LIST OF APPENDICES

APPENDIX 1 - Drill Logs APPENDIX 2 - Analytical Results APPENDIX 3 - Cost Statement APPENDIX 4 - Statement of Qualifications **1.0 SUMMARY** (Note: Portions of the following section are excerpted from the 1996 Assessment Report on the Attwood Property and Bombini Option by Linda Caron, for Kettle River Resources.)

The Attwood property is located about 4 kilometres east-southeast of Greenwood, B.C., on the north and west facing slopes of Mt. Attwood. Access to the claims is good, with numerous two and four wheel drive roads. The claims are underlain by Permian Attwood Group rocks, argillite, phyllite, limestone and volcanics, sandwiched between the underlying Mt. Attwood thrust fault and the overlying Lind Creek thrust. Serpentine is common along these thrusts. A number of different probable Cretaceous intrusions cut the older rocks.

Two areas of VMS type mineralization occur on the property. In the west, massive to finely laminated and disseminated pyrite and pyrrhotite occurs in argillite and hornfels, and at the contact of these rocks with overlying limestone, at the Croesus and Johannesberg showings. In the Croesus workings, the sulfide horizon can exceed 2 metres in thickness, and is exposed over a strike length of in excess of 100 metres. Copper, arsenic, bismuth, silver, and to a lesser extent, tungsten and gold, may be anomalous in samples of sulfide mineralization. Approximately 4 kilometres east, and on what may be the same stratigraphic horizon, massive sulfides (sphalerite, galena, pyrrhotite and pyrite) are exposed at the Sunnyside workings. Historical production from these workings was in the order of 50 tons, at an average grade of 0.24 opt Au, 52 opt Au, 9% Pb and 1% Zn. Again, sulfide material is anomalous in As, Bi, Cu, W, Ag and Au, plus Zn and Pb.

Although dril results are negative, an extended, more detailed heavy mineral survey could further test the claim area for potential gold zones. An airbome mag-EM survey is suggested to identify further pods of sulfide and to assist in defining positions of thrust faults.

2.0 INTRODUCTION

2.1 Location, Access and Terrain

Work described in this report was done on the Croesus claim, located about 4 kilometres eastsoutheast of Greenwood, B.C. (see Figure 1). Access to the property is east from Greenwood on Lind Creek road, then south on various logging, mining and fire access roads. There is good road access to most parts of the claim block.

The claim is situated on the north and west facing slopes of Mount Attwood. Elevation ranges from about 3,000 feet in the Lind Creek valley in the northwest portion of the property, to about 5,000 feet near the summit of Mount Attwood in the southeast. The terrain is moderate to steep and vegetation is highly variable across the property. Much of this area was burned in the Attwood Fire in 1973 and locally, regeneration since the fire has been in the form of thick to virtually impassible alder forest (the Fanny Joe Basin area). To the west and at higher elevations, the forest is more open, consisting of pine, larch and fir, with little underbrush. In the Lind Creek valley, dense cedar forest is common.

The climate is generally quite dry, with hot summers and little rainfall. Snowfall is minimal, generally less than 1 metre. Water is available for drilling from the upper portion of Porter Creek.

2.2 Property and Ownership

The 1997 Croesus drilling is applied to 5 groupings of claims, Attwood 97-1 through Attwood 97-5. These groups consist of a total of 83 mineral claims (a total of 254 units), as shown in the Notices to Group and the accompanying claim maps in the preface pages of this report.

<u>2.3</u> **History** (Note: The following section is excerpted from the 1996 Assessment Report on the Attwood Property and Bombini Option by Linda Caron, for Kettle River Resources.)

The Attwood property includes a number of historical workings on lapsed or reverted crown grants, including the Sunnyside, Rattler and Fanny Joe in the east and the Croesus, Johannesberg, Tanglefoot, Eholt in the west. A number of other lapsed historical claims and crown grants occur on the property and the reader is referred to the historical claim map of the Greenwood Mining District for locations of these properties (which include among others the Evening Star, Morning Star, Lexicon and Lead King). A brief summary of the history of the property is given below.

- 1894: The Lead King and Johannesberg claims were staked. A 9 foot vein of silver bearing rock with 40% lead is reported on the Lead King, exposed for 1000 feet (Ministry of Mines Annual Report).
- 1900-4: Reference made to the Rattler, Johannesberg, Lead King, Sunnyside (Ministry of Mines Annual Reports).
- 1908: Reference is made to the Fanny Joe (Ministry of Mines Annual Report).
- 1911: First reference is made to the Croesus and Lexicon in the Ministry of Mines Annual Reports.

- 1913: Reference is made to the Sunnyside showing, which is said to be similar to the Riverside in the Rock Creek area (Ministry of Mines Annual Report). Production of 30 tons of ore is reported from the Sunnyside. A total production of 50 tons (at an average grade of 0.24 opt Au, 52 opt Ag, 9% Pb and 1% Zn) is reported in the Minfile for the Sunnyside, from the years 1913, 1918-20, and 1934. Note that a second Sunnyside (L1646) occurs in the Jewel Creek area, which has caused some confusion in the historical reports.
- 1933: A 10' deep shaft is reported on the Fanny Joe, on a 4" quartz vein containing pyrite and galena, which strikes northerly and dips steeply east. A considerable amount of manganese is reported. (Ministry of Mines Annual Report). Similar quartz veins are reported in workings on the Rattler.
- 1950: W.E. McArthur shipped 8 tons of lead ore to Trail from the Lead King claims, which returned 22 oz Ag, 1143 lbs Pb and 1250 lbs Zn (Ministry of Mines Annual Report 1950).
- 1968: Ortega Minerals completed a soil sampling program in the Croesus Johannesberg area at 200 foot intervals on 400 foot spaced lines, analysed for copper only. A number of areas of + 100 ppm Cu were detected (Hemsworth, 1968).
- 1969: Ortega Minerals completed IP and mag surveys over in the Croesus Johannesberg area. Eight anomalies were identified and a zone encompassing 5 of these anomalies was defined, approximately 1.5 km in length, striking northwest and open in both directions along strike (Baird, 1969a and 1969b).
- 1973: A soil survey was completed over the Att claims (now lapsed the claims covered a portion of the east side of the current Attwood property), by Granby. Analysis was for Cu and Zn only. Several strong Zn anomalies occurred in the southwest part of the grid (in the vicinity of the Sunnyside claim).
- 1976: Silver Falls Resouces did a very minor program of geological mapping, soil and rock sampling (Cu, Pb, Au analyses) and ground mag over a limited area on the Sunnyside and Fanny Joe claims. Anomalous gold values to 2 g/t were obtained from rock samples collected at old workings and a number of anomalous gold soils (to 120 ppb) occurred (McLeod, 1976).
- 1979: An insignificant program of geological mapping, ground mag and VLF was completed on the Okum property (in the vicinity of the Rattler northcentral part of Attwood claim) (McLeod, 1979).
- 1980: Reconnaissance soil and silt sampling and preliminary geological mapping was done on the Okum and Rattler claims, for March Resources. Several anomalous gold values were detected, with values to + 200 ppb Au. (Madeisky and Symonds, 1980).
- 1983: Ashnola Mining Co. completed minor rock sampling in the Croesus Johannesberg area for precious metal content (Blanchflower, 1983).
- 1995: Kettle River Resources acquired the Attwood claim (including the lapsed Sunnyside, Fanny Joe and Rattler crown grants) by staking.

 1996:
 Kettle River Resources staked the Att claims, and optioned the Croesus-Johannesberg property from

 Croesus Assessment Report
 Page 3

Samuel Bombini. The geological mapping and rock sampling program described in this report was completed. Following this program, heavy mineral drainage samples were collected, and contour soil sampling done over a portion of the property.

1997: Kettle River Resources entered into an Exploration and Option Agreement with Echo Bay Minerals Co., Republic, WA. Echo Bay drilled six diamond core holes on the Croesus claim to test the VMS model for the property and to search for gold enrichment. Drill results suggest mineralization at Croesus is associated with intrusion-related silicification, rather than a syngenetic horizon. Highest gold intercept in the program was 0.049 opt Au over 5 feet.

2.4 Summary of Work Done, October, 1997

Six holes were drilled by diamond drill methods by Bergeron Drilling of Greenwood, B.C. A total of 1828 feet of drill core were obtained, logged, and sampled. Sampled core was split, and stored with unsampled core in the core yard facility of Kettle River Resources, Greenwood, B.C. Mike Rasmussen, Echo Bay Minerals Co., was project geologist, and was assisted by Tom Johnson (geologist) and John Hanks (geothechnician).

3.0 GEOLOGY AND STRUCTURE (Note: The following section is excerpted from the 1996 Assessment Report on the Attwood Property and Bornbini Option by Linda Caron, for Kettle River Resources.)

The Greenwood area has been mapped on a regional basis by Fyles (1990), and prior to this, by Little (1983) and Church (1986). Fyles' mapping shows the pre-Tertiary rocks form a series of thrust slices, which lie above a basement high grade metamorphic complex. A total of at least five thrust slices are recognised, all dipping gently to the north, and marked in many places by bodies of serpentine. Fyles' interprets these serpentinite bodies as representing part of a disrupted ophiolite suite, belonging to the Knob Hill Group of late Paleozoic age. Commonly, these serpentinite bodies have undergone Fe-carbonate alteration to listwanite, as a result of the thrusting event.

The Greenwood area has been mapped on a regional basis by Fyles (1990), and prior to this, by Little (1983) and Church (1986). The distribution of rocks in the Greenwood area is controlled by a series of faults, including both Jurassic thust faults and Tertiary extensional (and detachment) faults hence an understanding of the structure of the area is critical to understanding the geology. The reader is referred to Fyles (1990) for an in-depth description of the regional geology and structure.

Fyles' mapping shows the pre-Tertiary rocks form a series of thrust slices, which lie above a basement high grade metamorphic complex. The thrusting event is felt to be an effect of the development of the Okanagan gneiss domes, which also results in the regional northward dip of rock units (Fyles, 1990). A total of at least five thrust slices are recognised, all dipping gently to the north, and marked in many places by *Croesus Assessment Report Page 4*

bodies of serpentine. Fyles' interprets these serpentinite bodies as representing part of a disrupted ophiolite suite, belonging to the Knob Hill Group of late Paleozoic age. Commonly, these serpentinite bodies have undergone Fe-carbonate alteration to listwanite, as a result of the thrusting event.

The oldest rocks in the camp belong to the late Paleozic Knob Hill Group of dominantly volcanic affinity, and consist mainly of chert, greenstone and related intrusives, and serpentine. Unconformably overlying these rocks are sediments and volcanics (largely argillite, siltstone, limestone and andesite) of the late Paleozoic Attwood Group. Rocks of the Knob Hill and Attwood Groups are in turn unconformably overlain by the Triassic Brooklyn Formation, represented largely by limestone, clastic sediments and pyroclastics. In many cases in the Greenwood area, evidence for thrusting is seen by the older Knob Hill Group rocks resting over the younger Attwood Group or Brooklyn Formation rocks. The historically important skarn deposits in the Greenwood area (i.e. Phoenix, Oro Denoro, Motherlode-Greyhound) area hosted within the Triassic rocks.

Three separate intrusive events are known regionally to cut the above sequence, the Jurassic aged Lexington porphyry, the Cretaceous Nelson intrusives, and the Eocene Coryell dykes and stocks.

Tertiary sediments and volcanics unconformably overly the older rocks with the distribution of these Tertiary rocks largely controlled by series faults. Regionally, three Tertiary fault sets are recognised, and early set gently east dipping set, a second set of low angle west dipping, listric normal detachment type faults, and a late, steep dipping, north to northeast trending set of right lateral or west side down normal faults (Fyles, 1990).

The Attwood property is located on the north and west facing slopes of Mount Attwood, within Fyles' fourth thrust slice. A wedge of Attwood Group rocks is sandwiched between the Mt. Attwood thrust fault below, and the Lind Creek thrust fault above, both which dip gently to the north. Both thrust faults are defined by exposures of serpentine. Fyles' mapping shows a basal volcanic unit, overlain by limestone (locally cherty), which is in turn overlain by a sedimentary package of siltstone, phyllite, and conglomerate. He describes the Attwood rocks as being tightly folded, with axial planes dipping moderately north, and on axes with low plunge to the northwest.

At the Croesus showings, massive, finely laminated pyrrhotite with pyrite and minor chalcopyrite occurs in a steeply dipping horizon up to 2 metres in width, at the contact of phyllite and limestone. Locally the massive sulfide horizon has well developed fragmental textures and clear glassy quartz eyes, to 4 mm in size.

To the northwest at the Johannesberg workings, finely lamellar, and locally massive, pyrrhotite, again with good vitreous quartz eyes within, occurs in a fine grained homfels. A late granodiorite intrusive with minor associated quartz veining along margins, intrudes the older rocks in the area of the Croesus and Johannesberg showings. The intrusive can become quite strongly bleached and altered, with pyrite-pyrrhotite stockworking veinlets. A number of quartz veins, with galena, sphalerite, pyrite and chalcopyrite are known in the western portion of the property (on the Tanglefoot, Johannesberg, etc), which may be related to these intrusives.

4.0 Drilling Program

4.1 Drill Hole Description

CR97-1 drilled toward and beneath the western trench of Croesus, where a tightly-folded horizon of massive pyrite plunges shallowly ESE against altered granodiorite. This hole would intersect at least one (the northern), or possibly both limbs of the fold if they persisted to a depth of 200 ft or more. Neither limb was encountered in the drilling, and the most ready explanation for the surface showing is a fault-related, post-intrusion fold in a sulfide-replaced horizon. No significant gold mineralization, although an interal (8 ft.) of pyroxene-epidote-marble skarn occurred within the limestone

CR97-2 intersected nearly 10 feet of massive pyrhhotite-pyrite-chalcopyrite (py-po-ccp) within a marble unit. Although no granodiorite occurs in this hole CR97-3 encountered a sill (?) of it 40 feet away. CR97-2 was stopped in old mine workings at 170 ft., CR97-3 steepened 10^O and drilled to 500 ft.; very little alteration or mineralization was seen in the CR97-3, which was surprising, given the massive sulfide showing in CR97-2.

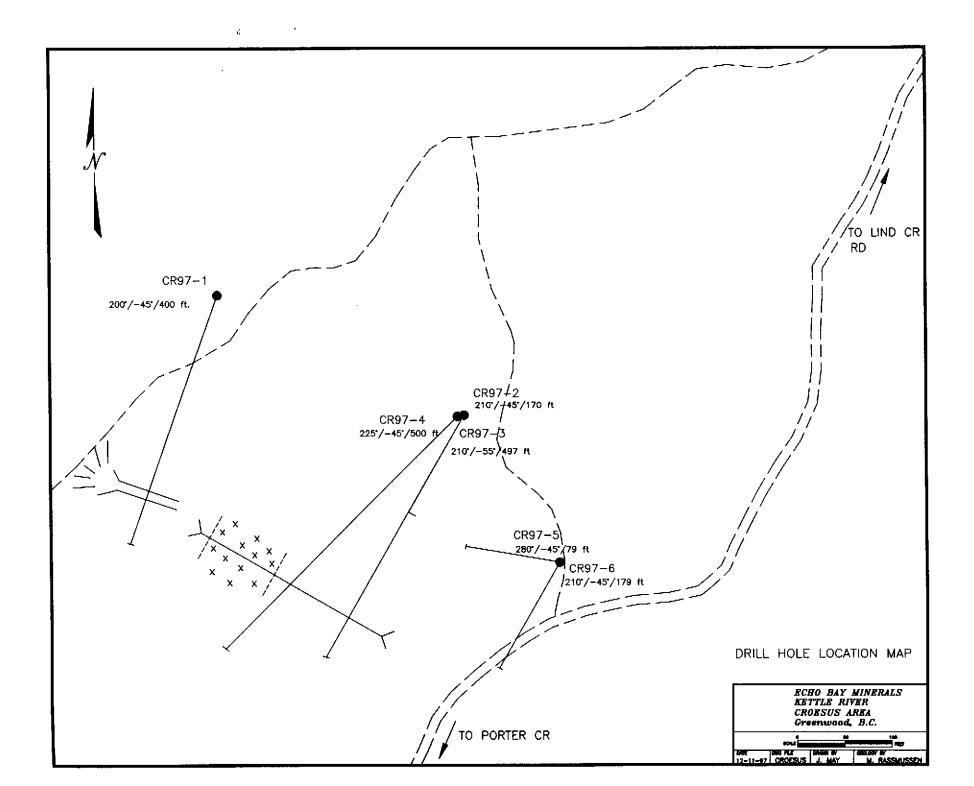

CR97-4 was an effort to intersect the massive py-po-ccp horizon again. It too failed. This core intersected 5 intervals of granodiorite, and most of the siltite was sharply hornfelsed. It seems likely that the massive sulfide of CR97-2 is an isolated pod without significant dimensions. The most continuous gold mineralization occurred within the hornfelsed siltite from 309-325 ft., where thin veinlets of qz-py-ccp were associated with three consecutive samples which ran 49, 24, and 19 milli-ounces per ton (e.g., 0.049 opt Au), each over about 5 ft.

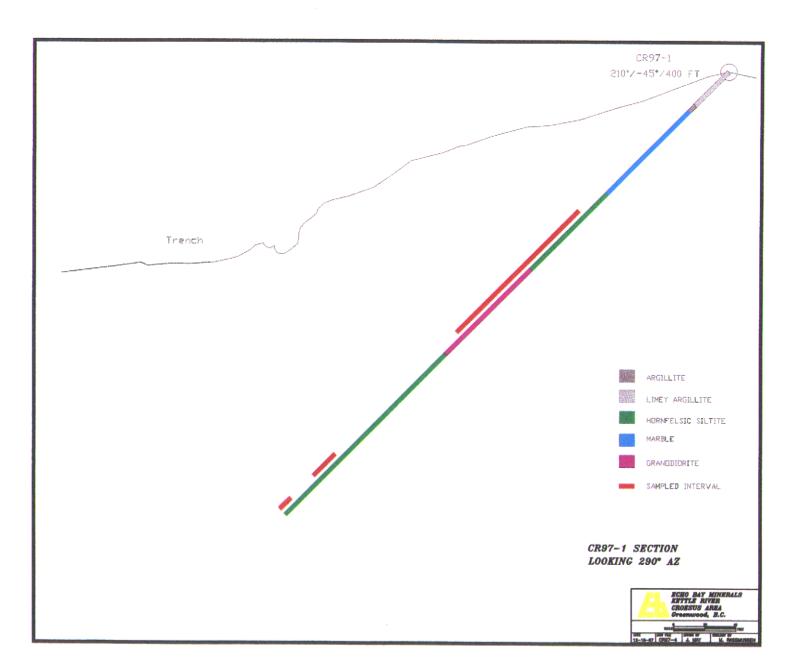

CR97-5 extended 79 feet westward into thoroughly silicified rock. Voluminous quartz, some of it possibly chert, most probably intrusion-related alteration, is perhaps controlled by a NE-striking structure or dike. A carbonate unit in this hole exhibited garnet spotty alteration over 20 ft.

CR97-6 drilled under the eastern end of the Croesus trench, through strongly silicified and Fe-oxide stained rock, none of which, unfortunately, carried gold mineralization.

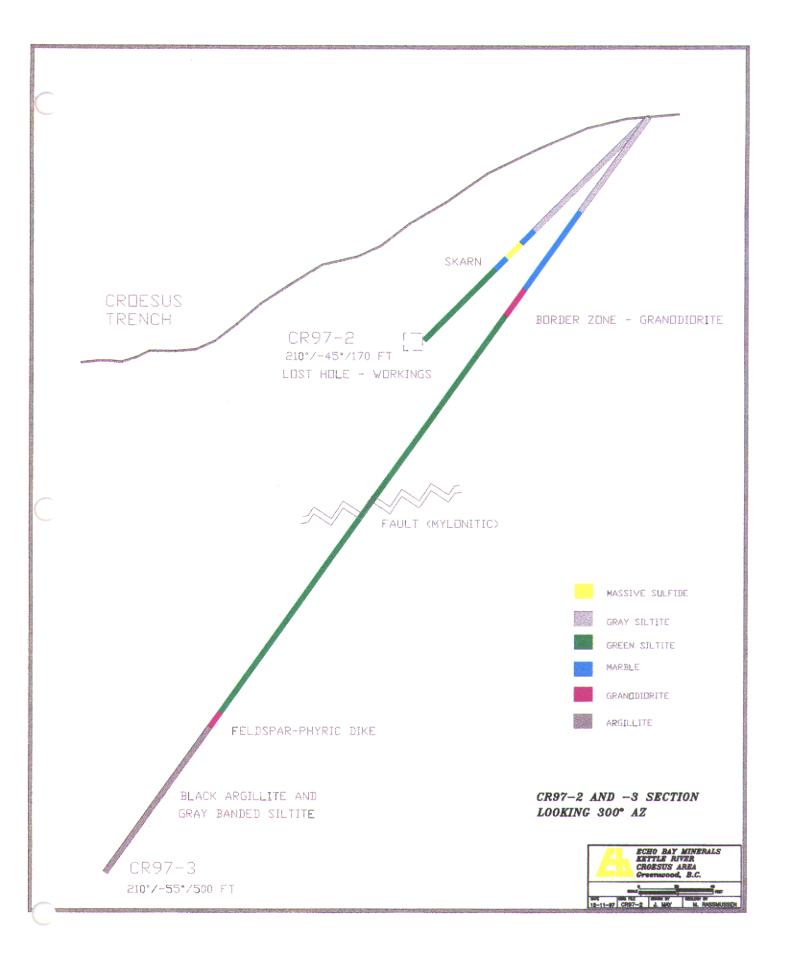

4.2 Interpretation

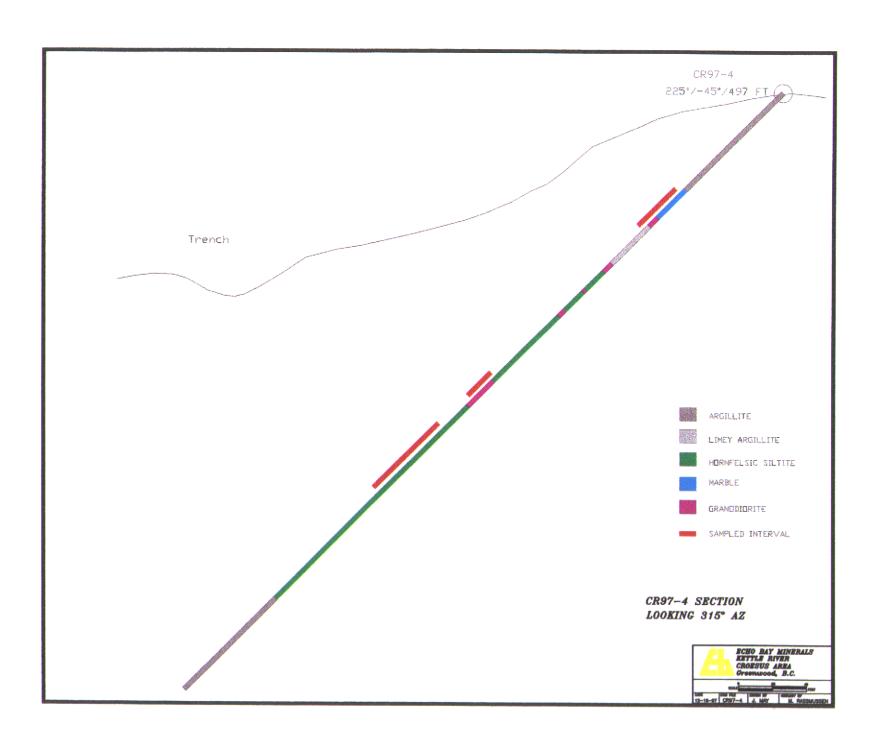

The core presents much more an appearance of intrusive-related alteration and sparse mineralization than it does of syngenetic stratbound mineralization. It is possible that intrusion-related recrystallization and skarning of carbonate and hornfelsing of clastic lithologies has overprinted a package of marine sediments containing a mineralized horizon or two, but that is not the simplest explanation of these results. Support, however, for the latter scenario is found in the felsic tuff(?) which is better exposed on the east end of the trench and in subcrop on the road. Perhaps an EM survey would elicit evidence of massive sulfide to the east of the trenches.

 \bigcirc

5.0 RECOMMENDATIONS

Geological mapping has identified a VMS horizon within Permian Attwood Group rocks, with several occurrences of typical VMS type mineralization. No areas of economic or strongly anomalous precious metal content have been identified. Detailed heavy mineral drainage sampling is recommended to determine whether a gold enriched portion of the VMS horizon could exist. Contour soil sampling is also recommended to test projected favourable areas with heavy cover. An airborne geophysical survey (mag/EM) would be useful in identifying areas of mineralization for follow-up.

Statement of Qualifications

£.

STATEMENT OF QUALIFICATIONS

I, Michael G. Rasmussen, certify that:

- 1. I am an exploration geologist residing at 868-7 Rupert Spur Rd., Republic, WA, USA
- 2. I obtained a B.A. in Biology at Andrews University, Berrien Springs, MI, in 1969.
- 3. Learned an M.S. degree in Geology at Loma Linda University, Riverside, CA, in 1983.
- 4. I graduated with a Ph.D. degree from the University of Washington in 1993 in Geological Sciences.
- 5. I have practised my current profession since 1990.
- 6. I am employed by Echo Bay Minerals Co. as a Senior Exploration Geologist.

equa-

Michael G. Rasmussen, Ph.D.

2 Feb. 1998
