1996 EXPLORATION PROGRAM

COVE PROPERTY

Nanaimo Mining Division
Vancouver Island, B.C.

GEOLOGICAL SURVEY BRANCH
ASSESSMENT REPORTS

24,718

By: R.Tim Henneberry, P.Geo.
December 20, 1996

SUMMARY

The Cove property was identified and acquired as part of regional exploration and assessment program undertaken on the north Island Quatsino limestone bands. A white limestone was located, projected to have use as both industrial fillers and 2 inch minus landscape stone.

The Cove property consists of the Cove 1-3 two-post mineral claims. The property is located 14 kilometres east of Port McNeill. A maintained logging skirts the north end of the property, with branch roads accessing most of it.

A two stage marketing assessment/ bulk sample and diamond drilling program is recommended. The market assessment will consist of obtaining 10 kg, 2 inch minus white limestone samples and displaying them to Island gravel and limestone supply firms. Upon a favorable interest level (and perhaps trial orders), a small 500 ton bulk sample is proposed to provide crushed, 2 inch minus white limestone for initial jobsite tests. On-going chemical and optical analyses will provide brightness and impurity data on fresh, unweathered limestone. The cost of this phase is estimated at \$14,830.

The second stage will consist of diamond drilling for reserves and for testing the chemical and optical properties with depth. This 1500 foot (452 metre) program is estimated at \$65,750.

| | |
|---------------------------------------|-----------------|
| Phase I - Market Assessment | \$1,650 |
| Phase II - 500 Ton Bulk Sample | \$13,180 |
| Phase III - Diamond Drilling | \$65,750 |
| | ----- |
| TOTAL BUDGET FOR COVE PROPERTY | \$80,580 |

Positive results from the drilling will initiate a preliminary feasibility study on a white limestone quarrying operation.

The 1996 sampling program cost \$1,070.00

INTRODUCTION

The purpose of this report is to document the 1996 exploration program on the Cove property. The exploration target is limestone for industrial filler applications or landscape applications.

After preliminary sampling was completed in 1995, a cross-stratigraphy traverse was made in 1996, to sample the limestone exposures at regular intervals. These samples were analyzed for their optical properties as well as for their impurities.

Initially, this property was examined for dimension stone as part of a regional exploration program. The fractured nature of the outcrops left little potential for dimension stone. The white color of the stone, however, may be appropriate for landscape stone. The white Cove limestone may also be suitable for industrial filler applications.

GENERAL BACKGROUND ON THE LIMESTONE INDUSTRY

Geology - (Condensed from Carr et al, 1994).

Carbonate rocks form about 15% of the earth's sedimentary crust, predominantly as limestone and dolomite or their metamorphosed equivalents, marble. Most limestones of economic importance were partially or wholly biologically derived from seawater and accumulated in a relatively shallow marine environment. Environment of deposition is important because it determines the economically significant characteristics of the carbonate deposit. Limestones formed in high energy zones generally contain little non-carbonate material and hence may be a source of high purity carbonate material. Micrites (very fine-grained carbonate muds), which accumulate in zones of low energy, are more likely to be diluted by clay and silt size non-carbonate material. Carbonate rocks are highly susceptible to postdepositional alteration and modification.

The principle carbonate rocks used by industry are limestone and dolomite. Limestones are sedimentary rocks composed mostly of the mineral calcite (CaCO₃). Dolomites are sedimentary rocks composed mostly of the mineral dolomite [CaMg(CO₃)₂].

Impurities in carbonate rock vary considerably in type and amount but are important from an economic standpoint only if they affect the usefulness of the rock. The most common impurity is clay, followed by chert, silica and organic matter. Color, an important property of carbonate rocks, can be a rough guide to purity, but it can also be misleading. Most high purity limestones are shades of light brown to grey to white.

Mining

Limestone and dolomite are high volume, low-value commodities, with production cost control being the critical element in any quarry operation. Mining is predominantly done from open pit quarries, though large scale underground operations do exist.

Carbonate rocks are quarried in 47 of the 50 United States and in all provinces in Canada except Saskatchewan. They are mined from rocks of almost every age in the geological time scale. (Carr et al, 1995).

Carbonate Rock Production in British Columbia for 1986 and 1987 (tonnes * 1000)
(From Fischl, 1992)

| Company | Location | 1986 | 1987 | Location | 1986 | 1987 |
|--------------------------------------|---------------|----------------|----------------|----------------|-------------|-------------|
| | | Limestone | | | Dolomite | |
| Holnam West Materials Ltd. | Texada Island | 1,149.8 | 1,907.5 | | | |
| Ashgrove Cement West Inc. | Texada Island | 1,046.5 | 1,046.3 | | | |
| Imperial Limestone Ltd. | Texada Island | 173.8 | 140.9 | | | |
| Lafarge Canada Inc. | Texada Island | 341.4 | 0.0 | | | |
| Lafarge Canada Inc. | Kamloops | 126.9 | 155.3 | | | |
| Steel Brothers Canada Ltd. | Marble Canyon | 146.1 | 194.6 | | | |
| Northrock Industries | Dahl Lake | 25.4 | 30.0 | | | |
| Quesnel Read-mix Cement Co. | Purden Lake | 10.0 | 0.0 | | | |
| International Marble & Stone Co Ltd. | Lost Creek | 7.1 | 6.6 | | | |
| International Marble & Stone Co Ltd. | Benson Lake | 9.9 | 13.2 | | | |
| International Marble & Stone Co Ltd. | | | | Crawford Creek | 27.7 | 31.9 |
| Mighty White Dolomite Ltd. | | | | Rock Creek | 8.0 | 8.0 |
| Totals | | 3,036.8 | 3,494.4 | Totals | 35.7 | 39.9 |

Limestone and dolomite are currently produced from a few locations throughout the province for a variety of uses. Most of the limestone production originates from Texada Island, while most of the dolomite production comes from Crawford Creek, east of Kootenay Lake. (Fischl, 1992).

Processing - (Condensed from Fischl, 1992).

Carbonate rocks generally do not undergo a milling process. Processing, though dependent on end uses, generally involves some type of crushing and size sorting by screening.

Fischl (1992) has described a chemical composition based classification system for British Columbia carbonate rocks, which needs to be outlined to follow the ensuing discussion on end uses:

| | | |
|-------------------------------------|---|--|
| Ultra high calcium limestone | +97 percent CaCO ₃ (54.3% CaO) | |
| High calcium limestone | +95 percent CaCO ₃ (53.2% CaO) | <2 percent MgCO ₃ (0.96% MgO) |
| Calcium limestone | +95 percent CaCO ₃ | <10 percent MgCO ₃ (4.79% MgO) |
| Magnesian limestone | | <40 percent MgCO ₃ (19.15% MgO) |
| Dolomitic limestone | | +40 percent MgCO ₃ |

The primary use of carbonate rock in British Columbia is in the manufacture of cement. Generally, high-calcium limestone is required for cement manufacture. Higher silica and alumina contents may be useful for manufacturing cement, but excessive amounts of alkalis cannot be tolerated, limited to less than 0.6%. Magnesia content cannot exceed 3 per cent.

Carbonate Rock Consumption in British Columbia for 1986 and 1987 (tonnes * 1000)
(From Fischl, 1992)

| | 1986 | 1987 |
|--------------------|----------------|----------------|
| Cement manufacture | | |
| Domestic | 1,282.8 | 1,051.1 |
| Foreign | 468.1 | 724.1 |
| Lime manufacture | | |
| Domestic | 290.7 | 388.1 |
| Foreign | 395.9 | 584.5 |
| Pulp and paper | 129.4 | 165.1 |
| Agriculture | 19.1 | 27.0 |
| Fillers (whiting) | 31.7 | 31.3 |
| Stucco dash | 14.4 | 18.1 |
| Crushed rock | 283.1 | 328.5 |
| Other | | |
| Domestic | 8.9 | 14.7 |
| Foreign | 149.7 | 142.5 |
| Totals | 3,073.7 | 3,475.1 |

Lime manufacture is another important use of British Columbia carbonate rock. Limestone used for lime manufacture must be at least high calcium in composition, with less than 2.5 percent MgO.

The pulp and paper industry consumes significant quantities of limestone to recover caustic soda in the pulping process. Limestone for the pulping process must be at least high calcium in composition, with less than 3.0 percent MgO.

Agricultural limestone is generally produced as a byproduct of major quarries, used to neutralize acidic conditions in soil. Limestone for this end use can range from high calcium to dolomitic in composition.

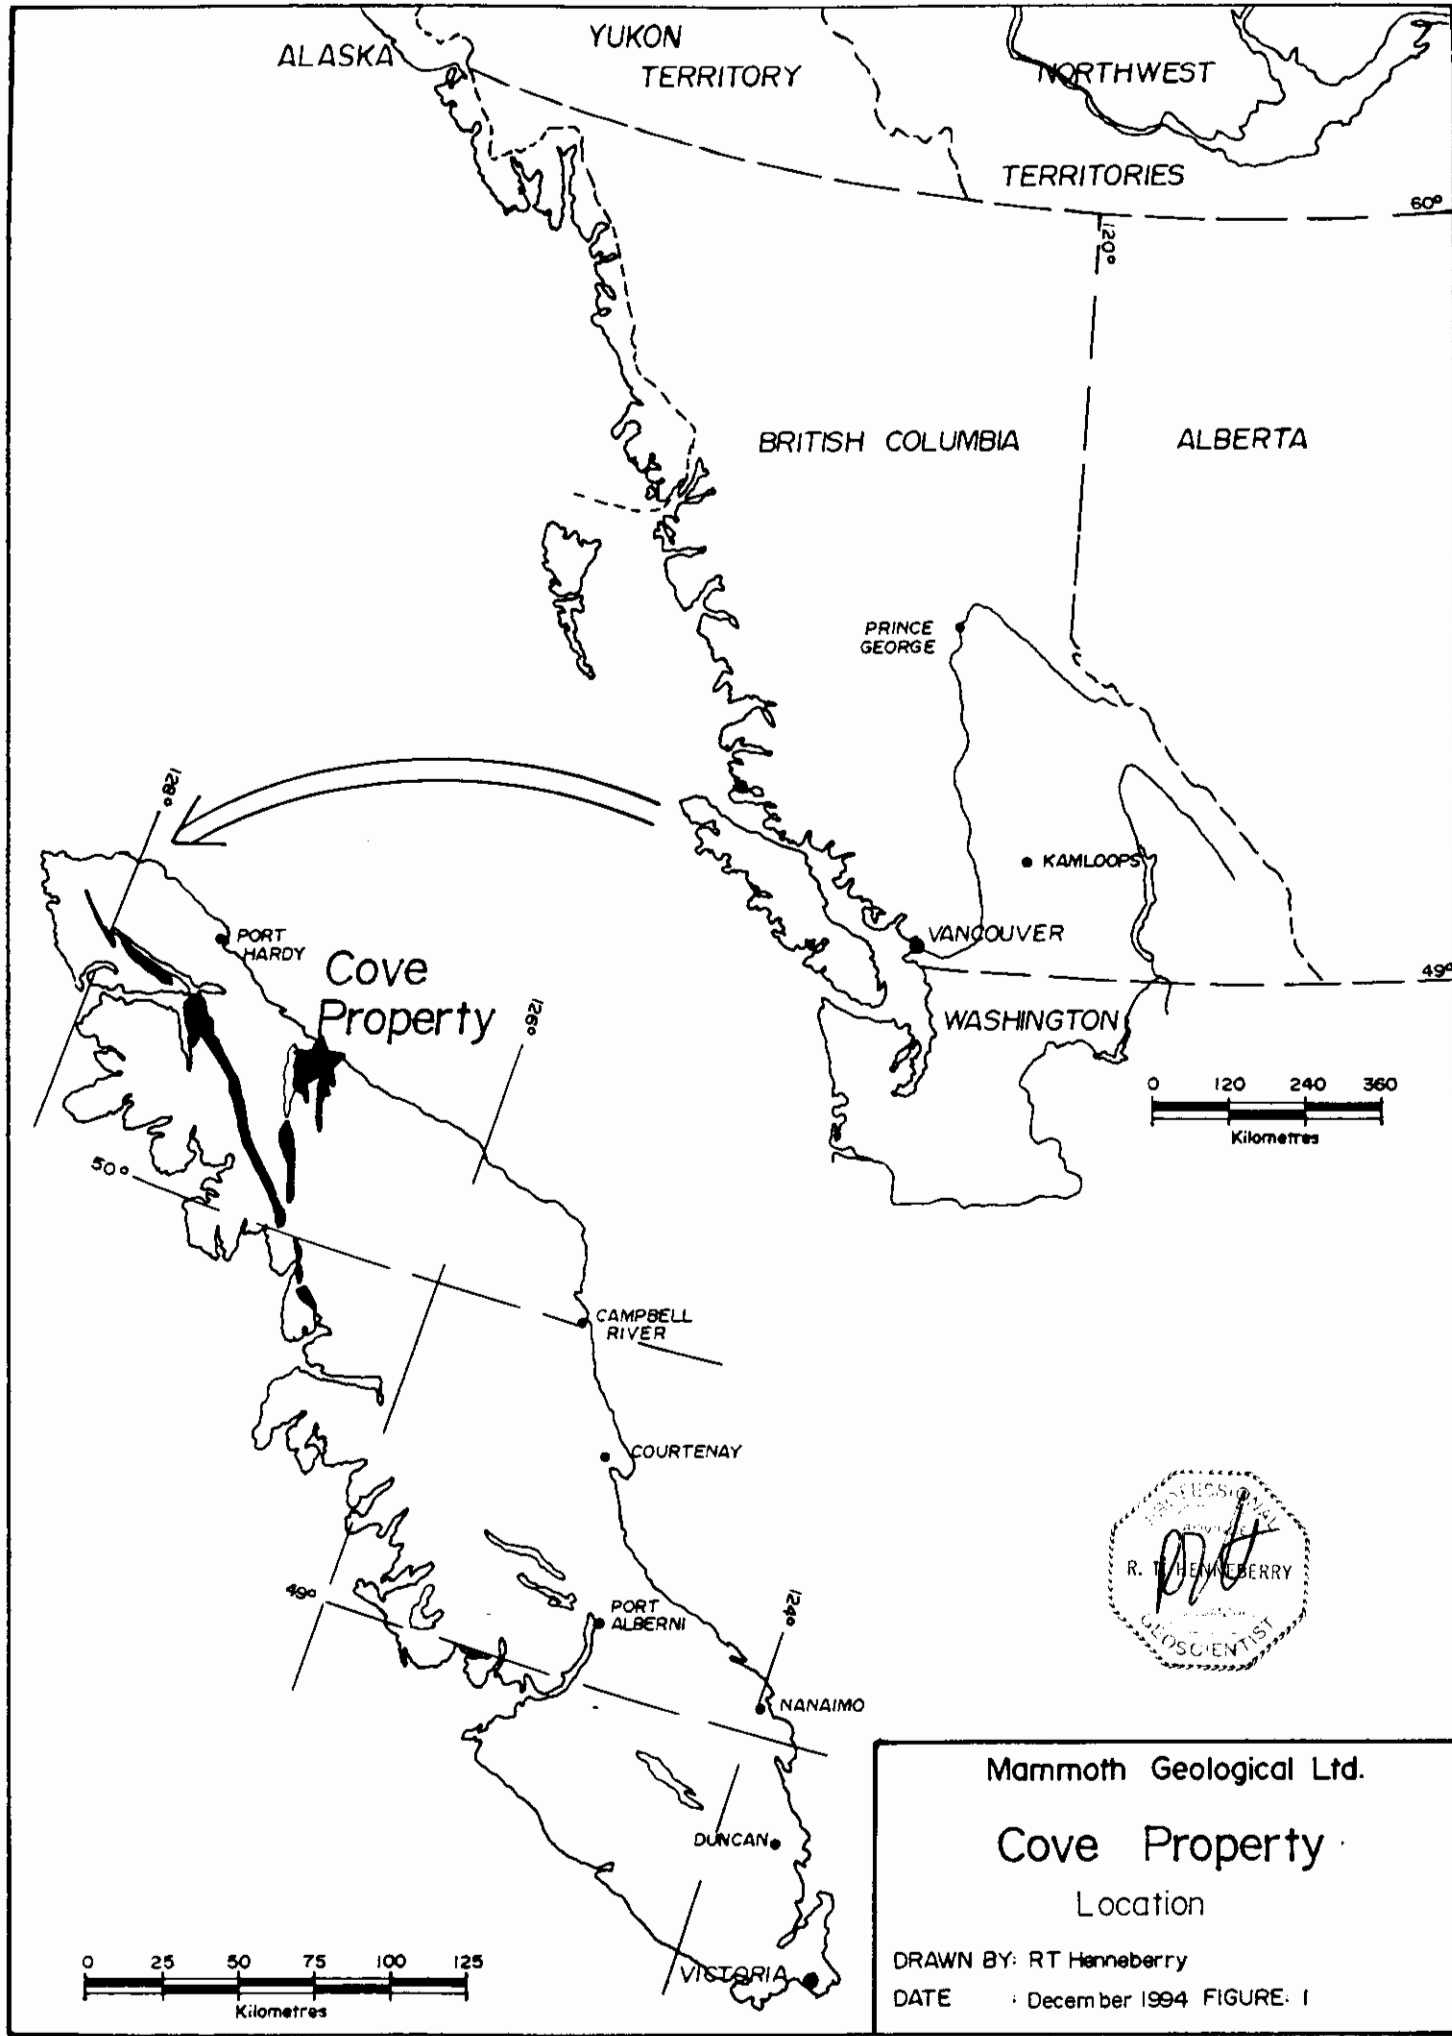

Carbonate rock is also used as fillers and extenders in paints and plastics, as chips and granules for architectural and decorative purposes and in the manufacture of glass. Limestone and dolomite for use in most fillers and extenders must have a brightness in excess of 85 percent (ideally 95 to 96 percent dry brightness in blue light), low iron contents and no silicates. Glass manufacturers require limestone with no more than 0.1 percent Fe_2O_3 .

Structurally competent beds of limestone, or more importantly marble, can be used for dimension stone. Waste product from these operations can also be considered for use as landscape stone.

Demand

According to Fischl (1992), the consumption of limestone and dolomite is expected to increase in a number of areas in the near future. The province's mining industry will be relying on limestone to control acid mine drainage and to neutralize waste cyanide. The pulp and paper industry is expected to consume increasing amounts.

Temanex Consulting Inc. (1994) in a report on industrial mineral opportunities in British Columbia pulp and paper forecast an increase from 300,000 to 750,000 tonnes per annum for pigments in the Western North American paper industry. The pigments they describe are kaolin and calcium carbonate. The carbonate is used as a coater and filler in alkali paper processes.

LOCATION, ACCESS

The area of interest is the northern section of Vancouver Island, between latitudes 49° 45' and 50° 45' and longitudes 126° 30' and 127° 55'. Topography ranges from Sea Level to 1050 metres, with valleys generally less than 300 metres. There are numerous lakes, creeks and streams where water for diamond drilling is readily obtainable. Heavy duty equipment for trenching and road-building will be accessible locally, in either Port Hardy or Port McNeill.

The climate on the north island is relatively mild. The summers are warm and generally dry, while the winters are cool and wet. Snow will accumulate on the higher peaks, but generally the valley bottoms and lower hills are clear for year round work.

There are several towns and lesser communities in the map area where accommodation and lodging can be readily obtained, including Port Hardy, Port McNeill and Woss. The Island Highway cuts through much of the map area. The numerous logging roads of Canadian Forest Products, Fletcher Challenge Canada and Canadian Pacific Forest Products provide access to different claim groups.

The Cove property lies on NTS Sheet 092L/10W, 14 kilometres east of Port McNeill. Access is 14 kilometres along the Beaver Cove Highway to Englewood Road, then 3 kilometres along this road to the property. The status of the property is recently logged.

REGIONAL GEOLOGY

The geology of the north end of Vancouver Island has been described by Muller et al (1974) and Muller et al (1980). The area lies in the Insular Belt of the Canadian Cordillera. The map area is chiefly underlain by the middle to upper Triassic Vancouver Group, overlain by the lower Jurassic Bonanza Group. The Vancouver Group is intruded by large and small bodies of middle Jurassic Island Intrusions and the related (?) Westcoast Complex, and overlain unconformably by remnants of a lower Cretaceous clastic wedge on the southwest side and similar upper Cretaceous beds on the northwest side of Vancouver Island. There are some small early Tertiary (Catface) intrusions also mapped. The region may be divided into several great structural blocks, separated mainly by important near-vertical faults and themselves fractured into many small fault segments.

The Vancouver Group is comprised of the lower Karmutsen Formation, middle Quatsino Formation and upper Parson Bay Formation. The Karmutsen Formation, the thickest and most widespread of the Vancouver Group formations, consists of basaltic pillow lavas, pillow breccias and lava flows with minor interbedded limestones, primarily in the upper part of the formation. Karmutsen rocks outcrop throughout the north part of Vancouver Island, primarily on the east side.

The Quatsino Formation overlies the basalts. The lower part of the Quatsino Formation consists of thick bedded to massive, brown-grey to light grey, grey to white weathering, fine to microcrystalline, commonly stylonitic limestone. The upper part is thin to thick bedded, darker brown and grey limestone, with fairly common layers of shell debris. The formation is in gradational contact with the overlying Parson Bay Formation by an increase in layers of calcareous pelites. Quatsino limestone outcrops as three narrow belts on the north part of Vancouver Island.

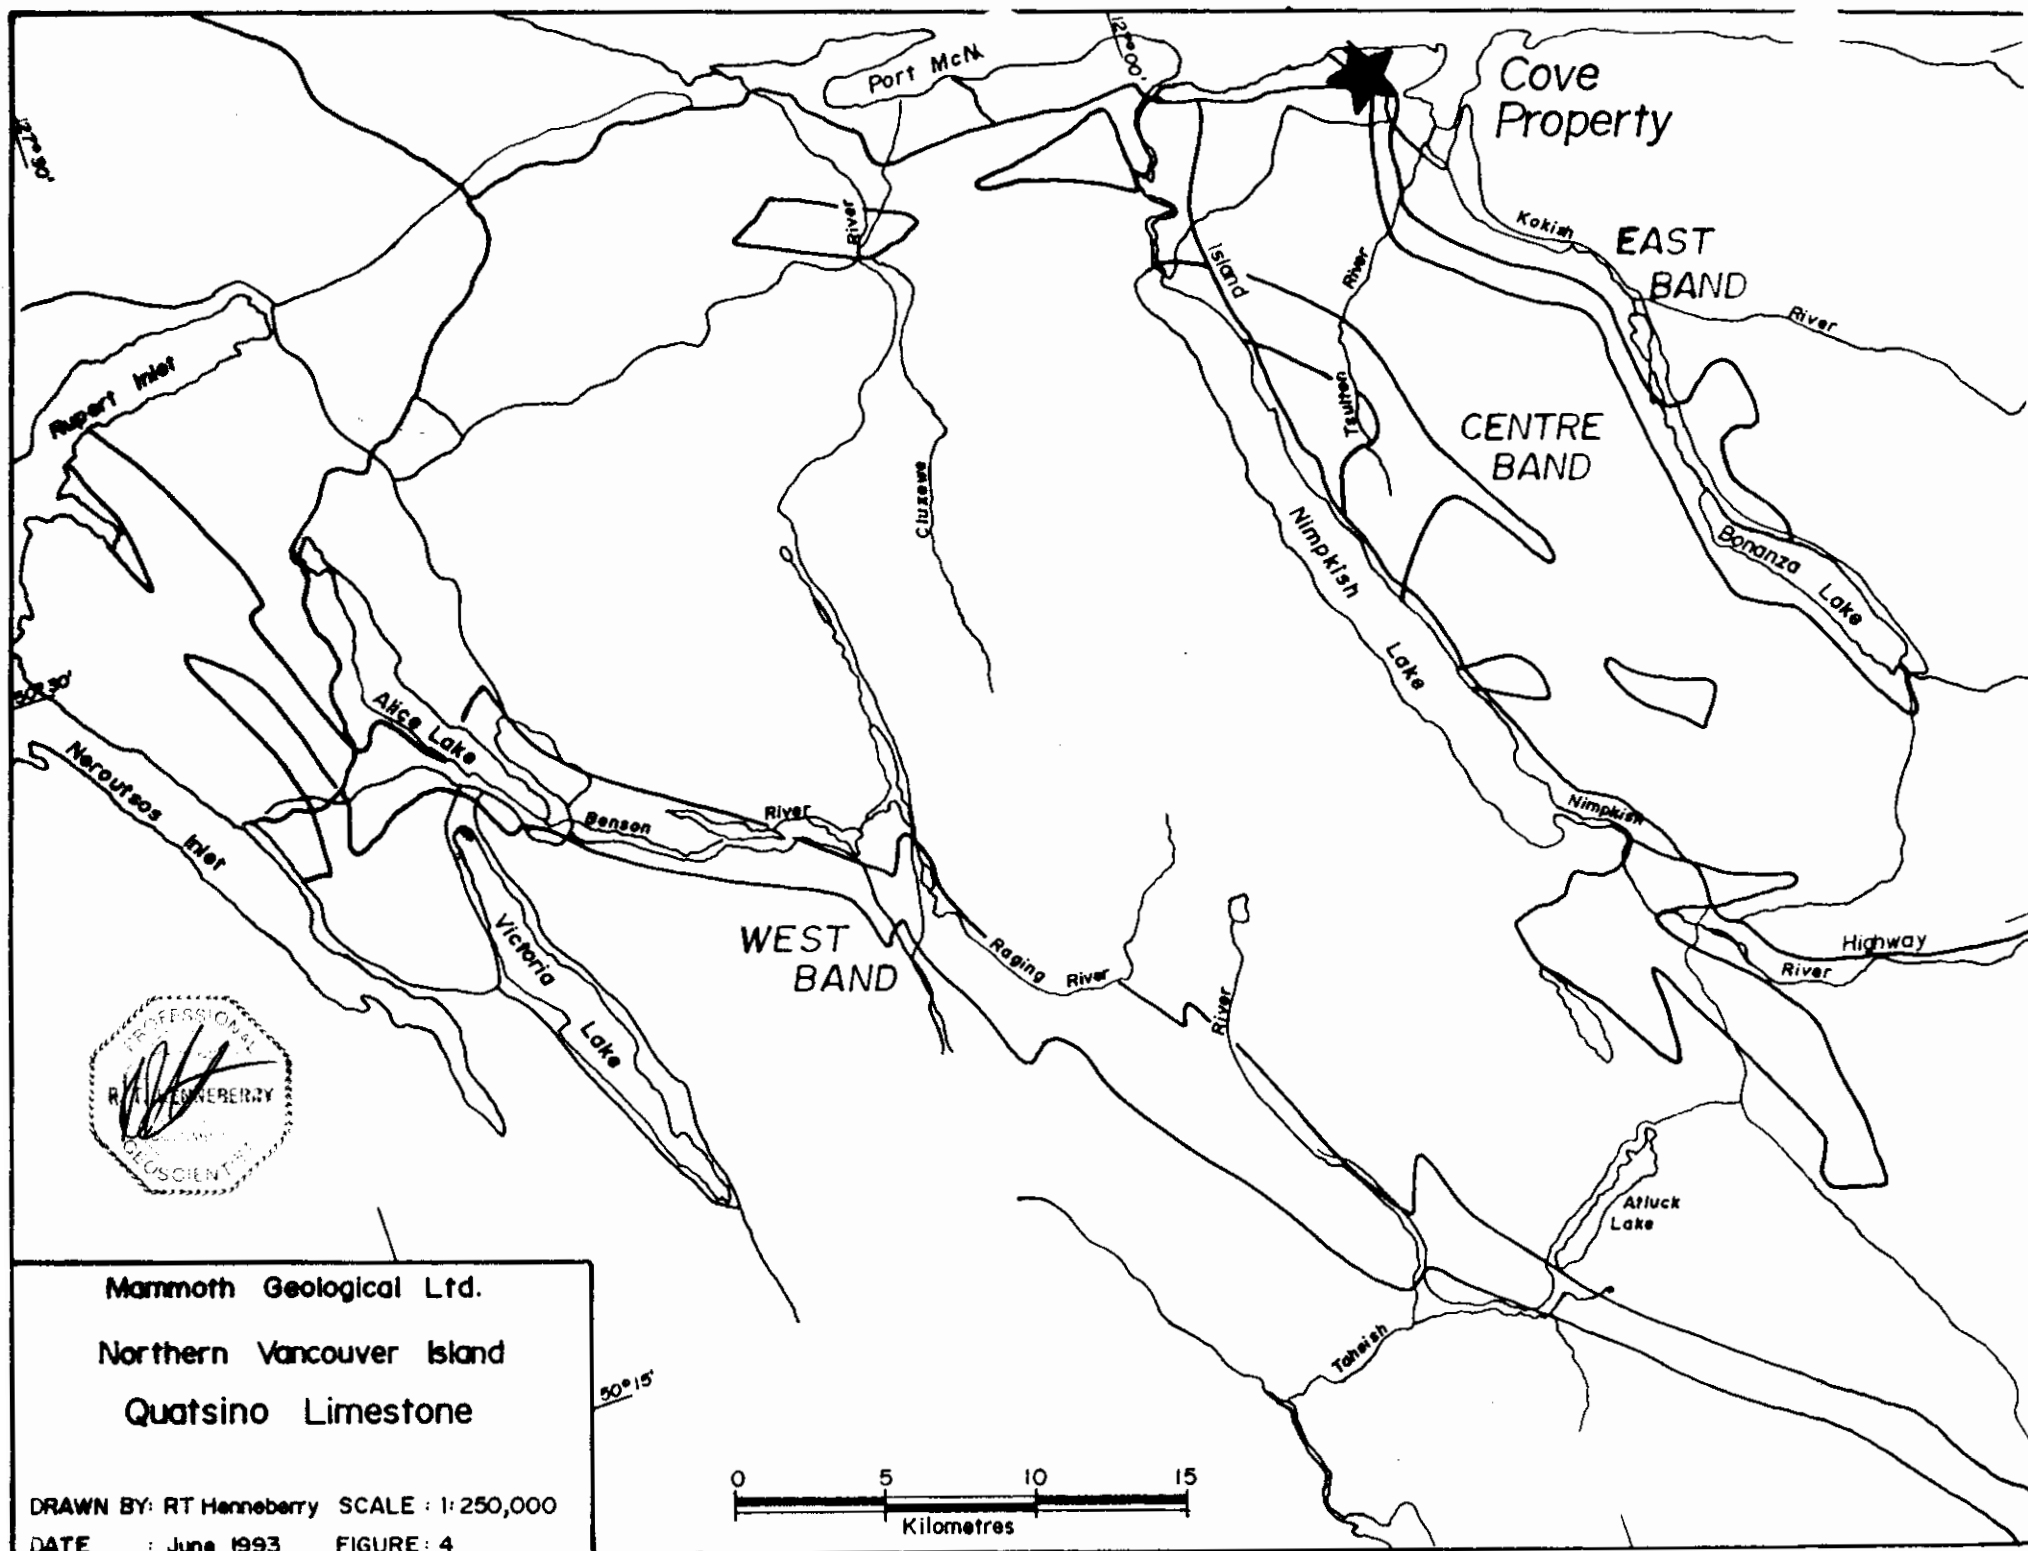

The Parson Bay Formation consists of a series of interbedded silty limestones and calcareous shales and sandstones, and occasional beds of pure limestone. Parson Bay rocks outcrop sporadically overlying the Quatsino limestone.

The Bonanza Group overlies the Vancouver Group. Bonanza Group rocks are primarily a Jurassic assemblage of interbedded lava, breccia and tuff with compositions ranging from basalt through andesite and dacite to rhyolite, deposited in a volcanic island arc environment. The Bonanza Group outcrop primarily on the west side of northern Vancouver Island.

The Westcoast Complex is a heterogeneous assemblage of amphibolite and basic migmatite with minor metasedimentary and metavolcanic rocks of greenschist metamorphic grade. The Westcoast Complex outcrops in a loosely defined belt on the west coast of Vancouver Island.

Granitoid batholiths and stocks of the Island Intrusions underlie large parts of Vancouver Island. These intrusions range in composition from quartz diorite and tonalite to granodiorite and granite. Island Intrusions outcrop in a belt through the central section of Vancouver Island.

The Cretaceous clastic wedge includes the Queen Charlotte and Nanaimo Groups. These groups consist of cyclical successions of sandstone, conglomerate and shale, with interbedded coal in the Nanaimo Group. These rocks outcrop around Quatsino Sound.

Mammoth Geological Ltd.
 Northern Vancouver Island
 Quatsino Limestone

DRAWN BY: RT Henneberry SCALE: 1:250,000
 DATE: June 1993 FIGURE: 4

Small intrusive stocks of early Tertiary age and of general quartz dioritic composition are known in many parts of Vancouver Island. These rocks are generally massive, light colored, fine to medium grained equigranular to locally porphyritic granitoid rocks. They are commonly regularly and closely jointed.

The network of faults displayed on the north end of Vancouver Island appears to be the super position of two or more fracture patterns, each with a characteristic directions and of different age and origin.

Quatsino Formation

The Quatsino Formation limestones are the main focus of the carbonate exploration. The larger, massive beds of limestone are white to grey in color and distinctly crystalline. Exceedingly fine-grained beds form a small percentage of the whole and siliceous or cherty varieties are likewise sparingly developed (Gunning, 1930). The Quatsino formation consists almost entirely of limestone, with a few thin flows of andesite or basalt. The limestone is fine to coarsely crystalline, and ranges from white to black, with various intermediate colors. Towards the base, it tends to be exceedingly fine grained, and grey and brownish or buff colors are characteristic. Midway of the formation the colors are predominantly white or grey, but towards the top the limestone becomes dark grey to black, due to a varying quantity of carbonaceous matter, and the formation grades upward into argillites and impure limestones of the overlying Parson Bay Formation. Even at the top, however, light grey or even white beds are interbedded with the darker varieties. The bedding, as represented by colour banding, is generally well preserved in the upper part of the formation but in the lower part, where white to brownish grey and buff colors predominate, it is poorly preserved. In the upper part, too, the beds are generally thin, thicknesses of 1-2 centimetres being common and more than 60-100 centimetres uncommon. The formation as a whole is dominantly a high-calcium limestone (Hoadley, 1953).

Within 1-3 kilometres of bodies of the Coast Intrusions, the limestone may be highly contorted and extremely jointed and fractured, cut by many acidic dykes, and partly to completely skarnified (Hoadley, 1953).

Limestone outcrops in three relatively narrow discontinuous bands of varying lengths on the north end of Vancouver Island (McCammon, 1968). The East Band reaches from the hill just west of Beaver Cove southeast across Tsulton River to Bonanza Lake and down the west side of the lake to its west end. The Centre Band extends from 5 kilometres south of Port McNeill southeast to 15 kilometres past the south end of Nimpkish Lake. The West Band extends from west of Nahwitti Lake southeast to Tlupana Inlet. An additional limestone occurrence extends along the south shore of Holberg Inlet.

The limestone from the East Band is generally grey-white to white in color with occasional beds of dark black. Structurally, this band is fairly competent in certain sections. Large blocks for dimension stone could be quarried from these locations.

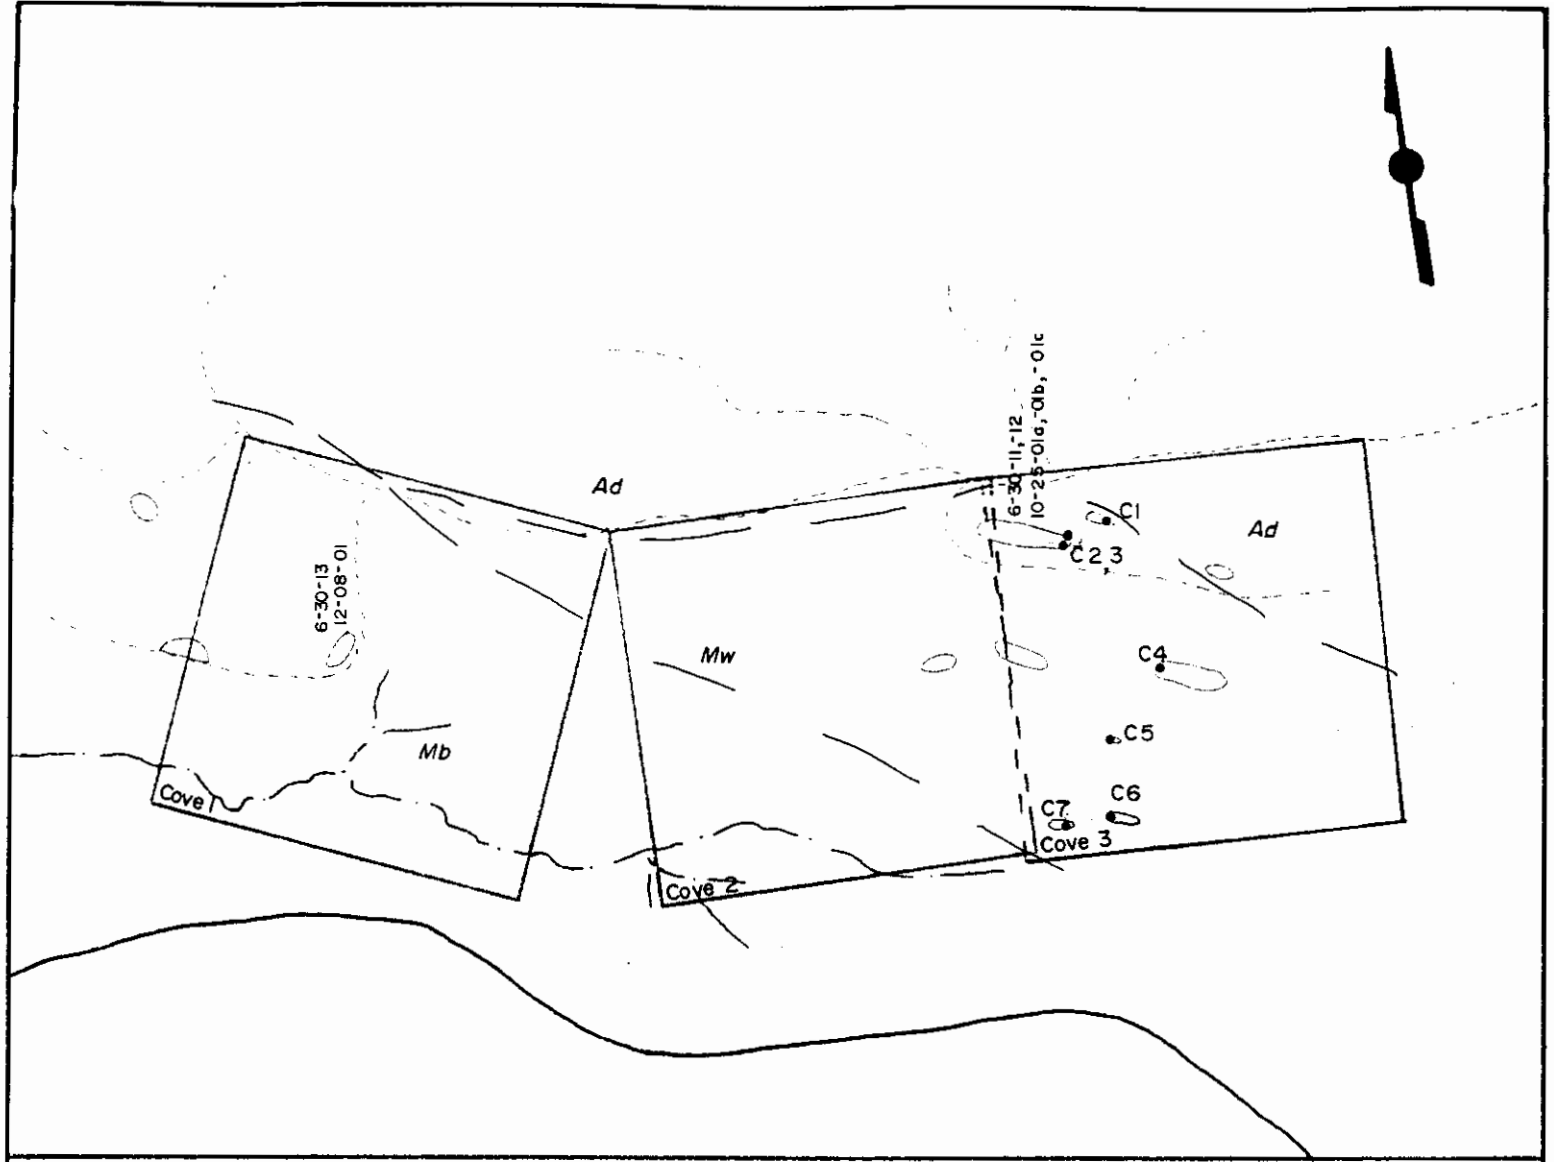

Several companies are exploring the East Band. On the north end of Bonanza Lake, Leo D'or Mining has established a quarry bench for dimension stone on the Leo D'or claim. Contiguous to the north, Industrial Fillers is exploring and holding the bulk of the ground (the Bonanza claims) for filler applications. These holdings include the old Doro adit, driven by IMASCO in the early 1980's to test the marble for industrial filler applications. Panorama Natural Stone Ltd. explored the Beaver property for dimension stone marble in the early 1990's.

The limestone from the Centre Band is generally medium grey to black or dark brown to black. The limestone becomes darker and argillaceous towards the top of the formation (Gunning, 1932a). White to dark grey limestones occur at several places on Nimpkish Lake where they are recrystallized and somewhat faulted and obtain a thickness of 150 to 300 metres (Gunning, 1930). Along the east side of Nimpkish Lake a section of "dirty" sugary grey white limestone was observed. Both Gunning (1930) and Hoadley (1953) consider the outcroppings along Nimpkish Lake too jointed in many places to serve as a building stone.

McMillan Bloedel continues to hold the old IM4 quarry at the north end of the Centre Band. This grey-white limestone was used for riprap at the McMillan Bloedel facility at Port McNeill. Ecowaste Management is exploring the band on the northeast shore of Nimpkish Lake for chemical lime. Industrial Fillers continues to hold the ground contiguous to the south of the Ecowaste ground for industrial fillers.

The limestone of the West Band is the most colorful of the three, ranging from light brown, through medium grey brown to dark grey, or dark brown to black. On Hisnet Inlet at the southern end of the band, quarrying of a dense, white-grey marble was undertaken at the turn of the century (Parks, 1917). Hoadley (1953) describes an "inexhaustible supply of limestone" along the east side of Tahsis Inlet. Further north in the Zeballos area, Stevenson (1950) described the limestone as medium to coarsely crystalline and, owing to extensive recrystallization, as having lost all evidence of bedding. On weathered surfaces the limestone is grey, but on freshly broken surfaces it ranges from white to cream. In the vicinity of Kathleen and Alice lakes, Gunning (1930) describes small interbeds of lava within the lower portion of the limestone with a mixed series of argillites, quartzites and volcanics in which there are small beds of argillaceous limestone lying above it.

Ecowaste Management is exploring a large section of the West Band south of Rupert Inlet for chemical lime. Several sites in the immediate Port Alice - Juene landing area were quarried by Western Forest Products for their pulp mill. International Marble and Stone Company is quarrying white limestone for industrial uses from a site at Benson Lake. Raging River Resources is also exploring for white limestone on claims contiguous to the Benson Lake Quarry. The Hisnet Inlet quarry is continually held by staking, but little exploration of significance has been undertaken.

PROPERTY GEOLOGY

The Cove property lies in the East Band of the Quatsino Limestone. The property is marked by ridges of grey-white and medium brown limestone. The grey-white stone is being explored for industrial grade limestone and/or landscape stone .

The property was first located during assessment of the East Band for dimension stone. Previous exploration consisted of mapping, prospecting and preliminary sampling. Mapping showed the stone to be too broken for consideration as dimension stone. The white color, however, suggested potential uses as industrial grade fillers and landscape stone.

The entire claim group is readily accessible by way of road or foot traverse. The topography is relatively flat, with the only relief supplied by the limestone ridges. These ridges have strike lengths of 20 to 200 metres. A small creek bordering the south boundary will be a ready source of water. The claim group is devoid of timber after recent clear-cutting.

The Cove property is entirely underlain by Quatsino limestone. Two distinct limestones have been mapped: a dense, fine-grained grey-white and a fine-grained, brecciated medium grey-brown. Andesite of the Karmutsen Formation has been mapped to the north and east of the property.

The grey-white limestone underlies the larger part of the Cove 2 and Cove 3 claims. It is a dense, fine- to medium-grained, well brecciated stone with a dull white-grey appearance. It can be delicately veined or "feathered" with dark material, believed to be stylolites. Traces of sulfides were noted, but only locally.

In outcrop, the marble is well-fractured to broken. There are abundant limonite and clays along the fractures. Pieces of dark grey marble to 1 metre in size have been noted within the grey-white. A bedding measurement is not possible due to the fractured nature of the main exposure, a road cut.

The medium grey-brown limestone underlies the Cove 1 and the southern part of Cove 2. This limestone is a dense, fine-grained dark brown-grey limestone, cut by a criss-crossing network of white carbonate veinlets and microveinlets. Pronounced black "feathering", (stylolites?) have also been mapped.

The primary exposures are road cuts at both ends of a long ridge. Both ends appear to be well fractured, due primarily to blasting. The fractures are coated by a combination of white carbonate and clays with minor limonite.

A sample of each of the grey-white limestone and brown-grey limestone were submitted for chemical analysis (Henneberry, 1995). The results were as follows:

| Limestone | CaO | MgO | SiO ₂ | R ₂ O ₃ | LOI |
|------------|-------|------|------------------|-------------------------------|-------|
| grey-white | 54.10 | 0.31 | 1.17 | 0.43 | 42.84 |
| brown-grey | 54.38 | 0.22 | 0.93 | 0.33 | 43.14 |

These results lie within the acceptable range for lower end filler applications. They are also suitable for high calcium applications.

1996 Program

During 1996, a traverse was made across stratigraphy to assess the industrial filler potential of the property. This program was carried out for ECC International as part of its evaluation of Mammoth Geological Ltd.'s northern Vancouver Island carbonate properties. These samples were tested for brightness and insolubles.

| Sample | Brightness | Insolubles |
|------------------|------------|------------|
| C-1 | 91 | 2.44 |
| C-2 | 91 | 1.50 |
| C-3 | 91 | 2.01 |
| C-4 | 87.65 | 1.94 |
| C-5 | 86.9 | 3.39 |
| C-6 | 87 | 1.65 |
| C-7 | 86.5 | 2.68 |
| 1995 (composite) | 95.9 | 1.58 |

These values are significantly lower than the composite sample taken in 1995 (Henneberry, 1995). They are, however, within the brightness range for industrial filler applications.

The limestone is fine-grained and white to light-grey in color. Rusty weathering fractures are frequently evident in outcrop.

MARKETING

The primary market for the limestone from the Cove property is in industrial applications and to a lesser extent, in landscape applications. The white color of the limestone and the brightness results suggest a potential market as industrial fillers. The insolubles and fracture limonite suggest lower end applications. The white color would also be suitable for crushed landscape stone.

The first stage of the marketing program is to ascertain product suitability. Initially, random 10 kilogram grab samples of ± 2 inch minus should be collected. These samples can then be forwarded to prospective industrial filler firms for testing. These samples could also be shown to landscape supply and gravel supply firms for comments on suitability. The key aspect of this phase of the marketing is to generate interest in the limestone, and to get the target firms to try the limestone.

The second stage will be a small scale bulk test of 500 to 5000 tons. The stone will be quarried, crushed and sent to the industrial filler plant for a full scale test. As well, a 200 to 500 ton sample can be supplied to landscaping firms for job site tests.

The other key aspect to be completed by this time is to establish transportation logistics. Small (<50 tons) tonnages can be trucked by Super B Trains, while samples of 500 tons or larger will need some type of mass transportation, likely water barge.

This information can then be compiled into a preliminary feasibility study to ensure the economics of the proposed operation are feasible.

Little of the marketing has been completed on the Cove property. A preliminary operations proforma to assess logistics has been completed. 10 kg samples for landscape applications have yet to be taken. Initially, the samples should be taken and shown to prospective landscape firms to initiate the marketing program.

DISCUSSION

The Cove property was originally acquired as a dimension stone target. Subsequent examination proved the marble to be too broken for dimension stone. Chemical and optical analyses completed on the limestone over the last two years yielded results within the limits acceptable for industrial filler applications.

The initial mapping and sampling has shown the limestone to be fairly consistent in brightness and color across stratigraphy. Further surface sampling will add little to the present state of knowledge of the property.

The next stage of exploration will be in the marketing area. A couple of ± 10 kilogram grab samples of ± 2 inch minus limestone should be taken. They can then be shown to landscape and gravel suppliers to generate preliminary interest and justify a small (± 500 ton) bulk sample.

Diamond drilling can then be utilized to establish reserves and confirm brightness and chemical qualities to depth.

CONCLUSIONS AND RECOMMENDATIONS

The Cove property was identified and staked as part of a regional exploration and assessment program of the north Island Quatsino limestone bands. The white limestone is being explored as a potential source of both ± 2 inch minus landscape stone and white limestone for industrial filler applications.

Exploration to date has consisted of property mapping and sampling. Optical and chemical analyses has shown the limestone lies within the acceptable brightness and chemical range for industrial fillers.

The next stage of exploration will be a small marketing program. A random 10 kg sample of ± 2 inch minus limestone should be taken. This sample can then be shown to suppliers to attempt to generate enough interest to justify a small (500 ton) bulk sample. This stone can then be supplied for some actual job site tests. As well, samples of this material can be submitted for chemical and optical analysis, to obtain initial readings below the zone of weathering. The cost of the stage is estimated at \$14,830.

Successful conclusion of this phase will require a small diamond drilling program to obtain a preliminary reserve summary. The core will be analyzed at systematic intervals to depth to confirm the chemical and optical properties to depth. The cost of this 500 metre (1650 foot) is estimated at \$65,750.

A decision on a detailed feasibility study for an eventual production decision can be made at the conclusion of this two phase exploration program.

| | |
|---------------------------------------|-----------------|
| Phase I - Market Assessment | \$1,650 |
| Phase II - 500 Ton Bulk Sample | \$13,180 |
| Phase III - Diamond Drilling | \$65,750 |
| | ----- |
| TOTAL BUDGET FOR COVE PROPERTY | \$80,580 |

The cost of the 1996 sampling program is \$1,070.

STATEMENT OF QUALIFICATIONS

I, R. Tim Henneberry, am the principle of Mammoth Geological Ltd., a geological consulting firm with offices at 9250 Carnarvon Road, Port Hardy, B.C. The mailing address is Box 5250, Port Hardy, B.C. Canada V0N 2P0.

I earned a Bachelor of Science Degree majoring in geology from Dalhousie University, graduating in May 1980.

I have practiced my profession continuously since graduation.

I am registered with the Association of Professional Engineers and Geoscientists in the Province of British Columbia as a Professional Geoscientist. I am also a Fellow of the Geological Association of Canada.

I supervised and assisted with the sampling program described in this report on May 11, 1996.

I am presently the registered owner of the Cove 1-3 mineral claims.

This report may be used for any purpose normal to the business of Mammoth Geological Ltd., provided no part is used in such a manner to convey a meaning different than that set out in the whole.

Dated this 27th day of December in the Town of Port Hardy, British Columbia.

A circular professional seal for the Province of British Columbia, Association of Professional Engineers and Geoscientists. The seal contains the text "PROFESSIONAL", "PROVINCE OF", "R. T. HENNEBERRY", and "GEOSCIENTIST". A handwritten signature is written over the seal.
R. Tim Henneberry, P. Geo

STATEMENT OF COST

Cove Property

| | | |
|-------------------|------------------------|----------|
| Project Manager | 1/4 days @ 450.00 /day | \$100.00 |
| Optical analysis | 1 samp @ 30.00 /sample | \$30.00 |
| Optical analysis | 7 samp @ 30.00 /sample | \$210.00 |
| Chemical analysis | 1 samp @ 30.00 /sample | \$30.00 |
| Documentation | 2 days @ 350.00 /day | \$700.00 |

Cove 1996 Property Costs

\$1,070.00

COST ESTIMATES

| | | |
|---|-----------------|----------|
| Phase I - Market Assessment (3 days) | | |
| Personnel | \$1,200 | |
| Support | \$450 | \$1,650 |
| Phase II - 500 Ton Bulk Sample (6 days) | | |
| Performance Bond | \$2,500 | |
| Personnel | \$3,000 | |
| Quarrying Equipment | \$798 | |
| Mobile Equipment | \$4,000 | |
| Explosives | \$1,232 | |
| Sundries | \$1,650 | \$13,180 |
| Phase III - Diamond Drilling (25 days) | | |
| Equipment | \$3,000 | |
| Diamond Drilling | \$31,000 | |
| Supervision | \$14,750 | |
| Analysis | \$12,000 | |
| Documentation | \$5,000 | \$65,750 |
| Phase I - Market Assessment | \$1,650 | |
| Phase II - 500 Ton Bulk Sample | \$13,180 | |
| Phase III - Diamond Drilling | \$65,750 | |
| TOTAL BUDGET FOR COVE PROPERTY | \$80,580 | |

ASSAY CERTIFICATE

The following samples have been analyzed for their optical properties (brightness) at the ECC International Inc. lab at Sandersville, Georgia.

All samples are surface samples taken as outcrop exposures allowed, across stratigraphy. The limestone was white to light grey in color and fine-grained.

ECC International Inc.

380 Smyrna Church Rd.
P. O. Box 1018
Sandersville, Georgia 31082
