SUMMARY

The Swan property is situated in north-central British Columbia. During the period September 9-25, a field program comprised of rock and soil geochemical sampling was carried out on the property. The soil geochemical program analyzed samples by a combination of conventional and enzyme leach techniques.

The work confirmed that highly anomalous levels of Pb, Zn, Ag, and Ba exist in soils and rocks over extensive areas of the Swan property but especially in the Swan, Knoll and Rain prospect areas. Previously unknown anomalous areas were tentatively identified by the enzyme leach method.

For all areas (Swan, Knoll, Rain and Crag), most of the mineralization appears to be associated with the specific stratigraphic interval below or at the base of the Echo Lake Group. This strongly suggests that the control on the mineralization is stratigraphic rather than structural. The control may be a particular lithological unit, an unconformity or a low-angle thrust fault. A traverse across the area underlain by Big Creek lithologies southwest of the Knoll identified two new anomalous areas.

The pilot study using enzyme leach analysis successfully identified previously unknown anomalous areas and has provided valuable information to aid in the design of the next exploration program on the property.

Further exploration comprising enzyme leach soil geochemical surveys is recommended for all prospect areas. A program of diamond drilling is recommended for the Swan grid.

1.0 INTRODUCTION

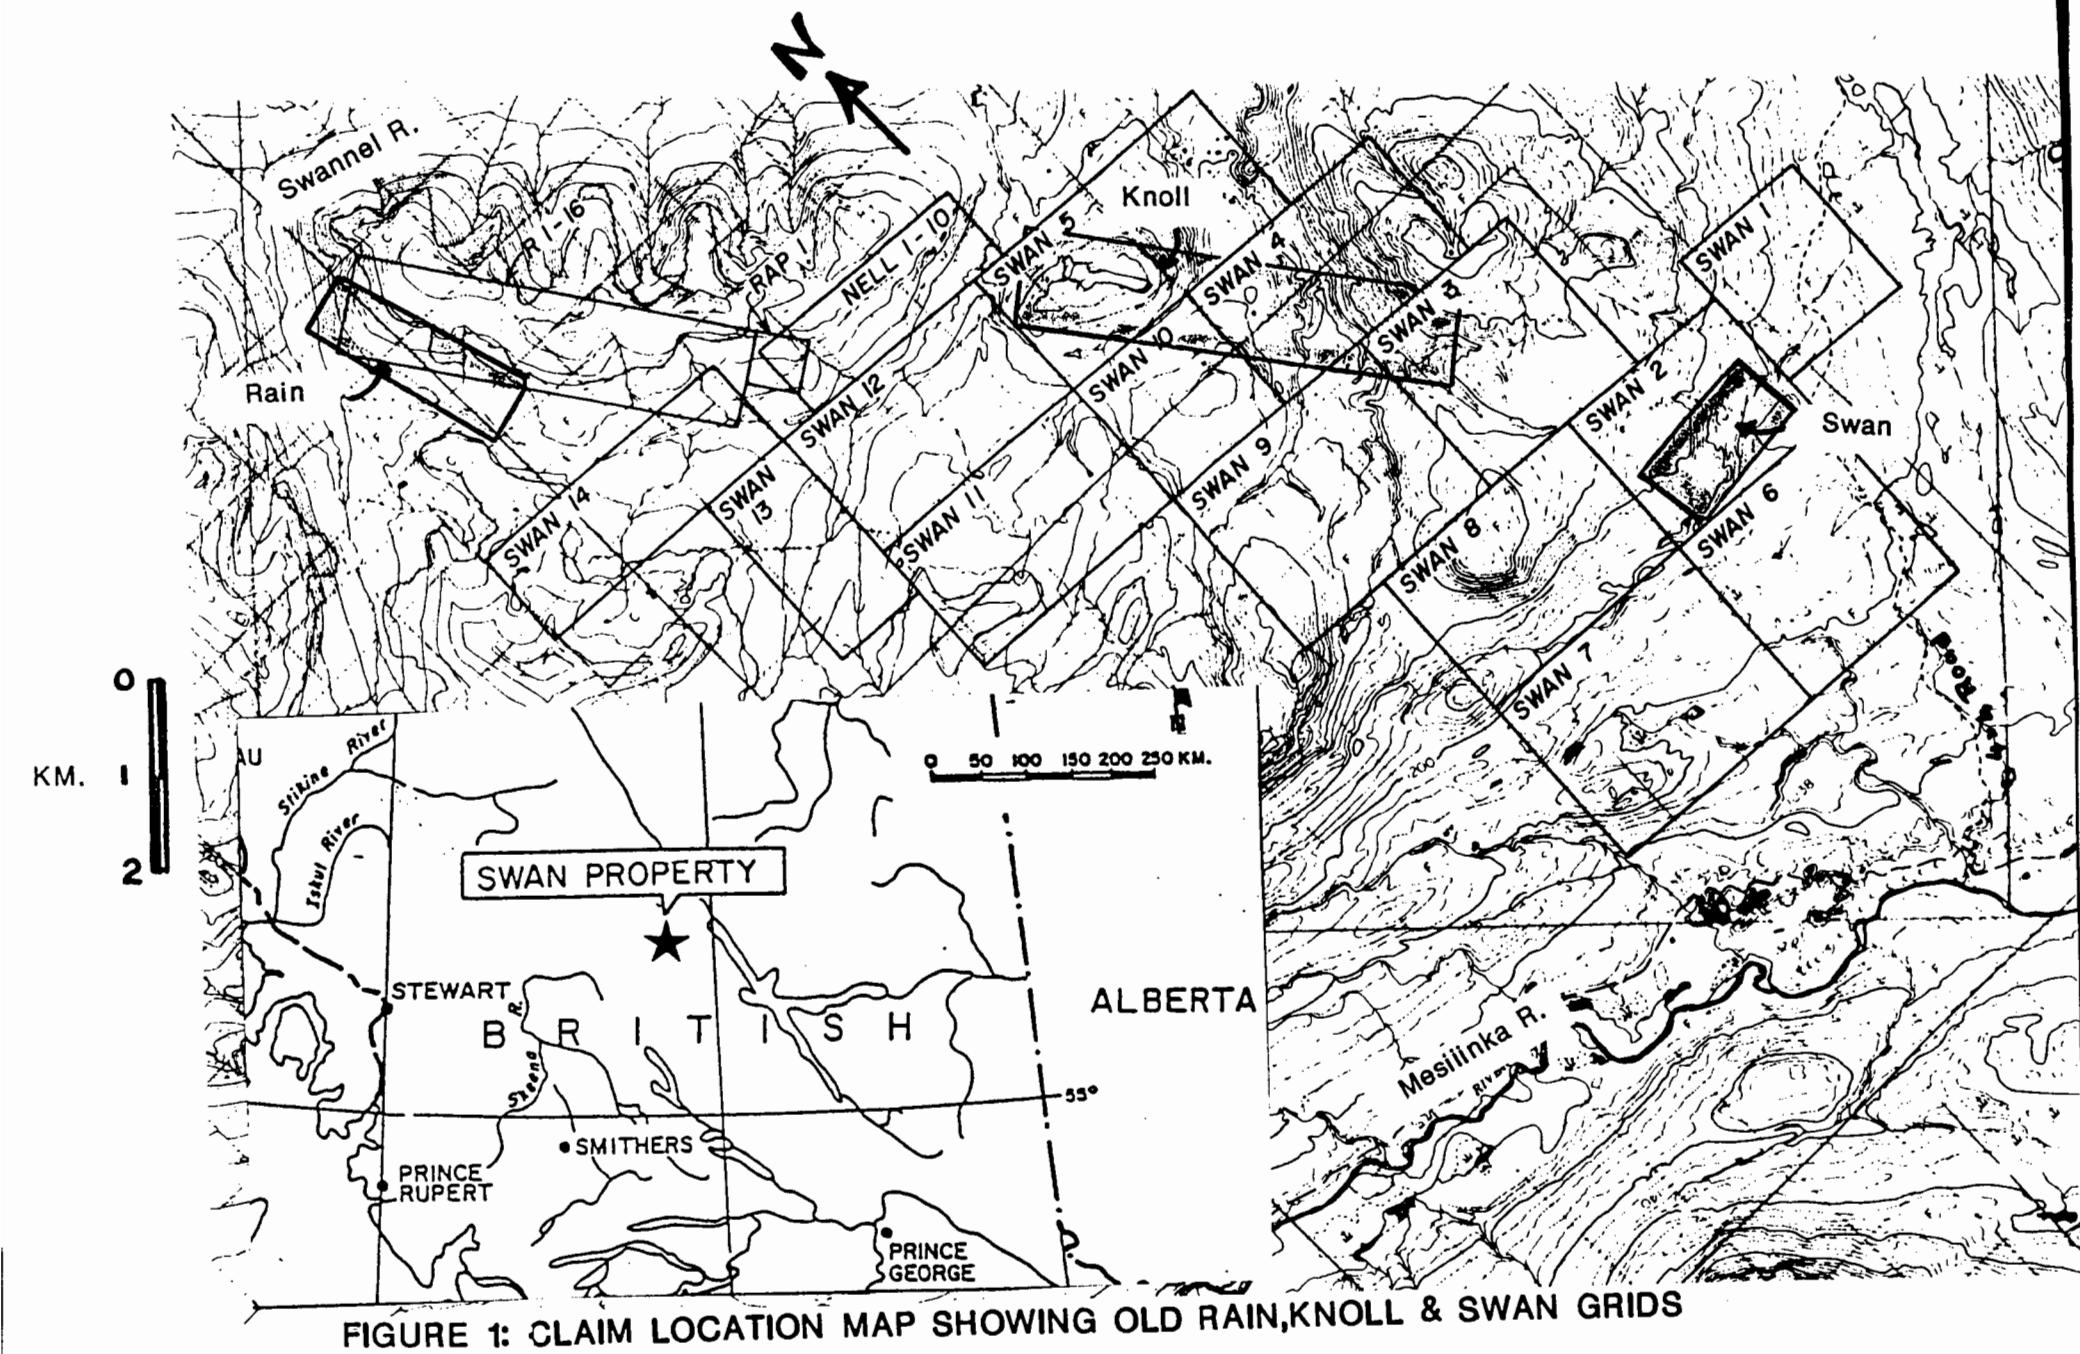

1.1 GENERAL

The Swan property is situated in north-central British Columbia. During the period September 9-25, a field program of rock and soil sampling was carried out on the property. The results of this work are described herein.

1.2 PROPERTY

The Swan property comprises 43 claims made up of 239 units. The claims were staked in March, 1992 and sold to Stratabound Minerals Corp. in 1993. Details of claim tenure are as shown in the following table and on Figure 1.

CLAIM NAME	TENURE	NO. UNITS	STAKED	DUE DATE
Swan 1	308212	12	March 17/92	March 17/96
Swan 2	308213	16	March 16/92	March 16/97
Swan 3	308214	16	March 16/92	March 16/96

1.3 LOCATION AND ACCESS

The Swan property is located at approximately 56°29'N, 125°30'W and is within NTS map-areas 94C/5,6 and 12. The property is approximately 210 kilometres northwest of Mackenzie and 250 kilometres north-northwest of Fort St. James (Figure 1). It straddles the height of land along the Lay Range between the Mesilinka and Swannell Rivers.

For this project, access to the property was by a series of gravel all-weather forest access roads from Mackenzie (by barge across Williston Lake) or Windy Point on Highway 97, and past the Osilinka Logging Camp to Louisville (home of Louie's Cafe), which is about 10 kilometres southwest of the property. From the cafe the property can be reached by a short helicopter ride. Although the southeastern portion of the Swan 2 claim is traversed by the old Ingenika Mining Road, this was found to be impassable by four-wheel drive pickup truck.

1.4 PREVIOUS WORK

The earliest record of exploration in the area is that of Cominco in the 1960's. Their work discovered most of the known showings.

During 1972, SEREM Ltd. carried out a regional stream sediment geochemical program throughout the Omineca Mountains. This led to the staking of what are referred to in this report as the Swan, Knoll and Rain prospects. In 1973, SEREM carried out line-cutting, soil geochemistry, geological mapping, trenching and ground geophysical surveys on each property and in 1974 they drilled 13 holes on the Rain property. As assessment work was not filed on the drilling the results are not known. All the claims were allowed to lapse.

In 1992, the present property covering all known showings as well as intervening areas and extensions, was staked. A program of soil geochemical sampling and limited geological mapping was carried out in the area of the old showings by Firesteel Resources. This work confirmed the existence of large highly significant Pb-Zn-Ag soil geochemical anomalies (Olfert, 1992).

In 1993, the property was sold to Stratabound Minerals Corp. which optioned it to Cominco Ltd. Cominco carried out an extensive work program which included detailed soil geochemical surveying and geological mapping over the Swan grid showings. Control for this work was a topofil and compass grid with lines at 100 metre intervals. Soil samples were taken every 50 metres along these lines. Figure 4 shows the approximate boundary of this grid. Reconnaissance geological mapping combined with contour soil geochemical sampling was done in the vicinity of the Rain and Knoll prospects and over some areas underlain by Gilliland Tuff. A regional silt sampling program was also undertaken. Some old trenches on the Rain and Swan showings were mapped and sampled in detail. Cominco concluded most of the Pb-Zn-Ag showings were apparently structurally controlled with limited potential and dropped their option on the property.

The same year the area was mapped at a scale of 1:50,000 by F. Ferri and crew of the B.C. Geological Survey.

1.5 WORK DONE

In the current program, work was carried out in three areas: the Swan grid, the Knoll prospect and the Rain prospect. A large part of the work was done on the Swan grid, where camp was set up near the Swan 93 trench beside a small stream. Approximately 10 days were spent in this location; all work was done by traversing by foot from this camp. Work on the Swan grid included four soil geochemical traverses with a total of 53 samples collected and sent to Bondar-Clegg for determination of Ag, Pb, Zn and Ba by a conventional analytical technique comprising ICP analysis following aqua regia digestion. Duplicate samples were collected at the same sites and sent to Activation Laboratories Ltd. for enzyme leach analysis.

Two trenches at the Swan 93 showing were cleaned out and channel sampled and grab samples were taken from the Main showing and from other areas of potential mineralization (see Fig 3) from both float and outcrop. Some of the work on the Swan grid was done on the old Serem grid lines which can still be located with some difficulty. These lines are plotted in their approximate location on figure 3.

On the Knoll prospect area, camp was set up beside a small lake just west of the large hill known as the Knoll. Work was done by foot from this camp with the exception of a brief helicopter visit to the area of the Burn prospect.

This work consisted primarily of soil geochemical sampling down the sides of the Knoll. Three of these traverses covered the previously known geochemical anomalies which occur on three sides of the Knoll and the other traverse ran out across the contact with the Big Creek group argillites and well into that unit. Work also included some rock sampling and inspection of mineralized areas.

At the Crag occurrence, two trenches were resampled (chips) and some sampling of float and outcrop was done in the area of the trenches. Near the Burn occurrence, rock samples were taken of the Big Creek Formation from near the reported location of the Burn occurrence, which was not located.

At the Rain prospect, work was carried out during two visits by helicopter. One traverse line of 13 soil samples was taken along the southwest side of the ridge crossing the trend of previously determined soil anomalies and mineralization. Grab samples of highly mineralized rock from a trench and from float were also taken.

2.0 GENERAL GEOLOGY

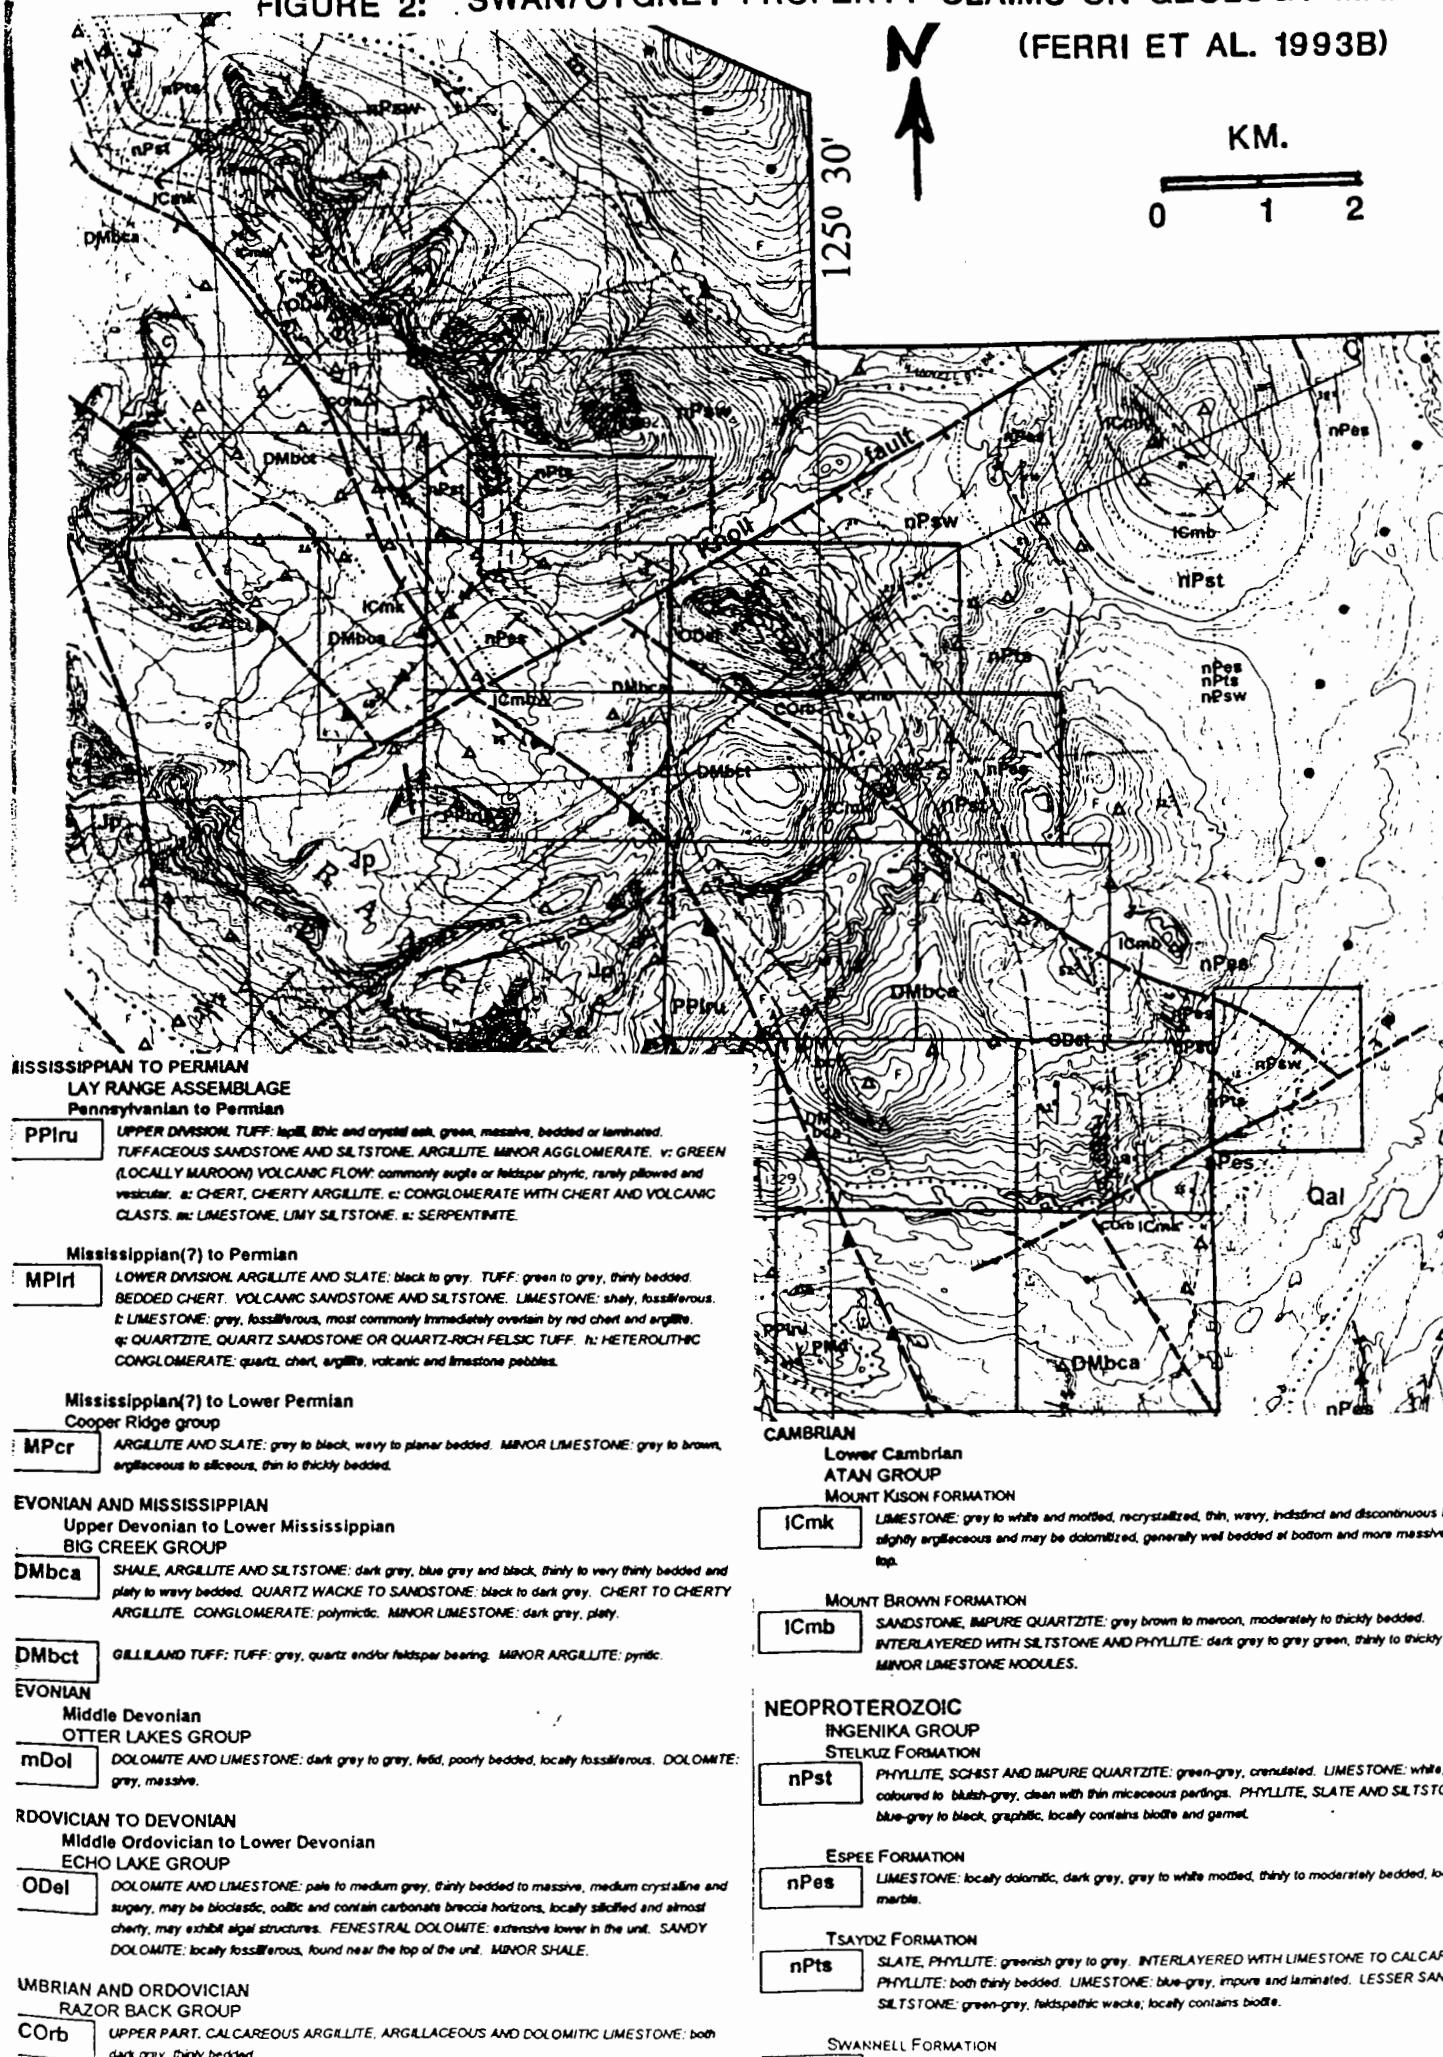

2.1 GENERAL

Rocks in the area covered by the claims are primarily sedimentary and range in age from upper Proterozoic through upper Devonian. They lie within the Cassiar Terrane, which is a portion of the ancestral North American continental margin. Figure 2 shows the geology of the Swan area, from Ferri, with the outline of the claims superimposed.

2.2 GLACIAL GEOLOGY

Roots (1954), in describing the glacial history, indicates that the predominant glacial direction was toward the northeast although this has been modified by or overprinted by valley glaciation toward the end of the glacial period. The result, therefore, is a somewhat complex picture which is beyond the scope of this report.

FIGURE 2: SWAN/CYGNEI PROPERTY CLAIMS ON GEOLOGY MAP
(FERRI ET AL. 1993B)

3.0 GEOLOGY OF PROPERTY

3.1 GENERAL

Most of the rock units within the report area are carbonates, with lesser shales which are often indistinguishable from each other. In the geological description of the three areas, the writer has relied heavily on Rhodes (1993) descriptions, as detailed geologic mapping and stratigraphic mapping were not part of this program. Although Rhodes (1993) preferred the use of older stratigraphic names to those proposed by Ferri (1993), this report will use Ferri's terminology with the older terminology in brackets.

Although no systematic mapping was done during this program, brief descriptive notes for some of the outcrops and float encountered during the traversing are shown on the figures.

3.2 GEOLOGY OF SWAN GRID AREA

3.2.1 Rock Types

Compiled geology of the Swan grid area is shown on Figure 3. Although in detail there is considerable variation in the interpretations of earlier workers, there is general agreement in the broad features. The area is underlain by rocks trending north and dipping at 40° to 50° to the west. Light coloured limestones of the Mt. Kison (Rosella) Formation, with some shaly carbonates, overlie quartzites and sericitic mudstones of the Mount Brown (Boya) Formation, which in turn overlie carbonates and clastics of the Ingenika Group. Overlying the Mount Kison (Rosella) carbonates are dolomites that contain 20 to 80% blue-grey to white silica. The silica commonly occurs as thin laminae, veinlets, breccia fillings, crude fragments and irregular masses. Although the origin of this rock is not clear, the textures can generally be described as either platy and possibly algal laminations or an unlayered breccia of unknown origin. This rock type comprises the top of the large hill immediately above the apparent bedrock source of the mineralization on the Swan East anomaly and lies a few tens of metres to the west of the trench at the Main showing. The spatial relationship between this rock and the mineralization suggests a possible genetic link as discussed in a later section.

3.2.2 Mineral Occurrences

Many showings are present, most of which are stringers, veins, disseminations and possibly massive replacement patches of sphalerite, smithsonite and lesser galena. This mineralization appears to occur most often within or near occasionally vuggy reddish-weathering yellowish ferrodolomite which may occur as altered areas within Mount Kison (Rosella) limestones. Both sphalerite and smithsonite are difficult to recognize and are detected in part by their high specific gravity. On the East Swan anomaly, several pieces of reddish brown to dark brown, partly to completely oxidized rock were found on the slope, presumably derived from an immediately upslope source.

3.3 GEOLOGY OF KNOLL PROSPECT AREA

3.3.1 Rock Types

The Knoll is a very prominent 300 metre high hill which is elongated in a northwest direction (Figure 5). The northeast side is somewhat steeper than the southwest. The top of the hill is underlain by dolomite that is 30 to 80% silicified into a chert-like rock. This rock shows the fenestral and cryptalgal laminae characteristic of the Echo Lake (Sandpile) Group. The silicified dolomite overlies limestones and dolomites that may be Mount Kison (Rosella) Formation. These are exposed on the flanks of the Knoll.

3.3.2. Mineral Occurrences

Rhodes describes the most prominent area of mineralization, one perched on a prominent scarp on the northwest face of the Knoll, as consisting of a 10 by 15 metre area of Mount Kison carbonates cut by a number of irregular barite-galena veins with minor sphalerite and smithsonite. These veins are up to 0.5 metres wide. The rock is somewhat brecciated and dolomitized and may in part be related to a fault. Disseminated mineralization is also reported on the southeast face of the Knoll and may occur elsewhere on the flanks of the Knoll.

3.4 GEOLOGY OF RAIN PROSPECT AREA

3.4.1 Rock Types

Rocks on the Rain prospect comprise a thin interval of Mt. Kison (Rosella) Formation carbonates exposed along the high point of the prominent ridge and forming the dip slope that falls away moderately steeply to the southwest. Ferri shows this to be overlain by a "slice" of limestone and dolomite of the Echo Lake Group (Figure 6). On the northeast side of the ridge, a thin interval of argillite or argillaceous and dolomitic limestone of the Razor Back Group lies between the Mt. Kison and Echo Lake rocks. Rhodes interpretation, not discussed here, differs substantially from that of Ferri.

3.4.2. Mineral Occurrences

Mineralization occurs on the lower part of the southwest facing slope. Phodes suggested that the favourable stratigraphy may be particularly fossiliferous with fossil hash zones showing up in several of the trenches. The showings, which cover a strike length of 1.5 km, have been described as stratabound ferrodolomite zones which may be in part controlled by cross cutting faults. Scattered float with significant barite, galena and smithsonite (see sample results below) occur along this zone. A trench at the north end of the zone has semi-massive galena and lesser sphalerite mineralization. An 800 metre interval of this zone was drilled by Serem.

4.0 ROCK SAMPLING

4.1 GENERAL COMMENTS

Analyses were done at Bondar-Clegg Laboratories in Vancouver. Results are included as Appendix 2 and shown on Figures 3, 5 and 6.

The analytical procedure was as follows. Samples were crushed, split and pulverized. A portion of the -150 mesh size fraction was subjected to an aqua regia digest and this solution was analyzed for Ag, Pb, Zn and Ba by the inductively coupled plasma (ICP) method. Samples which returned values greater than the limits of 50 ppm Ag, 10,000 ppm Pb, 20,000 ppm Zn and 2,000 ppm Ba were reanalyzed following new digestions. Methods used for this are Atomic Absorption for Ba and Zn, AAS low level assay or titrimetric assay for Pb and fire assay/gravimetric finish for Ag.

4.2 SWAN GRID AREA

Forty-one rock samples were collected from the Swan grid area. The best of these is described below.

4.2.1 Swan 93 Trench and Adjacent Areas

An old trench referred to in the Cominco (1993) report as Swan 93 was cleaned out and lengthened and channel sampled. Four samples were taken; from south to north these are: SW95-W004 (0.5m), then 0.5m of no sample, W005 (2.0m), W006 (2.0m), and W007 (2.0m). Values to 0.41%Pb, 15.26% Zn and 52 ppm Ag over 2.0 metres were obtained from this sampling.

Sample W025 gave 5.7% Zn over 0.7 m from a small outcrop(?) 20 metres east of the Swan 93 trench. Sample W041, from a 1 m float or outcrop 100 to 150 m WSW of the Swan 93 trench and near soil sample SW-SO-9550 gave 27.1 ppm Ag, >10,000 ppm Pb, 6.8% Zn.

4.2.2 Main Showing and Adjacent Areas

Grab sample SW95-W038 from the large trench at the Swan Main showing gave 15.7 ppm Ag, >10,000 ppm Pb and 4,394 ppm Zn.

4.2.3 Swan East Area

The best sample obtained from the Swan East anomaly area was W034, a grab sample of oxidized talus at the base of the slope and near old line 0W (see Figure 3). This gave 15.1 ppm Ag, 3015 ppm Pb, and 3.0% Zn. Samples W017 to W019, collected from well up the slope on line 8W and close to the presumed bedrock source of the mineralized talus as well as the soil anomaly, also gave highly anomalous metal values including 7527 ppm Zn.

4.2.4 Swan North

Two samples of float or "detached bedrock" from old trenches in overburden at what has been referred to as the Swan North showing gave highly anomalous results. Sample SW95-W001 yielded 9.2 ppm Ag, 4837 ppm Pb and 3.6% Zn. Sample W020 from the most westerly trench gave 1.2 ppm Ag, 225 ppm Pb and 13,798 ppm Zn.

4.3 KNOLL PROSPECT AREA

Thirty-five rock samples were collected from this area, including nine from two trenches at the Crag showing and four from the Burn occurrence.

4.3.1 Main Knoll Area

The only significant sample from the area of the Knoll was KN95-W002. This piece of float from the bottom of the slope below the Knoll showing gave 8.8 ppm Ag, 2986 ppm Pb and 2.89% Zn. This was a re-sampling of an occurrence that Cominco work had erroneously identified as outcrop.

4.3.2 Crag and Burn Areas

Two trenches were chip sampled at the Crag prospect. From north to south the sample locations are as follows:

<u>Trench 1</u>	<u>Trench 2</u> (approx. 50 NE of Tr. 1)
W015 - 1.6m	W017 - 1.8m
W016 - 2.6m	W018 - 1.8m
W020 - loose grab sample	W019 - 2.4m
	3.0 m not sampled
	W021 - 2.0m
	W022 - 3.0m
	W023A,B - Loose grab samples

Samples BU95-W030 to W033 were collected near the reported location of the Burn occurrence. The first three are of dark grey Big Creek argillite exposed as a steep hillside. The best of these gave 2.6 ppm Ag, 88 ppm Pb, 220 ppm Zn, and 1940 ppm Ba. The fourth sample was a cobble of barite breccia from the creek.

4.4 RAIN PROSPECT AREA

Five rock samples were collected from the Rain prospect. Samples KN95-W031 to W033 are grab samples from an old blasted trench north of the soil traverse carried out in this report. These samples gave high values to 9.99 oz/t Ag, 22.31% Pb, and 957 ppm Zn. Grab samples RA95-W001, W002 were of float found adjacent to the soil traverse line.

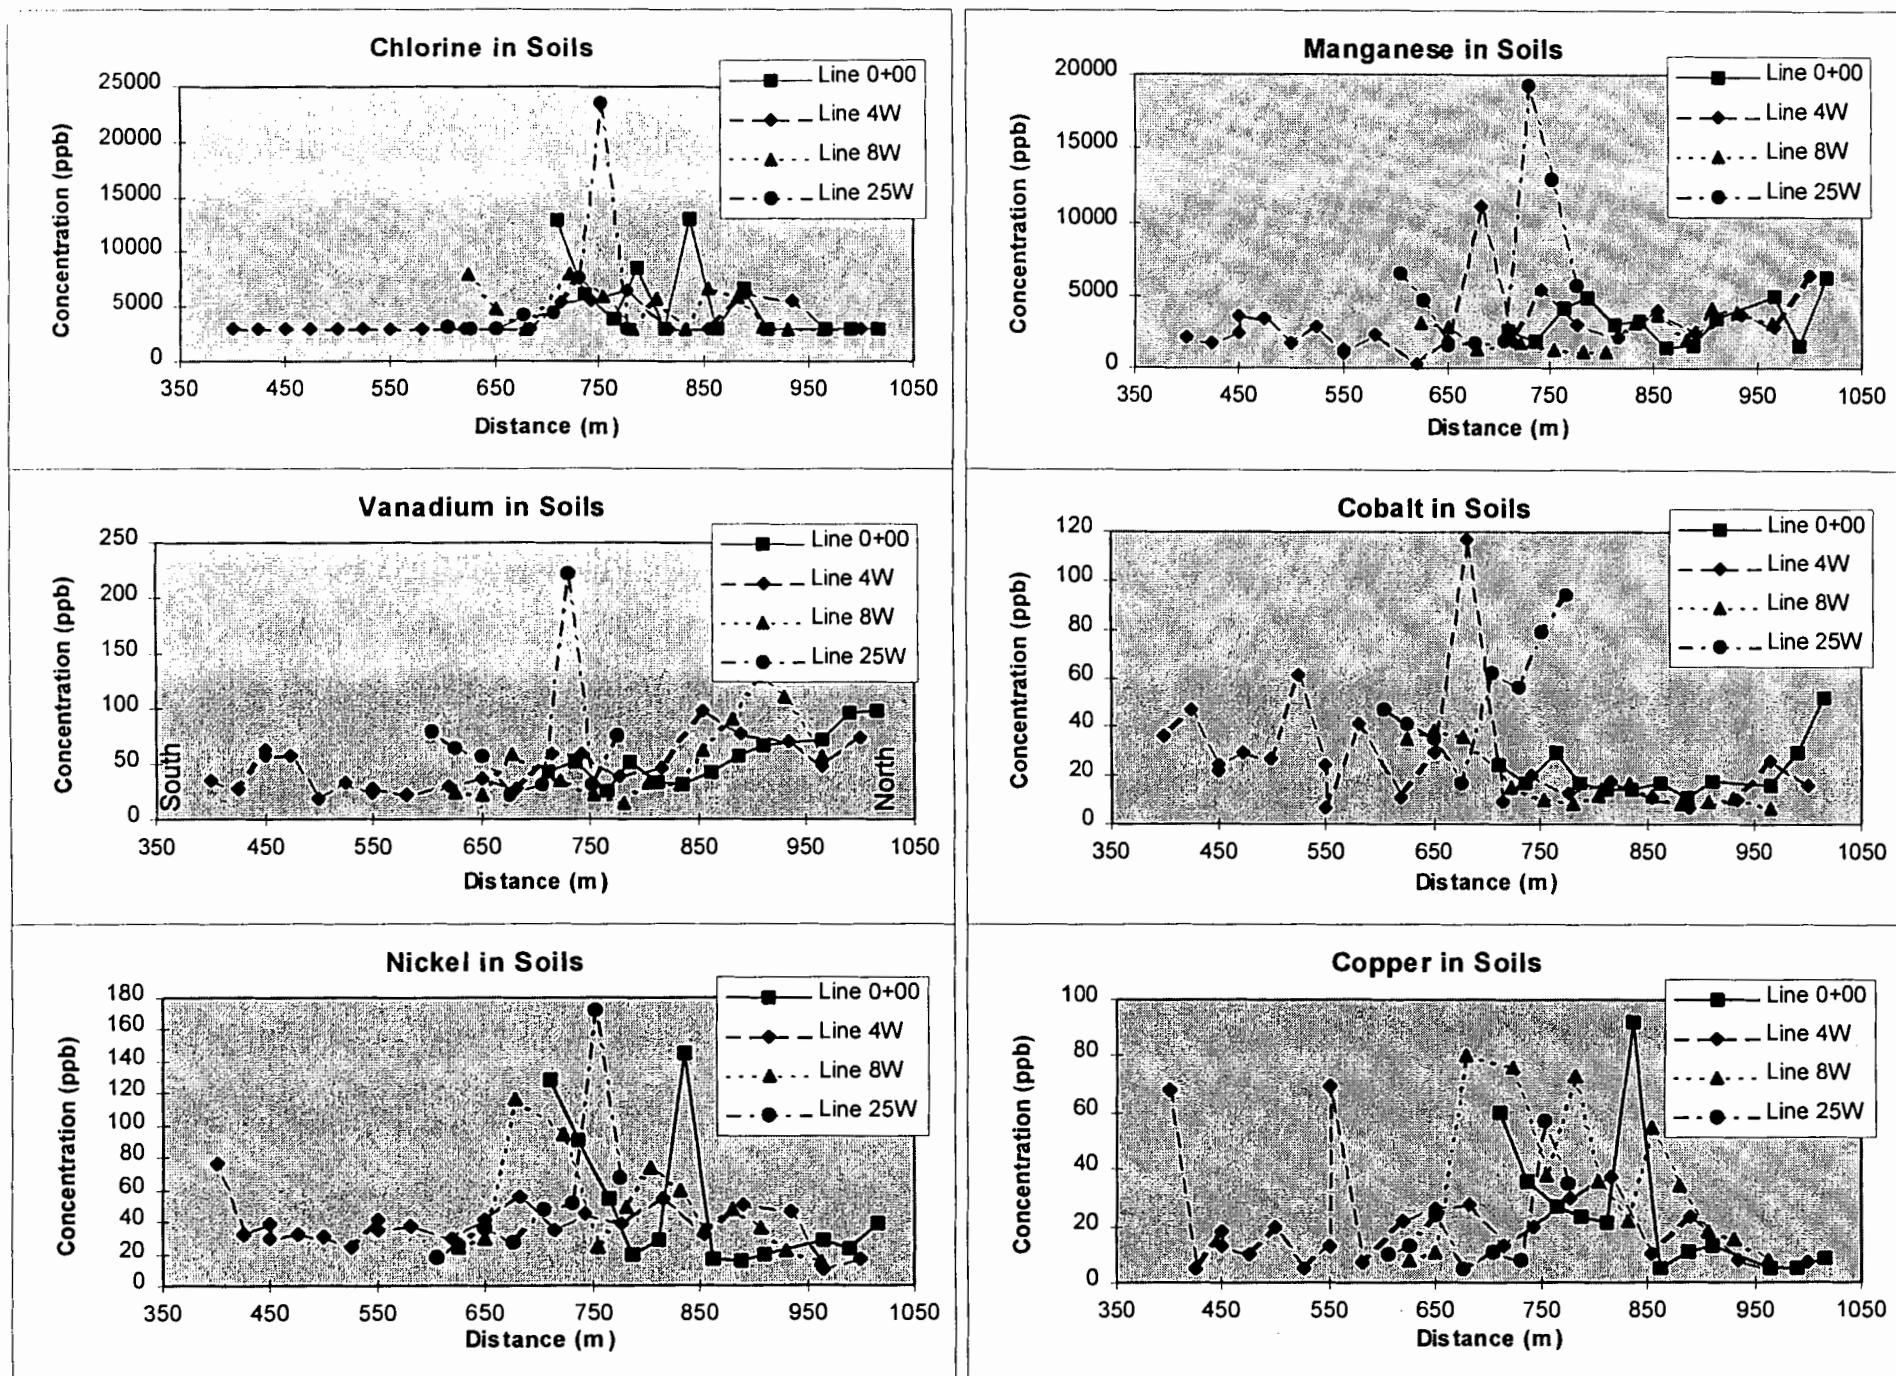

Figure 7a Enzyme Leach determined Cl, Mn, V, Co Ni and Cu in soil samples collected from the Swan Grid on the Swan Property. Overlapping profiles for Lines 0+00, 4W, 8W and 25W with south on the left and north on the right hand side of each profile.

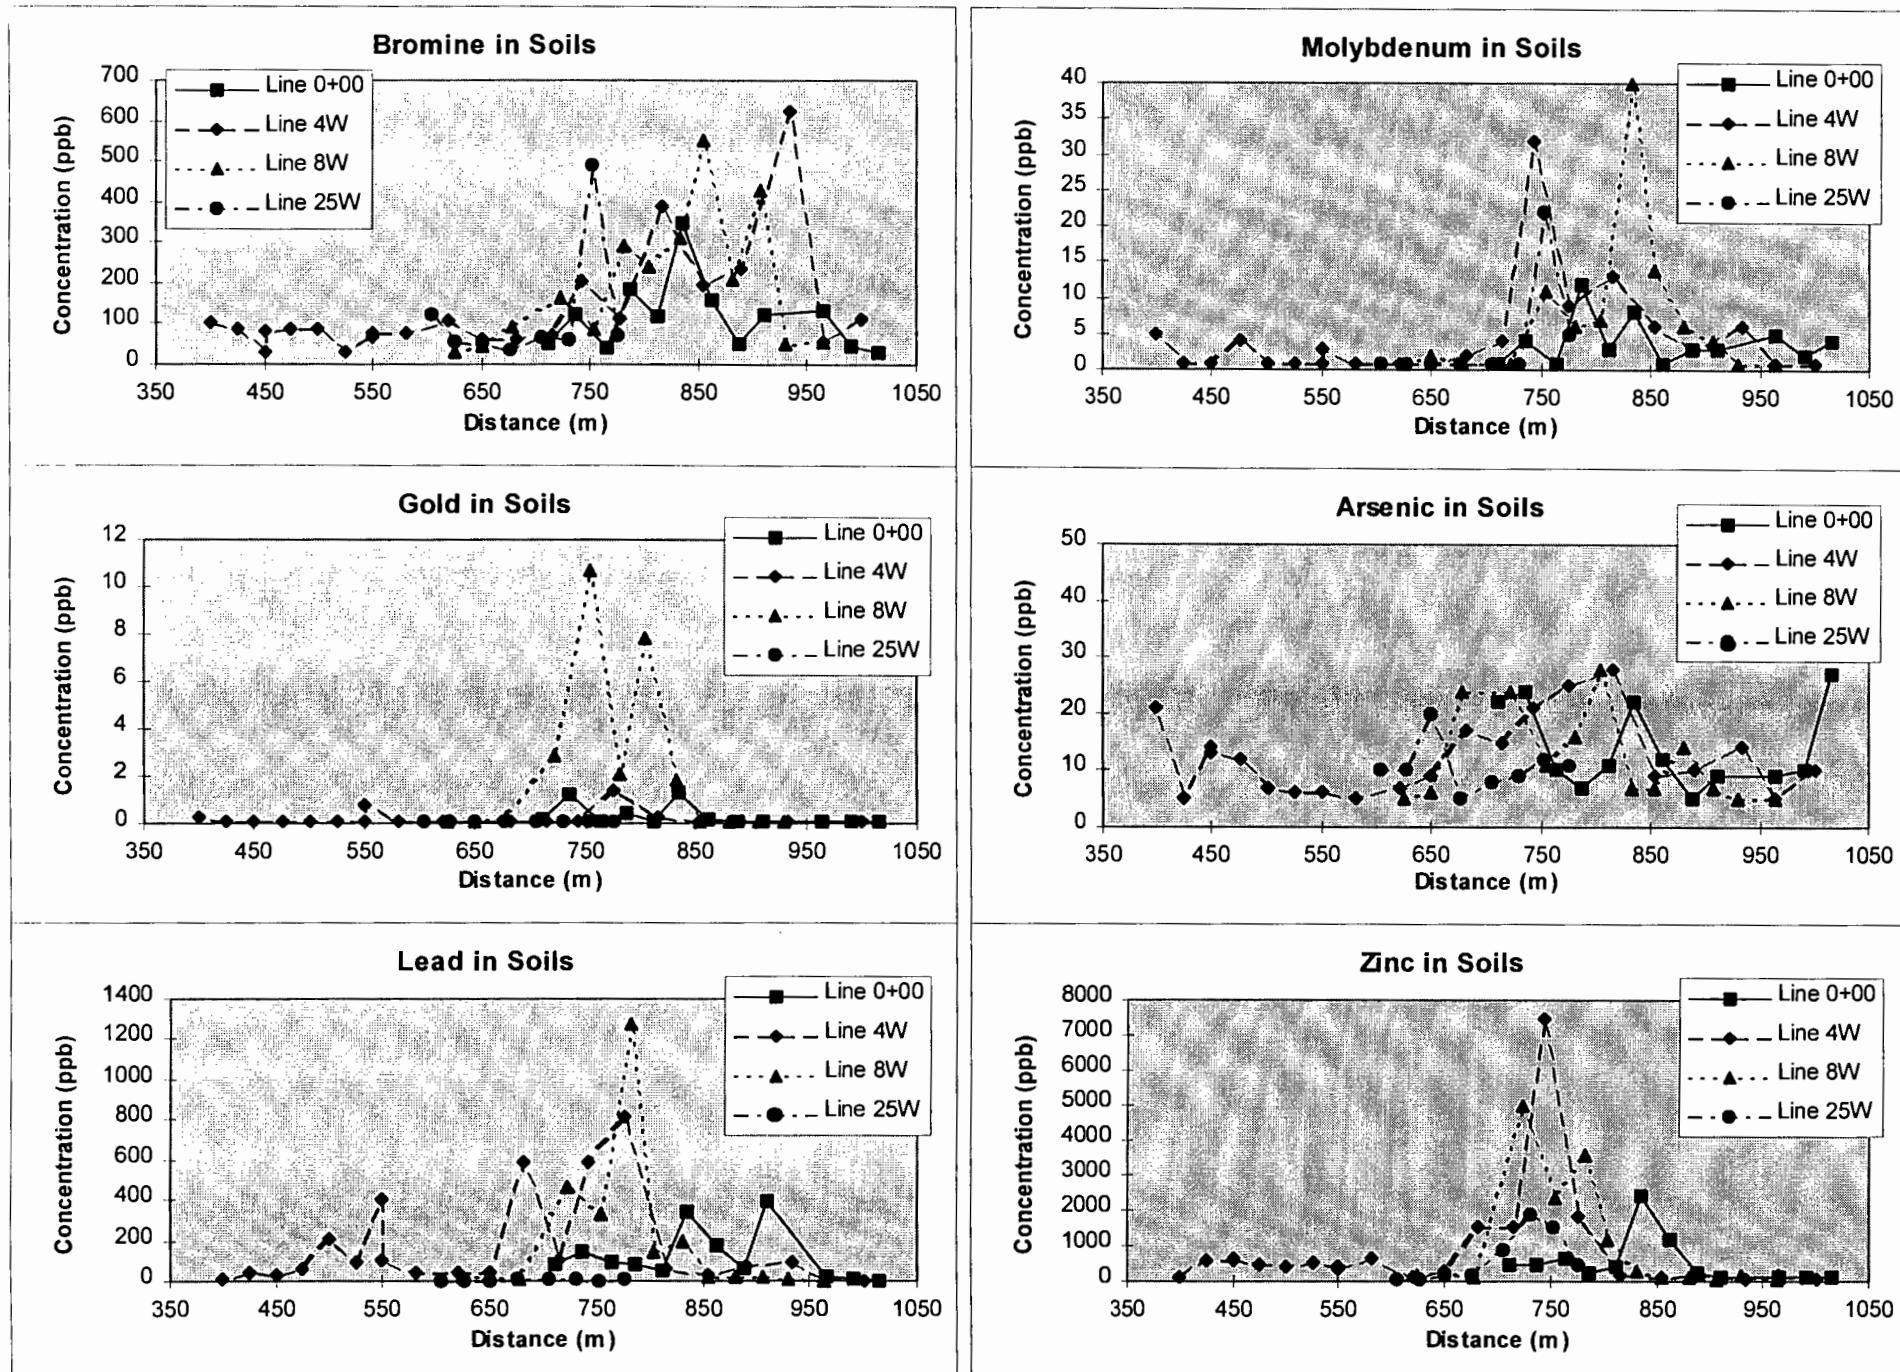

Figure 7b Enzyme Leach determined Br, Mo, Au, As, Pb and Zn in soil samples collected from the Swan Grid on the Swan Property. Overlapping profiles for Lines 0+00, 4W, 8W and 25W with south on the left and north on the right hand side of each profile.

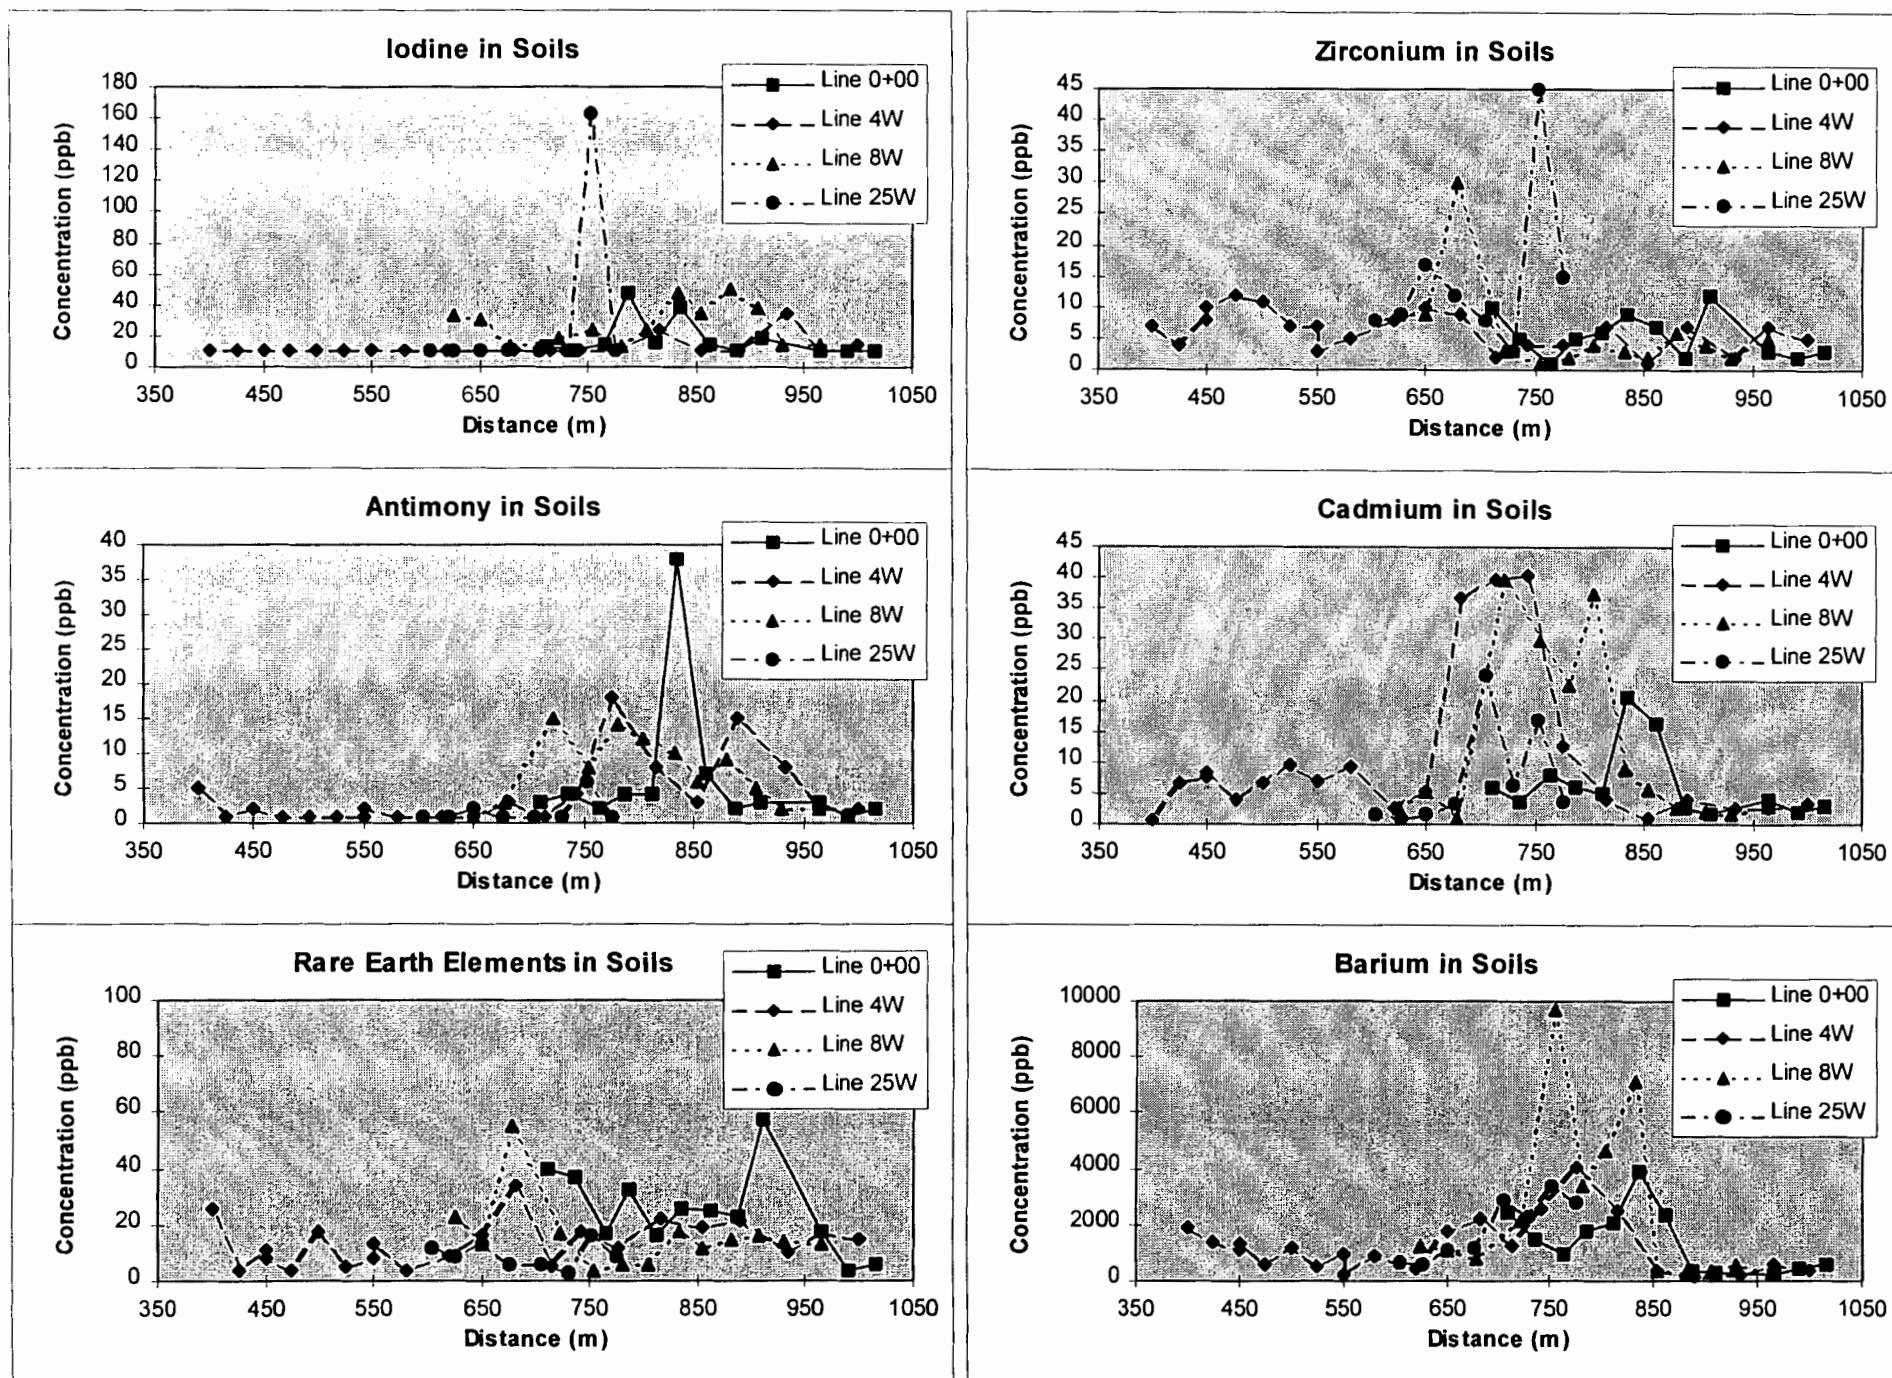

Figure 7c Enzyme Leach determined I, Zr, Sb, Cd, REEs (La+Nd+Pr) and Ba in soil samples collected from the Swan Grid on the Swan Property. Overlapping profiles for Lines 0+00, 4W, 8W and 25W with south on the left and north on the right hand side of each profile.

5.0 SOIL GEOCHEMICAL SURVEYS

5.1 SAMPLING METHOD AND ANALYTICAL PROCEDURE

On many sampling traverses, two soil samples were taken at each sample site - one to be analyzed by the conventional soil geochemical procedure at Bondar-Clegg and one to be analyzed by the enzyme leach procedure at Activation Laboratories at Ancaster, Ontario.

All samples were taken from a depth of about 30 cm in holes dug by grub hoe. Most samples are of B horizon soil but at some sites where the soil is poorly developed, the material is relatively fresh talus or other rock debris. Samples are described in Appendix 4.

5.1.1 Conventional Soil Geochemistry

Analyses were done at Bondar-Clegg Laboratories in Vancouver. The analytical procedure was as follows. Samples were dried and sieved to -80 mesh. A portion of this size fraction was subjected to an aqua regia digest and this solution was analyzed for Ag, Pb, Zn and Ba by the inductively coupled plasma (ICP) method. Results are included as Appendix 2 and shown on accompanying figures. Because many samples were taken over known mineralized areas, several different areas were sampled, and sample populations are small, no statistical treatment was applied to the results. However, the terms "weakly anomalous", "anomalous", and "strongly anomalous" - all determined arbitrarily - are used when describing and interpreting the geochemical results.

5.1.2 Enzyme Leach Soil Geochemistry

Theory

The problem, when trying to perform geochemical exploration in terrains that are covered by transported overburden, is that the overburden is usually exotic to the bedrock that it covers. Thus, conventional chemical analyses reveal the composition of the overburden and not of the underlying bedrock. For this reason, the enzyme leach technique was developed to yield clues to the bedrock chemistry.

The theory behind the technique is that trace elements released by oxidation of sulphide mineral deposits in the bedrock migrate up through overburden by groundwater flow, capillary action, or diffusion of volatile compounds. Since the amount of these bedrock-related trace elements is a very small component of the total concentration of these elements in the overburden, a method must be devised to determine the amount of a trace element that has been added to the transported overburden. One of the most effective traps for trace elements migrating through overburden is amorphous manganese dioxide, which is usually a very small component of the total manganese oxide phases in the coatings of the soil sample. The sample medium most commonly analyzed with this method is B-horizon soil.

Procedure

B-horizon soils are collected and dried at temperatures not exceeding 40C and sieved at -60

mesh. A minimum of 2 grams, and preferably 10-20 grams of sieved material is required. The samples are then subjected to a partial leach in which an enzyme reaction preferentially leaches manganese oxide coatings on mineral grains. Analyses of the leach solution are made by inductively coupled plasma/mass spectrometry (ICP/MS). Further details on this process can be obtained from Activation Laboratories Ltd. in Ancaster, Ontario.

The procedure analyzes a suite of 62 elements (see Appendix 3). Because of the difficulty in presenting this large number of elements on the surface plan, only the sample number is shown. The data are presented pictorially as a series of stacked profiles for those elements which show significant variations.

5.2 RESULTS FROM SWAN GRID AREA

5.2.1 Swan East Anomaly

Soil sampling was done on four traverse lines - three crossing the Swan East soil anomaly (SW-WO-9501 to 46) as indicated by previous work and one at right angles to the line joining the Main showing and Swan 93 trench (SW-SO-9547 to 54).

The three traverses across the Swan East anomaly were in part along old grid lines 0, 4W and 8W cut by Serem in 1973. All of these samples were analyzed by both conventional and enzyme leach methods.

The conventional soil geochemical results (Figure 3) confirm the approximate location and magnitude of the soil anomaly as determined by previous studies, with values to 4742 ppm Pb, 9438 ppm Zn and 5.3 ppm Ag. On all three lines the strongest portion of the anomalies is 75 to 150 metres wide, although the anomalies are "smeared" downslope for a considerable distance and to a lesser extent upslope. The bedrock source of the anomaly appears to be high on the slope, with the upper boundary of the anomaly located at the base of the "silica-dolomite" rock of the Echo Lake Formation. Note that on line 4W, Zn and Pb continue to be weakly anomalous south of the old baseline. The wide dispersal of Pb and Zn is believed to be due to a combination of factors: anomalous values in talus over a considerable distance downslope of the subcropping mineralization; glacial dispersion, which may explain the anomalous values above the presumed bedrock source; and hydromorphic dispersion.

The enzyme leach analyses were carried out to locate the bedrock source of the anomaly and to provide information as to the shape, size and orientation of the source.

On the three figures (7a to 7c), note that the distance shown along the bottom of the drawings is an arbitrary unit - 550 metres is the old Serem baseline and the sample spacing is approximately 25 metres.

The interpretation of the anomalies is taken largely from a report by R. Clark (1996) and is as follows. Clark states "the suite of anomalous elements suggests that oxidizing sulfides are present in the bedrock. The 'central low' in CI between [approximately 150 and 325 metres north of the old baseline] on line 4W suggests that the mineralized body in the subsurface may be centred in that area. This central low is not as clear with some of the other anomalous

oxidation suite elements (Br, I, Mo, As and Sb). Generally, the Zn, Cd and Pb levels here are extremely high and there appears to be a set of apical anomalies for these elements between [100 and 400 metres north of the baseline]. Apical anomalies generally form almost directly above their source." Note that these apical anomalies for Cd, Pb and Zn correspond with the Pb, Zn and Ag anomalies determined by conventional analysis. This supports our interpretation that the bedrock source is in this area. The data may also support a conclusion that the bedrock source has a significant width.

5.2.2 Traverse Between Main Showing and Swan 93 Trench

This traverse along old line 24W (shown on the figures as 25W) returned weakly anomalous Zn values of 94 to 416 ppm Zn with low Pb and Ag from the conventional analyses.

The enzyme leach analyses from the four most westerly samples analyzed (SW-SO-9547, 48, 49, 51) showed more highly anomalous Zn values than did the conventional analyses. This accompanies generally higher values in Mn, Co, Ni, Cd and Ba. This anomalous area in the northern part of the traverse corresponds in part to high Pb, Zn and Ag values in possible outcrop. This may constitute a new mineralized area which lies between the Main trench and the Swan 93 trench. It should be noted that this is generally within the limits of Serem Pb and Zn anomalies of moderate strength as shown in the compiled data in Figure 4. Also of possible significance is a fault suggested by Clark in the approximate area of the creek.

Perhaps the most significant idea here is that quite anomalous Ba and Zn values are obtained from enzyme leach analyses in the northern half of the line but the same area yielded only weakly anomalous Zn from the conventional analyses. This suggests that the soil anomaly is caused by an anomaly in the bedrock which occurs between samples 9547 and 9550 and encompasses the area in which rock sample SW95-W041 returned highly anomalous Ag, Pb and Zn from outcrop.

5.3 RESULTS FROM KNOLL PROSPECT AREA

Results of Conventional Analyses

Only twenty-three conventional analyses were done on soil samples from the Knoll Prospect area. These samples were taken from the northwest traverse (KN-SO-9537 to 47) and the southwest traverse on the knoll only (KN-SO-9525 to 36). Sample results are shown on Figure 5 and in Appendix 2.

Sample 9546, near the lower end of the northwest traverse, was anomalous in all elements: 3.4 ppm Ag, 939 ppm Pb, 2006 ppm Zn and 834 ppm Ba. This sample lies within the anomalous boundary of the Serem geochemical survey at elevation 1520 metres and is at approximately the same location as several anomalous samples collected by Cominco, which obtained values to 3585 ppm Pb, 4965 ppm Zn and 12.3 ppm Ag . The three samples spanning the 60 metre interval immediately above sample 9546 also have weakly anomalous levels of Ag, Pb, and Zn, suggesting a possible bedrock source of mineralization at the approximate location of sample 9543, that is, at the 1580 metre elevation. It should be noted, however, that several samples above this elevation have detectable Ag levels to 0.5 ppm.

No highly anomalous metal values were indicated by the southwest traverse. Only two samples - in the upper part of the traverse - have detectable Ag levels. Several samples, however, had weakly anomalous levels of Pb and Zn. These include one sample (9526) near the top of the knoll and a sequence (9530 to 9534) in the lower part of the traverse which returned up to 153 ppm Pb and 661 ppm Zn. These occur at elevation 1500 to 1580 metres, roughly the same elevation as for the interval of anomalous and weakly anomalous samples on the north side of the knoll. Since different rock units are exposed on the two sides of the knoll sampled by these traverses, this suggests a partial control on soil geochemistry other than, or in addition to, bedrock and its contained mineralization.

Enzyme Leach Results

For Zn, for all traverses, there are anomalies in the lower third of the traverses, roughly at the 1500 to 1600 metre elevation (Figures 8a to 8c). This relationship to elevation warrants further consideration.

On the west traverse (samples KN-SO-9501 to 9514), which runs along the spine of the hill, the western (lowest) end of the traverse - samples 9501 to 3 - has the highest Pb values. These were taken from an elevation of roughly 1535 to 1575 metres. There is also a weaker Pb anomaly at sample KN-SO-9507 which is part way up the spine of the ridge in the area of karsted carbonates. Samples 9502 and 9507 are also the sites of the strongest Zn anomalies for this traverse. Samples 9501 and 9502 yielded the only significant Ba anomalies from the Knoll prospect. These samples, which are south of the Knoll showing and slightly lower than it, may be reflecting the possible southerly extension of the showing.

On the north traverse line (samples KN-SO- 9515 to 9523), samples KN-SO-9519 to 21 gave high values in Pb and seem to indicate the centre of the Pb anomaly. These samples were taken between 1540 and 1580 metres elevation. There are also several samples with high Zn values - these span the interval between samples 9517 and 9523, a somewhat broader range than for the Pb. Samples 9522 and 9523 are also anomalous in Cd. Anomalous gold occurs in samples 9520 to 9523. The latter sample also has high As values. Conventional analyses were not done for this traverse.

On the southwest traverse, there is a weak Pb anomaly at sample 9532. Presumably an apical anomaly, this falls in the midle of the interval of weakly anomalous conventional analyses. This sample is also the site of the strongest Zn anomaly on this traverse and is anomalous in Cd.

On the northwest traverse, there is a Pb anomaly centred at sample KN-SO-9546 which corresponds with previously obtained data and with the conventional analyses as described above. This is also the centre of the Zn anomaly and has anomalous Cd.

Interesting results were obtained from the long traverse which runs from near the small lake at the base of the Knoll in a southwesterly direction for approximately 1700 metres (Figures 9a to 9d). This traverse crosses the fault(?) contact between the carbonates of the Echo Lake Group, which comprise the Knoll, and the argillite, siltstone, sandstone, and tuff (Gilliland Tuff) of the Big Creek Group. Most of the traverse is within the area presumed to be underlain by argillite, siltstone and tuff.

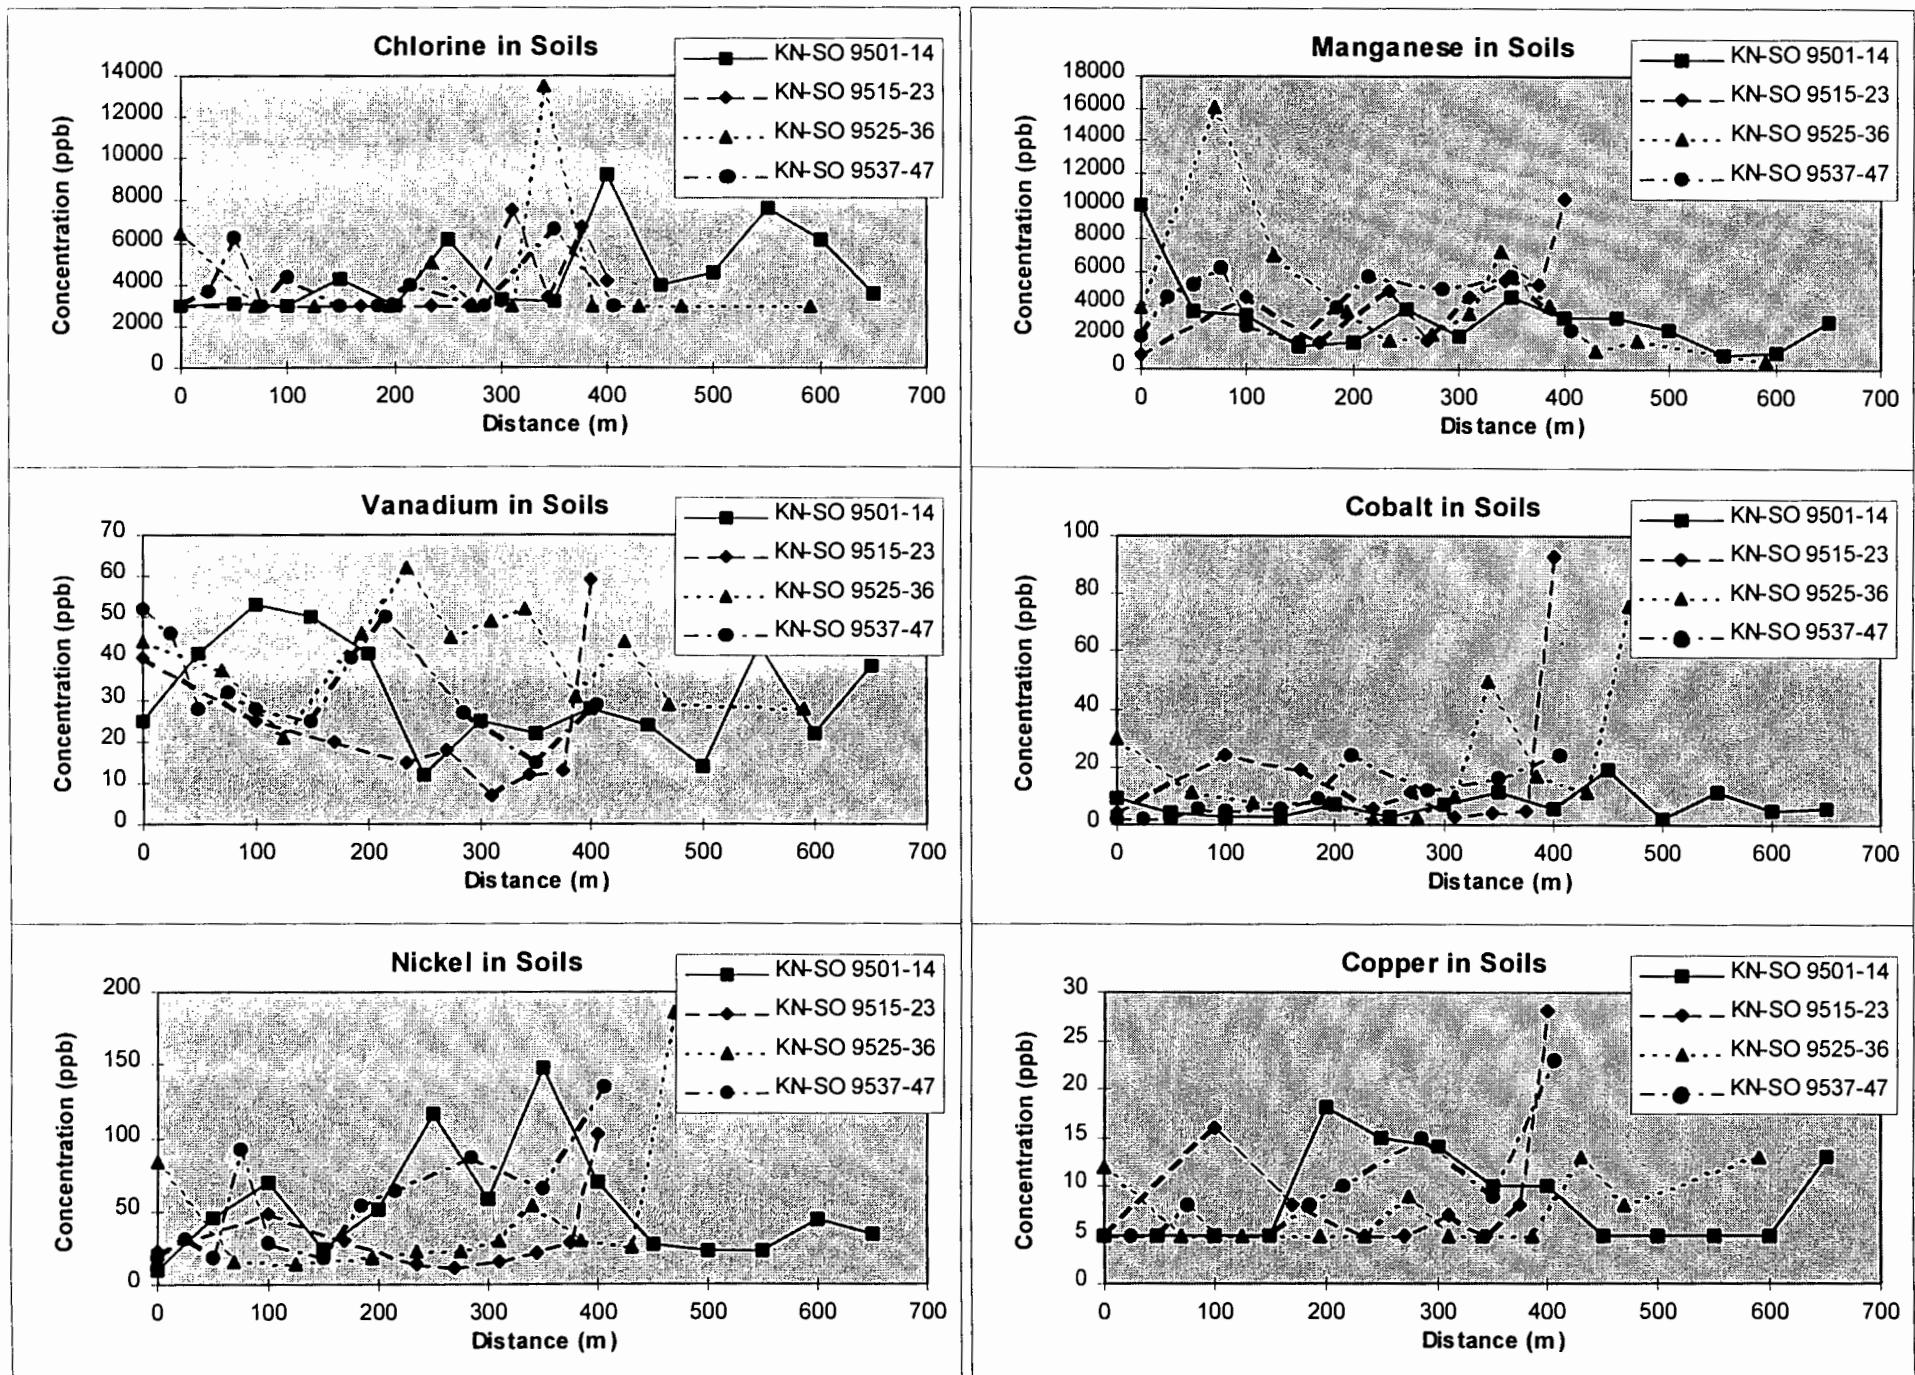

Figure 8a Enzyme Leach determined Cl, Mn, V, Co, Ni and Cu in soil samples collected from the Knoll Prospect on the Swan Property. Overlapping profiles are for four lines radiating from the knoll. Distance 0 marks the top of the knoll.

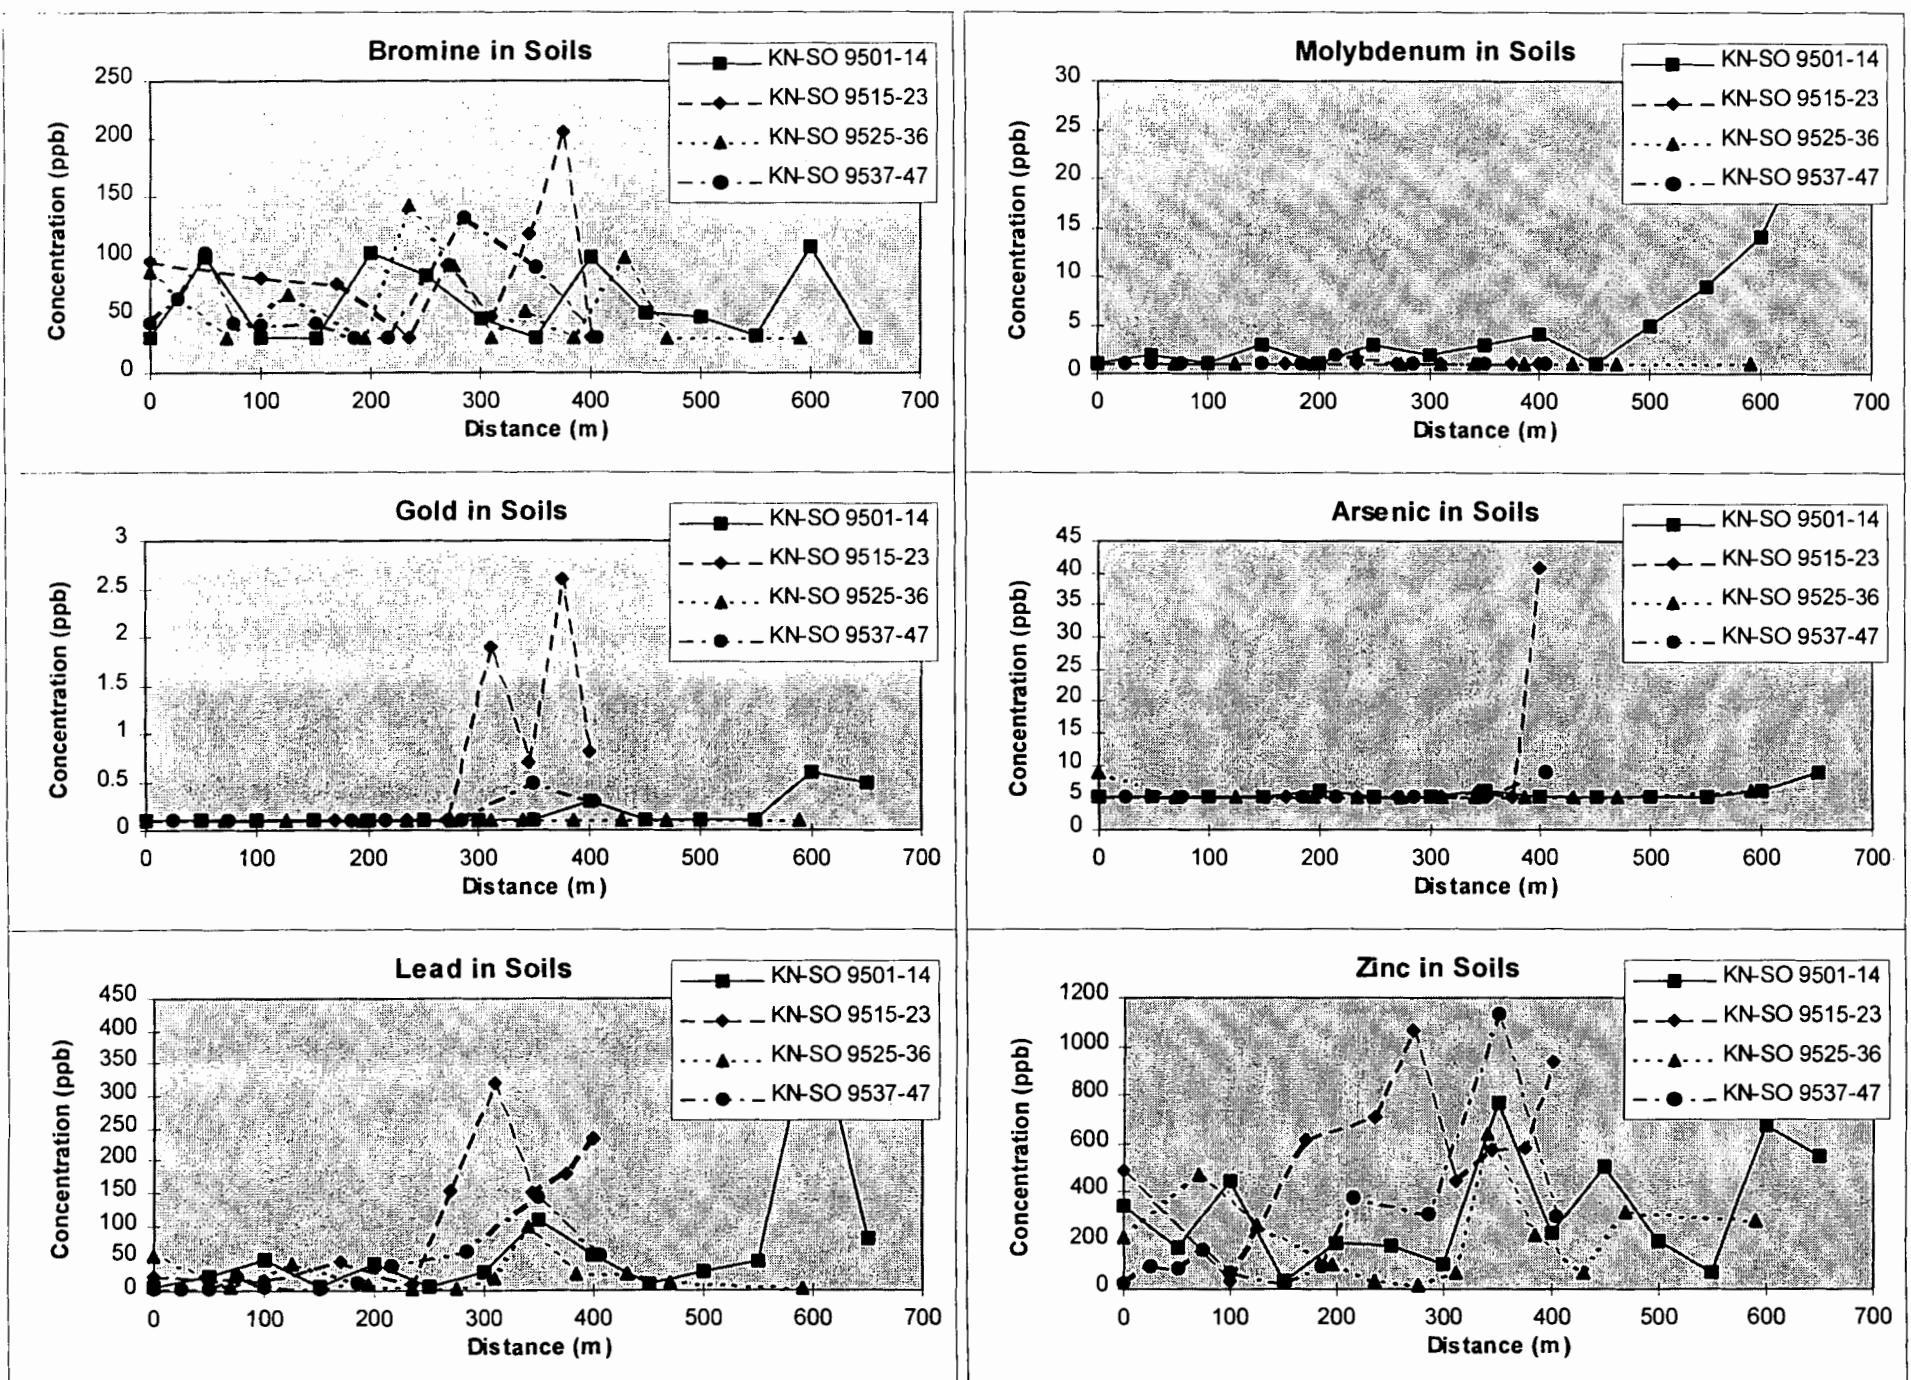

Figure 8b Enzyme Leach determined Br, Mo, Au, As, Pb and Zn in soil samples collected from the Knoll Prospect on the Swan Property. Overlapping profiles are for four lines radiating from the knoll. Distance 0 marks the top of the knoll.

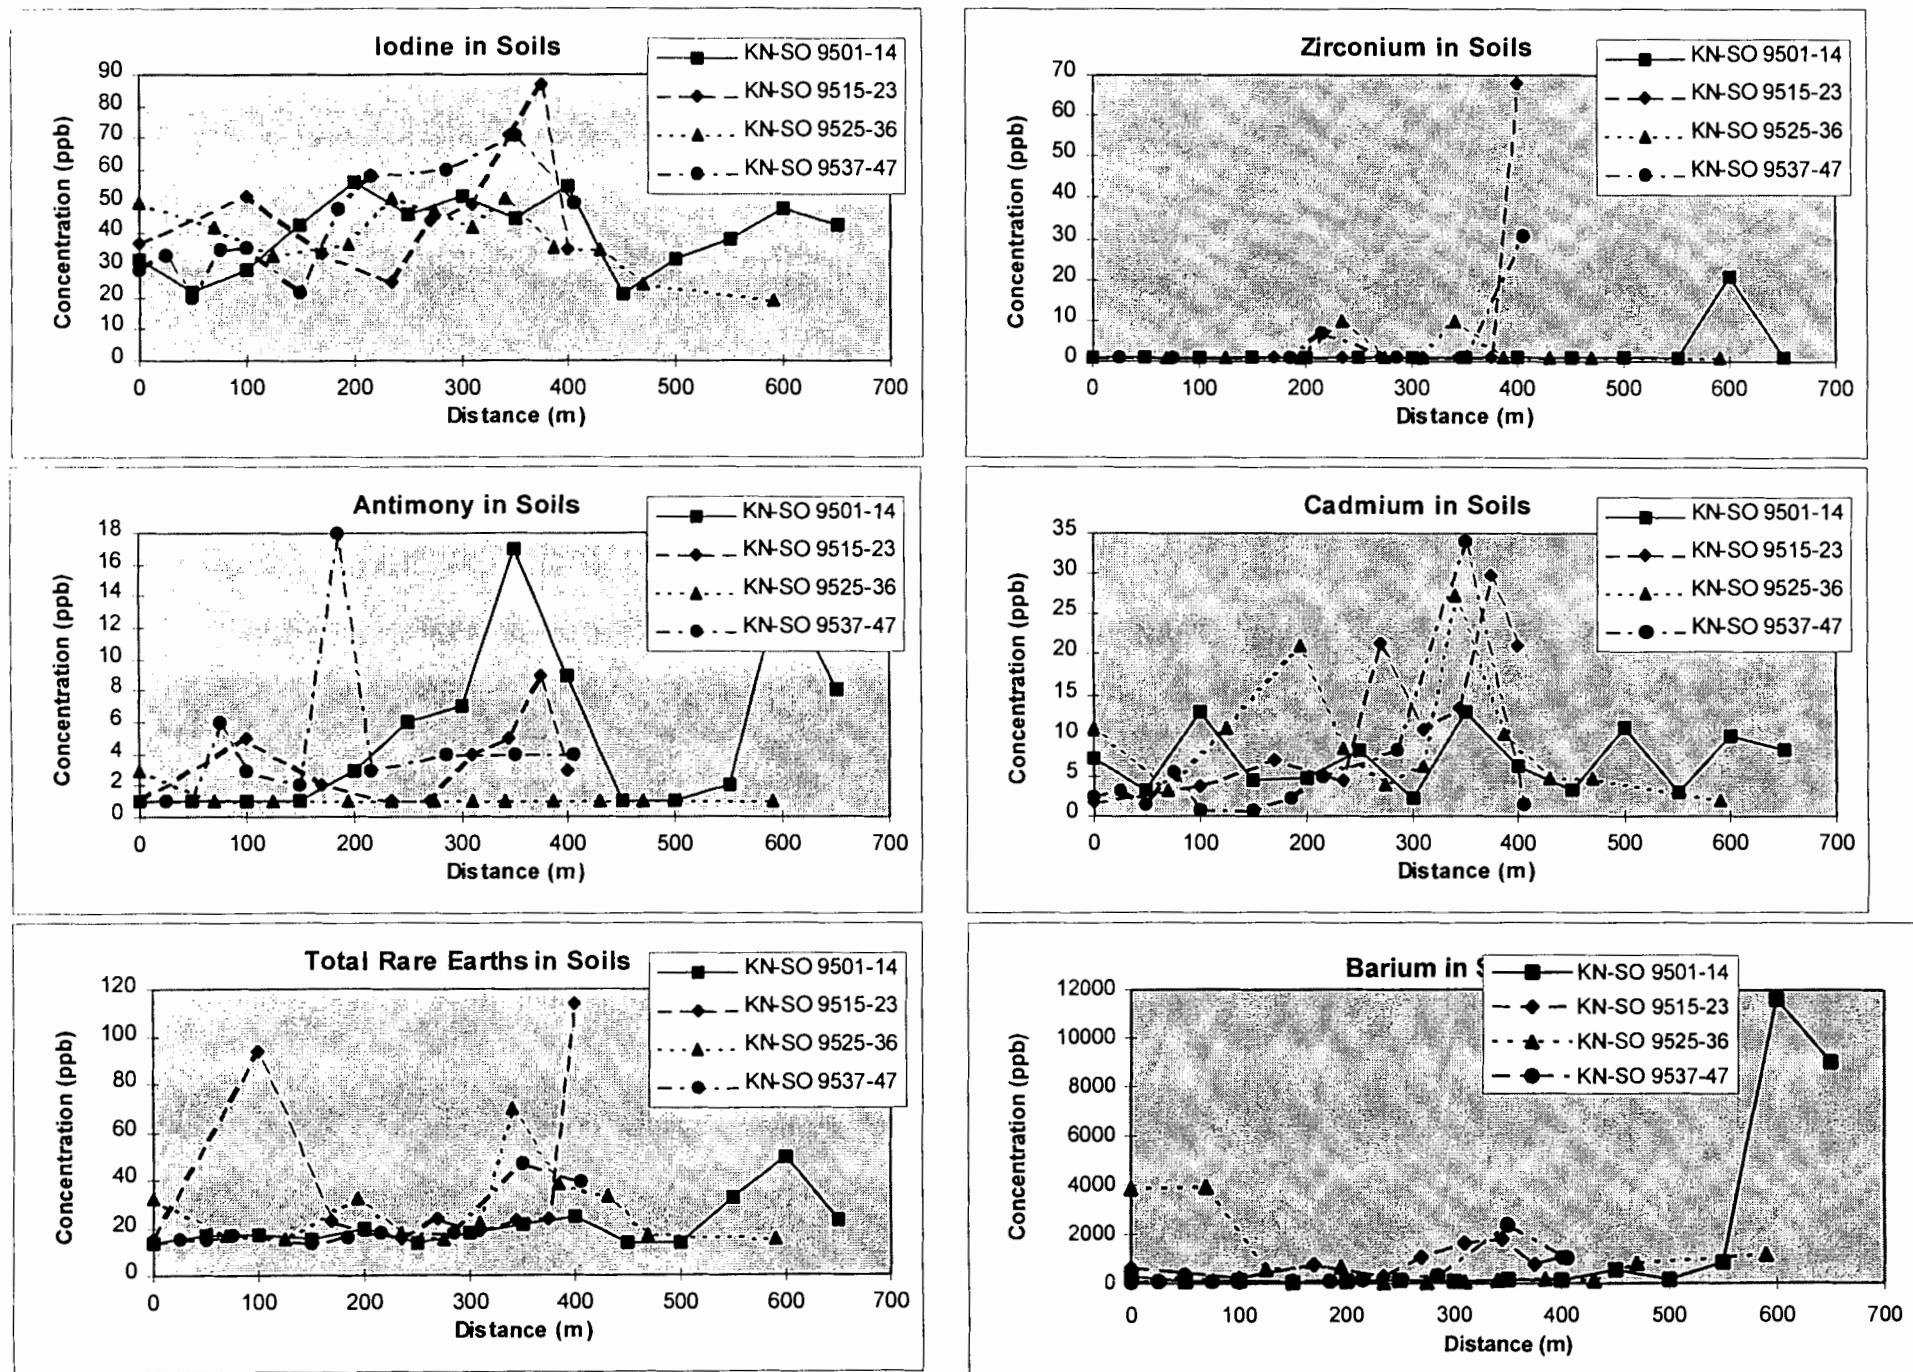

Figure 8c Enzyme Leach determined I, Zr, Sb, Cd, Total Rare Earths and Ba in soil samples collected from the Knoll Prospect on the Swan Property. Overlapping profiles are for four lines radiating from the knoll. Distance 0 marks the top of the knoll.

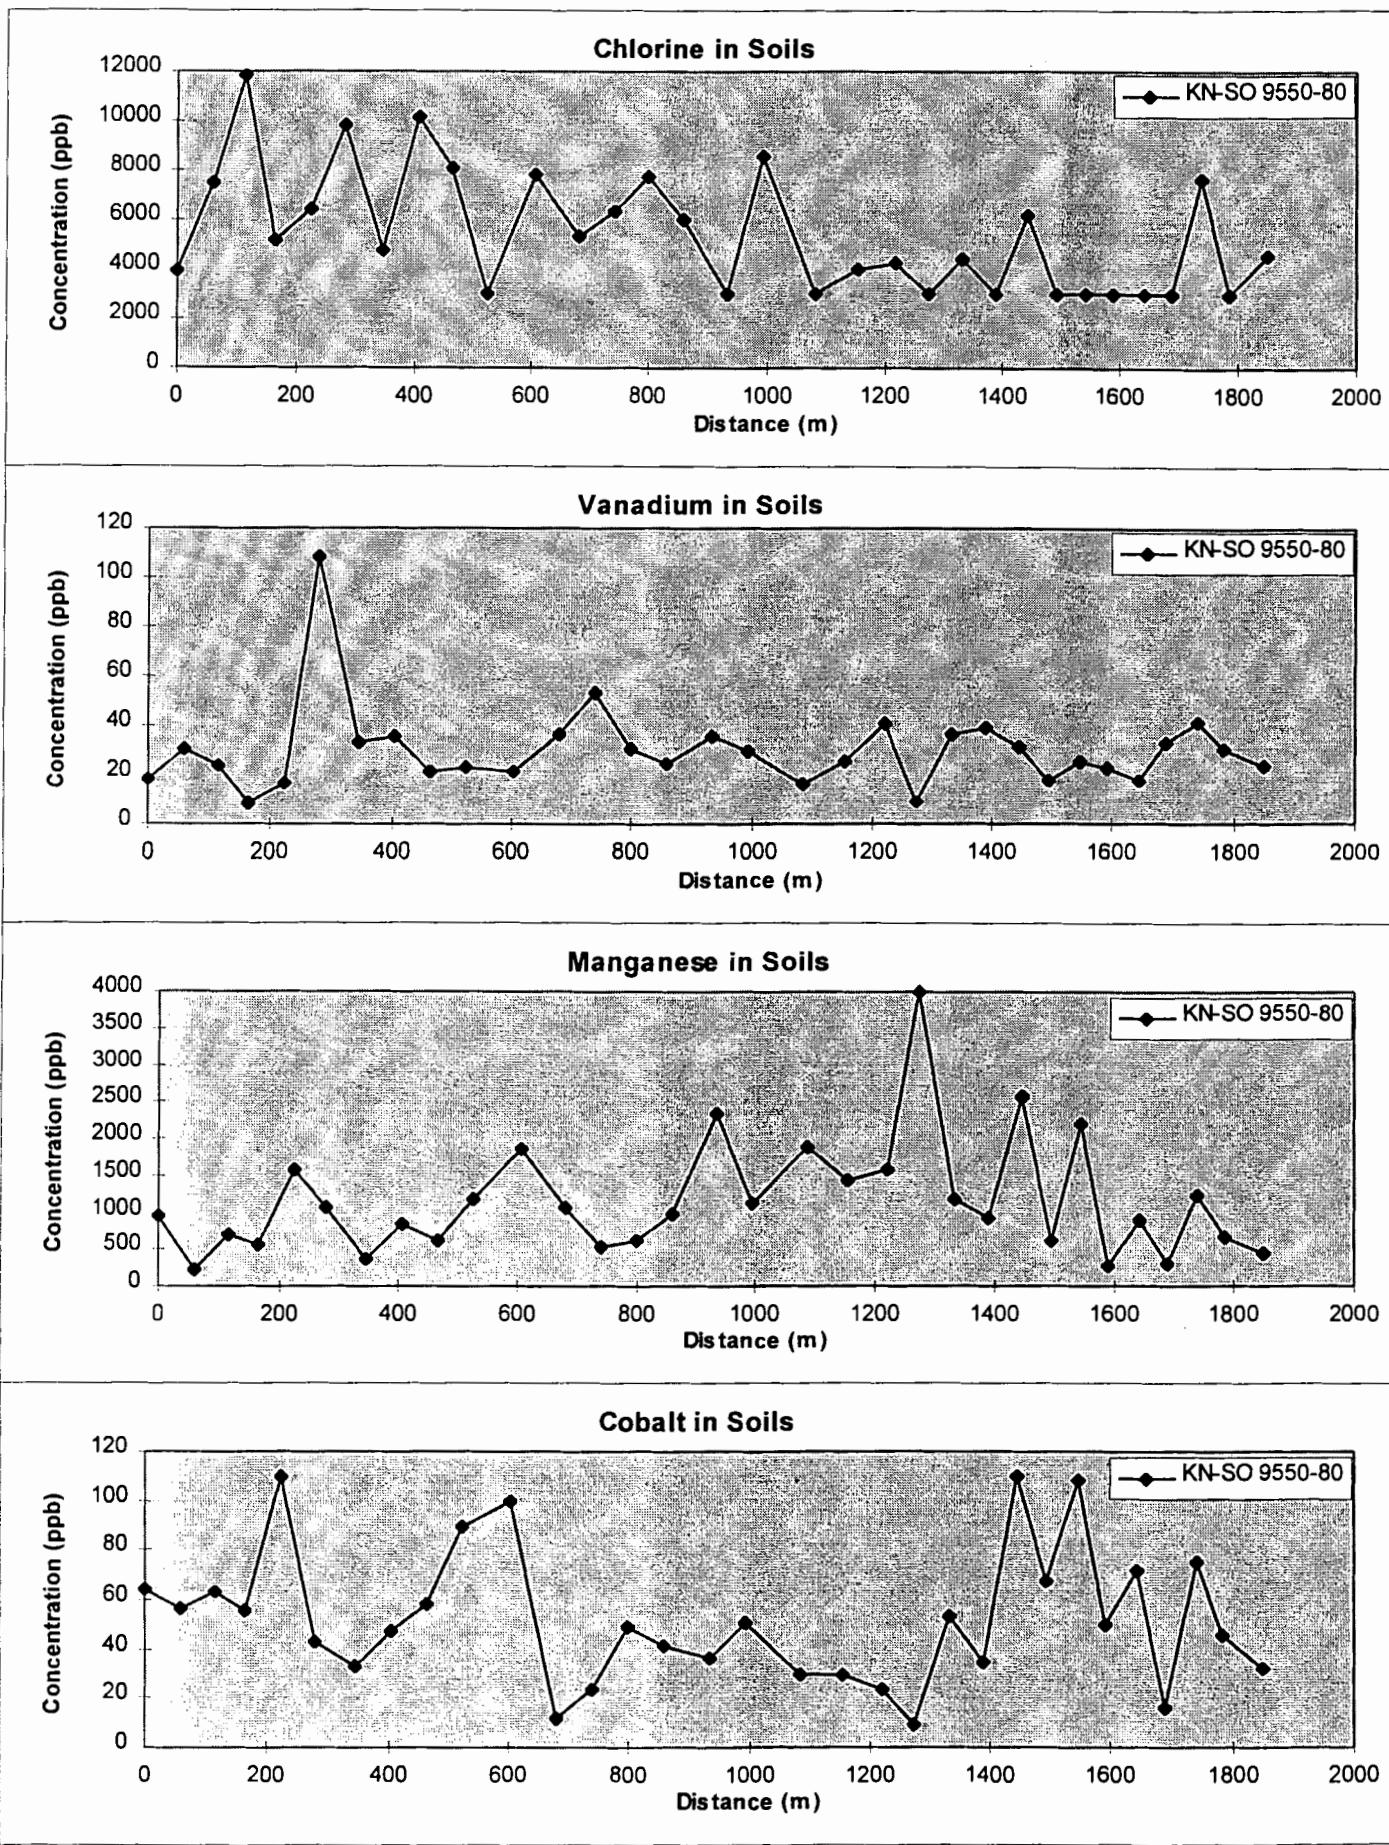

Figure 9a Enzyme Leach determined Cl, V, Mn and Co in soil samples collected from the Knoll Prospect on the Swan Property. Samples are from a long traverse extending southwest from the knoll. Distance 0 marks the northeast end of the traverse.

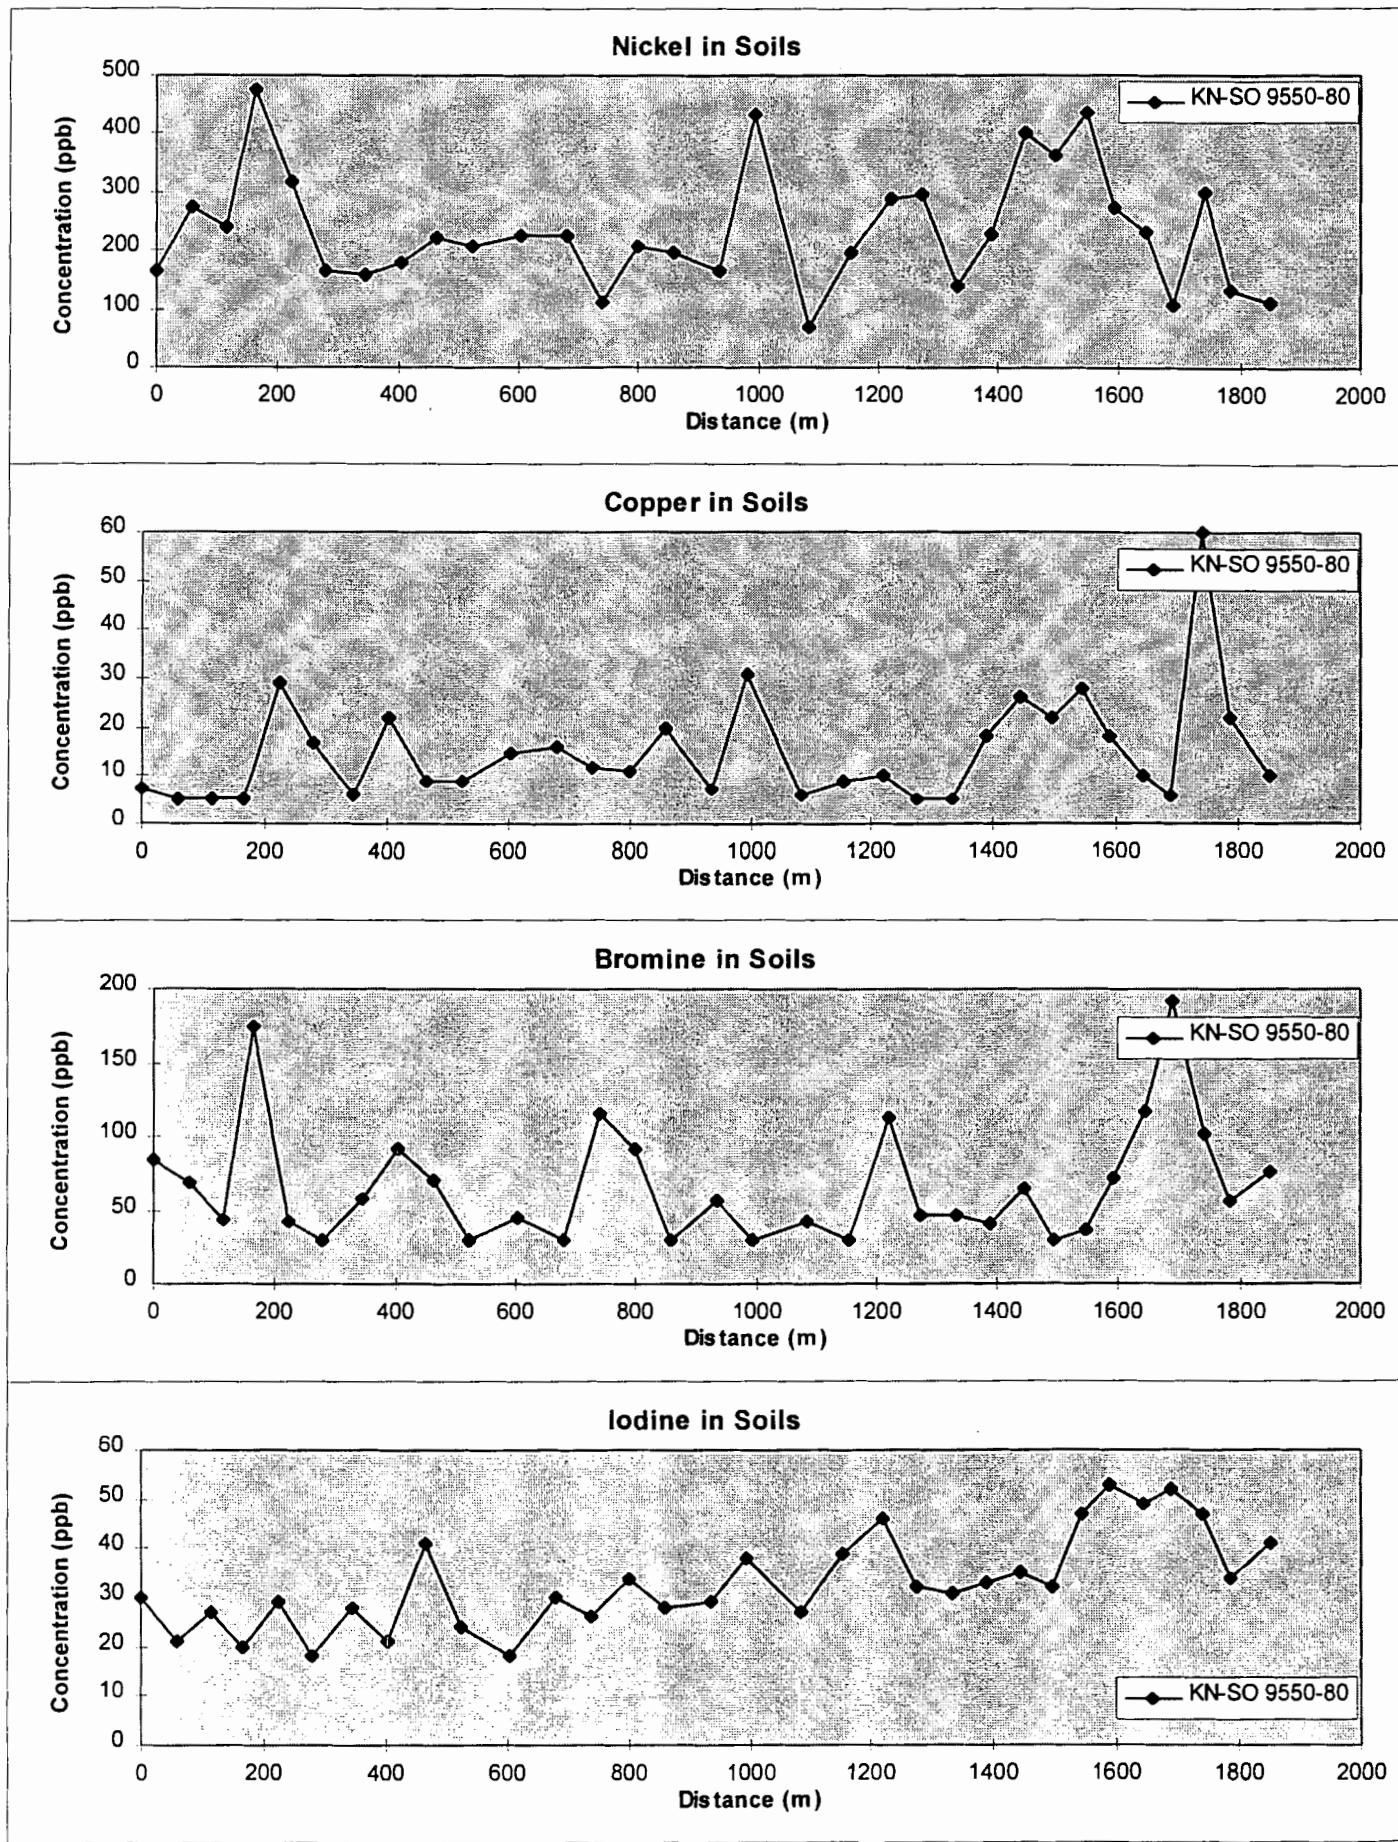

Figure 9b Enzyme Leach determined Ni, Cu, Br and I in soil samples collected from the Knoll Prospect on the Swan Property. Samples are from a long traverse extending southwest from the knoll. Distance 0 marks the northeast end of the traverse.

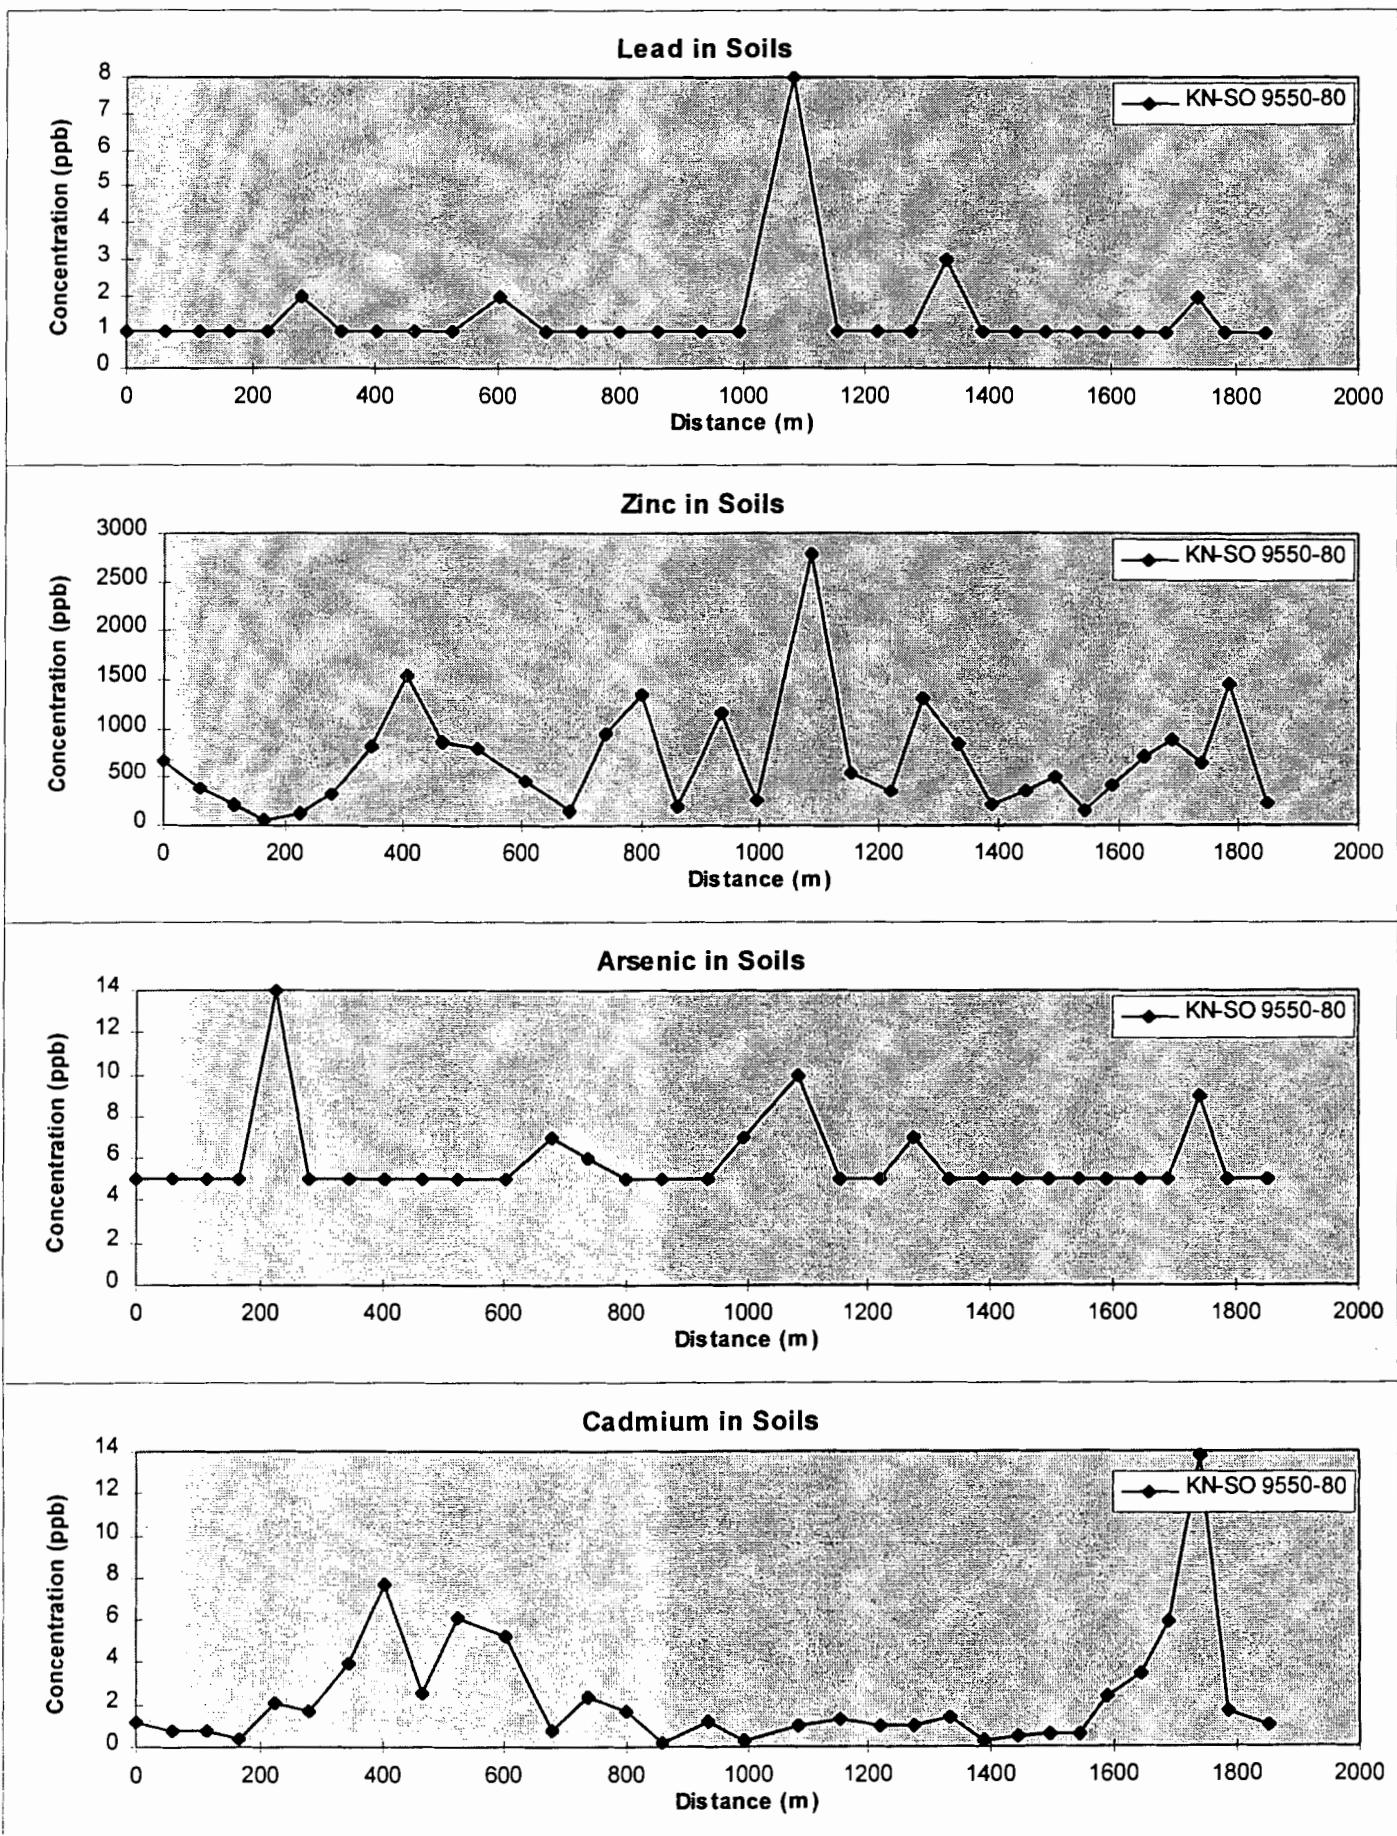

Figure 9c Enzyme Leach determined Pb, Zn, As and Cd in soil samples collected from the Knoll Prospect on the Swan Property. Samples are from a long traverse extending southwest from the knoll. Distance 0 marks the northeast end of the traverse.

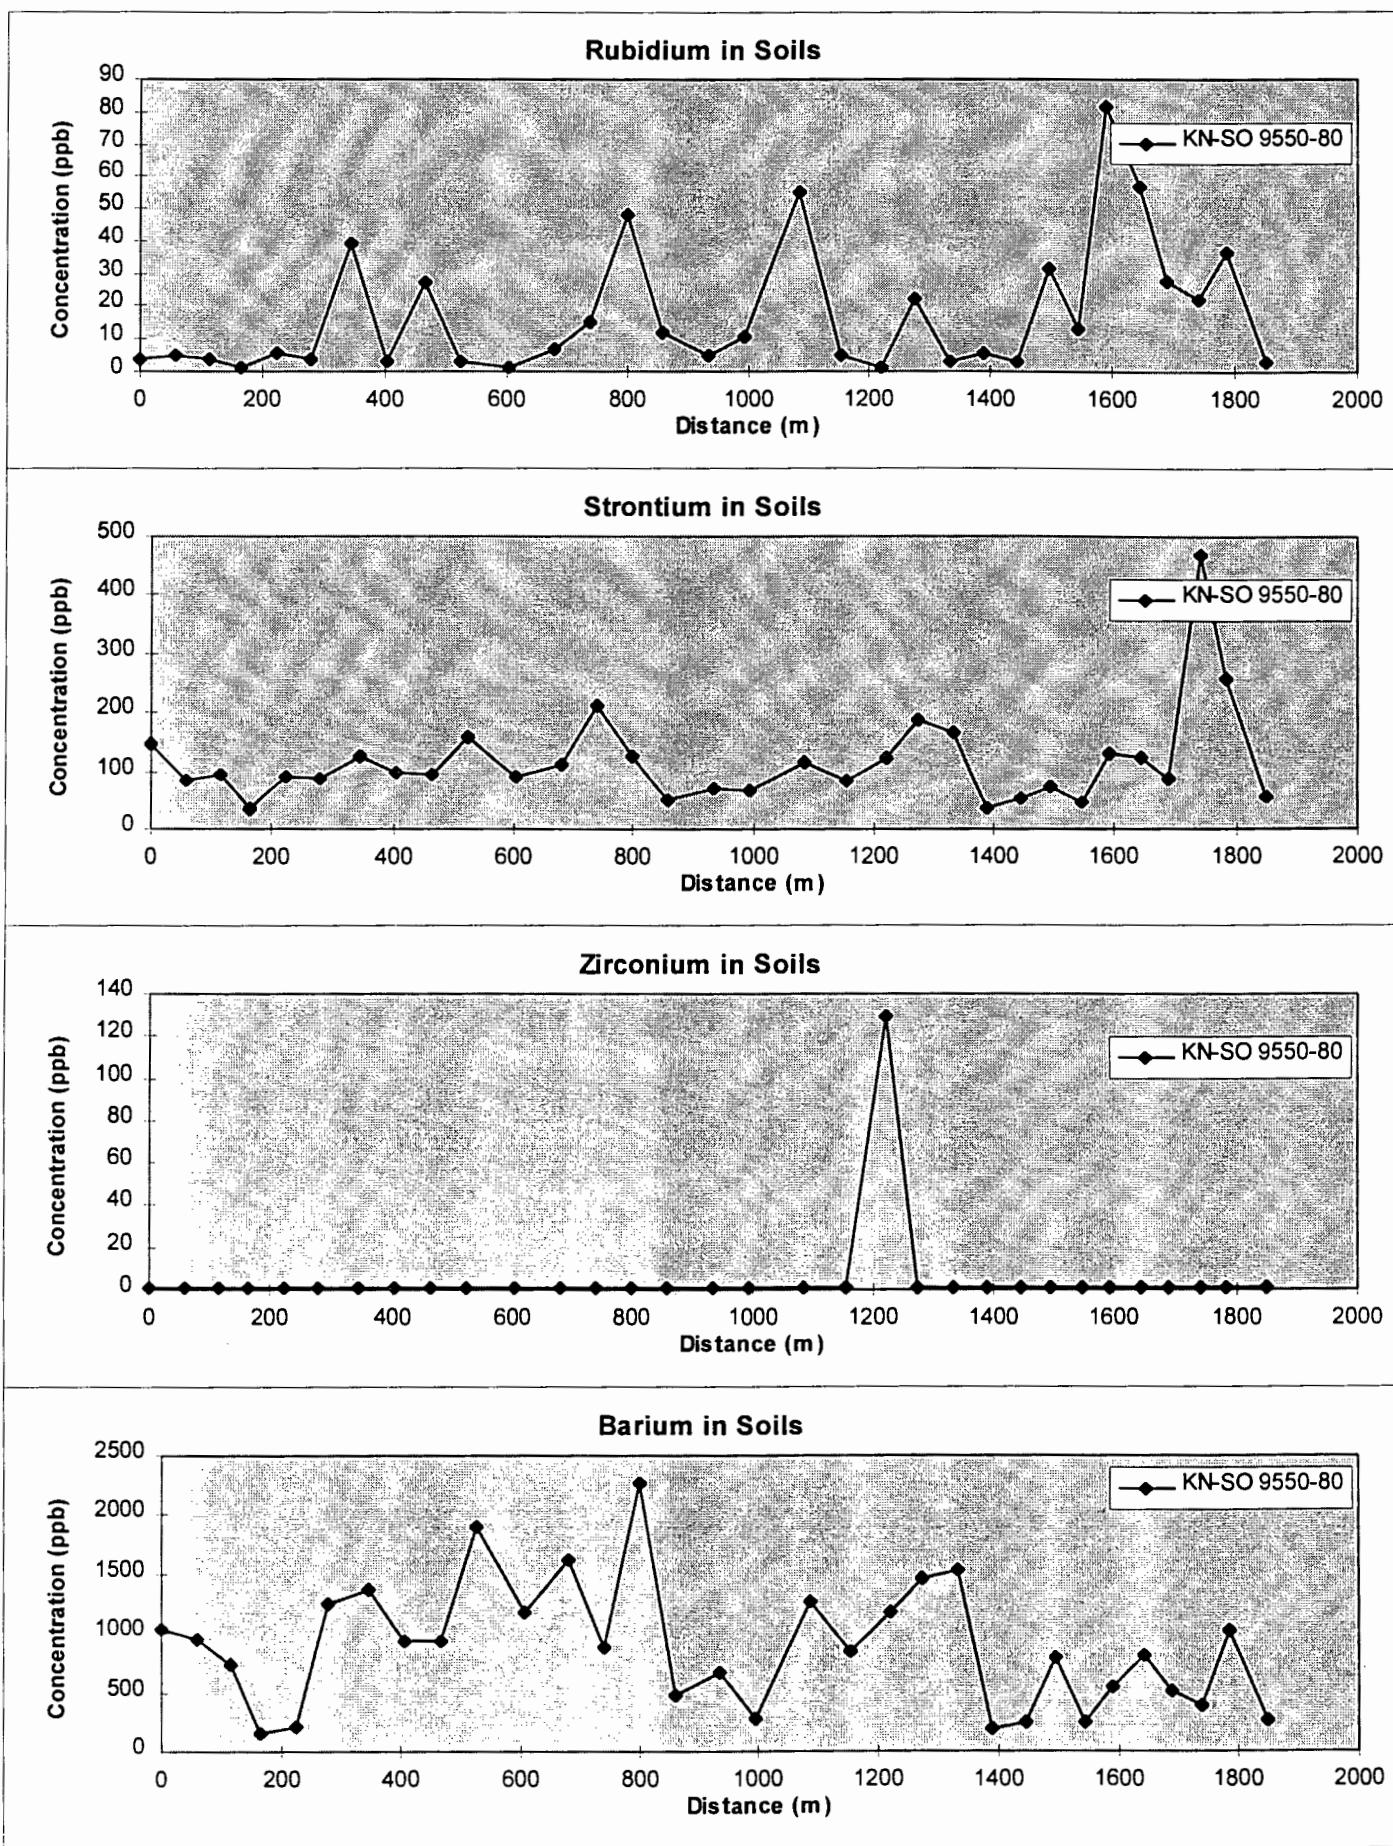

Figure 9d Enzyme Leach determined Rb, Sr, Zr and Ba in soil samples collected from the Knoll Prospect on the Swan Property. Samples are from a long traverse extending southwest from the knoll. Distance 0 marks the northeast end of the traverse.

At the southwest end of the traverse, sample KN-SO-9551 is strongly anomalous in Cd, As, Pb, Sr, Ni, and Cu. The adjacent sample 9550 is strongly anomalous in Zn. These samples were from a small area of possible moraine comprised of sand and ultramafic boulders derived from the Polaris Ultramafic Complex.

Several anomalous samples were obtained from an area where Big Creek Group rocks are exposed. Sample 9560 returned the highest Mn values for this traverse. Weak Zn, As and Ba and moderate Ni values were also obtained at this location. Nearby sample 9561 yielded a Zr anomaly at the location of outcropping Gilliland Tuff. Strongly anomalous values for Pb and Zn, the highest values from the traverse, were obtained from sample 9563, where rubbly outcrop of crystal tuff occurs on both sides of the valley. As is also moderately anomalous here and Mn is not particularly anomalous. This Zn/Pb/As anomaly in part occurs within a Br and, to a lesser extent, low which may indicate an oxidized sulphide body in the subsurface. It should be noted that these samples (9560 to 9563) have more underlying bedrock component and less transported material than do most of the samples on this traverse. The scatter between Mn and the other elements for samples from this traverse does not indicate that high metal values are related to high Mn values.

The results from this traverse indicate that two area should be further investigated and evaluated - the areas of samples 9550 to 9551 and samples 9560 to 9563.

5.4 RESULTS FROM RAIN PROSPECT AREA

Thirteen soil samples (RA-SO-9501 to 9513) were collected from one traverse at the Rain prospect. The traverse starts at the top of the ridge, runs down the slope of the ridge toward the southwest; near the lower end of the traverse, it crosses the presumed zone of mineralization.

Sample locations and conventional geochemical analyses are shown in Figure 6. The conventional results are summarized as follows. Most of the samples have above normal levels of Ag, Pb, Zn and Ba. Ag (5.4 ppm), Pb (2458 ppm), Zn (625 ppm) and Ba (>2000 ppm) are all highest in sample 9511, collected a few metres from two samples of float which yielded values to 16.7 ppm Ag, 1.74% Pb, and 3.06% Zn. Although samples 9503 to 9506 have weakly anomalous levels of Ag and Pb, the interval between 9507 and 9513 (the end of the traverse) is the main portion of the anomalous interval. The upper part of the most anomalous zone is roughly at 1880 metres, which may represent the uppermost part of the bedrock source.

Enzyme leach analyses (plotted in Figures 10a to 10c) were performed on all samples from this traverse. The results fairly closely mirror those of the conventional analyses. Lead, Zn, Au, Cd and Ba all have their high value for the traverse at sample 9511; some of these elements have adjacent anomalous values. Clark says "Lead, Cd and Zn are incredibly anomalous between [sample 9505] and the end of the line [sample 9513]. The Cl data seems to suggest a 'central low' of an oxidation halo between about [sample 9506] and [sample 9511]. If this is the case, then the sampling does not extend far enough to define the halo and the Pb-Zn-Cd anomaly within that area would represent an apical over the source."

Antimony, Ba, As, Mn, Co, Cu, Ni, V and Cl all have their highest or nearly highest values in

sample 9501 at the top of the ridge. The reason for this is not known but it may be related to the high Mn content; Pb and Zn are not anomalous in this sample.

In summary, the enzyme leach analyses, particularly the Cl and Br data, appear to indicate a wider zone of mineralization - up to 200 metres - than previously thought. The most intense mineralization may occur in the vicinity of sample 9511. This possibly widespread occurrence of Pb and Zn mineralization in the underlying bedrock should be further investigated.

It should be noted that this prospect appears to be much more Pb-rich than the Knoll and Swan.

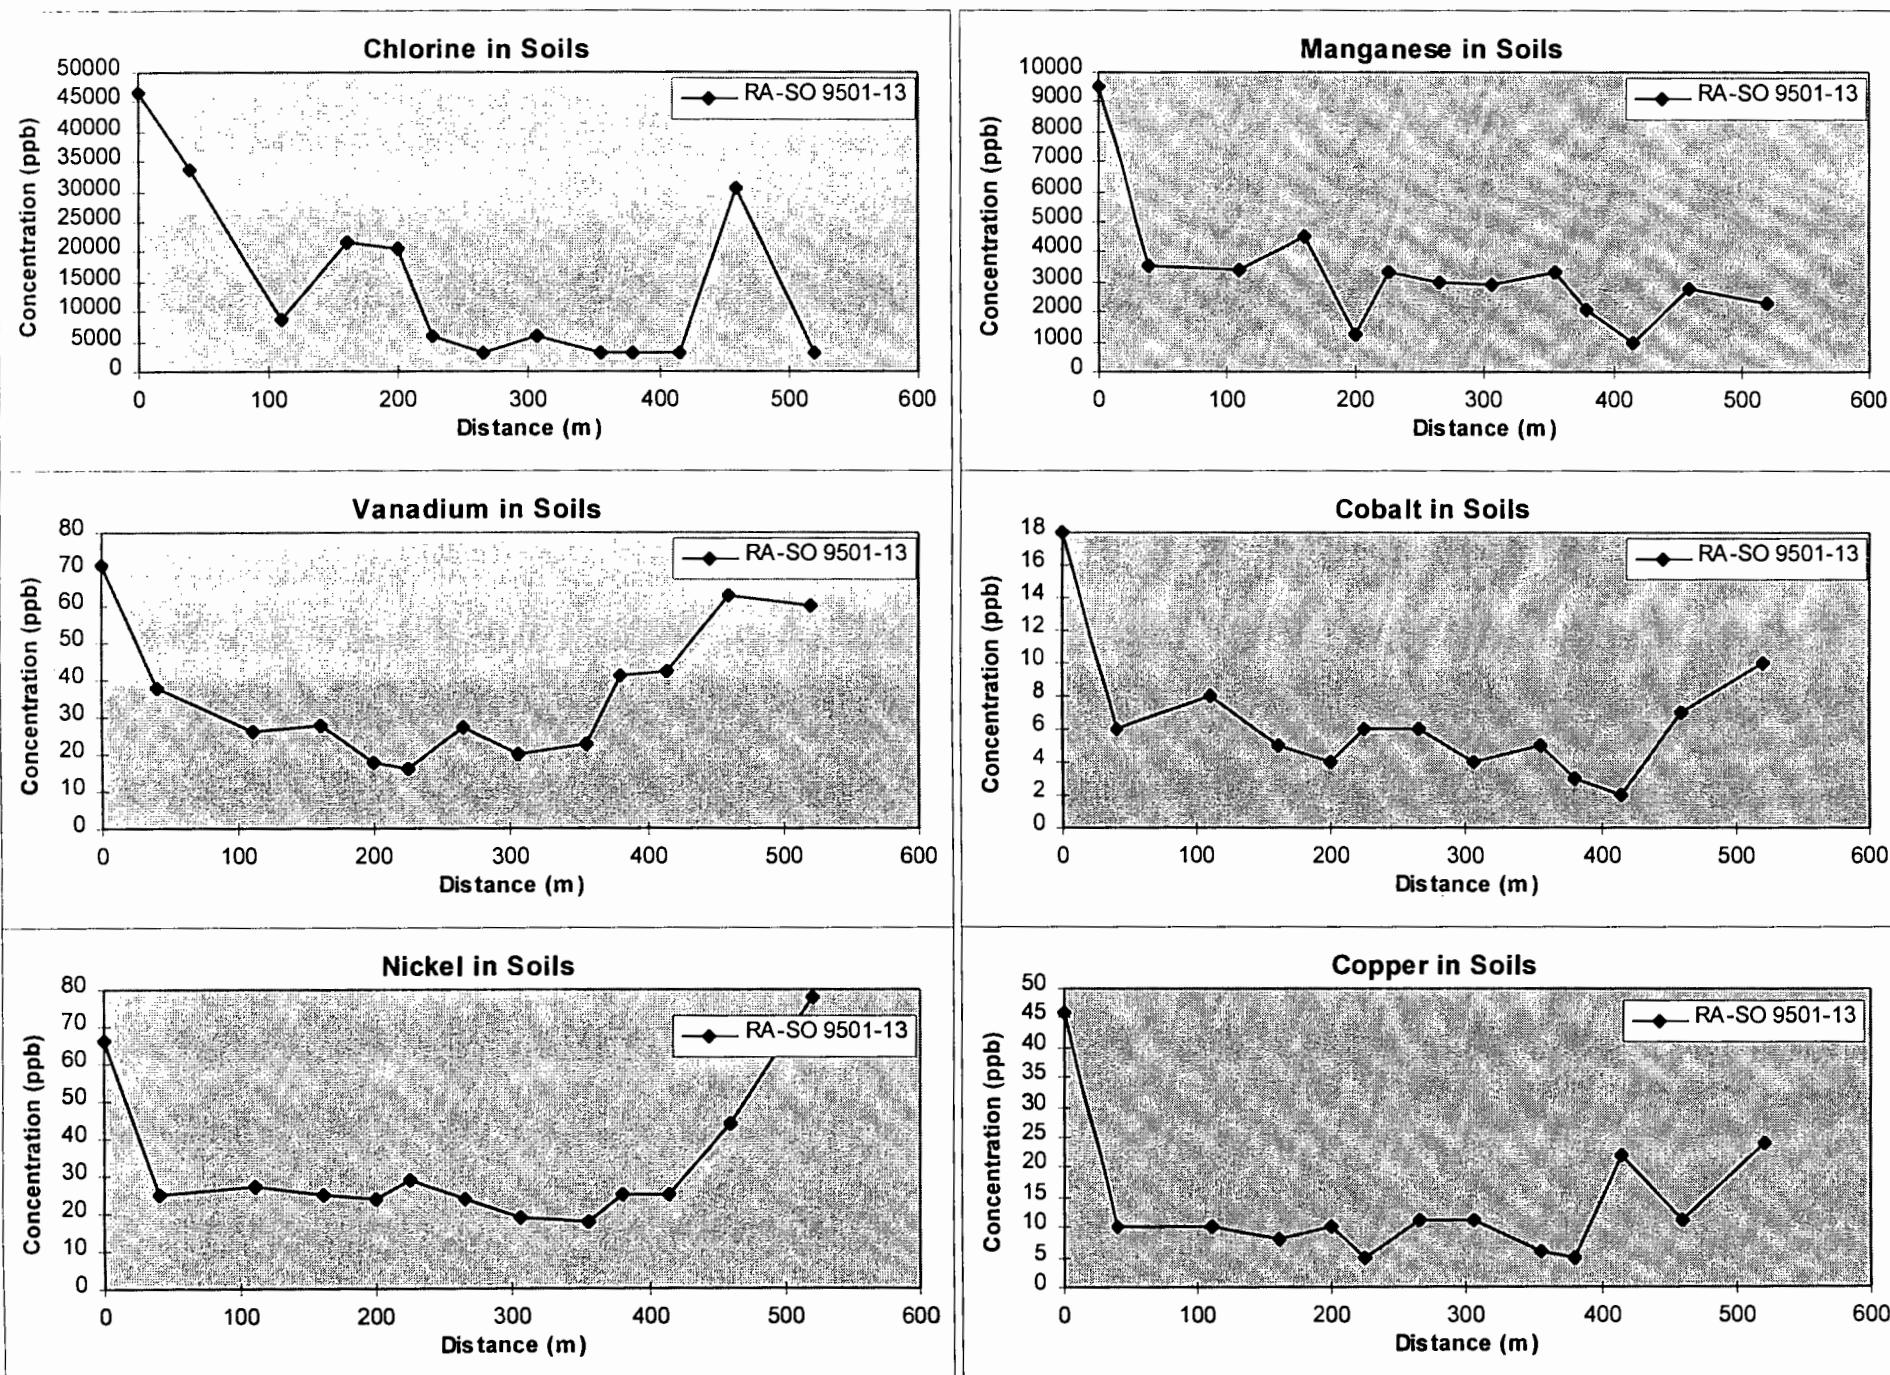

Figure 10a Enzyme Leach determined Cl, Mn, V, Co, Ni and Cu in soil samples collected from the Rain Prospect on the Swan Property. Traverse extends southwest from a small hill. Distance 0 marks the top of the hill.

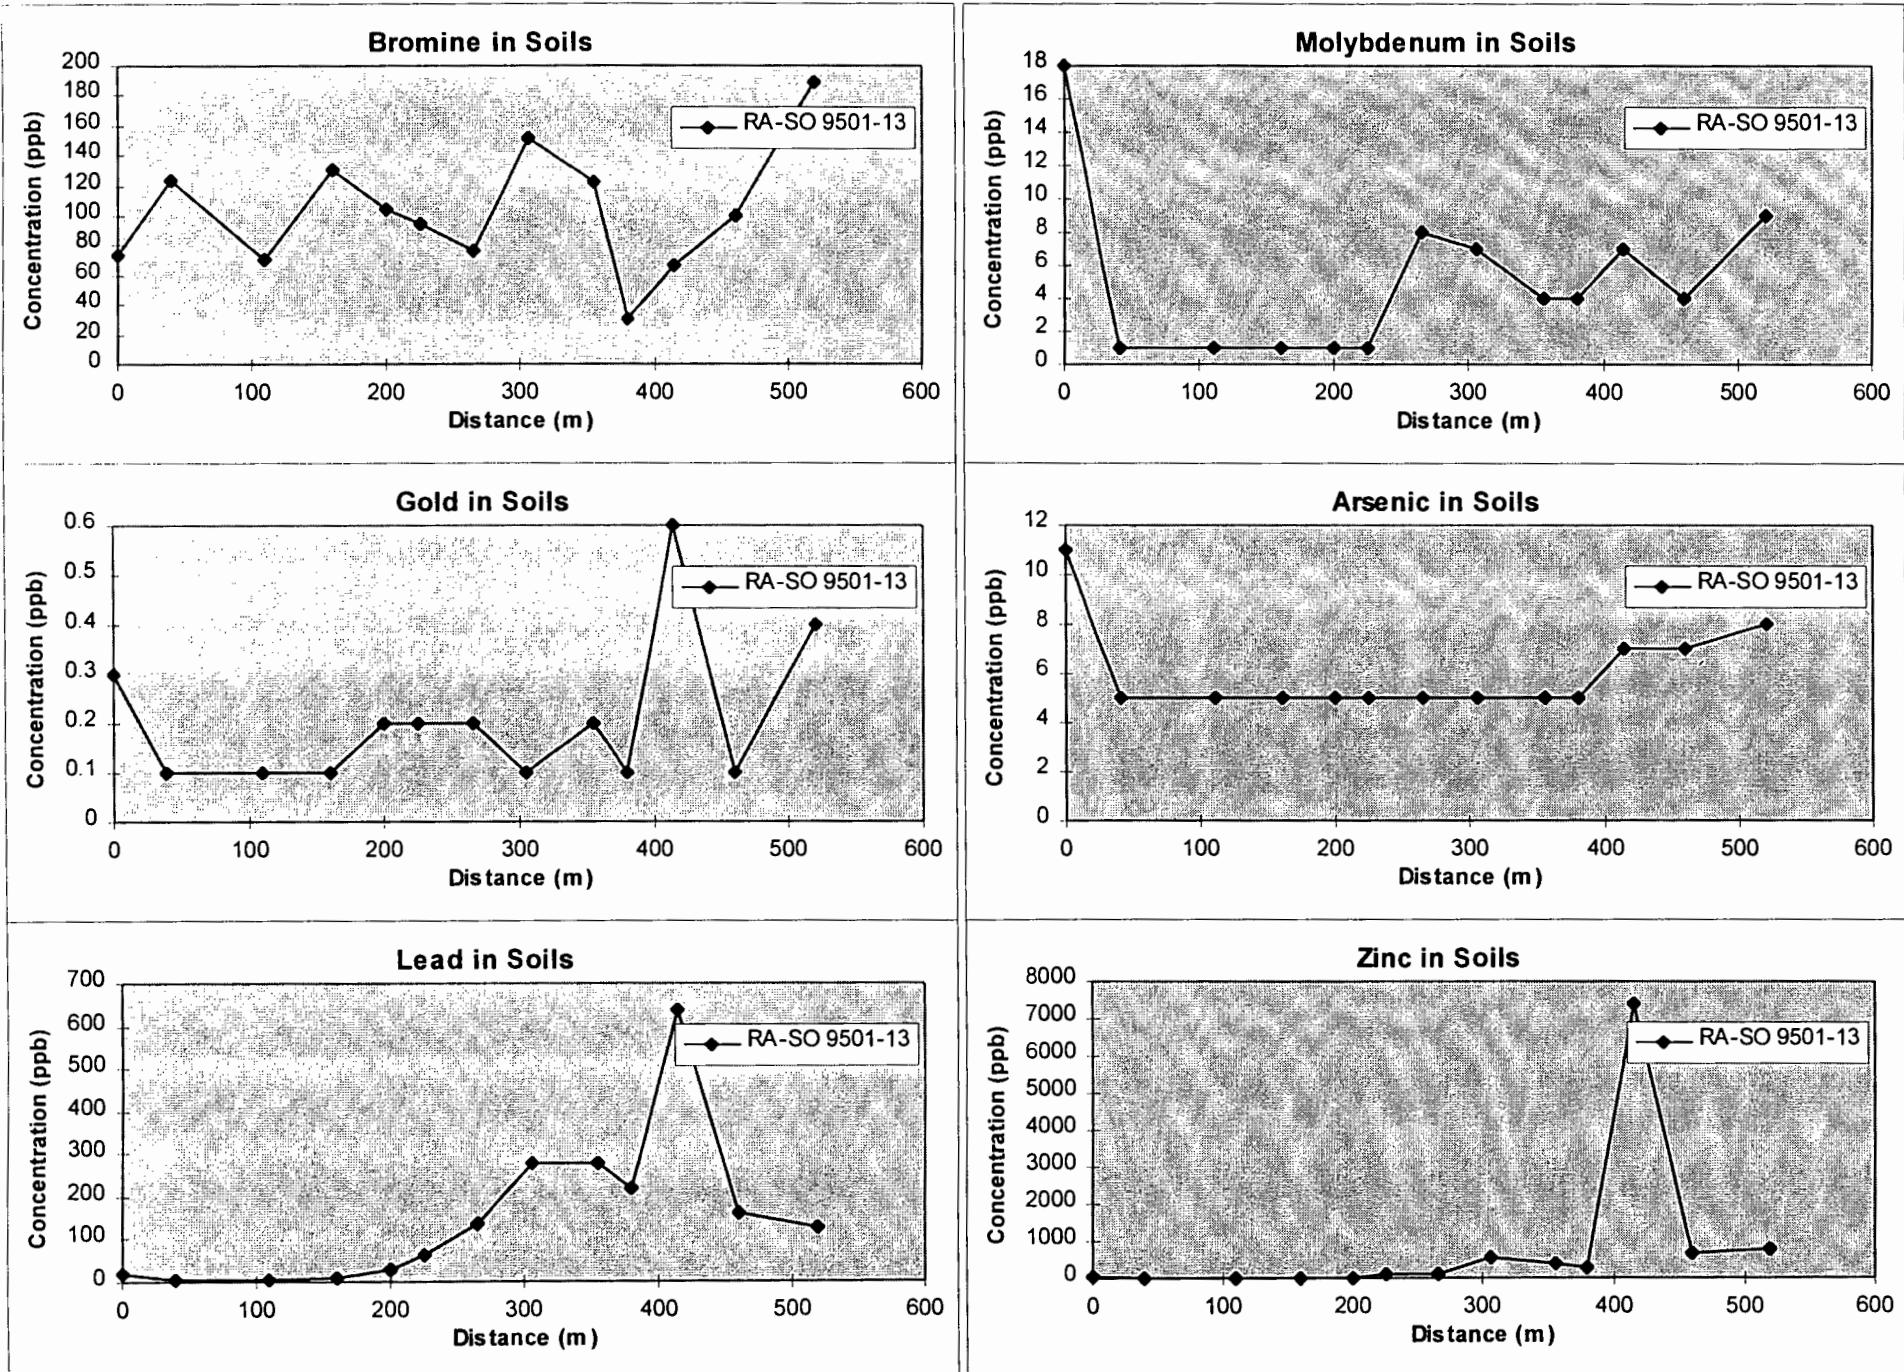

Figure 10b Enzyme Leach determined Br, Mo, Au, As, Pb and Zn in soil samples collected from the Rain Prospect on the Swan Property. Traverse extends southwest from a small hill. Distance 0 marks the top of the hill.

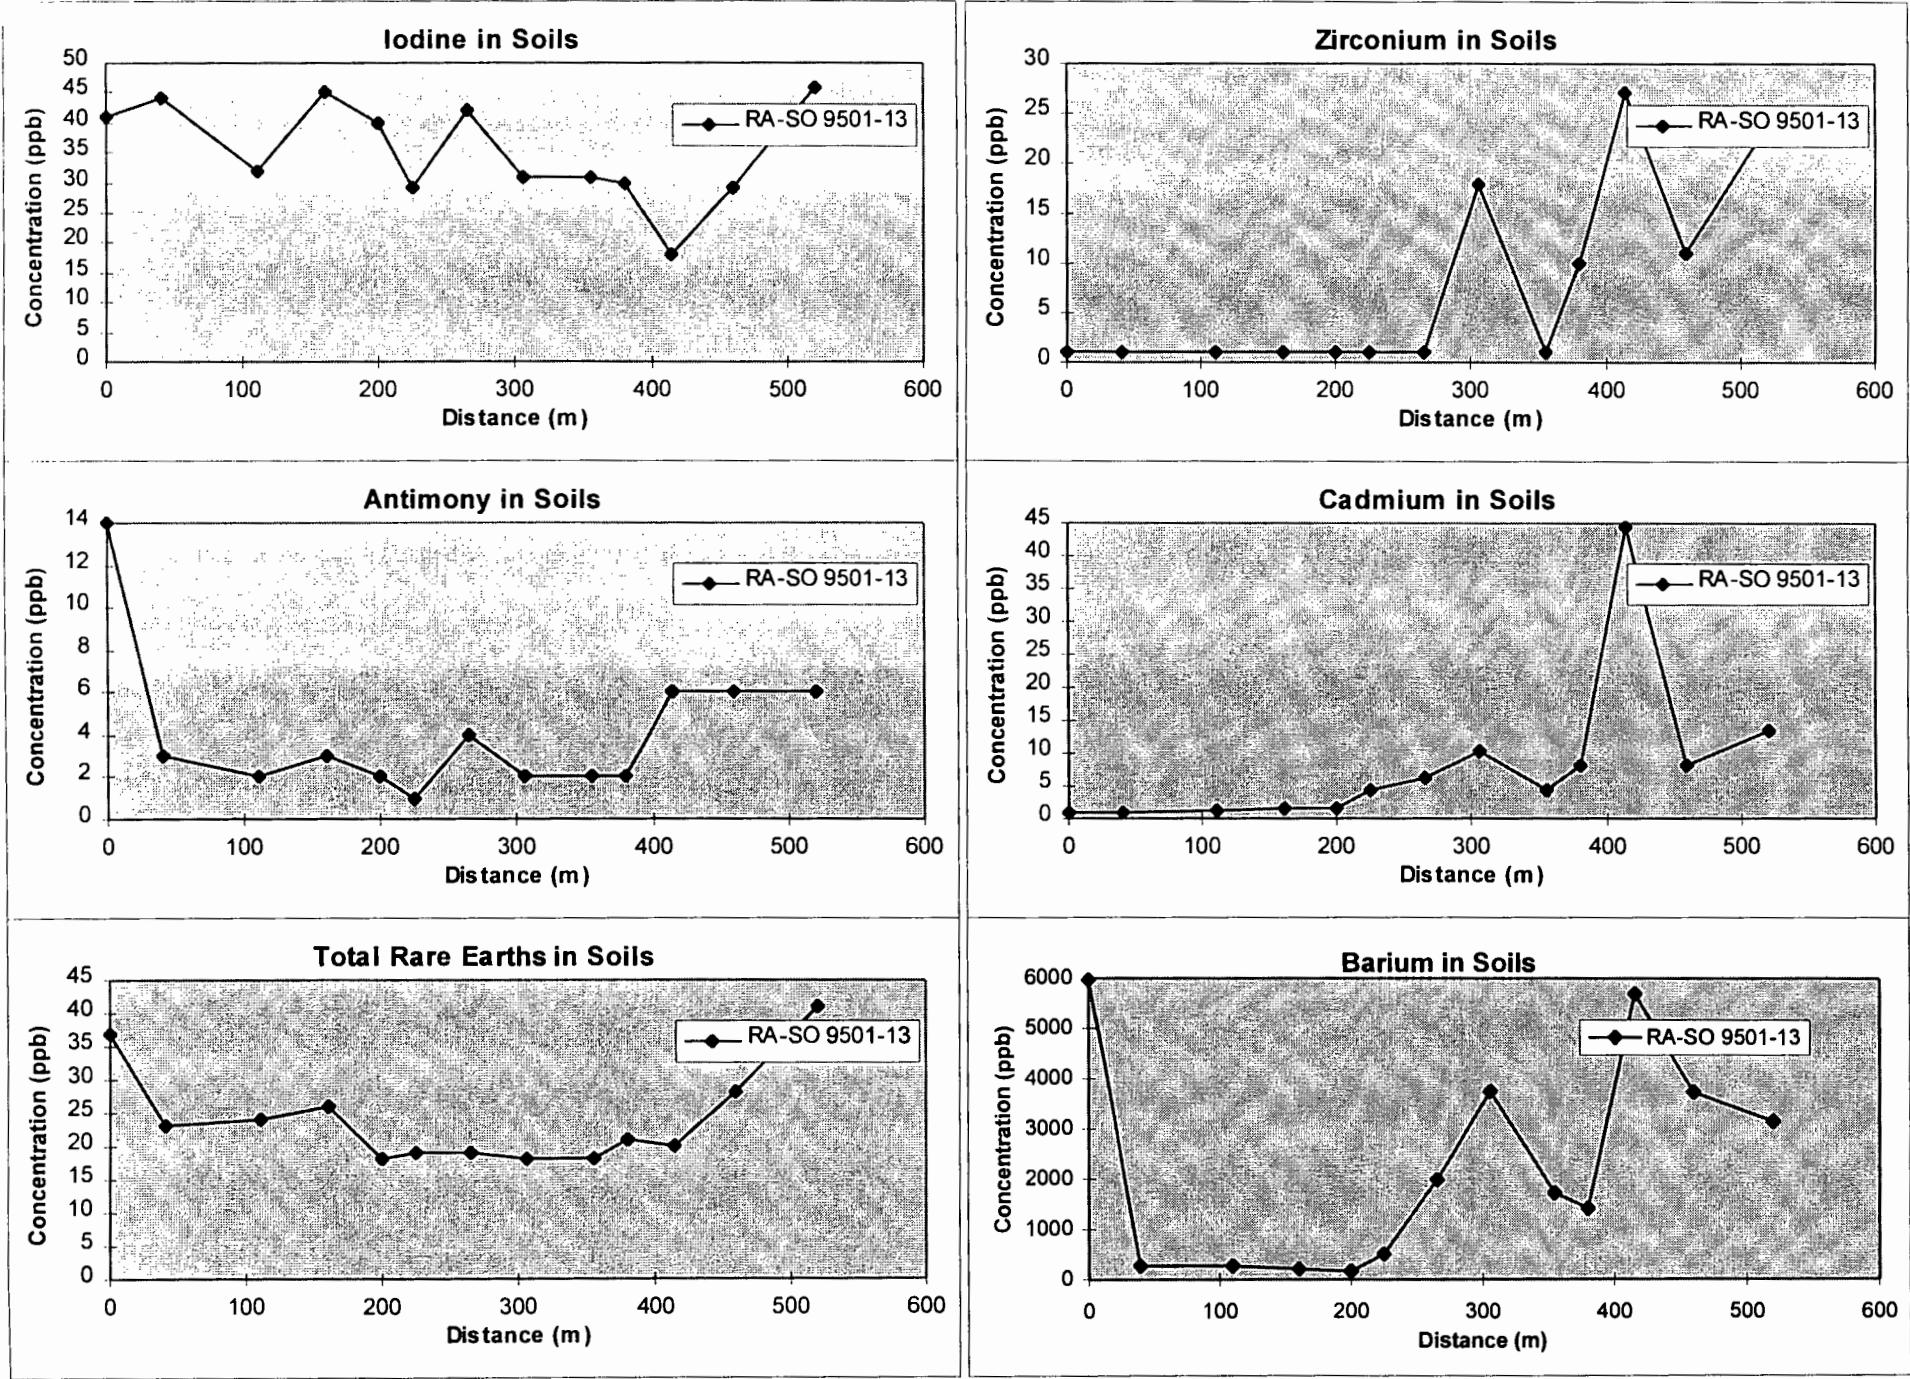

Figure 10c Enzyme Leach determined I, Zr, Sb, Cd, Total Rare Earths and Ba in soil samples collected from the Rain Prospect on the Swan Property. Traverse extends southwest from a small hill. Distance 0 marks the top of the hill.

6.0 CONCLUSIONS

6.1 GENERAL

1. Highly anomalous levels of Pb, Zn, Ag, and Ba exist in soils and rocks over extensive areas of the Swan property but especially in the Swan, Knoll and Rain prospect areas.
2. For all areas (Swan, Knoll, Rain and Crag), the mineralization is associated with the specific stratigraphic interval below or at the base of the Echo Lake Group. This strongly suggests that the control on the mineralization is stratigraphic rather than structural. The control may be a particular lithological unit, an unconformity or a low-angle thrust fault.
3. The apparently irregular nature of the known occurrences of Pb-Zn-Ag-(Ba) mineralization may be a result of topographic relief, weathering, structural and stratigraphic complexity and varying overburden cover.
4. The pilot study using enzyme leach analysis successfully identified previously unknown anomalous areas and has provided valuable information to aid in the design of the next exploration program on the property.
5. Trenching will be of very limited use in future work given the overburden cover and the logistical and regulatory problems involved in trenching on the slopes.

6.2 SWAN GRID

1. Rock sampling on the Swan East, Main and Swan 93 zones confirm the existence of high grade Zn-Pb-Ag mineralization. Swan 93 is a zone of porous, vuggy, oxidized rock. Swan East is also deeply oxidized, as indicated by float or talus on the slope.
2. The Swan East soil anomaly is significant and derives from bedrock not exposed on the hillside. It appears to be related to the stratigraphic interval below the silica-dolomite rock of the Echo Lake Group, possibly within dolomitized limestone of the upper part of the Mount Kison Formation.
3. Soil and rock sampling between the Main zone and the Swan 93 trench indicates a previously unknown zone with anomalous values in Pb, Zn and Ag. This suggests a potential for a continuous zone of mineralization between the Main Zone and the Swan 93 zone.
4. The Enzyme Leach analyses for the Swan East zone appear to identify apical Pb-Zn anomalies within a central low which may be overlying oxidizing sulphides in the bedrock. This work also indicates anomalous gold values, particularly on line 8W.

6.3 KNOLL PROSPECT

1. This program has confirmed the occurrence of anomalous values of Ag-Pb-Zn in soils on the sides of the Knoll. The most anomalous soil samples appear to be confined to a particular elevation interval. The reason for this is unknown, but may in part reflect a relationship between

stratigraphy, elevation and anomalous soil.

2. The nature of the mineralization accounting for the soil anomalies has not been determined as it is not well exposed. Only talus was sampled in this program.
3. The soil geochemical traverse over the Big Creek Group to the southwest of the Knoll indicated two areas of anomalous metal values which may indicate mineralization in the subsurface. These results also tend to confirm the usefulness of this approach in exploring in areas of thick glacial cover.

6.4 RAIN PROSPECT

1. The work has confirmed the existence on the Rain prospect of a very significant soil geochemical anomaly. The area of the anomaly, on the southwest-facing side of the ridge, appears to be at the approximate location of the lower contact of the Echo Lake Group with the underlying Mount Kison Formation, as mapped by Ferri and co-workers. Previous drilling may not have tested a syngenetic stratabound model for the mineralization.
2. Well-mineralized rock samples, obtained from float and an old trench, are within the confines of the soil geochemical anomaly. This appears to be at the same stratigraphic position as mineralization and soil anomalies on the Swan and Knoll prospects. It is not known if drilling tested a stratigraphic model.

7.0 RECOMMENDATIONS

1. For all three areas in which work was done, additional enzyme leach soil geochemical surveys should be done over the areas of interest as identified above to further define and understand the source of the anomalies. Lines should be long enough to get well beyond the mineralized areas so as to provide background data.
2. For all three areas, detailed careful stratigraphic and structural mapping should be done in the area of mineralization and soil anomalies. This is critical to the development of a working model which will incorporate all the data.
3. For future work on all areas, accurate metric grids should be established for control. On the Swan grid, it may be possible and practical to use the old Serem baseline although this should be checked for straightness. All old grids and sample locations (now identified by ribbons) should be tied to the new grids so that all old data can be utilized.
4. For the Swan grid area, a program of diamond drilling is recommended for the Swan East and the area between the Main and Swan 93. On the Swan East zone, holes should be collared on the hillside or the top of the hill above the soil anomaly and drilled toward the south or southeast to intersect interpreted north- or northwest-dipping stratigraphically controlled mineralization. A program of approximately five holes is recommended for the initial phase.
5. For the Knoll prospect area, a decision on diamond drilling should await the completion of the soil geochemical surveys and the mapping.
6. For the Rain prospect, a decision on diamond drilling should await the completion of the soil geochemical surveys and the mapping, as well as the work on the other areas of the Swan property. An attempt should be made to acquire the results of the Serem drilling.

Respectfully submitted,

Wayne Johnson

APPENDIX 1. GEOLOGIST'S CERTIFICATE

I, Wayne Johnson of 5 Pine St. N., Port Hope, Ontario certify as follows:

1. I am the author of the report "Geology and Geochemistry, Cygnet Project/Swan Property". I performed the field work on the property, with the help of one assistant.
2. I am a Fellow of the Geological Association of Canada and a Licencee of the Association of Professional Engineers, Geologists and Geophysicists of the N.W.T.
3. I have no interest in the property or in Stratabound Minerals Corp.
4. I have a B.Sc. Degree in Geology from Queen's University and an M.Sc. Degree in Geology from the University of Western Ontario.
5. I have practised as a geologist from 1974 to the present, most of this time as a consulting geologist and the President of Target Exploration Services Ltd.

ENZYME LEACH ANALYSES

9144RPT.XLS

Enzyme Leach Job #: 9144

Customer: Stratabound Minerals Corp.

Geologist: ----

Customer's Job #: CYGNET

Trace Element Values Are in Parts Per Billion. Negative Values Equal Not Detected at That Lower Limit.

Values = 999999 are greater than working range of instrument. S.Q. = That element is determined SEMIQUANTITATIVELY.

Enzyme Leach Job #: 9050

Customer: Stratabound Minerals Corp.

Geologist: W. Johnson

Customer's Job #: CYGNET

Trace Element Values Are in Parts Per Billion. Negative Values Equal Not Detected at That Lower Limit.

Values = 999999 are greater than working range of instrument. S.Q. = That element is determined SEMIQUANTITATIVELY.

APPENDIX 4

SOIL SAMPLE DESCRIPTIONS

APPENDIX 4. SOIL SAMPLE DESCRIPTIONS

Swan Grid

SW-SO-9501 : sandy, gravelly; yellow/brown soil; well drained; 15 degree slope to NE

SW-SO-9502 : tan pale brown/grey; clayey gravelly; well drained slope; GPS location 7

SW-SO-9503 : light grey/brown; clay, sand, gravel

SW-SO-9504 : dark brown; sandy, very stony, silty; on steep slope; 10-15m below carb. ocp.
with rusty patches

SW-SO-9505 : red brown soil with oxidized rock fragments; appears to be near source of anom ;
actively eroded (no A Hor.); steep slope

SW-SO-9506 : medium brown; sandy, silty, sl stony

SW-SO-9507 : medium brown ; sandy silty stony soil; steep slope (45-55 degrees)

SW-SO-9508 : light brown ,slightly reddish soil; fine sandy, occasional stones; grassy, pines ;
slope slightly less steep than below (40-45 degrees)

SW-SO-9509 :

SW-SO-9510 : light brown; stony silty, sandy; in talus slope of sil-dol rk.

SW-SO-9511 : mostly rock; very little light brown sandy, silty soil

SW-SO-9512 : sandy, silty; light brown with numerous rock fragments; basically ocp of sil-dol
rk

SW-SO-9513 :

SW-SO-9514 : light reddish brown sandy, silty, stony flat on top of hill; sil-dol ocps nearby

SW-SO-9515 : top of cliff ; site of three photos

SW-SO-9516 : on very steep slope, just below cliff; dark brown soil; some organics: very little
soil here

SW-SO-9517 : on steep old talus slope with scattered jackpines ; light brown soi ; sandy silty;
num. rx; slightly reddish

SW-SO-9518 : light reddish brown; sandy, silty, stony on talus slope with low shrubs and ground cover; edge of vegetation kill zone

SW-SO-9519 : brown; stony

SW-SO-9520 : medium brown with slightly reddish tinge; on ocps of calc. marble and c.g. dol.

SW-SO-9521 : black organic soil; probably slid from above; steep slope

SW-SO-9522 : in grove of large spruce ; dark brown soil reddish tinge; probably some organic content

SW-SO-9523 : slight reddish brown B horizon over grey/brown C; many rounded pebbles; looks like gravel, rather than from above, probably on esker or similar deposit

SW-SO-9524 :probably esker; grey/brown; silty, sandy, stony; rounded pebbles; low slope

SW-SO-9525 : same as last two; lower edge of esker

SW-SO-9526 : at toe of hill to W, just a few metres from meadow; medium orange/brown ; very stony; silt, sand; rounded stones; esker type material

SW-SO-9527 : 50m from last sample; on old baseline; sandy gravel; dark brown; slightly reddish; Glacial material

SW-SO-9528 : light brown; silty; few pebbles; similar to next three or four relatively flat

SW-SO-9529 : flat; same as 9530; light medium brown; silty, fine sand with few pebbles

SW-SO-9530 : light grey/brown; silty, clayey; minor pebbles; flat; edge of meadow

SW-SO-9531 : flat; spruce trees; just SW of meadow/muskeg; light grey/brown; silty soil with few pebbles

SW-SO-9532 : flat area; medium brown; clayey, silty soil; few pebbles

SW-SO-9533 : old cut line 4m W ; medium brown; sandy, silty; grassy with scattered poplar and spruce; just S of 2-3m high boulder ridges

SW-SO-9534 : at base of slope, probably old bank of stream; light brown; mostly sand, silt ; 40% pebbles; Glacial ?

SW-SO-9535 : old cut line 4m W; low to medium slope to NE and E (on a nose); forested; no ocp, light brown sand with rounded cobbles to 15 cm; esker or terrace; no local material

SW-SO-9536 : light brown; sandy, gravelly material with some silt; not as sandy as last;
very stony; cobbles are mostly subangular sil-dol with minor rounded exotics;
large local content

SW-SO-9537 : sample from beside pile of silica-dolomite; locally derived; light brown silty soil;
num. rx

SW-SO-9538 : light brown; sandy, silty soil; two cobbles of exotic material; looks mostly
Glacial material here; some pieces of sil-dol nearby

SW-SO-9539 : low slope; light brown (sandy colour); silt sand with pebbles and cobbles and
angular float of sil-dol.

SW-SO-9540 : steep slope; brown; sandy; (not as sandy as 9541)

SW-SO-9541 : dark brown; sandy loam; medium rounded cobbles; steep slope; probably some
organic content

SW-SO-9542 : medium brown; sandy, gravelly

SW-SO-9543 : moderately steep slope; 50% exotic boulders and cobbles and 50% talus;
medium brown; silty soil; feels slightly organic

SW-SO-9544 : steep slope; in trees, as all above; dark brown; silty, sandy, gravelly; talus and
Glacial material

SW-SO-9545 : moderately steep near bottom of slope - 15m ; dark brown; sand/gravel round
and angular from above

SW-SO-9546 : medium brown; silty, stony (30%); appears to be mostly rounded pebbles and
small cobbles; low slope; some sort of terrace ?

Knoll Prospect Area

KN-SO-9501 : SW side of hill; sandy loam soil; dark brown; possible kill zone; no trees, only grass

KN-SO-9502 : right at top of bank overlooking showing; sandy loam; dark reddish brown; note- distances corrected for slope

KN-SO- 9503 : on path leading along edge of ridge; dark brown/grey; gravelly; numerous carb. pebbles

KN-SO- 9504 : between here and last station, slope littered with sil-dol float generally to < 1'; soil is essentially gravel (light sandy colour) with 50% pebbles and balance mostly sand

KN-SO-9505 : between here and last slope, still littered with sil-dol rk; low slope (plateau); mixture of light sandy loam and light grey sand/gravel; about 20m back we saw soil

KN-SO-9506 : relatively flat mossy (groundcover); light loam; silty with few pebbles; probably underlain by carb. here; abundant sil-dol float not apparent here

KN-SO-9507 : area of sink holes; mixture of light brown silt and grey/brown sand (gravelly);

KN-SO- 9508 : in area of many sink holes; scattered fir, thin grassy; light brown sandy and gravelly

KN-SO-9509 : at site of rock sample KN95-W006; light brown sandy and gravelly; beside sink hole; 44200 *

KN-SO-9510 : yellowish sand/gravel; low slope; sink holes; 45100 *

KN-SO-9511 : rubble on bare slope; medium brown; 50m from last @ 110 degrees; on steep slope to next bench; 34300 *

KN-SO-9512 : most of rubble on slope (fairly small pieces) is dol, i.p. w. bx as below, i.p. w. up to 20% sil; light sandy grey; 35200*

KN-SO-9513 : grey sand/gravel sil-dol rubble; 36100 *

KN-SO-9514 : top of hill - sil-dol ocp; 45100 *

KN-SO-9515 : start traverse in notch; light brown; sandy gravelly; 24400 *

* **35200 = 30% stones, 50% sand, 20% silt, 0% clay, 0% organics**

- KN-SO-9516 : top minus 15m; dark brown; stony, sandy, silty; low slope; 23500 *
- KN-SO-9517 : light brown/yellow; moderate slope; 35200 *
- KN-SO-9518 : like crushed aggregate; light grey gravel; moderate slope; abundant sil-dol float; forested all the way down but relatively open; 64000 *
- KN-SO-9519 : reddish brown loam; near ocp of red. weath. dol.; 43300 *
- KN-SO-9520 : very stony; red dol. float; dark brown, slightly reddish; 62200 *
- KN-SO-9521 : dark brown; loamy organic; steep slope with trees; 40402 *
- KN-SO-9522 : dark reddish brown; loamy ; silty organic; 41401 *
- KN-SO-9523 : slope starts to flatten; light brown; blocky, clayey till ?; 31150 *
- KN-SO-9524 : on slope above Crag prospect; medium brown; silty, sandy loam; 24400 *
- KN-SO-9525 : light brown/grey; sandy, silty stony; area of abundant ocps of sil-dol rk; 35200 *
- KN-SO-9526 : light sandy brown; moderate slope; 44200 *
- KN-SO-9527 : light brown/grey; sandy, gravelly; 34300 *
- KN-SO-9528 : medium brown; sandy, silty stony soil; 33400 *
- KN-SO-9529 : medium brown/dark brown; sandy, silty; moderate slope ; 34300 *
- KN-SO-9530 : light sandy brown (more sandy and lighter than above); moderate slope; 25300 *
- KN-SO-9531 : light yellow/sandy brown; looks like fluvial Glacial sand; moderate slope; 24400 *
- KN-SO-9532 : same as above but more loamy; moderate slope; 23500 *
- KN-SO-9533 : similar to above ; light yellow/brown; silty; moderate slope ; 23500 *
- KN-SO-9534 : similar to above but light yellow/brown; silty loam; moderate slope finer-grained; light forest, junipers, spreading fir, occasional large tree; 22600 *

* **35200 = 30% stones, 50% sand, 20% silt, 0% clay, 0% organics**

KN-SO-9535 : slightly darker than above; medium brown, slightly reddish; silty, stony; first break in slope, all above was moderate slope, small hump here, small bench ? ; first heavy forest, 23500 *

KN-SO-9536 : low slope in thick forest with many deadfalls; medium brown; silty, fine gravelly; 33400 *

KN-SO-9537 : moderately steep slope, traverse down N face of knol ; medium dark brown/grey gravelly; double samples; 34300 *

KN-SO-9538 : similar to above, mostly rk talus here; tough to get a sample; basically gravel; 63100*

KN-SO-9539 : moderately steep slope; dark brown; grave ; we are following the gully down; 52201 *

KN-SO-9540 : grey/brown; gravelly; numerous talus pieces of v. siliceous dol (porcellamite); appears to be a sil-bx below the carb. bx; 44200 *

KN-SO-9541 : light/medium slightly reddish brown; moderately steep, as above; samples taken all along from just beside gully, on bank; 34300 *

KN-SO-9542 : very stony; mostly rk talus; mediumgrey/brown; sandy, stony debris; note - some of the samples may be from the edge of the slide (gully) and not just talus; 44200 *

KN-SO-9543 : possibly in slide that runs down side of knoll; mixture of light yellowish sandy silt and dark brown silt or loam; possibly mixed by slide ?; 24400 *

KN-SO-9544 : site of Cominco sample; near edge of slide area; no number on ribbon; light brown sandy ,stony, silty ; 24400 *

KN-SO-9545 : light brown (slightly yellowish ; silty fine talus; 32500 *

KN-SO-9546 : in woods at edge of old slide, which here is 50-75m wide; reddish brown; silty (loamy) slightly organic ?; 22501 *

KN-SO-9547 : end of traverse; this site veered off into the woods to the W; medium brown; gravelly; feel talcose some clay; note - large boulder (2x2m) beside site; 31420 *

KN-SO-9548 : at site of Cominco 222503, just S of confluence of two creeks; about 4m above grassy flood plain in bank of coarse Glacial fluvial material; exotic boulders and cobbles; slightly reddish medium brown; sand/silt; 43300 *

* 35200 = 30% stones, 50% sand, 20% silt, 0% clay, 0% organics

KN-SO-9549 : in meadow on small knoll of umaf. boulders; probably derived from cirque at 240 degrees; light grey brown; sand/silt; very stony; start of traverse; flat ; 43300 *

KN-SO-9550 : in meadow just E of creek; flat knoll w. umaf. bldrs and gravel; slightly reddish, medium brown; 43300 *

KN-SO-9551 : edge of meadow; flat; beside woods; dark brown ; gravelly ; possibly slightly organic ; 42301 *

KN-SO-9552 : flat; in valley (draw); very stony; just (5m) from base of hill; dark brown; slightly clayey 32320 *

KN-SO-9553 : low slope; on N side of draw, just above base of slope; medium brown; sand/silt; 24400 *

KN-SO-9554 : low slope; base of slope just above path; medium yellow/brown; slightly clayey; 23320 *

KN-SO-9555 : on low slope 3m above path; all samples on N side; medium brown; 32320 *

KN-SO-9556 : near W end of pond; on N slope 3m above pond level; medium slope; reset counter; light brown; sandy gravel; slightly reddish; 23500 *

KN-SO-9557 : 3m above pond; medium brown sandy loam; on moose path ; 23401 *

KN-SO-9558 : medium brown (slightly reddish tinge); silty; 23500 *

KN-SO-9559 : on S slope 5m above stream; steep slope; pebbles of Gilliland Tuff (GT); very stony; some angular; pebbles mostly; medium brown; 32500 *

KN-SO-9560 : on N slope 3m above stream; dark brown, slightly organic;small talus GT? ; 52201 *

KN-SO-9561 : on S slope 3m above stream; very rocky; dark brown; old talus of G.T.; 52201 *

KN-SO-9562 : on S slope 2m above stream; medium brown; slightly clayey; 32320 *

KN-SO-9563 : S side, 1m above valley; old talus; much black shale; all angular talus; small dark brown; 33400 *

KN-SO-9564 : S side 3m above stream talus; and boulders; mainly boulders; dark brown; 42301 *

* 35200 = 30% stones, 50% sand, 20% silt, 0% clay, 0% organics

- KN-SO-9565 : S side 2.5m above; dark reddish brown; gravelly Glacial-fluvial deposit; 43300 *
- KN-SO-9566 : S side, up 3m; medium brown; slightly clayey; 32410 *
- KN-SO-9567 : S side, up 3m; light medium brown; 32410 *
- KN-SO-9568 : S side, low grassy slope, 3m above stream ; medium reddish brown; slightly gravelly ; 43300 *
- KN-SO-9569 : on small knoll on N side of stream, just down from junction; medium dark brown; sandy, gravelly; 34300 *
- KN-SO-9570 : light grey/brown; rounded pebbles and cobbles; wooded; 43300 *
- KN-SO-9571 : low slope, wooded; light/medium; yellow/brown ; 32410 *
- KN-SO-9572 : flat, sparsely wooded; medium yellow/brown; 32410 *
- KN-SO-9573 : flat, wooded; medium yellow reddish brown; silty ; 22510 *
- KN-SO-9574 : flat, park like, wooded; medium yellow/brown; silty; slight knol ; 22510 *
- KN-SO-9575 : moderate slope to E, thickly wooded; light grey/brown; sandy soil with rounded cobbles; 25300 *
- KN-SO-9576 : slope to E; wooded; dark reddish brown; very gravelly; 43300 *
- KN-SO-9577 : flat; pile of large boulders; wooded; dark reddish brown; silty ; 43300 *
- KN-SO-9578 : flat, rocky, just SE of our lake, wooded; medium reddish brown; silty; 33400 *
- KN-SO-9579 : low, wooded, just behind camp; medium reddish brown; gravelly soil with possible talus; 33400 *
- KN-SO-9580 : on steep slope (from knoll) 3m above old stream channel; medium reddish brown; very stony; mostly rounded cobbles and pebbles; 43300 *

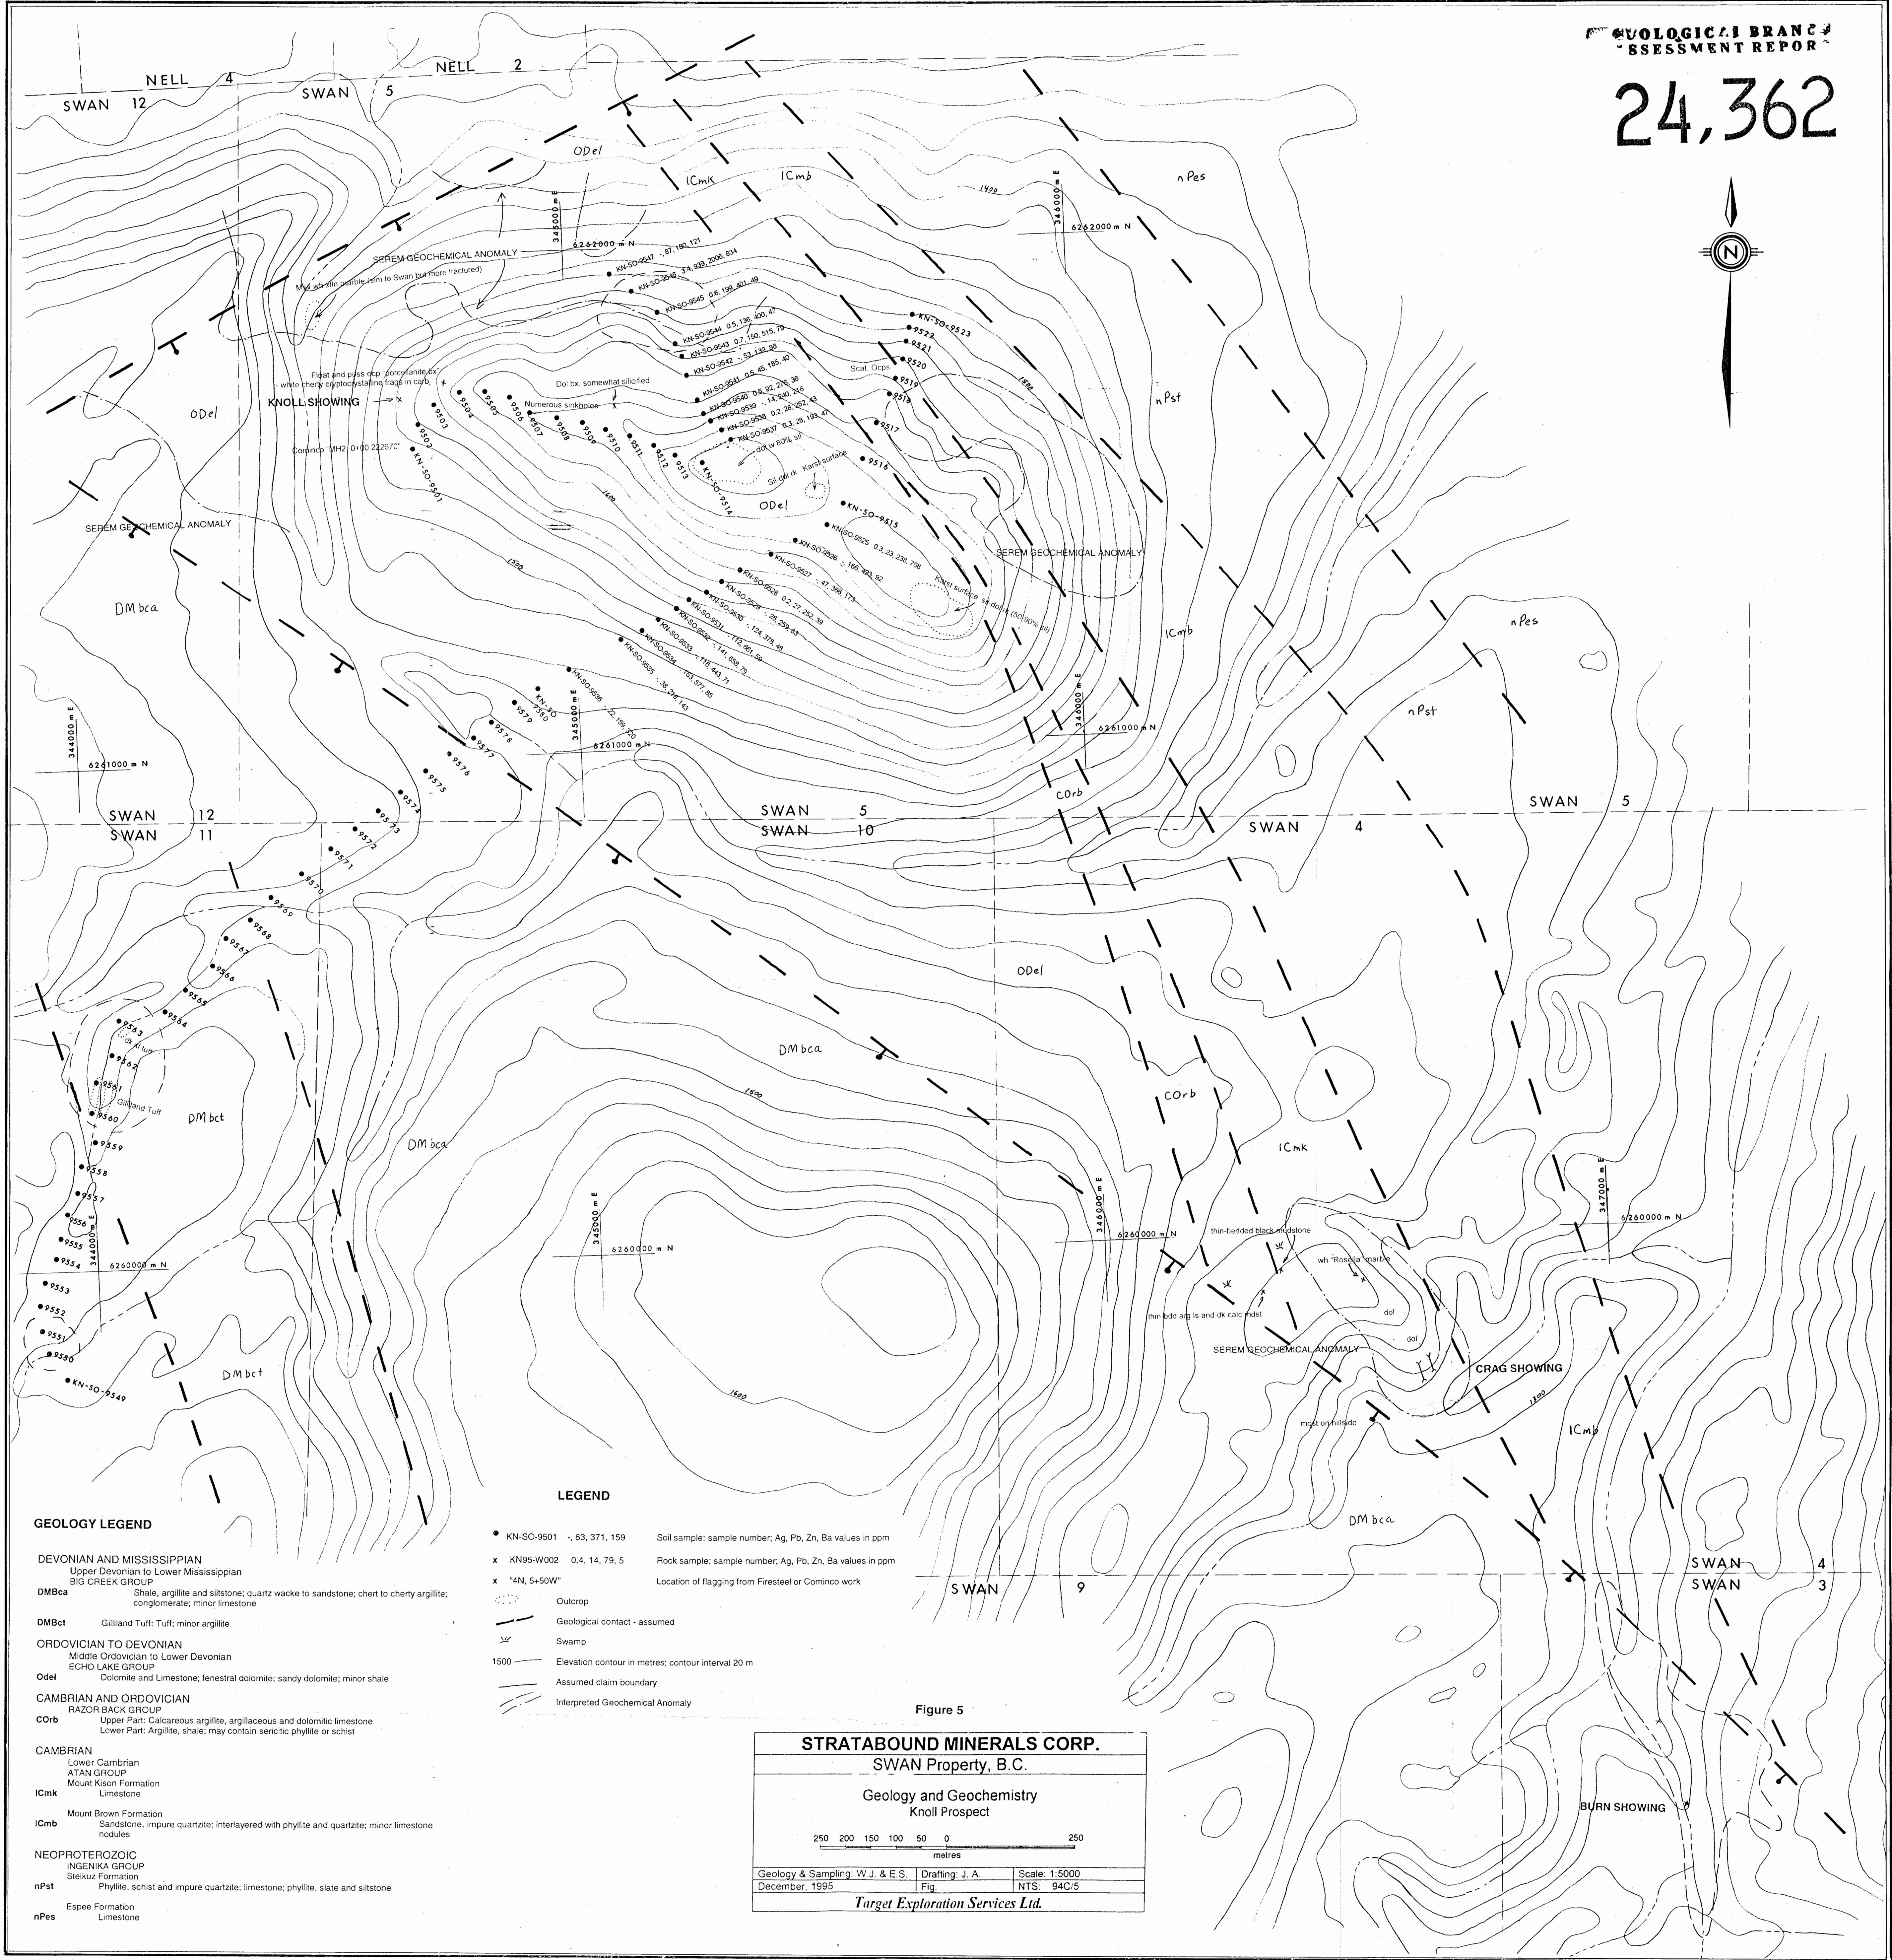

* **35200 = 30% stones, 50% sand, 20% silt, 0% clay, 0% organics**

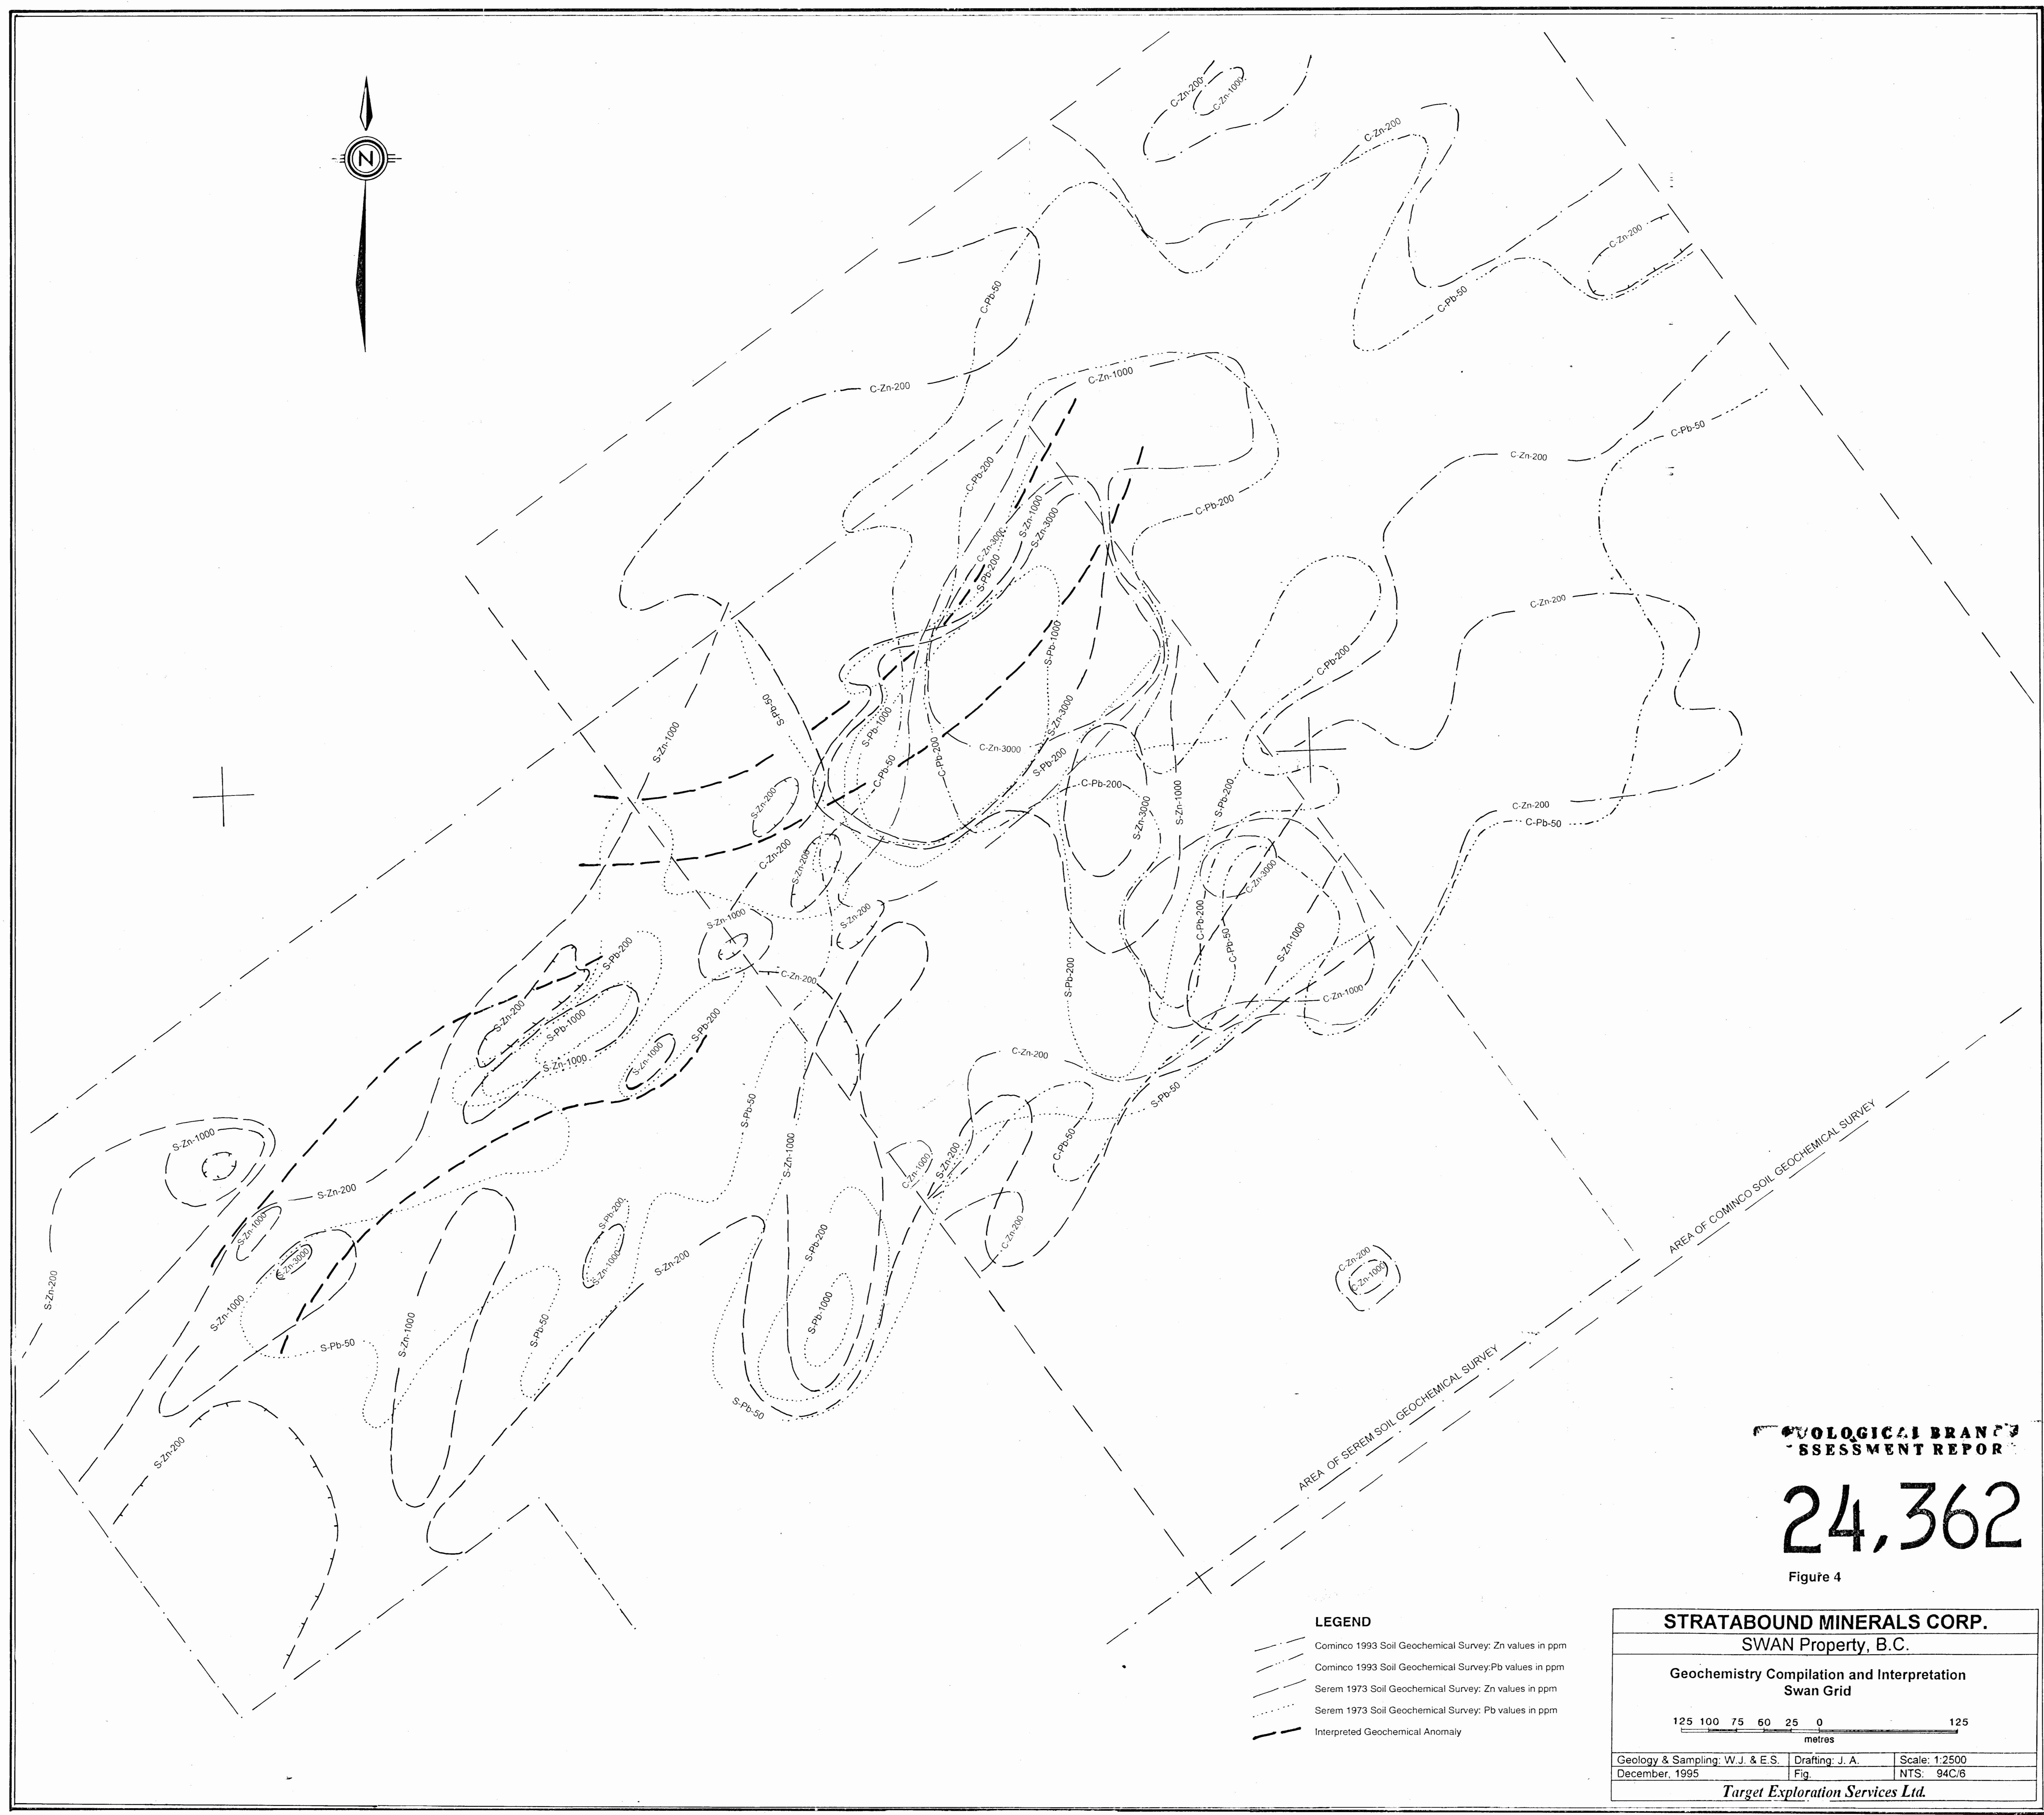

APPENDIX 5 STATEMENT OF EXPENDITURES

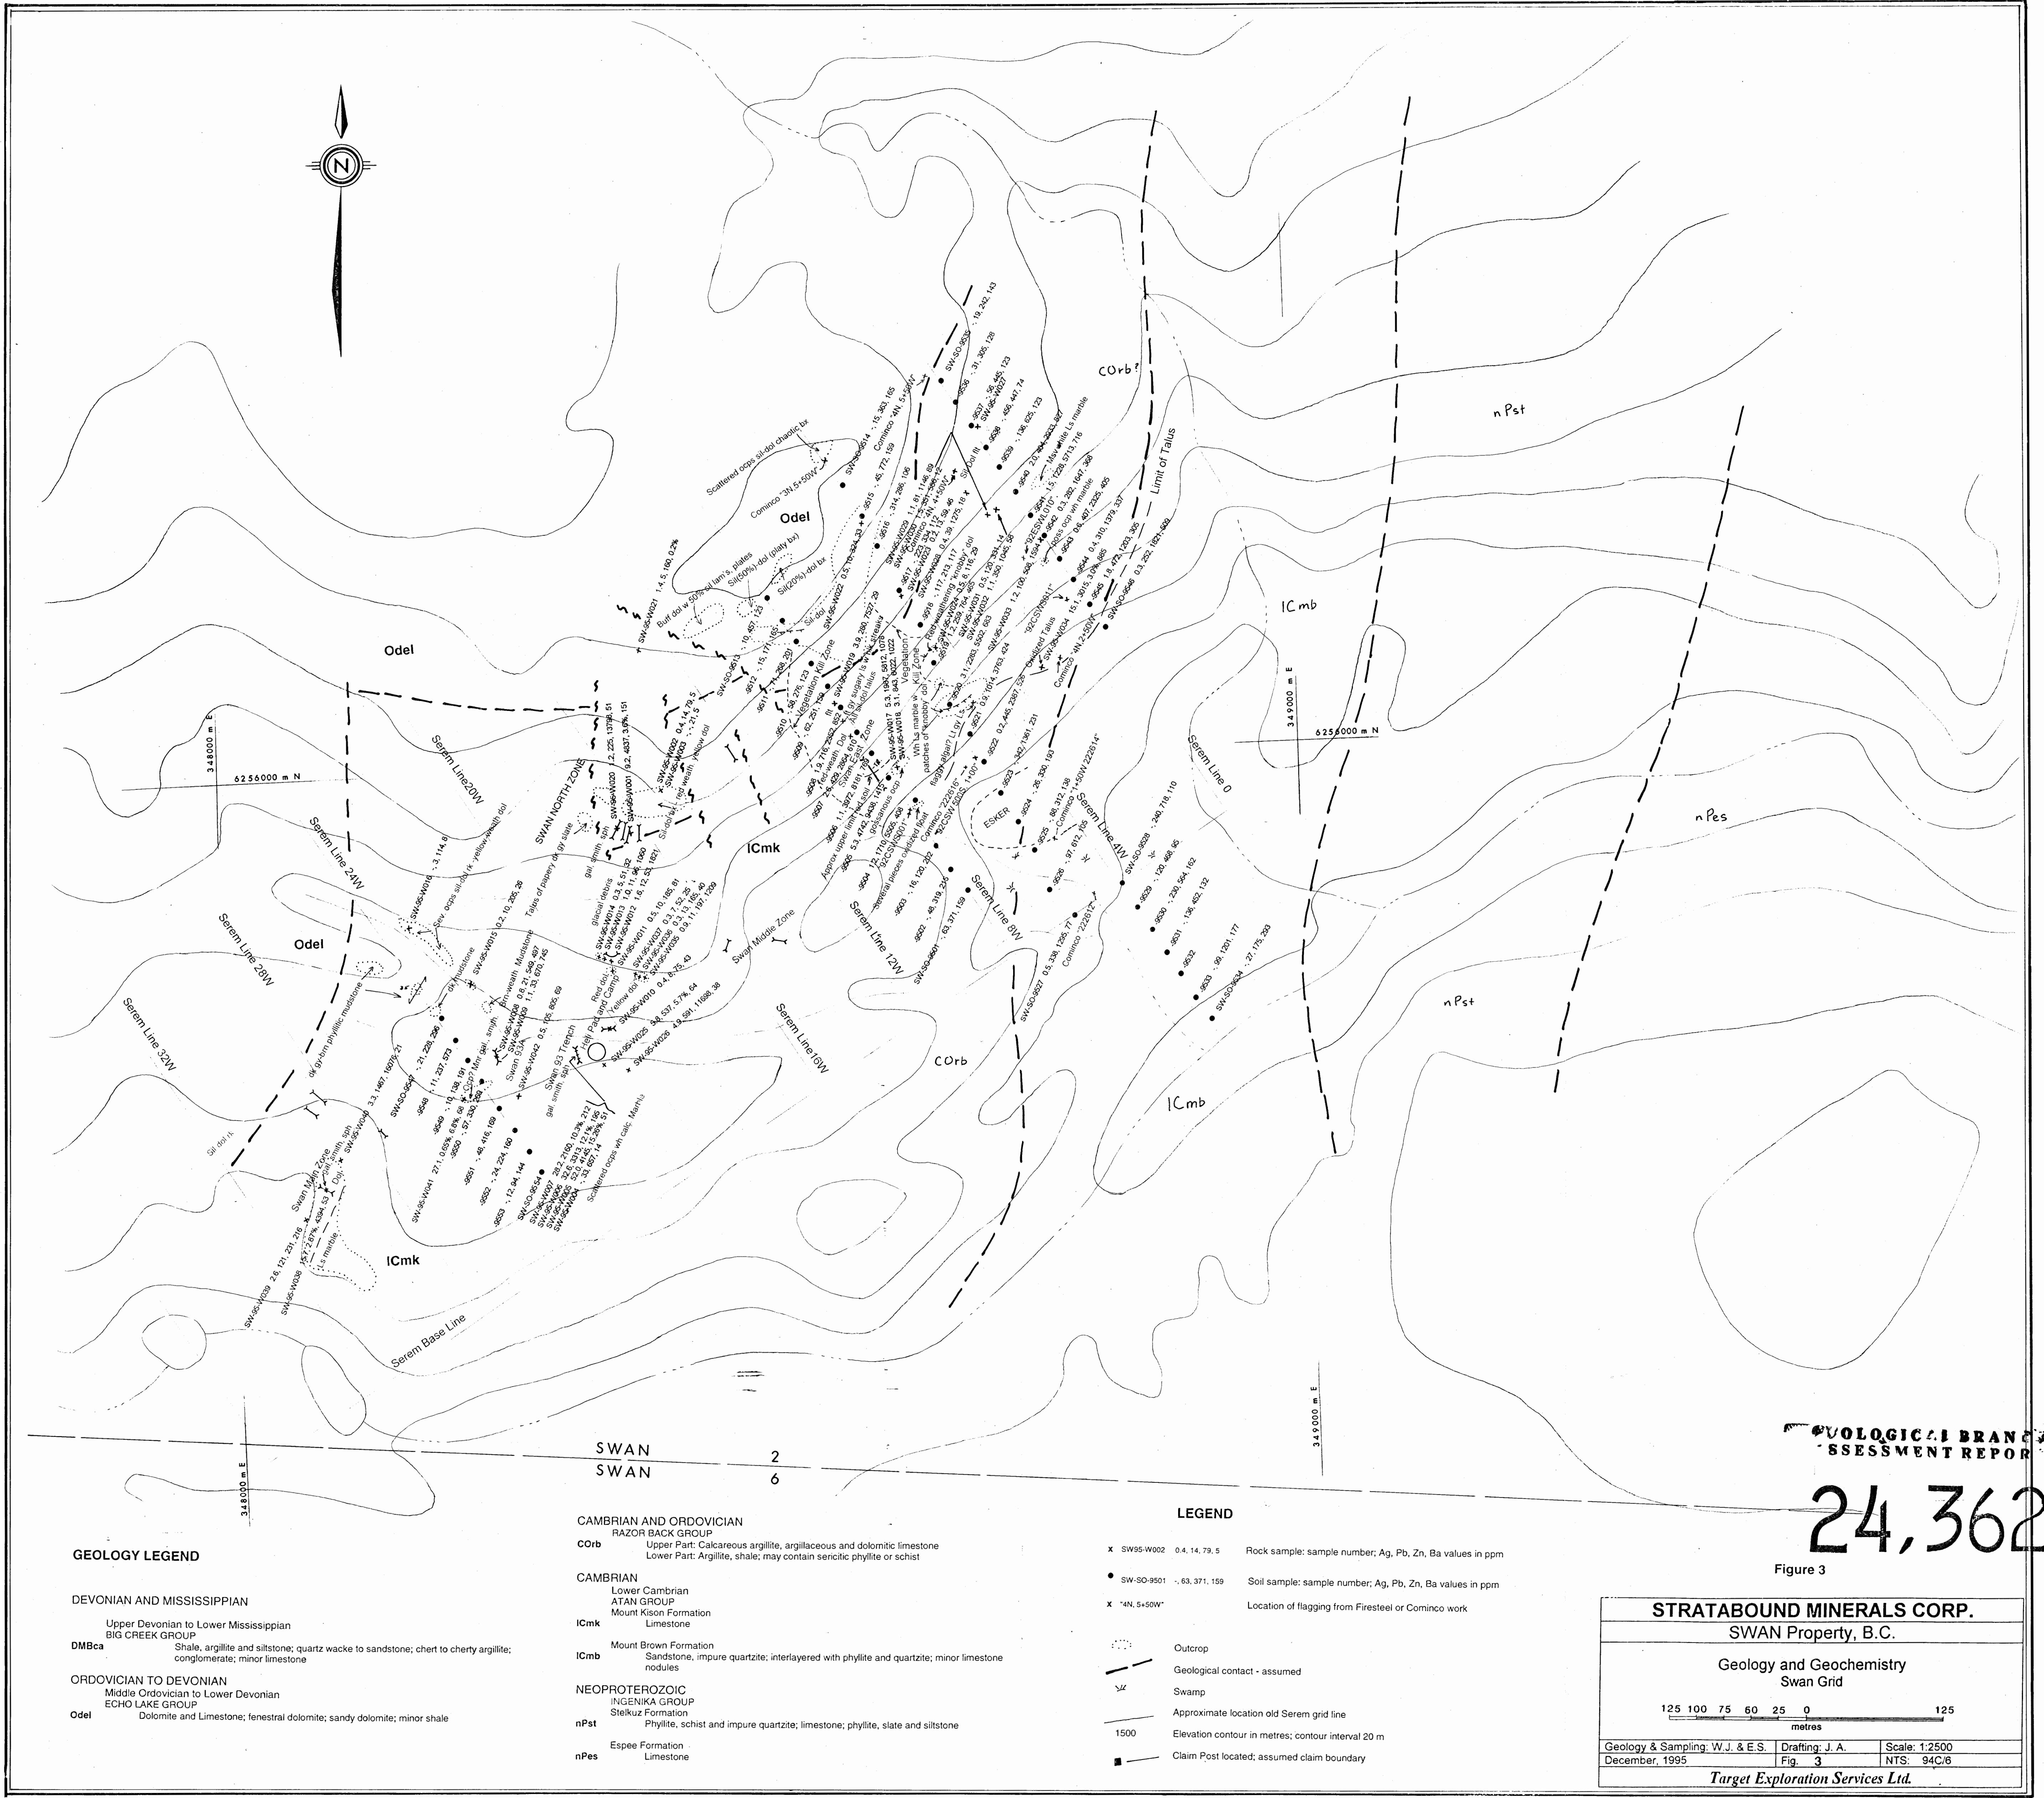

FIELD PERSONNEL/CONSULTANT	\$11,776.25
FOOD AND ACCOMMODATION	1531.53
MOB/DEMOB IN BC	193.28
AIRCRAFT	8,315.33
VEHICLE RENTAL	939.39
EQUIPMENT AND SUPPLIES	1,256.22
INSTRUMENT RENTALS	268.00
LABORATORY	4,680.15
REPORT AND PREPARATION	6,562.58
CONTRACT	519.25
MANAGEMENT	1,200.00

	\$37,241.98

APPENDIX 5 - PAGE 2 - SWAN PROJECT

1. The Rap and Swan properties were worked on as part of the same project. The expenses shown above represent the portion of the total expenses for the combined Rap and Swan properties charged to each property. All expenses were pro-rated according to the approximate number of field days spent on the property - approximately 33% Rap and 67% Swan - worked on the property, except for helicopter costs which were charged 100% to Swan and for Lab charges which were charged according to the actual number of analyses from each property.
2. Personnel for the project were:

Geologist and Party leader

Wayne Johnson
5 Pine St. N.
Port Hope, Ont. L1A 3G4

Days worked	- preparation	- Aug 15-29	- 6 days
	- mob and demob	- Aug 30 - Sept. 2	
	- field work	- Sept 29, 30	- 4 days
	- report and wrapup	- Sept 9-25	- 17 days
		- Oct 1/95-Feb.29/96	- 21 days
Daily Rate	- \$300		

Assistant, soil sampling, trenching

Earl Scott
Toronto Road
Port Hope, Ont.

Days worked	- mob and demob	- Aug 30 - Sept. 2	
	- field work	- Sept 29, 30	- 3.5 days
		- Sept 9-25	- 17 days
Daily rate	- \$175		

3. Helicopter charters were provided by Pacific Western Helicopters Ltd. from a base at Mackenzie. The rate for the 206B was \$640 per hour plus fuel which was priced at \$0.65 or \$1.25 depending on location. Helicopter was used for camp moves and some field work with total time 11.3 hours.

4. Analytical charges were as follows:

Bondar Clegg - Inchcape Testing Services:

Crush/split and pulverize (rock)	\$5.00
Dry, sieve (soil)	1.75
Analysis of Ba, Ag, Pb, Zn	4.50 to 5.50 (for 4 elements)
Analysis by dilution or semiquant.	2.00
Assays - various prices depending On method and element	4.50 to 15.60

Activation Laboratories Ltd.

Sieving	2.50
Enzyme Leach - ICPMS	20.00
