SUMMARY

The Kendall copper property is situated in the Cariboo Mountains in east central British Columbia 44 kilometres northwest of McBride and is accessed by helicopter from McBride. A program of prospecting and chip sampling was completed in late September 1997.

The property is underlain by northwest trending dolomite, shale, siltstone quartzite and phyllite units which in the central claim area are cut by a north-trending west dipping normal fault. Copper mineralization, hosted in quartz and quartz-carbonate breccia within the fault, has been traced on surface in a zone some 1500 meters long and 5 metres to 10 metres wide.

Grab samples collected over 1200 metres of the mineralized zone returned copper tenors up to 5.10% and silver up to 2826ppb. Three 7 to 9 metre long chip samples averaged 0.37%, 0.72% and 0.51% copper. Similar copper bearing quartz float samples collected at the base of a moraine covered cirque 1500 metres north of the mineralized zone may lie near the northern extension of the zone.

INTRODUCTION

Results of a geochemical rock sampling program conducted on the Kendall property and completed between September 25th and October 1 is recorded herein. Work was staged from the town of McBride.

LOCATION AND ACCESS

The property is situated in the rugged Cariboo Mountains in east central British Columbia about 44 kilometres northwest of McBride (Figure 1) and is accessible by helicopter only. The property lies above tree line and two glaciers cover 30% of the claim area. The approximate geographic center of the property is 53E27°North and 120E48°West.

CLAIM INFORMATION

The Kendall property consists of one 2 post claim and two modified grid system claims. The claims are located in the Cariboo Mining Division and are shown on B.C. Ministry of Employment and Investment claim map 093H07W and on Figure 1. Pertinent tenure details are tabulated below. Dates listed assume work reported herein is accepted for assessment purposes.

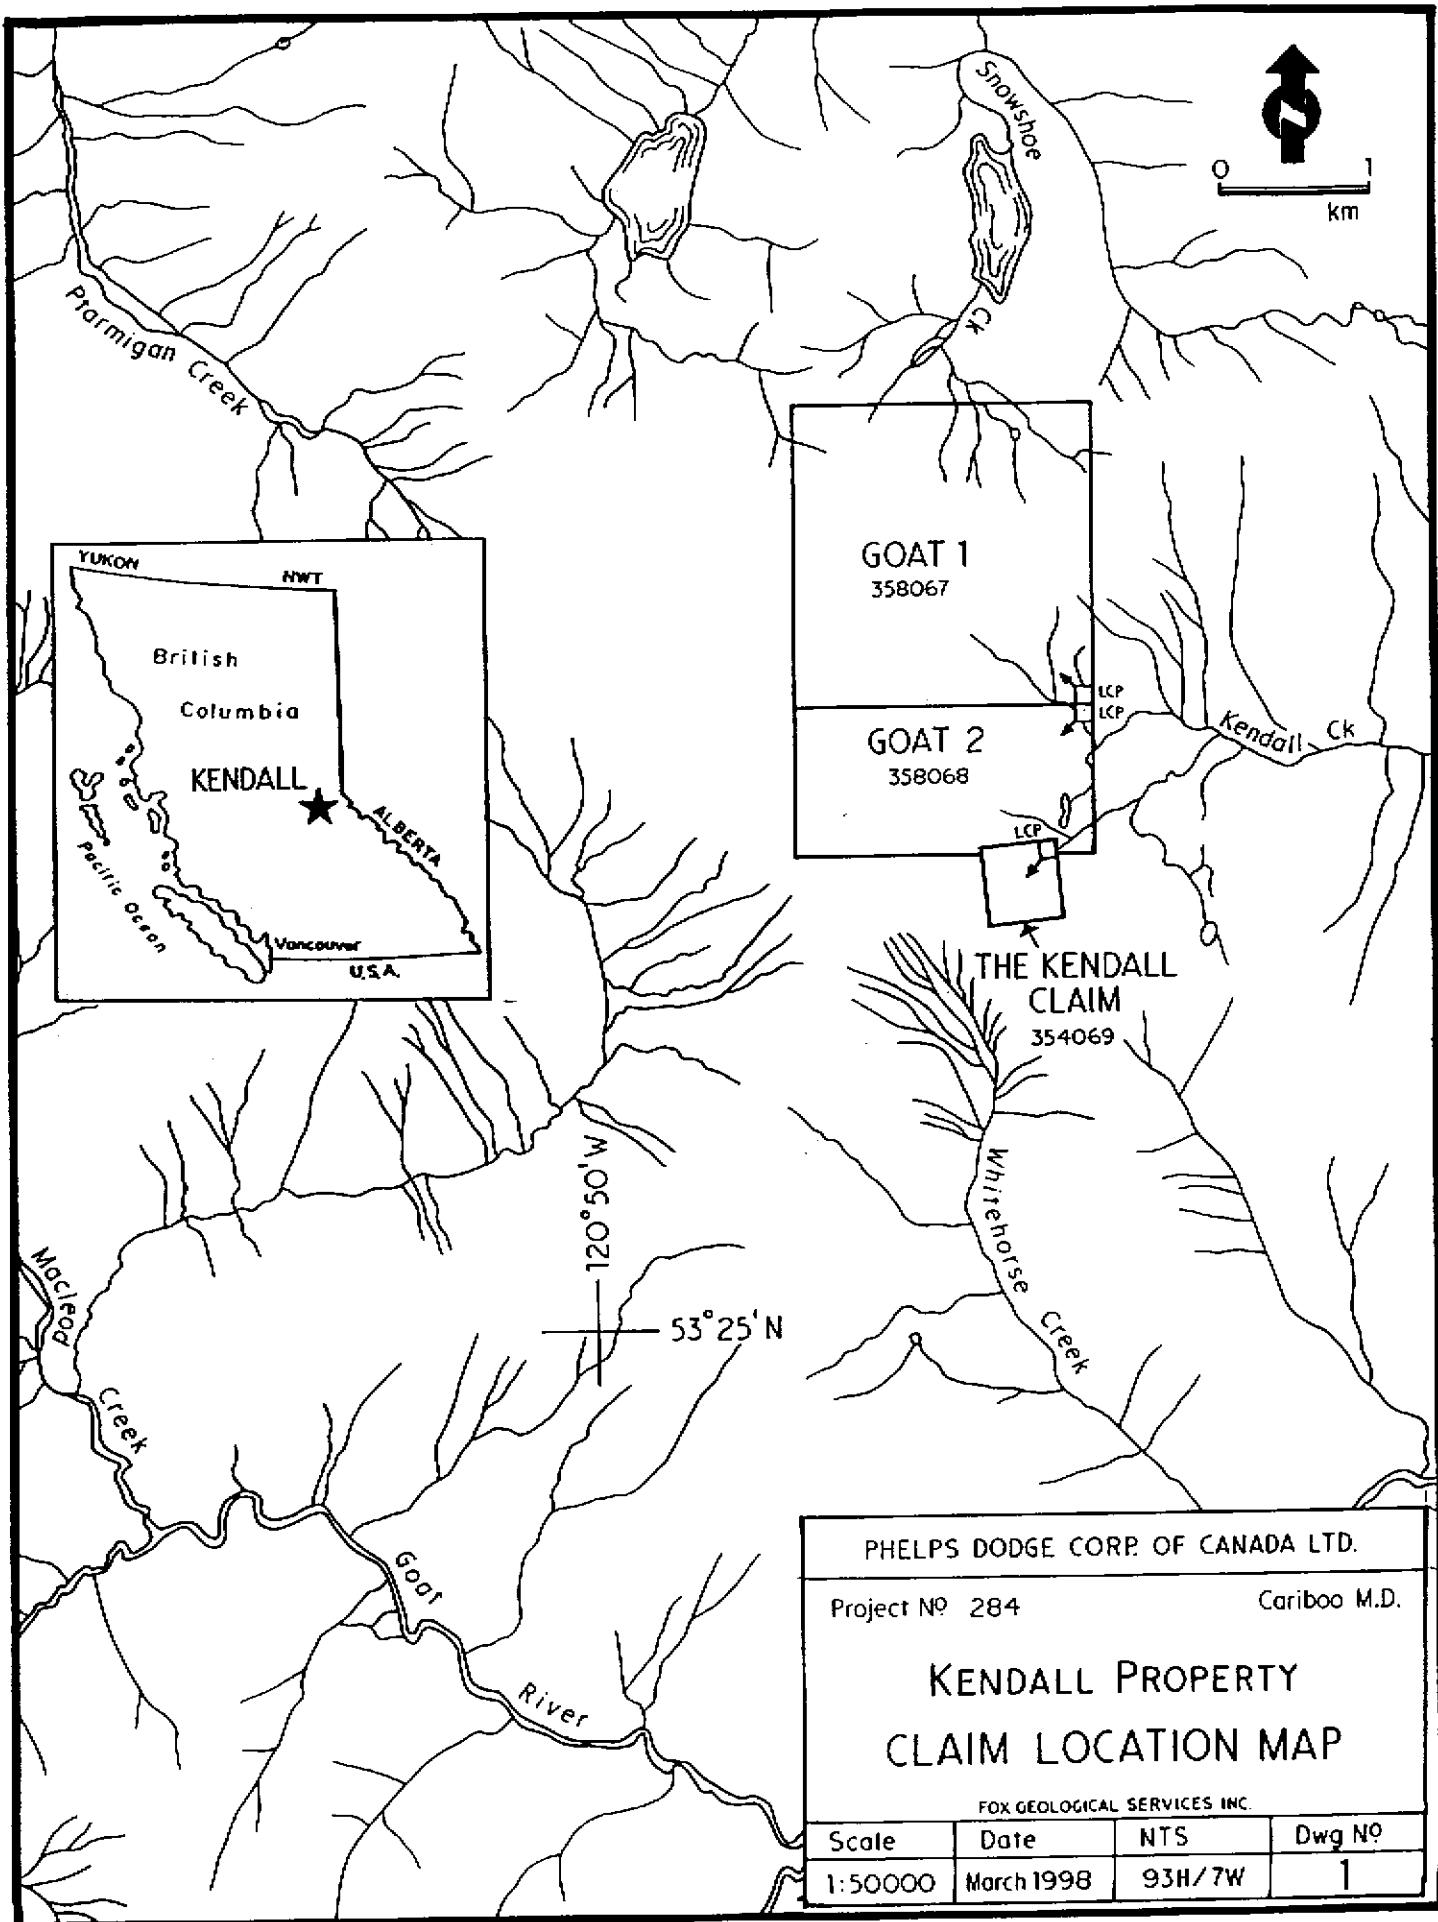

Claim Name	Record Number	Units	Expiry Date
The Kendall Claim	354069	1	February 24, 2000
Goat 1	358067	16	July 13, 2000
Goat 2	358068	2	July 13, 2000

HISTORY

There is no documented work on or around the property and no nearby mineral occurrence is recorded in the BC Minfile database. The area immediately to the north was staked in 1988 but the claims were canceled shortly thereafter. Samples collected in 1996 from the discovery showing returned from 1% to 6.64% copper.

ENVIRONMENTAL

The 1997 work was done under work approval number PGR1997-1101895-8637 and reclamation permit number MX-11-104.

REGIONAL GEOLOGY

The Cariboo Mountain area lies within the Omenica structural belt of the Canadian Cordillera. Geologic interpretations by Campbell et al (GSC Paper 72-35) and Monger et al (GSC Map 1712a), and summarized in Figure 2, show the area is underlain by a northwest plunging synform cored with Upper Proterozoic Windermere rocks and flanked on the east and west by Lower Cambrian Gog rocks. The Windermere and Gog assemblages consist of thick sequences of gritty, feldspathic sandstone, siltstone, shale and limestone which are variably metamorphosed from lower greenschist to upper amphibolite facies. Cambrian Rocky Mountain carbonate and shale form a minor part of the stratigraphic pile here.

LOCAL GEOLOGY

From northeast to southwest the Kendall property is underlain by northwest trending dolomite, shale and siltstone, siltstone and quartzite and phyllite with moderate dips to the southwest (see Figure 3). This sequence of rocks is mapped by Campbell et al. (GSC Paper 72-35) as the Upper Windermere Cunningham, Yankee Belle, Yanks Peak and Midas Formations respectively. These units are weakly foliated and locally are tightly folded and in the north and south claim area appear to form an uninterrupted sequence. In the central claim area a prominent siltstone and quartzite ledge some 30+ m thick is truncated by a normal fault some 1500 meters long trending 150° SE and dipping 85° W. From north to south the fault appears to cut up-section from siltstone and quartzite to phyllite and then, some 1200 meters south, down section from phyllite into quartzite and siltstone. The fault is 5 metres to 10 metres wide, hosts a variety of lithologies in a quartz and quartz-carbonate matrix and where in contact with the hanging-wall phyllite hosts the bulk of the copper mineralization.

MINERALIZATION

Pyrite, chalcopyrite, and arsenopyrite form irregular stringers and pods of semi-massive sulphides. Locally semi-massive sulphides form zones some 2m long and up to 50cm thick. Trace bornite, chalcocite, native copper and galena are also present. Fractures within the veins commonly contain malachite and lesser azurite.

1997 WORK PROGRAM

The 1997 program of mapping, prospecting and chip sampling was carried out between September 25 and October 1, 1997 during which 30 rock samples were collected. Ultratrace analytical work was done by Acme Analytical Laboratories in Vancouver. Geochemical sample results with descriptions are given in Appendix I and complete

Figure 2

analytical results in Appendix II. A geology /sample location plan is given in Figure 3.

RESULTS

Grab samples collected over 1200 metres of the mineralized zone in the central claim area returned copper tenors from 76.6 ppm up to 5.10% and silver content from 111ppb to 2826ppb. Eight grab samples returned copper greater than 1.00%. Three chip samples spaced approximately 50 metres apart returned 0.37% Cu over 9 metres 0.72% Cu over 7 metres and 0.51% Cu over 8 metres. Numerous boulders of chalcopyrite-bearing quartz float were observed in a cirque some 1.5km north of the showing. Samples from two of the boulders returned 1.80% and 2.29% copper.

CONCLUSIONS AND RECOMMENDATIONS

A steep west-dipping fault in the central claim area and traced on surface for some 1500 metres in a north-northwest direction appears to be a host for a zone of copper-bearing quartz-carbonate breccia and quartz stockwork 1200 meter long and 5 metres to 10 metres wide. Sampling over the zone returned low grade intervals overall with local patches of high grade material. The best result is 0.72% over 7 metres.

Discovery of copper-bearing float in the cirque north of the mineralized zones warrants further detailed prospecting.

DISBURSEMENTS

Disbursements to the end of December 1997 are summarised below.

Accommodation and Board - 12 mandays@\$65/day(2 man crew)	\$780
Assays - 30 rock samples@\$18/sample	540
Labour - 12 mandays@\$525/day(2 man crew)	6,300
Helicopter - 6hr@\$800/hr	4,800
Project Total	<u>\$ 12,420</u>

CERTIFICATE

I, Gregory Kenneth Kulla certify to the following:

1. I am a consulting geologist residing at 9756 Crown Crescent, Surrey, B.C.
2. I am a Professional Geoscientist registered in the Association of Professional Engineers and Geoscientists of British Columbia.
3. I obtained a Bachelor of Science (geology) from the University of British Columbia in 1988.
4. I have been engaged in geological work since graduation in 1988.
5. I conducted the work reported herein.

Standard is STANDARD D2/C3/AU-R.

ICP - 30 GRAM SAMPLE IS DIGESTED WITH 180 ML 3-1-2 HCL-HNO3-H2O AT 95 DEG. C FOR ONE HOUR AND IS DILUTED TO 600 ML WITH WATER. THIS LEACH IS PARTIAL FOR MN FE SR CA P LA CR MG BA TI B W AND LIMITED FOR NA K GA AND AL. SOLUTION ANALYSED DIRECTLY BY ICP. MO CU PB ZN AG AS AU CD SB BI TL

HG SE TE AND GA ARE EXTRACTED WITH MIBK-ALIQUAT 336 AND ANALYSED BY ICP. ELEVATED DETECTION LIMITS FOR SAMPLES CONTAIN CU,PB,ZN,AS>1500 PPM, Fe>20%.

- SAMPLE TYPE: ROCK AU+ - AQUA-REGIA/MIBK EXTRACT, GF/AA FINISHED. Samples beginning 'RE' are Reruns and 'RRE' are Reject Reruns.

All results are considered the confidential property of the client. Acme assumes the liabilities for actual cost of the analysis only.
