of metres in thickness. Unit 2, green to grey andesitic tuff and breccia includes fine bedded (local cherty) to coarse lapilli tuffs and agglomerates. These may be monolithic to heterolithic with andesite, chert and locally dacite fragments. Epidote carbonate alteration is common within the finer tuffs. Unit 3 consists of calc-silicate altered (hornfels) tuffs and immature sediments. These are predominantly fine grained, fine bedded to massive siliceous rocks with variable epidote, carbonate, light pink to brown garnet, disseminated pyrite and, or pyrrhotite. The main calc-silicate unit is northwest trending and up to 50 metres wide with associated tuffs (Unit 2). Calc-silicate rocks and tuffs also occur along the Mike skarn trend (Figure 6). Two or more dikes of quartz-feldspar porphyry (Unit 5) intrude the Nicola Sequence and have northwesterly trend. These intrusives are of rhyolite to dacite composition and may be subvolcanic equivalents to Nicola (western facies) felsic extrusives. Unit 4 skarn zones will be described later.

(b) Structure

The Nicola Sequence strikes northwest to northeast with steep east to west dips. Bedding attitudes and the configuration of tuff units suggest tight folding. A probable synform fold axis lies close to the base line along the Mike skarn trend and features strong fracturing.

A number of northwesterly trending fault zones are apparent from the mapping. The earliest of these predate and control the quartz feldspar porphyry dikes. These may also control skarn alteration (hematite, epidote, carbonate, pyrite). A later fault set with similar to more northerly trend offsets the dikes and Nicola stratigraphy. The predominate orientation of joints in the grid area is also northwest with vertical to south dips. A northerly trending fault zone is probable along the valley (road) on the eastern edge of the grid.

(c) Metamorphism

The effects of thermal metamorphism on the Nicola Group rocks is widespread throughout the grid area. This metamorphism can be related to the Jesse Creek (monzonite) stock which lies less than one kilometre to the north and possibly at depth below the grid area. Unit 5 quartz-feldspar porphyry dikes may be related to the buried stock.

The mafic volcanics (Unit 1) are variably magnetic with local magnetite veinlets and can often be described as hornfels. Limy tuffs, breccias and sedimentary units have been converted to calc-silicate rocks and hornfels with much epidote and variable carbonate. Evidence of recrystallization is widespread, and fine plagioclase porphyroblasts may be present. The predominantly fine to medium grained calc silicate (hornfels) of Unit 3 have been distinguished from the medium to coarse grained skarn assemblages (Unit 4).

(d) Alteration and Mineralization

A number of styles of mineralization and associated alteration occur on the Mike grid. Several discontinuous, dislocated copper-iron mineralized skarn zones are exposed in the Mike trenches over 300 metres strike length (north-south). Chalcopyrite, malachite and minor azurite are associated with medium to coarse grained magnetite rich, epidote, calcite skarn with dark chlorite and local actinolite. Pink to light brown garnet skarn with epidote has little copper. In more fractured and brecciated areas, coarse specular hematite and calcite occurs with epidote, minor amphibole, chlorite and chalcopyrite (coarse blebby). K-feldspar veinlets, pods and coarse, semi-massive pyrite may be present locally. The specular hematite-chalcopyrite assemblage probably represents a secondary skarn (later phase-overprint). Copper values for the mineralized skarns exposed in the Mike trenches were in the 0.1% to 0.4% range over 1.25 to 4.3 metre range (sample widths). Gold was not associated with the better copper mineralization. However, a 5 metre sample width from epidote, actinolite, magnetite skarn yielded 260 ppb Au and 3.6 ppm Ag (5+00 N just west of baseline).

Chalcopyrite bearing epidote, calcite (minor garnet) skarn with disseminated pyrite and pyrrhotite occurs within the main calc silicate band north of the main feldspar porphyry dike (Unit 5) near Line 4+00N. Sampling in this area returned copper values up to 0.4%.

A 1.8 metre (true width) chip sample ran 458 ppm Cu and 335 ppb Au. This is highly significant as it indicates the presence of gold in the weak copper

mineralized parts of the calc silicate, skarn system. Further sampling is warranted.

Prospecting in the southern part of the grid located amphibole skarn float with coarse pyrrhotite and pyrite. This float returned 0.21% Cu and can not be related to any of the known skarn zones on the grid.

Northerly trending quartz-carbonate-chalcopyrite veins and fracture zones occur in the eastern part of the grid. These are generally less than a metre in width and returned copper values up to 0.35% with local anomalous gold (135 ppb).

2.0 PHASE 1 DIAMOND DRILLING PROGRAM (1994)

2.1 INTRODUCTION

In late October and November 1994 a small drill program was conducted on the Jesse Creek Property. The area drilled was on the Mike grid, QZ #3 mineral claim in the western part of the property. A total of four NQ diamond drill holes were proposed to test a 300 metre strike length of the skarn altered stratigraphy at shallow depth (the Mike trench area). Two of the holes (192.93) metres were completed, the others were postponed until 1995 due largely to bad weather conditions, poor access and insufficient water (high costs).

The drilling was preformed by Allen Diamond Drilling Ltd of Merritt B.C. using a Longyear Super-38 rig. Water for drilling was hauled by truck from a location on Jesse Creek to the north. This water source because of low water conditions only permitted a single drilling shift per day.

The drill program was supervised by Kamloops Geological Services Ltd and financed by Conlon Copper Corporation. R.C. Wells, consulting geologist logged all the core. Split core samples were transported to Eco Tech Laboratories in Kamloops B.C. and analyzed geochemically for gold plus 30 element ICP. All of the remaining drill core from the program is presently housed on the property at the allen drill yard on the QZ#4 mineral claim.

2.2 DRILL TARGETS AND RESULTS

The Phase 1 drill program consisted of two holes, the location of these are shown on Figure 7. Drill logs and analytical results for both holes can be found in Appendix 3.

Diamond drillhole JC 94-1 collar was located at grid 6+18N, 0+25W and drilled to the east. This hole was targeted to hit two skarn zones which have northerly trend and are 40 metres apart at surface (Figure 8). These zones at surface feature medium to coarse grained (1) magnetite-epidote-chlorite-calcite skarn with local chalcopyrite, (2) garnet rich skarn (barren of chalcopyrite) and (3) later specular hematite-calcite-epidote skarn with chalcopyrite. K. feldspar is locally present and may be an intermediate stage skarn component. The drillhole intersected both skarn zones (Figure 8) which dip between 70 and 80 degrees to the west (in the profile). They are within a mixed sequence of andesitic to basaltic lithic tuffs and hornfelsed flows. Both zones feature narrow (strong) skarn altered and fractured core areas with wider envelopes of

epidote-carbonate alteration and variable magnetite veining. Early magnetite rich skarn has some disseminated chalcopyrite. However, the better and coarser grained copper mineralization is fracture controlled and associated with specular hematite and epidote (late skarn overprint). The core to the upper skarn returned 0.35% Cu and weakly anomalous gold (22 ppb) over 1.67m. The lower skarn had a weaker (late) skarn overprint and consequently copper values were less than 0.1%. Several one to two metre wide calc-silicate (epidote-fine garnet-carbonate) altered tuff zones occurred near the bottom of the hole. These locally returned weakly anomalous copper values.

Diamond drillhole JC94-2 collar was located at grid 5+45N, 0+65W and drilled to the east. The hole was targeted to hit a skarn zone over 4 metres wide that had returned a strongly anomalous gold value (260 ppb) from a chip sample in 1993. This skarn at surface has similar features to those in the JC 92-1 area and probably represents the strike continuation of the lower zone (east zone). The hole intersected similar volcanic stratigraphy to JC 94-1 but a significantly less tuff component and far less skarn, calc-silicate alteration. A structurally controlled specular hematite skarn zone in the upper part of the hole overprints massive and narrow magnetite-epidote-calcite skarn. Core angles strongly suggest that the late structurally controlled alteration is sub parallel to the hole. The hole did not hit the projection of the surface skarn zone. It may however, have been displaced by a strong fault zone which was encountered at the bottom of the hole. Surface mapping in 1993 did indicate a significant northwest trending fault close and to the south of the hole. Anomalous copper values were returned from the late specular hematite skarn and the lower fault area.

The pad for a third hole was constructed near 4+400N, 2+00W with access by an old logging trail from DDH JC 92-2. Rehabilitation of this trail resulted in exposure of a skarn zone at 5+00N, 1+10W. This zone is over 3 metres wide and features garnet, epidote and magnetite rich bands in strongly bleached tuffs. Massive magnetite and epidote rich bands contain significant chalcopyrite weathering to azurite and malachite. Sample 142633 a 2.0m true width chip returned 3176 ppm Cu, sample 142634 a 2.4m chip a few metres to the south returned 2720 ppm Cu.

2.3 CONCLUSIONS

The drill program was not completed therefore it is premature to form conclusions based on the results to date.

5.0 STATEMENT OF QUALIFICATIONS

I, Ronald C. Wells, of the City of Kamloops, British Columbia, hereby certify that:

1. I am a Member of the Geological Association of Canada

2. I am a member in good standing of the Association of Professional Engineers and Geoscientists of British Columbia.

3. I am a graduate of the University of Wales, U.K. with a B. Sc. Hons. in Geology (1974), did post graduate (M. Sc.) studies at Laurentian University, Sudbury, Ontario (1976-77) in Economic Geology.

4. I am presently employed as Consulting Geologist and President of Kamloops Geological Services Ltd., Kamloops, B.C.

5. I have practised continuously as a geologist for the last 15 years throughout Canada and USA and have past experience and employment as a geologist in Europe.

6. Ten of these years were in the capacity of Regional Geologist for Lacana Mining Corp. then Corona Corporation in both N. Ontario/Quebec and S. British Columbia.

R.C. Wells, P.Geo., F.G.A.C.

Dated 14 Dec 1994
