LIST OF MAPS:

1.0 SUMMARY

The Reed Group Two property comprises 22 claims totalling 81 units located approximately 22.4 km northeast of Cassiar, B.C. Access to the property is from the Mile 72 turn-off to Hot Lake from Highway #37. The property is accessed via the old Della Mines road which forks to the right off the main Hot Lake road and is passable by 4-wheel drive vehicles.

The property is located in the Good Hope Lake map area in north-central B.C. and covers an area of low to high relief with exposed bedrock mostly in the high relief areas.

The claims are underlain by thrust imbricated Boya, Rosella and Kechika strata, Cambrian to Ordovician in age, which are cut by later high-angle fault swarms that centre on the north trending Rosella Creek Fault. These sedimentary rocks have been intruded by a 48.8-51.5 Ma monzogranite in the southeast portion of the claim group. The sedimentary strata surrounding this intrusive have undergone contact metamorphism and locally contain strongly mineralized zones of massive sulphide in skarn with strong concentrations of Zn, Pb, Cu and Ag.

The 1997 exploration program consisted of 4x4 supported reconnaissance prospecting and geological mapping followed by the construction of a 1,200 x 450 metre linecut grid called the Brett Grid. The Brett Grid was constructed over a previously discovered zone containing anomalous zinc values and the newly defined granite intrusive. A soil geochemical survey was conducted over the entire grid which returned anomalous zinc and lead values over the eastern and western portion of the grid. A ground proton magnetometer survey was conducted over the entire grid and outlined several anomalous target sites. Phase two of the program entailed the diamond drilling of 9 BQ size drill holes for a total of 1,019.25 metres of drill core. The purpose of the diamond drilling was to follow-up the high magnetometer readings in hopes of intersecting massive sulphide in skarn hosting Zn, Ag and Pb.

2.0 INTRODUCTION

The field exploration program was conducted during the 1997 summer season on the Reed Group Two property located in the Good Hope Lake map area of north-central B.C. Exploration work was carried out by a 3-man crew based out of the Cusac Gold Mines camp.

The objective of this program was to evaluate and survey the property's economic potential through geochemical and geophysical surveys followed-up by diamond drilling on the anomalous magnetometer sites. Hand trenching was performed on a previously undiscovered skarn hosted massive sulphide with strong zinc values. The 1997 program was conducted during the period of June 10 to August 22, 1997. A total of 456 soil samples were collected from the Bret Grid and only 268 of those samples were analyzed to lower exploration costs. Geological and geochemical data was compiled on 1:2,500 scale contour maps. Diamond drilling data was compiled on a 1:500 scale contour map.

All samples were shipped to Acme Analytical Labs in Vancouver for geochemical analysis utilizing the 30-element ICP and wet Au extraction method. Analytical procedures are described in Appendix III and analytical results are presented in Appendices IV, V and VI.

2.1 LOCATION AND ACCESS:

The Reed Group Two property is located 22.4 km (by air) northeast of Cassiar (Figure 1). The claims are situated within the NTS map sheet 104P06W-05E and centered about 59° 19' 10"N latitude and 129° 27' 30"W longitude. Access to the property is via 4-wheel drive vehicles along the old Della Mines road off Highway #37 approximately 12 kilometers northeast of the Cassiar Junction. The road extends northward and splits into the Hot Lake road and the old Della Mines road. Access to the property is along the east fork of the old Della Mines road.

2.2 PHYSIOGRAPHY, VEGETATION AND CLIMATE:

The Reed Group Two property is located within the McDame area which is characterized by steep to moderately sloping mountains separated by broad open valleys. The property has relief up to 900 metres and lies within the Cassiar Mountain Range near the eastern flank of the Cassiar Batholith. In low relief areas, bedrock exposures are rare owing to the dense cover of forest, swamp and Pleistocene glacial and glaciofluvial deposits.

Forests of alpine spruce, balsam, willow and jackpine cover half of the property with the remainder above treeline. Precipitation is moderate to heavy with a 4-5 metre snow base in the winter and temperatures ranging from -35° to 30° Celsius. The climate is a continental type with short, warm summers and long, cold winters.

2.3 PROPERTY STATUS AND OWNERSHIP:

The Reed Group Two property (Figure 2) consists of 22 claims totalling 81 units located within the Liard Mining Division. The claims are 100% owned by Demand Gold Ltd. Relevant claims data are tabulated in the following Table 1.

TABLE 1 - PROPERTY CLAIM STATUS

3.0 EXPLORATION HISTORY

3.1 PROPERTY HISTORY:

The first recorded mineral discovery in the immediate area was in 1937 by Joe Reed who discovered a Pb-Zn-Ag vein on the southwestern flank of Reed Mountain and staked the first claims. These claims were allowed to lapse and were subsequently restaked by Jack Ashton. During the boom period of porphyry exploration between 1965-1975, stockwork-type molybdenite mineralization was discovered and subsequently drilled on Mounts Haskin and Reed. Work done by several companies delineated a "Moly Zone" containing 13.5 million tons grading 0.16% MoS_2 on Mount Haskin. W-Mo skarns were the drill targets for mineral exploration by Glen Copper Mines in 1969. Canadian Superior Exploration optioned the property from Jack Ashton in 1978-1982, and drilled seven holes, totalling 570m, on Reed Mountain to determine the extent of skarn mineralization.

In 1965, the discovery, by United States Smelting, Refining & Mining Company, of the "Main Zone" on Mount Haskin boasted an ore reserve of 426,000 tons of 1.94% Pb, 5.54% Zn and 1.36 oz/ton Ag. In the early 1970's Della Mines made an unsuccessful attempt to mine this deposit. They drove two tracked drifts in attempt to intersect the main zone. Adverse metal prices and changing political climate at the time, forced the company to discontinue exploration. The claims were held by cash in lieu from the mid-1970's until 1993 when the claims were allowed to lapse. From 1995-1996, Dan Brett acquired a considerable portion of the presently claimed area and sold 100% of the claims to Demand Gold Ltd. Demand Gold consequently acquired the rest of the present ground in 1997 and conducted the 1997 Haskin/Reed exploration program during the summer season.

3.2 EXPLORATION PROGRAM 1997:

The 1997 exploration program conducted by Francis Moyle, consisted of 2 months of field work. Initially, a 1200 x 450 metre grid was established and linecut in preparation for a geochemical and geophysical survey. The Brett Grid started at the 1320 metre elevation from the main road built by Canadian Superior in 1978, that accesses the west flank of Reed Mountain (Map 1). The baseline runs out from the road at 310°. Cross lines were cut perpendicular to the baseline in 50 metre intervals. The cross lines ran out 300 metres to the northeast and 150 metres to the southwest of the baseline. Soil samples were collected every 25 metres along the cross lines. A total of 456 soil samples were collected from the Brett Grid with only 268 of these samples analyzed due to budget constraints. The remaining soil samples are being kept in storage for possible further analysis. Rock samples were taken from the grid areas that returned anomalous values in Zn, Pb, Cd and Ag.

A small grid was also flagged out for a geophysical survey on the eastern extension of the Dako Zone. A proton magnetometer was used to locate the possible eastern extension of the Dako Zone which was assumed to terminate abruptly. The magnetometer survey located an extremely anomalous zone 150 metres from the exposed outcrop (Map 6).

Further investigation led to the discovery of sub-crop of skarn hosted massive sulphide. Hand trenching around the sub-crop revealed a magnetite-epidote rich skarn with strong concentrations of Zn, Pb and Cpy (Map 5). Hand trenching exposed a 10 x 2 metre zone that was subsequently assayed and returned values of 5% Zn, 0.177% Cu, 5.6 ppm Ag and 244.2 ppm Cd over a 2 metre wide zone which is assumed to be the apparent width of the mineralized deposit.

From July 4th to July 15th, 1997, phase two of the program was conducted with BQ sized diamond drilling by DJ Drilling from Watson Lake, Yukon and was supervised by Ned Reid, a contract geologist hired to orchestrate the drilling operations on the Brett Zone (Map 3). The drilling was based on anomalous readings from the magnetometer survey (Map 4), combined with drill records from the 1980's that intersected strong mineralized zones of zinc. The first two holes were drilled from the same pad. The first hole DGBZ 97-1 was drilled at 180° azimuth with a -45° dip and intersected 3 lenses. Lens 1 assayed 7.,03% Zn over 4.7 metres, lens 2 assayed 13.26% Zn over 7.0 metres, and lens 3 assayed 4.92% Zn over 5.2 metres. The second hole DGBZ 97-2 was drilled at 180° azimuth with a -65° dip and intersected 2 lenses. Lens 1 assayed 5.08% Zn over 0.9 metres, lens 2 assayed 10.7% Zn over 10.3 metres. This data combined with the 1980 data from Canadian Superior led Ned Reid to calculate a drill-inferred reserve of 500,000 tons of 10% Zinc. The subsequent 7 holes were drilled to the east and west of drill holes 1 and 2 with only drill hole DGBZ 97-9 intersecting significant zones. Drill hole DGBZ 97-09 was drilled to the northeast of drill hole 1 and 2 at 219° azimuth with a -52° dip and intersected 2.6 metres of 8.15% zinc very deep in the hole, as would be expected, assuming the deposit is dipping to the north.

4.0 GEOLOGY

4.1 REGIONAL GEOLOGY

The property lies within the northern extension of the Omineca lithotectonic domain. Mounts Reed and Haskin are underlain by a northwest trending belt of Cambro-Ordivician Kechika Group and Lower Cambrian Atan Group sediments (Rosella and Boya Formations) which have been intruded by Eocene granitic stocks.

Exposed on Mount Haskin are the Boya quartzites, Rosella limestones and the Kechika siltstones (Table 2). The siltstones have been hornfelsed pervasively. The rocks exposed on Mount Reed are the Boya quartzite and Rosella limestone which have been locally skarnified above the quartzite contact on the west flank of Mount Reed.

4.2 PROPERTY GEOLOGY:

The Reed Group Two property was lithogeochemically sampled. The data was plotted on a 1:2,500 scale contour map (Map I). Approximately 80% of the property is covered by forest and scrub vegetation. Approximately 70% of the property is overlain by glacially deposited sediment up to 1 metre deep. Outcrop accounts for approximately 30% of the claims area and occurs primarily in isolated exposures on hillsides, ridges and along road cuts.

4.2.1. Lithologies:

Geological mapping has identified the primary lithologies underlying the claims area as a package of Atan Group sediments with overlying Kechika Group sediments.

The bedrock geology underlying the Christa and Silver Mtn 1-4 claims consists of northwest striking moderately to steeply dipping Cambrian to Silurian sediments. These conformable sediments form the eastern limb of the McDame synclinorium. The youngest exposed rocks underlying the northern and southern boundaries of the claim block are the Cambrian to Ordovician Kechika Group sediments. The Kechika Group consists of pale coloured calcareous slate, siltstone, limestone, calcsilicate and biotite hornfels (Table 2). Underlying the Kechika Group sediments are the Lower Cambrian Atan Group sediments which is subdivided into the Rosella and Boya Formations. The Rosella formation is composed of limestone, dolostone, calcareous slate and red and green slate. The Boya Formation underlies the Rosella Formation and is composed of quartzite, siltstone, slate and phyllite. Within and easterly of the Silver Mtn claims lies a blind granitic intrusion which was located and semi defined by drilling between 1968-1972. This granitic intrusion is dated from early to middle Eocene (48.8-51.5 Ma). It is composed of three facies; a coarse granite, a fine granite and an aplitic facies. The granite stock is a coarse grained quartz and alkali-feldspar megacrystic monzogranite.

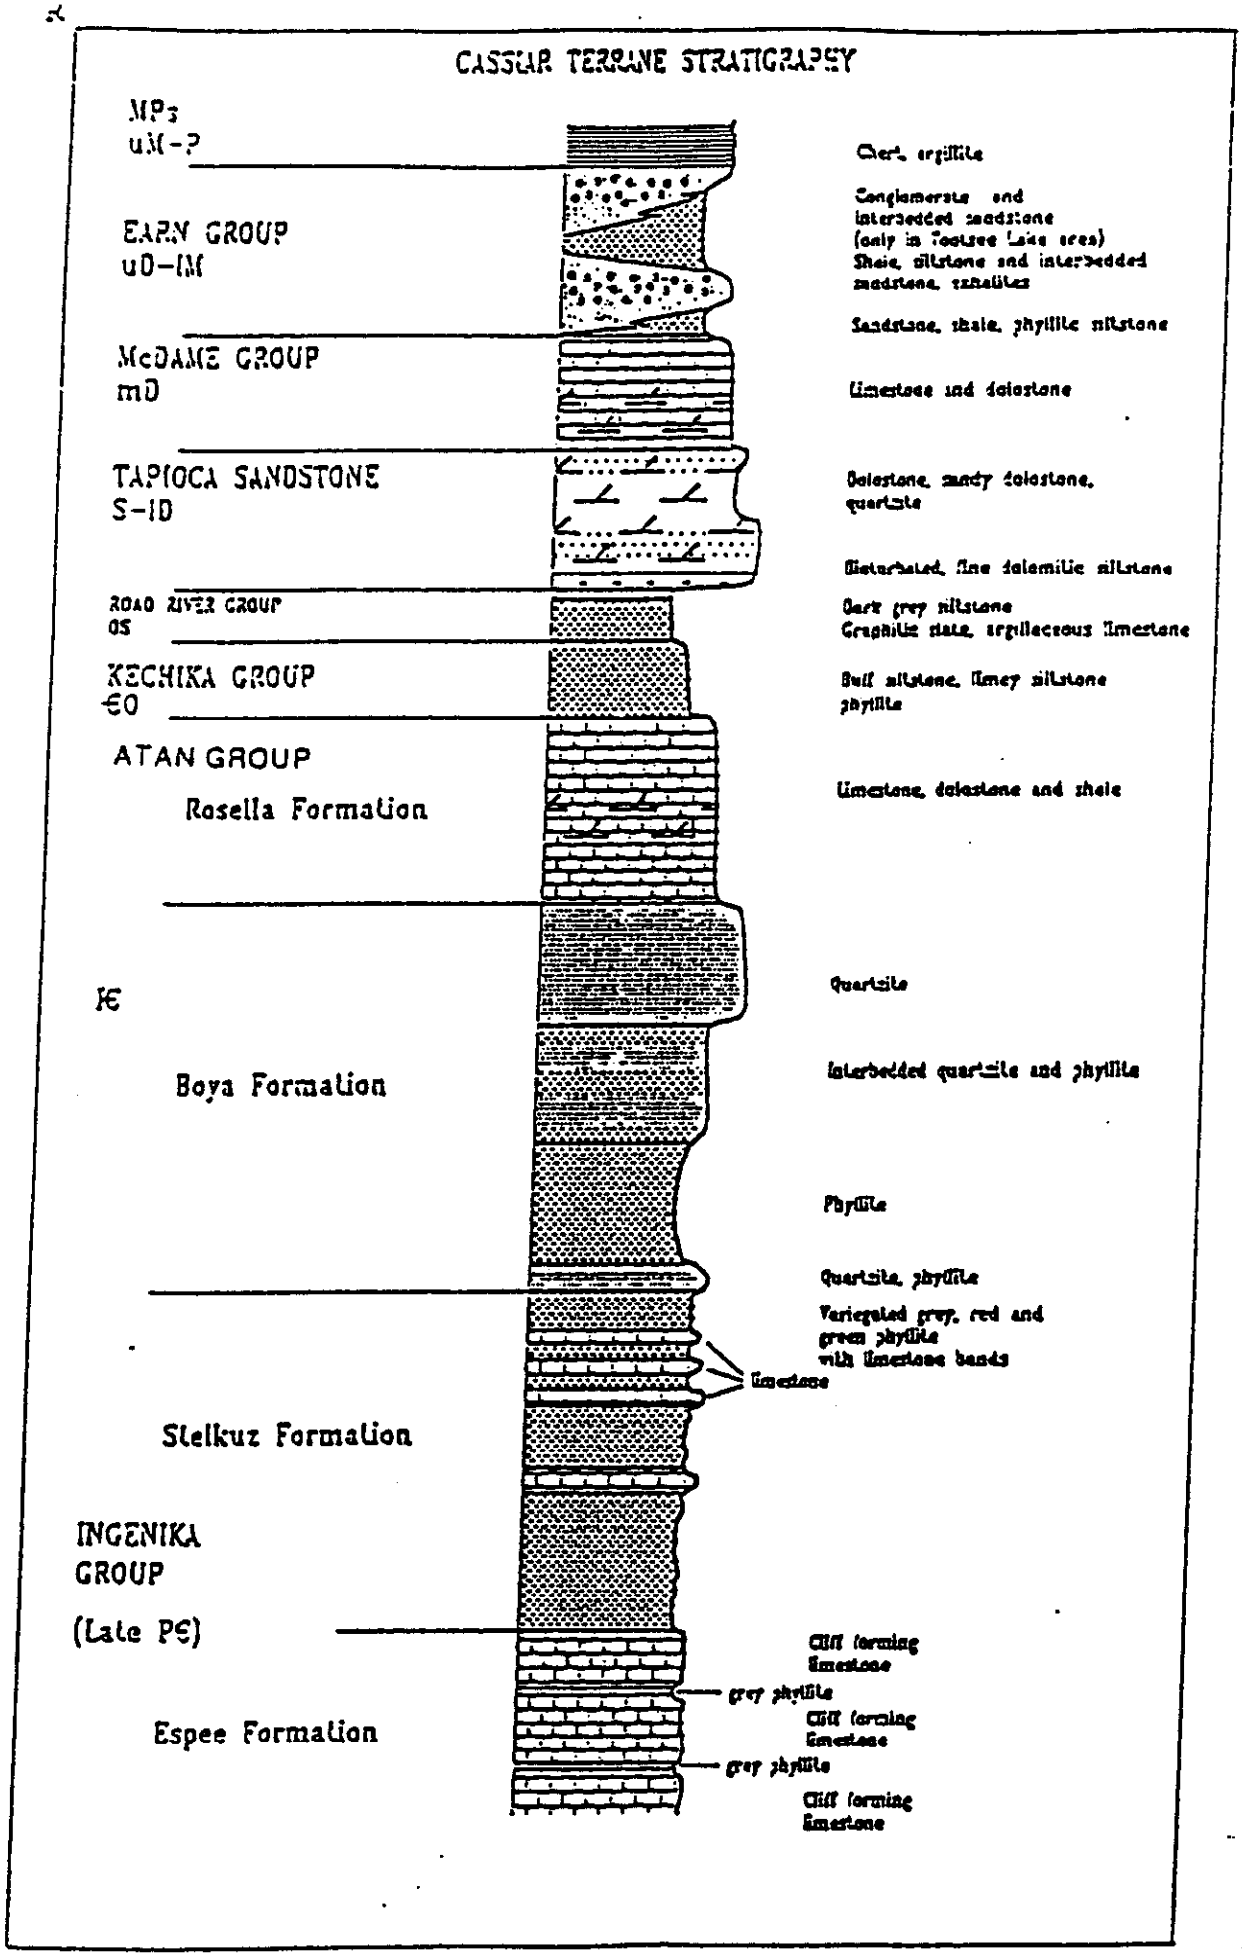

TABLE 2

Table of Formations, Good Hope Lake map area

Past geochemical analysis and study revealed the granite contains 30% quartz, 1-3% biotite and equal portions of K-feldspar and plagioclase. Xenoliths of aplite, cut by quartz veins, are found within the main granitic stock and coarse granitic dykes cut the aplite facies, indicating the aplitic rocks were emplaced prior to granitic intrusion. It has been postulated through past study, that the mineralization peripheral to the intrusive is mostly related to the aplitic intrusive stage.

4.2.2 Structure:

The Reed Group Two property is located on the eastern limb of the broad northwest striking McDame synclinorium, which dips 25° to 60° to the southwest. Deviations to this strike/dip pattern occur close to the intrusive where the limestones have been squeezed and locally folded into a series of tight anticlines and recumbent drag folds. The Atan Group sediments have been repeatedly tilted and lifted to the surface on a complex series of northwest striking bedding thrust faults. A later period of transverse faulting has resulted in lateral displacement of the tilted beds. These northeasterly trending faults are centered about the Rosella Creek fault and are a controlling factor on the extent of skarn development and Ag-Pb-Zn bearing veins.

4.2.3 Alteration and Mineralization:

There are four types of mineralization associated with the blind granitic intrusion on the west side of Mount Reed.

1) Quartz-Moly stockwork of fine quartz veinlets controlled by fracturing in the granitic stock and surrounding quartzite unit;
2) Metasomatized metapelitic hornfels containing molybdenite;
3) Disseminated sulphides in the form of fine grained pyrite, pyrrhotite, sphalerite and galena with traces of arsenopyrite are found in the sedimentary rocks at or near the contact with the intrusive;
4) Massive sulphide lenses containing magnetite, pyrrhotite, sphalerite, chalcopyrite, galena and arsenopyrite are associated with skarnification of the limestone units usually at the contact with the quartzite.

The patterns of mineralization and alteration around the blind intrusion are related to the emplacement of two separate pulses of granitoid magmas which created complex hydrothermal systems nearby. The metamorphic minerals formed in the Rosella carbonates include tremolite, actinolite and diopside. The exact age relationships between the two episodes of intrusion and the development of the exoskarns are unclear. Evidence from previous drilling shows that the exoskarn system was cut by the granitic stock, thus suggesting that the monzogranite emplacement post-dated the main stage skarn development. It is possible that the main stage exoskarns were associated with earlier aplitic intrusions.

5.0 1997 EXPLORATION PROGRAM

5.1 GEOLOGICAL MAPPING:

Approximately 10% of the property was evaluated by geological mapping and prospecting during the 1997 exploration program. Lithogeochemical sampling was conducted concurrent with the mapping survey (Map 1).

5.2 GEOCHEMISTRY:

5.2.1. Sampling Procedure

A total of 432 soil samples were collected, however, only 268 of those soil samples were analyzed during the 1997 property evaluation. Rock grab and chip samples were collected from test pits and outcrop exposures exhibiting favourable characteristics such as gossanous staining, sulphide content and alteration. Rock specimens were placed in marked plastic bags. All sample sites were marked with fluorescent ribbon displaying the corresponding sample code. Ground control for mapping and sampling was provided by altimeter, compass, topo chain and a 1:2,500 scale topographic map for plotting data. Soil samples were collected on a 1200 x 450 metre grid. The baseline started at the 1,320 metre elevation on the Canadian Superior road built in 1978 that accesses the west flank of Reed Mountain. The baseline runs at 310° from the road with cross lines perpendicular to the baseline every 50 metres. The cross lines ran out 300 metres to the northeast and 150 metres to the southwest. Soil samples were collected every 25 metres along the cross lines. Soil samples were analyzed every 50 metres to lower assay costs. The remainder of collected soil samples are being held in storage for possible further analysis. Glacial and glaciofluvial deposition covers most of the area with bedrock occurring generally less than one metre from surface except in low lying areas that contain thicker glacial debris. The soil samples were placed in marked Kraft soil bags and the sample sites were marked with fluorescent ribbon displaying the corresponding sample code. Test pits were dug and sampled on the Brett Grid where anomalous soil geochemical results occurred. These 1 x 1 metre pits exposed the soil horizon and were sampled every 0.3 metres down to bedrock. A geophysical anomaly exists over a 100 x 30 metre area on the east extension of the Dako Zone. This area contains a skarn hosted massive sulphide outcrop previously undiscovered (Map 5). A 10 x 2 metre hand trench was dug around the outcrop to properly expose it. A 2 metre wide chip sample was taken across the apparent width. The rock chips were placed in a marked plastic bag. The sample site was marked with a fluorescent ribbon displaying the corresponding sample code. Analytical results are presented in Appendix IV and geochemical values are plotted on Map 1.

5.2.2 Rock Geochemistry:

During the 1997 exploration program, 43 rock samples were collected. Lithogeochemical analytical results are presented in Appendix IV. The majority of the samples were sulphide bearing and were collected from anomalous soil sample sites, exposed areas of alteration (skarnification) and lithological contacts (Map 1).

Table 3 records anomalous values for Cu, Pb, Zn, Ag, Cd, Co, Bi, W and Au.

TABLE 3 - LITHOGEOCHEMICAL ANALYSIS

5.2.3 Soil Geochemistry:

During the 1997 exploration program, 432 soil samples were collected from the Brett Grid (Map 2). 268 soil samples were analyzed and are presented in Appendix V. The soil samples were collected every 25 metres along 50 metre spaced lines. Anomalous sample sites were dug down to bedrock and soil samples were collected in 0.3 metre intervals. Table 5 records anomalous values for Pb, Zn, Ag, Cd, Co and Au.

TABLE 5 - SOIL GEOCHEMICAL ANALYSIS

Sample #	Pb ppm	Zn ppm	Ag ppm	Co ppm	Cd ppm	Au ppm

The anomalous Pb, Zn, Cd and Au values in the 1200N + 00E-175E area indicates a possible ore body close by.

5.3 GEOPHYSICS:

A ground proton magnetometer survey was performed on the Brett Grid (Map 4) and Dako Grid (Map 6). The purpose of this survey was to locate anomalous magnetic zones that are generally associated with zinc mineralization. The survey was conducted with an MP-2 portable proton procession magnetometer with station readings taken every 10 metres along 25 metre spaced lines on each grid. The MP-2 proton procession magnetometer utilizes the phenomenon of nuclear magnetic resonance to measure the flux density of the total magnetic field at each station. The MP-2 sensor is mounted on a 2 metre staff and consists of a chamber filled with a proton rich fluid, such as kerosene, enclosed within two wire wound coils. When current passes through these coils, a magnetic field is set up which aligns the spinning protons. When the polarizing current is abruptly turned off, the protons

precess around the earth's magnetic field and eventually realigns with it. This precession induces a small, exponentially decaying, AC signal in the sensor coils whose frequency is proportional to the flux of the ambient magnetic field (23.4874 gammas/H_z). This frequency is measured by the signal processing electronics of the MP-2 and converted to a gamma value and presented on the digital display.

After a complete reading cycle (down 1 line and back on the next line), a reading is taken on the same site as when started. The difference in reading (if there was one) was corrected for diurnal variation and the gamma drift (> +/- 20 gamma) was adjusted to each reading on that cycle. The readings were recorded on paper and plotted on 1:500 scale grid maps. The results were plotted on Autocad and a colour-contoured map was produced, highlighting the anomalous zones. Results of this survey are presented in Map 4 and 6.

6.0 CONCLUSIONS

Lithogeochemical and soil sampling followed by magnetometer surveys and diamond drilling was the focus of exploration activity on the Reed Group Two property during the 1997 exploration program. Geological mapping has shown that the property covers an assemblage of northwest striking units of Lower Cambrian Atan Group, Rosella and Boya Formations and Cambrian to Ordovician Kechika Group sediments. With the onset of Eocene intrusion, many of these sedimentary units were metamorphically altered and became the host rocks for ore deposition. These skarnified zones generally occur in contact with the intrusive and peripherally, less that 1 kilometer away. Evaluation of the data indicates four types of mineralization spatially related to the granitic stock underlying the southeast corner of the property. The four styles of mineralization are summarized below:

1) In the thermal metamorphic aureoles at Mount Reed, biotite hornfels in contact with the carbonate units have been converted to calc-silicate hornfels hosting stockwork Mo-W mineralization. Molybdenite bearing quartz stockworks occur within the intrusive as well.
2) Exoskarn hosted Mo mineralization in marble, in contact with the granitic intrusion.
3) Massive base metal sulphide hosted in skarn lenses along the carbonate-hornfels/carbonate-quartzite contacts.
4) The series of northwest and northeast trending faults exert a control on the extent of skarn-hosted base metal sulphide deposition and the locations of Ag-Pb-Zn bearing veins within the sedimentary units.

The nature of the mineralizations indicate that strong concentrations of Fe, Si, Al, B and F with Mo, W and base metals were carried into the depositional environments via hydrothermal fluids resulting from the Eocene porphyritic granite intrusion.

Geological mapping, lithogeochemical sampling and a magenetometer survey failed to outline another granitic body, however, significant lithogeochemical and magnetic results on the northwest end of the Brett Grid indicate another possible skarn hosted massive sulphide deposit. The Mount Reed intrusive is more than 1 kilometre away from these anomalous zones which indicates another intrusive source at depth below the sedimentary package. If another intrusive source is located, the potential for more base metal mineralization, including W and Mo would increase the known tonnage for the area and open up new areas for exploration.

7.0 RECOMMENDATIONS

Results from the 1997 exploration program on the Reed Group Two property were encouraging. Geochemical and proton magnetometer surveys assisted in delineating targets for immediate follow-up work in the form of close-spaced EM surveys. The purpose of the follow-up work would be to delineate a target for diamond drilling in hopes of locating more skarn-hosted massive sulphide to add to the tonnage already indicated on the Brett Zone.

The work program is recommended as follows:

1) Extend the Dako Grid southeast so that it overlaps the west end of the Brett Grid. A geochemical survey should be conducted over the extension to determine the extent of the mineralized zone.
2) A ground geophysical program should be initiated following the geochemical survey on the Dako extension and over the Brett Grid northeast of the baseline. The geophysical program should involve a horizontal loop EM survey, which would outline any structural variances within the sedimentary units.
3) Diamond drilling is recommended for a Phase II exploration program contingent upon positive results from the geochemical and geophysical surveys.

Summary of Personnel

SUMMARY OF PERSONNEL

The following personnel are credited with the field and office work on the Reed Group Two property during the 1997 field season:

Francis Moyle	Geologist
Christa Steinhage	Field Assistant
Batoche Gagnon	Field Assistant

APENDIX III

Analytical Procedure

ACME ANALYTICAL LABORATORIES LTD.
Assaying & Trace Analysis
852 E. Hastings St., Vancouver, B.C., Canada V6A 1R6
Telephone: (604) 253-3158 Fax: (604) 253-1716

METHOD FOR WET GEOCHEM GOLD ANALYSIS

Sample Preparation:

Soils and sediments are dried (60°C) and sieve to -80 mesh.

Rocks and cores are crushed and pulverized to -100 mesh.

Sample Digestion

1. 10g samples in 250 ml beaker, ignite at 600°C for four hours.
2. Add 40 ml of 3:1:2 mixture HCL:HNO_3:H_2O.
3. Cover beaker with lids.
4. Boil in hot water bath for one hour.
5. Swirl samples 2 to 3 times within the hour.
6. Cool, add 60 ml of distilled water and settle.
7. Pour 50 ml of leached solution using a graduated cylinder into 100 ml volumetric flask.
8. Add 10 ml of MIBK and 25 ml of distilled water.
9. Shake 3 to 4 minutes in shaker.
10. Add additional 25 ml of distilled water to stripe out excess iron.
11. Shake each flask 10 times.
12. Pour MIBK into container for graphite AA finished.

METHODS AND SPECIFICATIONS FOR ANALYTICAL PACKAGE GROUP 1D - 30 ELEMENT ICP BY AQUA REGIA

Sample Preparation:

Soils and sediments are dried (60°C) and sieved to -80 mesh (-177 microns), rocks and drill core are crushed and pulverized to -100 mesh (-150 microns). Plant samples are dried (60°C) and pulverized or dry ashed (550°C). Moss-mat samples are dried (60°C), pounded to loosen trapped sediment then sieved to -80 mesh. At the clients request, moss mats can be ashed at 550°C then sieved to -80 mesh although this can result in the potential loss by volatilization of Hg, As, Sb, Bi and Cr. A 0.5 g split from each sample is placed in a test tube. A duplicate split is taken from 1 sample in each batch of 34 samples for monitoring precision. A sample standard is added to each batch of samples to monitor accuracy.

Sample Digestion:

Aqua Regia is a 3:1:2 mixture of ACS grade conc. HCl, conc. HNO_3 and demineralized H_2O. Aqua Regia is added to each sample and to the empty reagent blank test tube in each batch of samples. Sample solutions are heated for 1 hour in a boiling hot water bath (95°C).

Sample Analysis:

Sample solutions are aspirated into an ICP emission spectrograph (Jarrel Ash Atom Comp model 800 or 975) for the determination of 30 elements comprising: Ag, Al, As, Au, B, Ba, Bi, Ca, Cd, Co, Cr, Cu, Fe, K, La, Mg, Mn, Mo, Na, Ni, P, Pb, Sb, Sr, Th, Ti, U, V, W, Zn.

Data Evaluation:

Raw and final data from the ICP-ES undergoes a final verification by a British Columbia Certified Assayer who then signs the Analytical Report before it is released to the client. Chief Assayer is Clarence Leong, other certified assayers are Dean Toye and Jacky Wang.

ICP - .500 GRAM SAMPLE IS DIGESTED WITH 3ML 3-1-2 HCL-HNO3-H2O AT 95 DEG. C FOR ONE HOUR AND IS DILUTED TO 10 ML WITH WATER.
THIS LEACH IS PARTIAL FOR MN FE SR CA P LA CR MG BA TI B W AND LIMITED FOR NA K AND AL.
- SAMPLE TYPE: SOIL AU* - AQUA-REGIA/MIBK EXTRACT, GF/AA FINISHED.(10 GM)
Samples beginning 'RE' are Reruns and 'RRE' are Reject Reruns.

DATE RECEIVED: JUL 17 1997 DATE REPORT MAILED: Jul 24/97 SIGNED BY. ..... D.TOYE, C.LEONG, J.WANG; CERTIFIED B.C. ASSAYERS

ICP - .500 GRAM SAMPLE IS DIGESTED WITH 3ML 3-1-2 HCL-HNO3-H2O AT 95 DEG. C FOR ONE HOUR AND IS DILUTED TO 10 ML WITH WATER.
THIS LEACH IS PARTIAL FOR MN FE SR CA P LA CR MG BA TI B W AND LIMITED FOR NA K AND AL.
- SAMPLE TYPE: SOIL AU* - AQUA-REGIA/MIBK EXTRACT, GF/AA FINISHED.(10 GM)
Samples beginning 'RE' are Reruns and 'RRE' are Reject Reruns.

			Brett Grid 450N+350E	149825	dense Lst - grab from Limestone cliff

APPENDIX X

Statement of Qualifications

STATEMENT OF QUALIFICATIONS

I, Francis S. Moyle, of 928 Berkley Road in the municipality of North Vancouver, British Columbia, do hereby certify that:

1) I am an independent contract geologist currently employed under contract to Demand Gold Ltd. The office is at #908-700 West Pender Street, Vancouver, B.C. V6C 1G8;

2) I am a graduate of the University of British Columbia (1994) with a B.Sc degree in geology and have practiced this profession continuously since graduation;

3) I have been employed in the mineral exploration industry in Canada since 1990;

4) I am the author of this report dated December, 1997 entitled "Geological, Geochemical, Geophysical and Diamond Drilling Assessment Report on the Reed Group Two Property", British Columbia;

5) I have personally performed the work discussed in this report;

6) I do not own or expect to receive any interest (direct, indirect or contingent) in the property described herein with respect of services in the preparation of this report.

Dated at Vancouver, B.C. this __1__ day of December, 1997.

Respectfully submitted:

Francis Moyle

Francis S. Moyle, B.Sc.
