1.0 Summary

The Endako porphyry molybdenite deposit is located 160 kilometres west of Prince George in central British Columbia. The property consists of 374 claims totaling 424 units, covering 7741 hectares, including 25 mineral leases. The claims are 75% owned by Thompson Creek Mining Ltd. and 25% by Nissho Iwai Corporation. The Endako Mine consists of three different open pits: the Endako, Denak East, and Denak West, with a total proven and probable reserve of 84,400,000 tonnes grading 0.064% molybdenum as of October 1, 2002, and is currently operating at a rate of approximately 28,000 tonnes per day.

The composite Endako batholith stretches from Burns Lake southeast to the Nechako River and is divided into three distinct magmatic suites, covering a time period from 220 to 145 million years ago, with several noted periods of quiescence. The Endako molybdenite deposit is hosted within the Endako Quartz Monzonite, bound by younger Casey Alaskite (monzogranite) and Francois Granite to the north and south, respectively. In the mine area, Endako Quartz Monzonite has been intruded by pre-ore aplite, andesite, quartz-feldspar porphyry and porphyritic granite dykes and post-ore basaltic dykes.

Fourteen diamond drill holes totaling 5,166 feet (1,574.6 metres) were completed along the South Wall and bottom of the Endako Pit. The first 3 holes, S-02-01 to 03, were completed in January 2002, and tested the continuity and grade of molybdenite mineralization below the current pit bottom. In March, S-02-04 and 05 tested a significant zone of uncertain grade in the south wall with the aim of enhancing the economics the proposed South Wall Pushback. Finally, between April 23rd and May 3rd, 2002, a series of 9 holes were completed from west to east along the current pit bottom at the south wall, again to determine grade and continuity of mineralization and assess the economics of the potential pushback.

Ore grades were encountered in all 14 holes although the distribution of high-grade mineralization continues to be erratic. Molybdenite mineralization occurs mainly in discrete quartz veins and stockworks within weakly to strongly kaolinized Endako Quartz Monzonite and fractured Quartz-Feldspar Porphyry dykes. Minor MoS_2 also occurs in quartz-kaolinite shears. Most MoS_2 is concentrated along vein selvages and is easily liberated during crushing and grinding, but MoS_2 in a fine-grained component called "black quartz ore" is difficult to recover.

Attempts to identify potential lower recovery zones in core logging were inconclusive. Standard bench-scale metallurgical tests were run to try to model zones of similar recovery. Based on these data and others, a comprehensive evaluation of the economic viability of a pushback along the South Wall of the Endako Pit is in progress.

2.0 Introduction

2.1 Terms of Reference

The principal author was contracted by Thompson Creek Mining Ltd. to assist in the design and implementation on an infill diamond drilling program along the southern margin of the Endako Open Pit. This report describes the results of 5,166 feet (1,574.6 metres) of diamond drilling in 14 holes completed between January 23 – May 3, 2002, and fulfills reporting requirements for assessment work on the mineral claims listed in Appendix 3. The authors selected all drill sites, supervised drilling, and are jointly responsible for all geological interpretations described in this report. Christopher J. Wild, P.Eng., logged all core and supervised core sampling.

2.2 Property Description and Location

The Endako porphyry molybdenite deposit is located 160 kilometres west of Prince George in central British Columbia (Figure 1). The centre of the property sits at 54^0 02'N and 125^0 07'W, or 5990212mN and 362020mE, UTM Zone 10, NAD 83.

The property consists of 374 claims covering 7741 hectares, including 25 mineral leases (Figure 2). Appendix I contains information on each individual claim. The claims are 75% owned by Thompson Creek Mining Ltd and 25% by Nissho Iwai Corporation.

The Endako Mine consists of three different open pits: the Endako, Denak East, and Denak West, with a total proven and probable reserve of 84,400,000 tonnes grading 0.064% molybdenum as of October 1, 2002 (Schroeter, 2003), and is currently operating at a rate of approximately 28,000 tonnes per day. Most of that reserve is in the Endako Pit. Figure 2 shows the location of pits and tailings ponds relative to the property outline.

2.3 Accessibility, Climate, Local Resources, Infrastructure and Physiography

The Endako Mine Property lies within the Interior Plateau, characterized by broad valleys, flat-topped hills, and generally gently rolling terrain. Glaciation moved across the area from the west leaving a distinct east-west grain. Elevations range from 670 metres at Endako village to 1,070 metres at the crest of the Endako Pit. Vegetation consists of relatively open pine forests.

Access to the mine is provided by 10 kilometres of paved road Highway 16, from the village of Endako, northeast of the mine. A network of mine roads provides excellent access to most parts of the property. Prince George, the largest service centre in northern British Columbia, is 160 kilometres east along Highway 16. Fraser Lake, 20 kilometres to the northeast, is the nearest significant community to the mine.

2.4 Property History

The Endako deposit was discovered in 1927 by local prospectors and explored with a short shaft and tunnel. The leached nature of the mineralization, extensive overburden, low grades, and lack of precious metals led to the claims being dropped in 1958. In 1962, R and P Metals Corporation acquired the property and after encouraging diamond drilling results incorporated Endako Mines Ltd. Further diamond drilling and bulk sampling led to a positive production decision in 1964 and official mine opening on June 8, 1965. Production was expanded from 9,070 tonnes per day to 24,500 tpd in 1967, 27,000 tpd by 1980, and 30,000 tpd in 1993.

Exploration has been ongoing from the mid-sixties to the present, including geochemical sampling, diamond and percussion drilling. Recent work included 14 diamond drill holes in 1989, 22 more in 1992,

44 in 1993, and 19 in 1994. Placer Dome Inc. conducted all these programs. In 1997, Endako was sold to Thompson Creek Mining Ltd. (75%) and Nissho Iwai Moly Resources Inc. (25%). A modest drill program and geophysical survey were carried out in 1997.

In 2001, 5 diamond drill holes totaling 772.7 metres were completed on two target areas (Wild and Thompson, 2002). Three holes were completed in the Water Tank Area to the northeast, and 2 more in the SE Dump Area to the southeast. All core was logged, split for sampling, and assayed for MoS_2 at the Endako Mine Laboratory.

2.5 2002 Program

A total of 5166 feet (1575 metres) of diamond drilling in 14 holes completed in three stages from January 23 – May 3, 2002. The first 3 holes, S-02-01 to 03, tested the continuity and grade of molybdenite mineralization below the current pit bottom. S-02-04 and 05 tested a significant zone of uncertain grade in the south wall with the aim of enhancing the economics the proposed South Wall Pushback. Nine holes, S-02-06 to 14, tested the south wall zone below the current pit bottom, again to determine grade and continuity of mineralization and assess the project economics. As part of that assessment, the entire core was sampled for metallurgical testing.

3.0 Geological Setting

3.1 Regional Geology

The composite Endako batholith stretches from Burns Lake southeast to the Nechako River and is divided into three distinct magmatic suites, covering a time period from 220 to 145 million years ago, with several noted periods of quiescence. The oldest, the Stem Creek Suite, recently dated at 219.3 Ma (Villeneuve et al, 2001), consists of foliated gabbros and diorites within the northern and eastern part of the batholith. The Stag Lake Suite consists of mafic to intermediate plutons ranging in age from 180 – 161 Ma and forms the western, northeastern and eastern margins of the Endako batholith. The Francois Lake Suite is divided into the older Glenannan subsuite (157 – 155 Ma) and the Endako subsuite (149 – 145 Ma), and consists of mainly felsic plutons. The Endako orebody is hosted in the Endako phase quartz monzonite and is genetically associated with the terminal stages of magmatic activity, the Casey monzogranite, dated at 145 Ma. (Villeneuve et al, 2001).

3.2 Property Geology

The Endako molybdenite deposit is hosted within the Endako Quartz Monzonite, bound by younger Casey Alaskite (monzogranite) and Francois Granite to the north and south, respectively. In the mine area, Endako Quartz Monzonite has been intruded by pre-ore aplite, andesite, quartz-feldspar porphyry and porphyritic granite dykes and post-ore basaltic dykes.

The deposit is aligned to the northwest with a maximum length of 3360 metres, a width of 370 metres and a maximum depth of 370 metres. Four structurally distinct zones have been identified from east to west, as Endako East, Endako West, Denak East, and Denak West (Bysouth and Wong, 1996). Five major fault trends have also been identified: the South Boundary Fault to the south, the Casey Fault further to the northeast, the north-trending Tailings Creek Fault also to the northeast, and West Basalt Fault at the west end of the Endako Pit and the Denak West Fault between the Denak East and Denak West Pits (Figure 3).

3.2.1 Lithology

Endako Quartz Monzonite

Pink to orange-pink Endako Quartz Monzonite is the dominant rock type encountered in diamond drilling in the Endako Pit. This phase is equigranular to weakly porphyritic with grain-size typically 3-4mm with K-feldspar crystals ranging up to 7mm. Its composition is typically 30% quartz, 35% K-feldspar, 30% plagioclase and 5-10% variably chloritized biotite. In the ore zone, the unit is variably kaolinized ranging in colour from pale greenish to creamy white.

Aplite Dykes

Aplites are typically pink and fine to medium-grained quartz-K-feldspar-rich dykes. These dykes range up to several metres thick, show sharp contacts with host rocks, and exhibit no chilled selvages. In the ore zone, aplite dykes are often mineralized with thin stockwork quartz-molybdenite veinlets. Above the South Basalt Fault, aplite often hosts quartz-pyrite stringers.

Basalt (Andesite) Dykes

Basaltic dykes are dark greenish grey, fine-grained and locally porphyritic in the Endako Pit, and often associated with major fault systems. The South Basalt Fault is the best exposed fault – basalt dyke structure, and was intersected in diamond drillholes S-02-04 and 05.

3.2.2 Structure

Pre-ore dykes associated with the Endako deposit strike to the northeast with vertical to steep westerly dips. These dykes have sharp contacts with little evidence of any deformation during intrusion. Post-ore basaltic dykes are marked by extensive gouge and brecciation, associated with major structures that likely predate ore deposition. The South Boundary Fault appears to a major controlling structure for both subsidiary structures and later hydrothermal activity (Bysouth and Wong, 1996).

As mentioned above, 4 structurally distinct zones have been identified from east to west: Endako East, Endako West, Denak East, and Denak West (Bysouth and Wong, 1996). These zones are separated by steep northeast-trending structures including the eastern pre-ore dyke swarm (between Endako East and West), West Basalt Fault, and Denak West Fault (Figure 3). The Endako East zone hosts veins that dip shallowly to the northwest. Endako West veins dip to the south; the South Basalt Fault appears to be a post-ore component of this south vein system (Bysouth and Wong, 1996). Ore structures in the Denak East dip southwesterly, turning abruptly to westerly dips in Denak West. Secondary controls include northeast trending structures with moderate southeast dips.

3.2.3 Mineralization and Alteration

Mineralization consists of molybdenite, pyrite, magnetite, minor chalcopyrite, and rare bornite, bismuthite, scheelite, and specularite. The orebody consists of a series of subparallel or en echelon quartz-molybdenite-pyrite veins and stockworks of thin veins, veinlets and mineralized fractures. Mineralization occurs in milky white to banded or ribboned quartz veins that are often brecciated and healed by quartz and late stage calcite and minor chalcedony. Molybdenite varies in grain size from very coarse and greasy to microscopic grains in quartz, referred to as "black quartz ore". A pyrite zone lies to the south of and adjacent to the orebody, with a transitional boundary in the immediate hangingwall of the South Basalt Fault.

Hydrothermal alteration occurs in three phases within the Endako ore zone. K-feldspar bearing envelopes develop around quartz-molybdenite veins and on barren quartz veins in the footwall of the deposit. Sericite envelopes consisting of quartz, sericite and pyrite are developed around quartz-molybdenite and quartz-magnetite veinlets in the orebody, and quartz-pyrite veins in the pyrite zone. Kaolinization is pervasive throughout the orebody, ranging from weak to intense.

4.0 Diamond Drilling

Fourteen diamond drill holes totaling 5,166 feet or 1,574.6 metres were completed along the South Wall and bottom of the Endako Pit. The first 3 holes, S-02-01 to 03, were completed in January 2002, and tested the continuity and grade of molybdenite mineralization below the current pit bottom. In March, S-02-04 and 05 tested a significant zone of uncertain grade in the south wall with the aim of enhancing the economics the proposed South Wall Pushback. Finally, between April 23 and May 3, 2002, a series of 9 holes were completed from west to east along the current pit bottom at the south wall (Figure 4), again to determine grade and continuity of mineralization and assess the project economics. As part of this third phase program, all the core was sampled for metallurgical testing.

The core from S-02-01 to S-02-05 was split using a manual splitter with half the core put in plastic bags for delivery to the assay lab and the other half retained for future reference. Core is stored in the core storage area on site; pulps are stored in the core shack. All core for drillholes S-02-06 to S-02-14 was sampled for metallurgical test work. The pulps and rejects for those 9 holes are also stored in the core shack. Sample intervals were usually 10 feet in length, varying between 2 and 18 feet. All core samples were analyzed for MoS_2 at the on site assay lab. Analytical procedures are described in Appendix 6; assay reports are included in Appendix 7.

S-02-14	28790	29235	2662	155	60	357	108.8
Total						**5,166**	**1,574.6**

4.1 S-02-01 to S-02-03

Three short holes tested areas of uncertain grade, based on previous drilling. All 3 vertical holes were collared near the centre of the pit bottom (Figure 4). The easternmost hole, **S-02-01**, encountered Endako Quartz Monzonite (EQM) hosting relatively weak quartz-molybdenite veining (Figure 5). Core was sampled between the bottom of the casing at 15 feet to the end of the hole at 257 feet, returning a weighted average grade of 0.085% MoS_2 over 242 feet. Aplitic or Quartz-Feldspar Porphyry (QFP) dykes were encountered from the bottom of the casing (15 feet) to 37.5 feet and 128.3 – 141.0 feet. Grades are elevated in and adjacent to these dykes.

S-02-03 was collared 290 feet northwest of S-02-01, encountering a few narrow QFP dykes and only minor veining in EQM (Figure 7). None of the samples collected returned results greater than 0.1%

MoS2. The hole averaged 0.046% MoS2 over 183 feet between 15 – 257 feet (collar to end of hole), including 0.057% MoS2 over 145 feet between 15 – 160 feet.

A further 620 feet to the north-northwest, **S-02-02** intersected no dykes and low to moderate grades hosted in EQM. Grades drop somewhat below 150 feet to the end of the hole at 207 feet (Figure 6). The hole averaged 0.081% MoS2 over 183 feet (from 24 – 207 feet), including 0.092% MoS2 over 126 feet between 24 feet (bottom of casing) and 150 feet.

4.2 S-02-04, S-02-05

Two holes collared at an elevation of 2970 feet on the southeast portion of the South Wall, tested a significant gap in the geologic block model. Both holes were inclined at moderate angles to the north and drilled through the South Basalt Fault (SBF) to an elevation of around 2075 feet. The SBF, an important structural feature of the Endako orebody, divides the south wall into an upper, sub-ore pyritic block ("pyrite zone"), and a lower, more strongly kaolinized ore zone. Both holes returned lower than anticipated grades, especially below and adjacent to the SBF (Figure 8).

In **S-02-04**, one 40-foot interval in the "pyrite zone" assayed 0.174% MoS_2. One 10-foot sample near the hangingwall contact of SBF assayed 0.550% MoS_2. However, most samples in the "pyrite zone" returned assays <0.05% MoS_2. Below the SBF, grades were higher and more evenly distributed, hosted mainly in EQM. The entire 377 feet below the SBF averages 0.101% MoS_2.

In **S-02-05**, grades in the "pyrite zone" are similar to those in S-02-04. The 380 feet below the SBF averages 0.077% MoS_2. Lower grades are the result of relatively long intervals of weakly mineralized QFP dykes, from 494 – 702 feet. These dykes typically strike northeasterly, dipping steeply to the northwest. These results largely reflect the grade within the dykes.

4.3 S-02-06 to S-02-14

Drillholes S-02-06 to S-02-14 stretched over 2300 feet along the South Wall (Figure 4). All but 2 were collared on 2662 Bench. The purpose of this phase of drilling was to provide geological and metallurgical data to determine the feasibility of a proposed South Wall Pushback. Metallurgical testing was also conducted to link various styles on mineralization with recoverability. Unfortunately, collar locations had to be modified due to ongoing instability from the Southeast Failure.

The westernmost hole, **S-02-06**, drilled vertically to a depth of 317 feet, intersected a series of 1-7 centimetre quartz-MoS_2 veins and weakly mineralized gougy shears in EQM. Moderate grades are fairly evenly distributed throughout the hole (Figure 9), averaging 0.096% MoS2 between 13 – 317 feet.

S-02-07 is located 190 feet southeast of S-02-06, and intersected a couple of thicker veins that boosted two 10-foot sample intervals to >0.44% MoS_2. The top of the hole, between the bottom of the casing and 250 feet averages 0.113% MoS_2 over 236 feet. Grades weaken below 250 feet, averaging only 0.036% MoS_2 over 67 feet (Figure 10).

S-02-08 and **S-02-09** were collared 385 and 640 feet east of S-02-07, respectively, and drilled to the south at an inclination of –68°. Both holes encountered considerable shearing and veining in EQM with moderate but erratic grades, especially in S-02-09. In that hole, an interval from 20-30 feet downhole assayed 1.67% MoS_2. In S-02-08, grades drop off significantly below 190 feet (Figure 11). A smaller drop occurs at 240 feet in S-02-09 (Figure 12). In both, a decline in the frequency and thickness of quartz-MoS_2 veins is responsible for lower grades. In S-02-08, grades average 0.123% MoS_2 between 20 – 160 feet and only 0.037% MoS_2 from 160 – 287 feet. S-02-09 averages 0.150% MoS_2 between 12 – 287 feet (bottom of the casing to end of hole), including 0.199% MoS_2 between 20 – 210 feet. A 60-centimetre thick seam of green clay gouge, identified at 208 feet in S-02-09, is tentatively correlated with the Southeast Fault.

S-02-10 was collared approximately 1225 feet southeast of S-02-09 and 500 feet north of S-02-04/05 (Figure 4). A vertical hole, S-02-10 intersected weakly altered and sheared EQM hosting a series of thin, moderately spaced quartz-MoS_2 veins and veinlets (Figure 13). Grades averaged 0.097% MoS_2 over the 305 feet sampled, including 0.128% MoS_2 between 40 – 200 feet downhole.

Immediately east of the Southeast Failure run-out, **S-02-11** intersected a series of thin quartz-MoS_2 veins and weakly mineralized shears in weakly to moderately kaolinized EQM (Figure 14). A couple of veins greater than 10 centimetres thick help to locally boost the grade. Intervening grades are quite low; the average from 21 – 317 feet is 0.095% MoS_2 and from 40 – 240 feet is 0.120% MoS_2.

Another vertical hole, **S-02-12**, was collared 195 feet southeast of S-02-11. Aplitic QFP dykes dominate from 225 feet to the bottom of the hole at 317 feet. Above 225 feet, weakly to moderately kaolinized EQM hosts a series of thin quartz-MoS_2 veins up to 15 centimetres thick (Figure 15). Grades are only 0.041% MoS_2 from 11 – 80 feet due to a lack of mineralized veins and associated kaolinization. Between 80 – 230 feet, strongly mineralized veins result in an average grade of 0.138% MoS_2. Below 230 feet, the average grade drops again to 0.061% MoS_2.

A second hole, **S-02-13**, was collared near S-02-11 and drilled at a –45° inclination toward 300° azimuth to partially test the zone rendered inaccessible by the Southeast Failure. An absence of veins from 18 – 190 feet suggests that the orientation of the hole is less than optimal to test flat to westerly dipping vein systems. Significant veining was intersected between 190 – 310 feet, falling off again to the end of the hole at 427 feet (Figure 16). No significant dyking was encountered. The interval from 18 – 190 feet averages 0.039% MoS_2, 190 – 310 feet averages 0.142% MoS_2, and 310 – 427 feet averages 0.048% MoS_2.

The easternmost hole, **S-02-14**, was collared approximately 260 feet southeast of S-02-10 and drilled at an inclination of –60° toward 155° azimuth. The hole intersected considerable QFP dyking and related shearing. Quartz-MoS_2 veining consists of finer veinlets and stockworks resulting in a more even distribution of grade throughout the hole. A few thicker, high-grade veins were identified between 230 – 260 feet. The average grade of the hole from 13 – 357 feet is 0.068% MoS_2, including 0.218% MoS_2 between 230 – 260 feet.

5.0 Conclusions and Recommendations

1. A diamond drill program consisting of 14 holes totaling 5166 feet or 1574.6 metres was completed in 3 phases between January and May, 2002. All 14 holes are located within the Endako Pit.

2. All drill core was assayed for MoS2. Core from drillholes S-02-01 to S-02-05 was split with half the core sent to the Endako assay lab and half stored for future reference. All core for drillholes S-02-06 to S-02-14 was sampled for analysis and metallurgical test work.

3. Ore grades were encountered in all 14 holes although the distribution of high-grade mineralization continues to be erratic. Thus, data from this program will be useful in further definition of potentially mineable zones below the current pit bottom and in the South Wall.

4. Molybdenite mineralization occurs mainly in discrete quartz veins and stockworks within weakly to strongly kaolinized Endako Quartz Monzonite and fractured Quartz-Feldspar Porphyry dykes. Minor MoS2 also occurs in quartz-kaolinite shears. Most MoS2 is concentrated along vein selvages and is easily liberated during crushing and grinding but a variable, fine-grained component called "black quartz ore" is difficult to recover.

5. Attempts to identify potential lower recovery zones in core logging were inconclusive. Standard bench-scale metallurgical tests were run to try to model zones of similar recovery.

6. A comprehensive evaluation of the economic viability of a pushback along the South Wall of the Endako Pit is ongoing.

Appendix 1
2002 Program Expenditures

2002 EXPLORATION EXPENSES - ENDAKO MINES

	January 21 - February 15, 2002		DDH #'s:	S-02-01, 02 & 03
LDS		Drilling Supplies and Labour		$10,536.19
Wildrock	Jan 1 - Feb 5, 2002	Consulting		$ 1,491.33
Mine Expenses				
	Assay	*(Internal)*		$ 596.78
	Labour	*(core splitter...)*		$ 675.62
Subtotal				$13,299.92
Overhead	@ 10%		10% *of $ 13,299.92*	$ 1,329.99
Total				***$ 14,629.91***

	March 8 - March 31, 2002		DDH #'s:	S-02-04 & 05
LDS		Drilling Supplies and Labour		$19,939.00
Wildrock		Consulting		$ 2,455.46
Mine Expenses				
	Assay	*(Internal)*		$ 1,170.93
	Labour	*(core splitter...)*		$ 1,649.22
	Sperry Sun Rental			$ 150.00
Subtotal				$25,364.61
Overhead	@ 10%		10% *of $ 25,364.61*	$ 2,536.46
Total				***$ 27,901.07***

	Apr 21 - May 15, 2002		DDH #'s:	S-02-06 to 14
LDS		Drilling Supplies and Labour		$38,388.00
Wildrock	Jan 1 - Feb 5, 2002	Consulting		$ 4,273.72
Mine Expenses				
	Assay	*(Internal)*		$ 330.00
	Labour	*(core splitter...)*		$ 279.14
Subtotal				$43,270.86
Overhead	@ 10%		10% *of $ 43,270.86*	$ 4,327.09
Total				***$ 47,597.95***

SUMMARY GEOLOGICAL REPORT

Wildrock	January 2003	Consulting	***$ 1,000.00***

Total expenditures for Endako Mines 2002 DDH Program	***$ 91,128.93***

Appendix 2
Statement of Qualifications

I, *Christopher J. Wild, do hereby certify that:*

1 I am a consulting geological engineer currently residing at #7 – 52 Lakeview Avenue, Williams Lake, British Columbia.

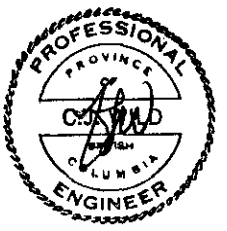
2 I am a graduate of the University of British Columbia, Geological Engineering, Mineral Exploration Option (1984).

3 I have worked in mineral exploration and mine geology in Canada and Argentina on a full-time basis since 1985.

4 I am Registered Member of the Association of Professional Engineers and Geoscientists of the Province of British Columbia (1994), and am a member of the Canadian Institute of Mining and Metallurgy (CIM).

5 I supervised most of the exploration activity and logged all the core documented in this report.

6 I hold no interest in Thompson Creek Mining Ltd., nor Nissho Iwai Corp., nor their subsidiaries; or in the claims described herein nor any adjoining properties.



Christopher J. Wild, P.Eng.
Consulting Geological Engineer

March 5, 2003

Appendix 2
Statement of Qualifications

I, Ian Thompson of Thompson Creek Mining, Endako Mines Division, Endako BC, do hereby certify that:

1. I am a mining engineer and currently hold the position of "Mine Engineer" with Endako Mines.
2. I am a Registered Member of the Association of Professional Engineers and Geoscientists of British Columbia (2002), and am a member of the Canadian Institute of Mining and Metallurgy (CIM)
3. I am a graduate of the University of British Columbia with a B.A.Sc. in Mining and Mineral Processing in 1989.
4. From 1989 until present, I have been engaged in both underground and open pit operations in Manitoba and British Columbia in both engineering and operations capacities.
5. I personally participated in the planning and supervision of the diamond drill program.

Ian Thompson, P.Eng.
Mine Engineer.

March 12, 2003

Analytical Procedures

RA-057

PREPARATION OF LOW GRADE MOLYBDENUM
SAMPLES FOR AA ANALYSIS

SCOPE: This document applies to all samples within the range of the concentration present in Rougher Tail, Flotation Feed and First Cleaner Tails. Mine drill hole cuttings and diamond drill core samples fall within this category.

PURPOSE: The purpose of this document is to describe the steps required for the analysis of samples containing 0.750% MoS_2 or less.

PROCEDURE: Weigh 2 grams into 250 ml beakers. Add 40 ml of 30% HCl, cover and digest for 10-15 minutes on a 3 switch plate. Filter through #2 fast fold papers into waste catch beakers. Wash 2 times with hot water to ensure that all oxides are removed.

NOTE-Before filtering, if oxide content of sample is required, place a 200 ml Phosphoric flask containing 25 ml of $AlCl_3$ solution under the funnel. Wash the sample 3-4 times, add 10 ml of HCl, cool and bulk to the mark. The sample is ready for analysis on the AA.

Now place the filter papers containing the sulphides back into the beakers and place in front of the fuming hood. Add 5 ml HCl, 10 ml HNO_3 and 8 ml of $HCLO_4$ to the samples. The addition of these acids must be done in this order and done in front of the fuming hood. Put covers back on the beakers.

Place the beakers on a 3 switch plate until vigorous white fumes have evolved. Move to the edge of the hot plate and fume a further 3-5 minutes. Remove from the hot plate and cool.

Wash the lids and sides of the beakers with distilled water and add 20 ml of concentrated HCl. Place on the hot plate and bring to a boil. Boil at least 3 minutes. Remove from the hot plate and place on the beaker shelf over the funnel racks in numerical order. Rinse off the lids using distilled water in a plastic wash bottle.

NOTE: Rougher tail and scavenger tail samples are filtered into 100 ml flasks, containing 12 ml $AlCl_3$. All other samples are filtered into 200 ml Phosphoric flasks containing 25 ml of $AlCl_3$ solution. This effectively doubles the concentration, increasing the accuracy of the assay. Standards for this range of samples must be divided in half. E.g. 0.040 to 0.020, 0.066 to 0.033 etc.

To continue---filter into the flasks using #2 fast fold Whatman papers. Wash 3-4 times with hot water. Bulk flasks to the neck and cool to 20 C. Bulk to line, stopper and shake well.

The samples are now ready for analysis on the Atomic Absorption Spectrophotometer.
