## 1. INTRODUCTION

A VLF-EM survey was carried out on a 90 hectare grid located on the Val \#2 mineral claim. The survey was carried during the period from July 20 to 26,1999 and was funded in part by the B.C. prospectors' assistance program. The writer was assisted by Jason McLaughlin, a recent U.B.C. geology graduate.

The Val claims are located approximately 50 km north of Fort St. James, in Central British Columbia. The area is underlain by metasedimentary and volcanic rocks of the Takla Group and coeval plutons within the Quesnel Terrane. This area lies north of northwest trending Pinchi and Prince George faults, the dominant structural elements of the area. The Prince George Fault marks the boundary of the Quesnel and Cache Creek Terranes in the area.

## 2. CLAIMS, LOCATION AND ACCESS

The Val claims are located in the Kleedlee Creek area, approximately 50 km north of Fort St . James, in central British Columbia, in NTS map area $93 \mathrm{~K} / 16$. Details of the claims are as follows:

| Claim Name | Units | Tenure Number | Expiry Date |
| :--- | :--- | :--- | :--- |
| Val \#1 | 4 | 334086 | $02 / 23 / 2000$ |
| Val \#2 | 18 | 334087 | $02 / 24 / 2000$ |
| Val \#3 | 12 | 334088 | $02 / 25 / 2000$ |
| Val \#5 | 9 | 334090 | $02 / 27 / 2000$ |

The claims are accessible by road from Fort St. James via the Germansen Road, which provides all-season access. Kleedlee Creek area lies west of Germansen Road, and is accessed via InzanaMain and Esker F.S. roads. Additional local access is provided by a number of bulldozer trails and clear cuts.

The approximate centre of the Val \#2 claim is $54^{\circ} 54^{\prime} \mathrm{N}$ latitude and $124^{\circ} 17^{\prime} \mathrm{W}$ longitude.

## 3. PHYSIOGRAPHY

The area lies with the Nechako Plateau at the northern edge of the Fraser Basin physiographic region. The area is predominantly covered by glacial till, with minor glaciofluvial and

glaciolacustrine deposits (Plouffe, 1994). Glaciers moved from west to east in the southern map area and gradually turned northeastward in the northern half of the map area. The terrain in the southern map area is characterized by low rolling hills with swamps and lakes in the low-lying areas. Elevations increase toward the northeast.

## 4. GEOLOGY

The map area lies within Quesnel and Cache Creek Terranes. The boundary between Cache Creek and Quesnel Terranes lies southwest of the claims and is defined by the northwest trending Prince George Fault (Struik, 1998). The erosional remnants of Miocene basalt flows are evident in the southeast map area.

The Quesnel Terrane rocks are represented by an Early Mesozoic island-arc assemblage of the Takla Group. This group comprises sedimentary, volcanic, pyroclastic, epiclastic and coeval plutonic rocks of Upper Triassic to Early Jurassic time. The Takla Group was subdivided by Nelson et al (1991), into four informal successions. The Tas area is underlain by the predominantly sedimentary, Inzana Lake Formation and early Jurassic intrusions, but no outcrops are known on the Val \#2 claim.

## 5. HISTORY AND WORK CARRIED OUT

This area has seen several episodes of mineral exploration. Early porphyry copper exploration occurred after the release of regional airborne magnetic maps by the G.S.C. in the late 1960's. Regional airborne EM and magnetic surveys in early 1980's led to the staking and drilling of several conductors in the search for VMS deposits.

The most significant exploration success in the area to date is the discovery of the Mt. Milligan Cu-Au porphyry deposit which is located approximately 38 km northeast of the claims. This alkalic porphyry system was discovered in 1987 and resulted in a reexamination of the porphyry potential of a number of magnetic anomalies underlain by Takla Group lithologies within NTS $93 \mathrm{~K} / 16$. The Tas, Bio, Max and Hat properties were intermittently explored during the period of 1987 to 1991. Of these properties, the Tas has received the most work. Much of the drilling to date has centered on gold-bearing sulphide-rich shear-veins, which are thought to be peripheral to an alkalic porphyry system. The Val \#2 claim is located at the eastern boundary of the Tas
property and has the potential to host gold-bearing sulphide-rich shear/veins similar to the Tas Ridge Zone.

A till sampling program along the eastern boundary of the Tas property was originally contemplated on the Val claims but due to thick glaciofluvial deposits in the area (Photo 1), this concept was abandoned in favor of a VLF-EM survey.

The VLF-EM survey was carried out on the Val \#2 claim over a $61 / 2$ day period in late July. The Val \#2 claim is one of four claims held by the writer, adjacent to the Tas property. A one kilometre wide perimeter area around the Tas property has received limited exploration to date because of previous ownership conflicts. The EM survey was designed to test a portion of this area.

The survey included the reestablishment of an existing north-trending base line and the surveying of flagged lines by hip-chain and compass, to the boundary of the Tas property. A VLF-EM survey was carried at 50 metre stations and 100 metre line spacing. A few 25 metre stations were added in areas of high field strength response. A Sabre model 27 VLF-EM was used in the survey. Relative field strength measurements were used in this survey to detect conductors. A contoured plot of the field strength data is presented in Fig. 2. The data were analyzed using Probplot software. Three populations were defined with population boundaries at 54 and 38. An upper threshold of 55 is plotted in Fig. 2. Values above 55 outline a strong conductor in the southwest comer of the grid. This conductor has a length of at least 200 metres in a southeast direction. The convergence of three survey lines in the vicinity of the conductor suggests that it is also a magnetic anomaly. This conductor continues in an east-west direction along line $36+00 \mathrm{~N}$. A weaker, northeast trend is defined by three areas, exceeding the field strength anomaly threshold.

A scintillometer survey was carried out concurrently as an overburden and K-silicate alteration mapping tool. The survey was conducted with an Urtec UG-130, threshold scintillometer. Total count readings, over a ten second sample interval, were recorded. A total of 10 line-kilometres were surveyed. The survey data are appended to this report.

Total count radioactivity data were also analyzed by the Probplot software. These data are also divisible into 3 populations having boundaries at approximately 61 and 32 cps . A contoured

Photo 1 Gravel deposits on Val 122 clain

version of the data is presented in Fig. 3. The data also show northeast trends on the east half of the grid. The lower threshold of 32 cps outlines swampy areas where radioactivity is suppressed by water, organics and clay deposits. The higher threshold probably outlines a higher proportion of igneous rock fragments in gravel deposits.

## Discussion of Results

The field strength anomaly in the southwest corner of the grid may have detected a massive sulphide shear/vein similar to the Tas veins. The east-west extension of this anomaly, along line $36+00 \mathrm{~N}$ looks suspicious. The higher background along this line may be caused by a calibration error. The Sabre Model 27 VLF-EM is recalibrated at the start of each day and this may have led to lower readings in the northern area of the grid.

## 6. CONCLUSIONS

A preliminary evaluation of a VLF-EM survey suggests that a massive sulphide shear/vein system, similar to the Tas Ridge Zone veins, may extend on to the Val \#2 claim.

## 7. RECOMMENDATIONS

The VLF-EM survey on the Val \#2 claim should be expanded. The survey interval needs to be reduced to 25 metres or less. Additional lines should be surveyed in the vicinity of the largest conductor. A magnetic survey should also be considered to help define this type of target.

## Certificate of Qualifications

## STATEMENT OF QUALIFICATIONS

I, Ewe Schmidt, of 656 Foresthill Place, Port Moody, B.C. do hereby declare:
(1) I am a consulting geologist and controlling shareholder of Northwest Geological Consulting Ltd.
(2) I am a 1971 graduate of the University of British Columbia with a B. Sc. degree in geology.
(3) I am a member of The Association of Professional Engineers and Geoscientists of British Columbia and a Fellow of the Geological Association of Canada.
(4) I have practiced my profession continuously since graduation.

Feb. 22, 2000

Port Moody, B.C.

## Appendix C

Instrumentation

## Sabrac Electironic Instruments Lad.

4248 EABT HASTINGS STREET - BURNAGY, 日.C. VBC 2J5 • TELEPHONE: 291.1817

## SABRE MODEL 27 VLF-EM RECEIVER

The model 27 EM unit was deaigned originally for a large Canadian mining company to overcome the defioiencies inherent in existing unita.

The instrument is so atable and selective that completely reliable measurements can be made on distant stations without interference from nearby powerful transmitters. Stability and selectivity are especially important when making field-strength measurements, which are now being emphasized as a means of locating conductors.

This EM recelver is very compact, requires no earphones or loudspeakers and is housed in a heavj scotch asddle leatber case. All of these features add up to make an ideal one-man EM unit of unexcelled electrical penformance and mechanical ruggedness. SPECIFICATIONS

Source of Primary Field - VLF radio stations (12 to $24 \mathrm{KHz}$. ) Number of Stations - 4, selected by awitch; Cutler, Main on 17.8 KHz . and Seattle, Washington on 18.6 KBz . are standard, leaving 2 other stations that can be selected by the user.

## Types of Measurement

1. Dip angle in degrees, read on a meter-type inclinometer uitb a range of $\pm 60^{\circ}$ and an accuracy of $\pm 1^{\circ}$.
2. Field atrength, read on meter and a precision digital dial with an accuracy oxceoding $2 \%$.
3. Out of phase component, read on the field strength meter as a residual reading when measuring the dip angle.

# SABRE MODEL 27 VLF．$E M$ RECEIVER <br> －（Continued） 

Dimensions and Weight
Approx．9童＂x 2尔＂x 8年＂；Weighs 5 lbs．

## Batteries

8 alkaline penlite cells．The instrument will run continuously on 1 set of batteries for over 200 hours；So that in normal on－off use，the batteries will last all season．The battery condition under load is shown by pushing a button and reading voltage on the field strength meter．

FOR A PORTABLE, FIVE-CHANNEL

## THRESHOLD BCINTILLOMETER

The UG 130 unit is a high-performance, threshold scintillometer for measuring all gamma radiation above five selectable energy levels. Each selectable energy level may be sampled at either one or ten second time intervals. The count rate displayed on the ruggedized five digit liquid crystal display is nomalized to CPS (counts per second) regaroless of the selected sample rate. When operated in the ten second sample mode, a decimal point is displayed automatically. UG 130 may be operated in two different total count modes or in a threshold mode for the measurement of Uranium, Potassium and Thorium.

The unit is a ruggedized, compact portable field instrument with simplified operational controls. The main enclosure is a single piece aluminum casting with sealed controls and battery compartment. The unit can be operated safely in the rain or in high humidity environments.

The detector is a custom designed ruggedized Nat (Ti) crystal detector which has a volume of $66 \mathrm{~cm}^{3}$ ( 4 cu in.). The geometry of the crystal has been optimized to provide a greater detection sensitivity compared to other simiar units. An audio signal generator has been incorporated which may be operated in a continuous mode or in an adjustable count rate threshotd mode. The frequency response of the audio is five times the actual displayed count rate in CPS. This feature allows for a greater audio response to low intensity anomalies.

The UG 130 is equipped with a unique calibration source. Supplied with the unit is a set of alkaline batteries, two carrying handles, genuine leather case with shoulder strap, operating manual and shipping container.

## TECHNICAL SUMMARY (Cont)

## Selectable energy levels:

CAL-Calibration
TCI - Total count I
TC2 - Total count II
KUT - Potassium +
Uranium + Thorium UT - Uranium + Thorium T. Thorium

Detector:

Spectral shitt as a function of count rate:

Energy response linearity error:

Wisual display:
Energy response linearity
error:

## TECHNICAL SUMMARY

All energy above 0.30 MeV All energy above 0.08 MeV All energy above 0.40 MeV All energy above 1.36 MeV

All energy above $1,66 \mathrm{MeV}$ All energy above $2,46 \mathrm{MeV}$

Nal (Til crystal; Volume, $66 \mathrm{~cm}^{3}(4.0 \mathrm{cu} \mathrm{in}$.$) .$ Mechanically ruggedized.
$3 \%$ or less from 0 CPS to 15000 CPS, Integrated over an energy Interval from 80 keV to 1500 keV

Less than 2\%

Ruggedized fow temperature versiom five digit liquid crystal display. Feadout in CPS regardless of selected sample rate. Excellent visibility in direct sumlight.

When count exceeds 99999 , two dots will indicate count rate overflow.
1.0 or 10.0 seconds, auto recycle. for all enargy levels, except the 'CAL' position

Three ' $C$ ' size alkaline betteries provide 40 hours continuous operation at $23^{\circ} \mathrm{C}$ ambient without audio.

Threa indicators provide battery charge status when required. When batteries are nearly discharged, a keyed audio alam is activated, overriding count rate audio.

The count rate may be monitored in a continuous mode or may be adjusted to monitor above any background threshold.
