1.0 SUMMARY

The Orofino Mountain property consists of six four-post mineral claims covering 32 units in the Osoyoos Mining Division and is owned and operated by Grant F. Crooker of Keremeos, BC. It is located 11 kilometres northeast of Keremeos and 7 kilometres southeast of Twin Lakes in southern British Columbia (NTS 82E-4E, 5E).

Access is via Highway 3A from Keremeos (23 kilometres) or Penticton (23 kilometres), turning south onto a secondary road at the Twin Lakes Golf Course. A network of logging and mining roads give access to all areas of the property.

The Orofino Mountain property (King property) is located within the Orofino Mountain Gold Camp that consists of three principal properties. These are the Orofino Mountain (King), Grandoro and Twin Lakes. Production from the entire camp is reported by Hedley and Watson (1945) to be 24,058 tons of ore yielding 8,858 ounces of gold and a little silver. The King Property is estimated to have produced 1000 to 2000 tons of "ore".

The Orofino Mountain Gold Camp is located about nine kilometers northwest of the better known Fairview Gold Camp. The Fairview Gold Camp produced over 500,000 tons of ore yielding 0.12 ounces gold/ton and 1.42 ounces silver per/ton. The geological, geochemical and structural setting of the Orofino Mountain Gold Camp is similar to the Fairview Gold Camp.

Mineralization on the Orofino Mountain property (King showings) consist of quartz veins containing pyrite, chalcopyrite, galena and visible gold. Gold values generally increase with an increase in sulphide content. The best mineralized quartz veins appear to strike north to northwesterly with near vertical dips. The King showing consists of the Upper King and Lower King adits. The Lower King adit has been driven for approximately 50 metres with the last 25 metres stoped. Production from the stope is estimated to be between 1000 and 2000 tons. The Upper King adit has been driven for approximately 25 metres with a winze to a lower level. The tonnage from the Upper King adit is not known as the winze is full of water.

During the period 1973 through 1987, the present owner, in conjunction with several junior mining companies carried out geological mapping, prospecting, rock sampling, magnetic and VLF-EM geophysical surveying and soil geochemical sampling over the property. The rock sampling yielded gold values ranging from nil up to 10.8 ounces /ton across 0.9 metres (Lower King adit). Surface sampling from a trench above the Lower King adit consistently yielded assays of over one ounce/ton gold across 12 to 24 inches. The encouraging results from these surveys culminated in a program of trenching and diamond during 1987, mainly in the area of the King adits.

The trenching program was successful in demonstrating 400 metres of strike length on the Lower King vein structure and 100 metres of strike length on the Upper King vein structure. Sampling of the trenches gave gold values from nil to 38,000 ppb. Samples taken from the northern extension of the Lower King vein structure gave the most encouraging results, with gold values of 38,000 ppb over 7 centimetres (calcite bearing, rusty pyritic wall rock) and 20,000 ppb over 1.7 metres (white guartz vein with no visible sulphides).

Christopher (1987) made the following comments on the 1987 drill program: "Drilling on the Upper and Lower King vein structures revealed a complex fault pattern with veins displaced left laterally by steep northeast faults and in an undetermined fashion by shallow faults. Drilling has indicated a non-uniform distribution of values with auriferous zones probably controlled by the intersections of structural trends".

Drill results varied from nil where the vein was faulted off, to 0.866 oz Au/ton in sludge from 23.48 to 25.0 metres in drill hole DDH-87-5 (Upper King). Drilling on the southern extension of the Lower King vein structure gave several intersections of gold greater than 0.05 ounces per ton across widths less than 1.0

metre, while drilling on the northern extension of the structure did not give any intersections of gold greater than 0.05 ounces per ton. Drilling on the southern extension of the Upper King vein structure gave two intersections of gold greater than 0.05 ounces per ton. Two holes drilled 250 metres south of the Lower King vein structure intersected three to six metres of quartz vein but no anomalous values in gold.

During 1998, stream sediment samples were collected from the major drainages on the property, and a grid was established over a portion of the King 5 mineral claim and magnetic and VLF-EM surveys carried out.

The stream sediment sampling yielded positive results, with five samples yielding weakly to moderately anomalous gold values (15 to 115 ppb). One anomalous sample was collected below the confluence of the East and West Forks of Park Rill, while the other four anomalous samples were collected from the West Fork. The stream sediment samples with anomalous gold values show a weak correlation with arsenic and lead values. On the basis of the stream sediment sampling, the area draining into the West Fork of Park Rill has the strongest potential to host additional gold mineralization.

The magnetic survey defined three zones of magnetism (low, moderate, high) within the grid area and shows a gradual increase in total field magnetic values from the northeast corner to the southwest corner of the grid. The area appears to be underlain by intrusive rocks, and the differences in magnetism may be caused by a variation in the content of magnetite or mafic minerals within the intrusive.

The VLF-EM survey delineated number of north and northeast trending conductor systems. No causes are apparent for the conductor systems, although some may be caused by faults or shear zones that may host auriferous quartz veins.

The 1999 work program consisted of completing the grid and magnetic and VLF-EM surveys on the King 5 mineral claim. The magnetic survey confirmed the prominent, northwest-southeast trending magnetic high in the central portion of the grid. Zones of moderate magnetic values flank the magnetic high to the southwest and northeast, with low magnetic values in the northeast corner of the grid. The grid area appears to be underlain by intrusive rocks, and the differences in magnetism may be caused by a variation in the content of magnetite or mafic minerals within the intrusive.

A number of weak to moderate to strong, north and northeast trending conductor systems were delineated by the VLF-EM survey. No causes are apparent for the conductor systems, although some may be caused by faults or shear zones that could host auriferous quartz veins.

Additional exploration is warranted on the property and should be conducted as follows:

- conduct geological mapping and prospecting determine the causes of the VLF-EM conductor systems

- conduct soil sampling over grid area to determine source of anomalous (gold) stream sediment samples from the West Fork of Park Rill (1998 survey)

Respectules aubmitted. Orooker, P.Geo., Grant. Consulting Geologist

2

2.0 INTRODUCTION

2.1 GENERAL

Fieldwork was carried out on the Orofino Mountain property (King claims) from March 23rd to April 28th, 1999. Grant F. Crooker, P.Geo. conducted the exploration program.

The exploration program consisted of completing grid lines and magnetic and VLF-EM surveying. over the remainder of the King 5 mineral claim not covered by the 1998 survey.

2.2 LOCATION AND ACCESS

The property (Figure 1.0) is located 11 kilometres northeast of Keremeos and 7 kilometres southeast of Twin Lakes in southern British Columbia. The property lies between 49° 14' and 49° 16' north latitude and 119° 40' and 119° 43' west longitude (NTS 82E-4E, 5E).

Access is via Highway 3A from Keremeos (23 kilometres) or Penticton (23 kilometres), turning south onto a secondary road at the Twin Lakes Golf Course. This all weather two wheel drive secondary road leads to the northern claim boundary of the property and is maintained 12 months of the year. A network of logging and mining roads give access to all areas of the property.

2.3 PHYSIOGRAPHY

The property is located in the Okanagan Highlands of southern British Columbia. Elevation varies from 1000 metres to 1600 metres above sea level and topography varies from rolling hills to steep slopes. Most of the area is timbered with larch, spruce, fir and pine trees, with open areas covered with bunch grass and sagebrush. Much of the area has been logged over the past 50 years by both clear cut and selective logging methods.

Park Rill flows through the western portion of the property and contains a flow of water all year long. Smaller branches of Park Rill drain many areas of the property, and springs and swamps are found in many locations.

2.4 PROPERTY AND CLAIM STATUS

The King, King 2 to 5 and MO mineral claims (Figure 2.0) are owned and operated by Grant F. Crooker of Box 404, Keremeos, BC, V0X 1N0. The property consists of six four-post mineral claims covering 32 units in the Osoyoos Mining Division.

2.5 AREA AND PROPERTY HISTORY

The Orofino Gold Camp dates to the 1890's when the Fairview Gold Camp was discovered. Mineralization at the Orofino Camp consists of quartz veins with pyrite, chalcopyrite, galena and visible gold.

4

The three main properties within the Orofino Camp are the Twin Lakes (Twin Lakes 1-4), Grandoro (Lots 1448 and 1449) and the Orofino Mountain property (MO, King, King 2 to King 5). The British Columbia minfile documents the occurrences as 82E-SW-10 (Twin Lakes), 82E-SW-11 (Grandoro) and 82E-SW-113 (Orofino Mountain). The Orofino Mountain property is the subject of this report.

Production from the entire camp is reported by Hedley and Watson (1945) to be 24,058 tons yielding 8,858 ounces of gold and a little silver. Most of the production has been from the Twin Lakes and Grandoro properties during the period 1930 to 1941. A limited amount of production came from the King showings on the Orofino Mountain property.

The Lower King adit has been driven for approximately 50 metres with the last 25 metres stoped. Production from the stope is estimated to be between 1000 and 2000 tons. The Upper King adit has been driven for approximately 25 metres with a winze to a lower level. The tonnage from the Upper King adit is not known as the winze is full of water.

During the period 1973 through 1987 the present owner, in conjunction with several junior mining companies carried out geological mapping, prospecting, rock sampling, magnetic and VLF-EM geophysical surveying and soil geochemical sampling over the property. These surveys gave encouraging results and in the summer of 1987 a program of trenching and diamond was carried out, mainly in the area of the King workings.

Thirty-one trenches were excavated on the property totalling 1200 metres in length and 3291 cubic metres of material excavated. The trenching program was successful in demonstrating 400 metres of strike length on the Lower King vein structure and 100 metres of strike length on the Upper King vein structure. Sampling of the trenches gave gold values from nil to 38,000 ppb. Samples taken from the northern extension of the Lower King vein structure gave the most encouraging results, with gold values of 38,000 ppb over 7 centimetres (calcite bearing, rusty pyritic wall rock) and 20,000 ppb over 1.7 metres (white quartz vein with no visible sulphides).

The 1987 drill program consisted of 23 NQ diamond drill holes totalling 1,404.56 metres, mainly on the King showings. Christopher (1987) made the following comments on the drill program:" Drilling on the Upper and Lower king vein structures revealed a complex fault pattern with veins displaced left laterally by steep northeast faults and in an undetermined fashion by shallow faults. Drilling has indicated a non-uniform distribution of values with auriferous zones probably controlled by the intersections of structural trends".

Drill results varied from nil where the vein was faulted off, to 0.866 oz Au/ton for sludge from 23.48 to 25.0 metres in drill hole DDH-87-5 (Upper King). Drilling on the southern extension of the Lower King vein structure gave several intersections of gold greater than 0.05 ounces per ton across widths less than 1.0 metre, while drilling on the northern extension of the structure did not give any intersections of gold greater than 0.05 ounces per ton. Drilling on the southern extension of the Upper King vein structure gave two intersections of gold greater than 0.05 ounces per ton. Drilling on the southern extension of the Upper King vein structure gave two intersections of gold greater than 0.05 ounces per ton. Two holes drilled 250 metres south of the Lower King vein structure intersected three to six metres of quartz vein but no anomalous values in gold.

Table 2.0 summarizes the drill results for all intersections greater than 0.05 oz Au/ton.

87-17	3.96-5.49	1.53	Sludge	0.261		

In 1990 the Orofino Mountain property was optioned jointly with the Grandoro property. Part of the 1990 work program consisted of evaluating an old tailings pond located on the MO claim. The tailings are believed to be from milling of ore from the Grandoro property.

Evaluation of the tailings was carried out using a flagged grid with a 20 metre line spacing and a ten metre spacing between samples. A two to eight kilogram sample of tailings were taken at each sample location. Determination of grade and tonnage was done using a crude polygon ore reserve calculation. Tailing reserves were calculated to be 12,850 tonnes grading 1.97 grams/tonne, giving a total of 25,314 grams or 814 ounces of gold.

No further work was carried out on the Orofino Mountain property until 1998, when stream sediment samples were collected over the entire property, and magnetic and VLF-EM surveys were carried out over a portion of the King 5 mineral claim. Four of the stream sediment samples from the West Fork of Park Rill yielded weakly to moderately anomalous gold values ranging from 15 to 115 ppb.

The magnetic survey defined three zones of magnetism (low, moderate, high) within the grid. The most prominent magnetic feature is a northwest-southeast trending magnetic high in the central portion of the King 5 mineral claim.

The VLF-EM survey delineated number of north and northeast trending conductor systems. No causes are apparent for the conductor systems, although some may be caused by faults or shear zones that may host auriferous quartz veins.

3.0 EXPLORATION PROCEDURE

The 1999 exploration program consisted of establishing grid lines and carrying out magnetic and VLF-EM surveying over the remainder of the King 5 mineral claim not covered by the 1998 survey.

3.1 GRID PARAMETERS

-baseline direction north-south -survey lines perpendicular to baseline -survey line separation 100 metres -survey station spacing 25 metres -survey total - 11.0 kilometres -declination 20°

3.2 GEOPHYSICAL SURVEY PARAMETERS

TOTAL FIELD MAGNETIC SURVEY

-survey line separation 100 metres -survey station spacing 25 metres -survey total - 10.0 kilometres -measured total magnetic field in nanoteslas -instrument - Scintrex MP-2 magnetometer -instrument accuracy ± 1 nanotesla -operated faced north for all readings

Readings were taken along the baseline to obtain standard readings for all baseline stations. All loops ran off the baseline were then corrected to these standard values by the straight line method.

The 1999 total field magnetic contours are illustrated on Figure 3.0 along with the 1998 contours. The data is listed in Appendix I.

VLF-EM SURVEY

-survey line separation 100 metres -survey station spacing 25 metres -survey total - 13.0 kilometres -transmitting station - Seattle - 24.8 KHz -direction faced - southeasterly -instrument - Geonics EM-16

-in-phase (dip angle) and out-of-phase (quadrature) components measured in percent

The 1999 VLF-EM profiles are illustrated on Figure 4.0 along with the 1998 profiles. The data is listed in Appendix I.

4.0 GEOLOGY AND MINERALIZATION

4.1 REGIONAL GEOLOGY

The Orofino Mountain property is located near the tectonic boundary of the Intermontane Belt and the Omineca Crystalline Belt. The regional geology has been mapped by Bostock (1940, 1941), Cairnes (1940) and Little (1961). The area is underlain by irregular, easterly trending belts of quartzite, chert and greenstone of Triassic and earlier age. These rocks belong to the Shoemaker and Old Tom formations.

These sedimentary and volcanic rocks have been intruded by Mesozoic age granitic bodies varying from gabbro to granodiorite in composition. Little (1961) has referred to these bodies as Nelson and Valhalla plutonic rocks. On the north and west Eocene volcanic rocks are block faulted against older sedimentary, volcanic and granitic units.

4.2 CLAIM GEOLOGY

The oldest rocks on the property are quartiztes of the Triassic Shoemaker Formation. These quartiztes form two relatively narrow bands that strike west and northwest across the King and King 2 mineral claims. They vary from massive to thinly bedded and are light grey in colour.

The sedimentary rocks appear to be rafts or pendants in an intrusive complex. The intrusive complex consists of three rock types; 1) Altered rocks of uncertain origin that vary from massive coarse grained hornblende gabbro and biotite diorite to finer biotite schist. 2) Pinkish, medium grained diorite containing hornblende and biotite and 3) Light grey, porphyritic and coarse grained granite containing biotite and hornblende.

4.3 MINERALIZATION

Mineralization on the Orofino Mountain property (King), consisting of quartz veins with significant gold values, forms part of the Orofino Mountain Gold Camp. The Orofino Mountain Gold Camp is adjacent to the Fairview Gold Camp and has similar characteristics.

The quartz veins on the Orofino Mountain property contain pyrite, chalcopyrite, galena and visible gold. Gold values generally increase with an increase in sulphide content. The best mineralized quartz veins appear to strike north to northwesterly with near vertical dips. Trenching and drilling has indicated left lateral offset of the King vein along steep faults with additional displacement by relatively flat structures.

Gold values on surface range from nil to greater than one ounce per ton across widths of one metre. Diamond drilling has shown that the quartz veins with gold values greater than 0.05 ounces per ton across widths of 30 centimetres persist to a vertical depth of 30 metres.

5.0 GEOPHYSICS

5.1 MAGNETIC SURVEY

A total of 10.0 kilometres of total field magnetic survey was carried out over the King 5 mineral claim during 1999. Magnetic contours for 1998 and 1999 are displayed on Figure 3.0, and the magnetic interpretation is based on the 1998 and 1999 data.

The magnetic data can generally be divided into three zones of magnetism, low, moderate and high. The high magnetic values (greater than 57,000 nT) form a northwest-southeast trending magnetic high in the central portion of the grid, extending from approximately line 700S and 900W to line 200N and 1900W. The magnetic high is flanked to the north and south by zones of moderate magnetic values (between 56,000 and 57,000 nT). Low magnetic values (less than 56,000 nT) occur in the extreme northeast corner of the grid, extending from approximately line 700N and 1900W.

Detailed geological mapping has not been carried out over the grid, so no definite conclusions can be made about the variation in magnetism. Most of the area appears to be underlain by intrusive rocks, and the differences in magnetism may be caused by a variation in the content of magnetite or mafic minerals within the intrusive.

Quartzite and chert have been mapped regionally in the vicinity of the northern portion of the grid, and the lower magnetic values in this area may be related to these less magnetic rocks.

5.2 VLF-EM SURVEY

A total of 13.0 kilometres of VLF-EM survey was carried out over the King 5 mineral claim during 1999. VLF-EM profiles for 1998 and 1999 are displayed on Figure 4.0, and the electromagnetic interpretation is based on the 1998 and 1999 data.

VLF-EM profiles show a weak to moderate response to conductivity. Topographic bias, due to up and downslope VLF instrument orientation is indicated on a number of grid lines in the southern portion of the grid. Topographic bias in rugged terrain can produce profile characteristics that resemble real conductors although they are usually broad and follow topographic contours.

A number of north and northeast trending, weak to strong conductor systems were delineated by the survey, with most conductor systems varying from 100 to 300 metres in length. The most significant conductor system (labelled A, Figure 4.0) trends northeasterly and extends from line 500N and 900W to line 200S and 1575W. This weak to strong conductor system is approximately 700 metres long, and no cause is apparent for it. A second conductor system (labelled B, Figure 4.0) also trends northeasterly and extends from line 600N and 1875W to line 700N and 1825W. This strong conductor system occurs near the contact of older intrusive rocks and younger volcanic rocks, and may represent a fault zone.

A number of other conductor systems occur within the grid area, but no causes are apparent for them.

and the general sector of the

\bigcirc

6.0 CONCLUSIONS

6.1 The magnetic survey defined three zones of magnetism (low, moderate, high) with the most prominent magnetic feature a northwest-southeast trending magnetic high in the central portion of the grid. Zones of moderate magnetic values flank the magnetic high to the southwest and northeast, with low magnetic values in the northeast corner of the grid. The grid area appears to be underlain by intrusive rocks, and the differences in magnetism may be caused by a variation in the content of magnetite or mafic minerals within the intrusive.

6.2 A number of weak to moderate to strong, north and northeast trending conductor systems were delineated by the VLF-EM survey. No causes are apparent for the conductor systems, although some may be caused by faults or shear zones that could host auriferous quartz veins.

7.0 RECOMMENDATIONS

7.1 Additional exploration is warranted on the property and should be conducted as follows:

- conduct geological mapping and prospecting determine the causes of the VLF-EM conductor systems

- conduct soil sampling over the grid area to determine source of anomalous (gold) stream sediment samples from the West Fork of Park Rill (1998 survey)

Respectfully submitted, ROVINCE CROOKER Grant P. Crooker, P.Geo., Consulting Geologist

Ulrich, G.D. (1973): Report on Geological and Geochemical Surveys of the Jetex Resources Ltd. Property, Blind Creek, B.C., Osoyoos Mining Division. Assessment report # 4,382.

9.0 CERTIFICATE OF QUALIFICATIONS

I, Grant F. Crooker, of Upper Bench Road, PO Box 404, Keremeos, British Columbia, Canada, VOX 1N0 do certify that:

I am a consulting Geologist registered with the Association of Professional Engineers and Geoscientists of the Province of British Columbia (Registration No. 18,961);

I am a Fellow of the Geological Association of Canada (Registration No. 3,758) and I am a Member of Canadian Institute of Mining, Metallurgy and Petroleum;

I am a graduate of the University of British Columbia with a Bachelor of Science degree (B.Sc.) from the Faculty of Science having completed the Major Program in Geology;

I have practised my profession as a geologist for over 25 years, and since 1980, I have been practising as a Consulting Geologist and, in this capacity have examined and reported on numerous mineral properties in North and South America;

I have based this report on field examinations within the area of interest and on a review of the technical and geological data;

I am the owner of the King Claim Group;

Respectively Submitted. CROOKER Grant F. Grooker, P'Geo., Consulting Geologist

GEOPHYSICAL EQUIPMENT SPECIFICATIONS

GEONICS LIF TED EM 16 V

Source of Primary Field VIE transmitting stations As y desired station frequency can Transmitting Stations Used: by supplied with the instrument in the form of plug-in tuning units. Two tuning units can be plugged in at ne time. A switch selects eit er station. λbout 15-25 Hz. **Operating Frequency Range:** 1- The vertical in-phase component Parameters Neasured: (tangent of the tilt angle of the polarization ellipsoid). 2- The vertical out-of-phase (quad -rature) component (the short axis of the polarization ellipsoid compared to the long axis). In-phase from a mechanical inclin-Method of Reading: ometer and quadrature from a calibrated dial. Nulling by audio tone In-phase ± 150%; quadrature ±40% Scale Range: Readability: ±1% Operating Temperature Range: -40 to 50° C. ON-OFF switch, battery testing **Operating Controls:** push button, station selector, switch, volume control, quadrature dial ±40%, inclinometer ± 150% 6 size AA alkaline cells ≈200 hrs. Power Supply: 42 x 14 x 9 cm (16 x 5.5 x 3.5 in) **Dimensions:** 1.6 kg. (3.5 lbs) Weight: Honotonic speaker, carrying case, Instrument Supplied With: manual of operation, 3 station selector plug-in tuning units (ad-"

overlapping steps.

20,000 to 100,000 gammas in 25

Total Field Accuracy: Range:

Internal Measuring Program:

A reading appears 1.5 seconds after depression of Operate Switch & remains displayed for 2.2 secs. Recycling feature permits automatic repetitive readings at 3.7 sec. intervals.

External trigger input permits use of sampling intervals longer than 3.7 seconds.

5 digit LED readout displaying total magnetic field in gammas or normalized battery voltage.

Multiplied precession frequency and gate time outputs for base station recording using interfacing optionally available from Scintrex.

Up to 5,000 gammas/meter.

8 size D cells ≈25,000 readings at 25° C under reasonable conditions.

Omnidirectional, shielded, noisecancelling dual coil, optimized for high gradient tolerance.

Complete for operation with staff or back pack sensor.

Operating Temperature Range: -35 to +60° C.
