1.0 Introduction

Bright Star Ventures Ltd. optioned the BJP 1, BJP 2, and BJP 3 claims during 2001 in order to evaluate the mineral potential of the Tulameen ultramafic complex. These claims occur in the Similkameen Mining Division, located approximately 21.5 kilometers west of the town of Princeton, in South Central British Columbia. These claims were optioned from Cusac Gold Mines, who hold a joint venture agreement with Aboriginal Investments Ltd. This property was subjected to a regional B-horizon soil geochemistry survey during the period from July 1st till August 30th, 2002. This report describes the results of the survey.

2.0 Property Location and Access

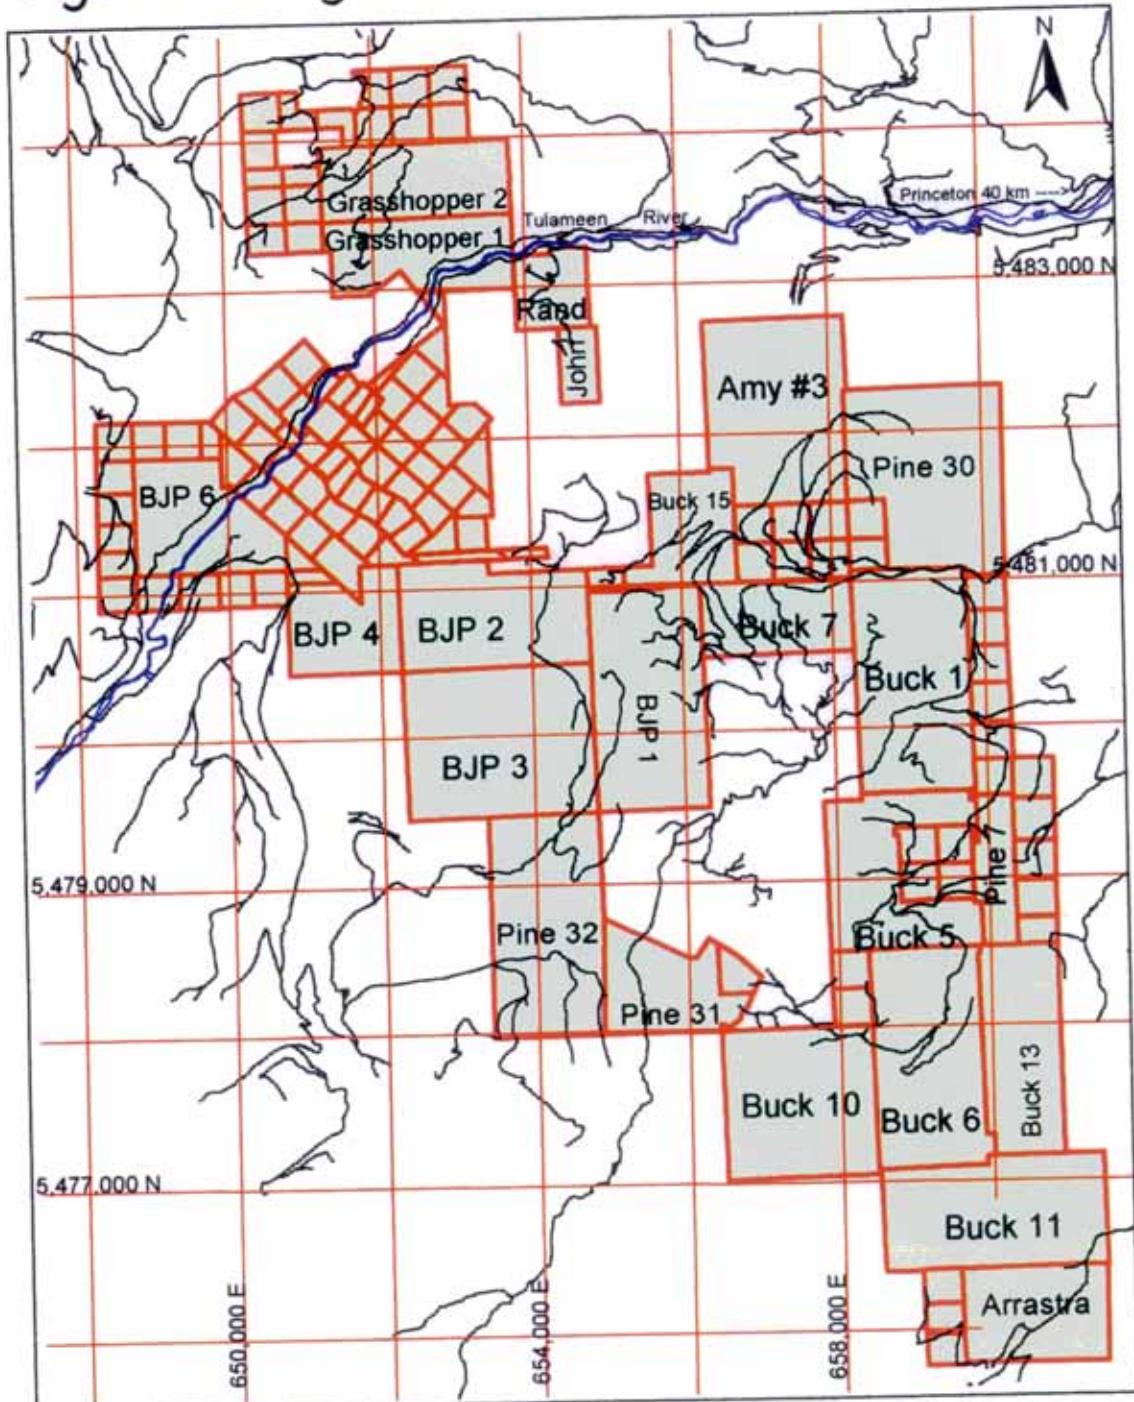

The Tulameen ultramafic complex is located in the Cascade Mountains of southwestern British Columbia, approximately 26 kilometers northwest of the town of Princeton, B.C. The property is located on 1:20,000 scale NTS mapsheet M092H046, centered at approximately 49 degrees - 27' - 48" north latitude and 120 degrees - 48' - 34" west longitude. Access to the property is via a 16 km paved road from Princeton to Coalmont and then branching off to the south on the all-season Granite Creek road to seasonal logging roads that go to the headwaters of Blakeburn Creek. Elevations in the area range from approximately 3,000 feet asl along the Tulameen River valley, to more than 5,000 feet asl on Olivine Mountain. Major tributaries within the Tulameen River basin in the area of interest include Olivine, Granite and Blakeburn Creeks.

The majority of the property is covered by mature fir forest, although it is logged out in many areas. Forested areas are generally covered by glacial till. Glaciofluvial deposits have also been observed at lower elevations in the river valley. Non-glacial features include massive outcrops with little or no soil development, talus slopes and fluvial terraces. The region lies in a transition zone between the Cascade Mountains to the west and the Interior Plateau, located further to the east.

The climate is transitional between that of the dry southern interior and the much moister Cascade and Coast Mountain ranges located to the west. Summers are hot and dry while winters are cold with heavy snowfall at high elevations. Patches of snow can remain on the plateau areas of Olivine and Grasshopper Mountain until early June, and snowfalls can take place as early as mid-September. Figure 1 is a 1: 250,000 scale property location map for the BJP 1, 2, and 3 claims in the Tulameen area that were optioned in 2001 by Bright Star Ventures Ltd., while Figure 2 is a more detailed claim map of the property.

3.0 Previous Work

One of the earliest gold rushes in Canadian history occurred along the Tulameen River and its tributaries during the summer of 1885. During that year, John Chance discovered coarse visible gold in surficial gravels along Granite Creek near the confluence with the Tulameen River. By October of that year the town of Granite City had grown to a population of 2000 people. Granite Creek was staked over a length of five miles to the south from the Tulameen River and sixty-two companies had alluvial mining operations.

During the late 1800's the Tulameen District was the most important producer of platinum in North America. Platinum was recovered with the placer gold from the Tulameen River and her tributaries, including Granite, Cedar, Slate, Britton and Lawless Creeks. The platinum occurred as a fine, hard, silver-white lustrous metal with a high specific gravity in the sluice boxes and gold pans, along with the gold and heavy concentrations of black sands (magnetite and chromitite). In some areas there was more platinum than gold in the concentrates. Platinum nuggets up to 0.5 ounces were found, and during the year 1888, 1,500 ounces of platinum was recovered. This gold / platinum rush subsided over the following ten years, and in 1907 a fire razed the town of Granite City, leaving only a few buildings remaining and abandoned at this time. Total platinum production from the alluvial operations was estimated to be approximately 20,000 ounces from the area between 1885 and 1934 (O'Neil and Gunning, 1934).

Preliminary geological investigations by government agencies in the Tulameen area included work by Kemp (1902) who examined the geological relationship between the alluvial platinum occurrences and the surrounding ultramafic rocks for the U.S. Geological Survey, while Camsell (1913) conducted several years of geological study of the Tulameen area for the Geological Survey of Canada. Poitevin (1924) examined similarities between the platinum-bearing rocks of the Tulameen area with similar ultramafic complexes that occur in the Ural Mountains of Russia.

O'Neill and Gunning (1934), Rice (1948), and Eastwood (1959) also made significant contributions to understanding the geological setting for platinum mineralization in the Tulameen area. Findlay (1969) conducted detailed petrological and geological studies and identified platinum minerals in bedrock during the course of his Ph. D. research on the Tulameen ultramafic complex. He established an association between chromite and platinum values in the central core of the intrusion. The mineralogical, geochemical, and petrological associations relative to the distribution of platinum group elements in the

complex were also studied and documented by St. Louis (1982, 1986), and more recently by Rublee (1986, 1994).

Evenchick et. al., 1986, Nixon (1987, 1988, 1990,), and Nixon and Rublee (1987) classified the Tulameen Alaskan-type ultramafic complex as potential hosts for commercially exploitable deposits of platinum metals. The structural setting of this complex was documented and compared with other Alaskan-type ultramafic intrusions in Alaska and the Ural Mountains in Russia.

Nixon et. al.(1989), were able to trace the source of platinum nuggets in the Tulameen River to chromitite horizons within the dunite core of the Tulameen ultramafic complex by matching the phase chemistry of the gangue minerals spinel and olivine, in both alluvial nuggets and bedrock lode occurrences. Outcrops of dunite within the Tulameen ultramafic complex were metallurgically tested for the economic potential of the industrial mineral olivine. The Foundry Section of the Physical Metallurgy Research Laboratories in Ottawa (CANMET) conducted several tests on unaltered dunite samples. White (1987) reported that initial test results from the CANMET research were encouraging and that there is economic potential for the industrial mineral olivine on Grasshopper Mountain. These conclusions were based upon the results from coarse fractions ranging from 1.5 inches to 4.5 inches in size.

South of the Tulameen River, the ultramafic complex has been subjected to sporadic exploration programs for platinum group metals, iron, base metals and gold. Exploration companies and individual prospectors completed soil geochemistry surveys, ground magnetic, VLF-EM-16 geophysics and a very limited amount of diamond drilling. This area represents approximately 75% of the entire Tulameen ultramafic complex, yet it has remained highly under-explored to date. Poor access into this part of the complex inhibited the amount of exploration conducted in this part of British Columbia.

Early mineral exploration over the southern half of the complex commenced during the 1960's, with Fort Reliance Minerals Limited conducting prospecting, geological mapping and trenching over the ultrabasic rocks on four blocks of claims (Blocks A, B, C, and D) covering Olivine Mountain, Tanglewood Hill, and two areas located south and west of Lodestone Mountain. Exploration was directed towards copper and nickel occurrences, and several copper showings were discovered during this period. Two trenches were excavated on Claim Block "C", on claims FRM 92 and FRM 99, which are situated near the southern limit of the complex between Newton Creek and Arrastras Creek. Trench mapping and sampling revealed greater than 1% copper over widths of 6 meters. North to northwest trending fracture zones within hornblende clinopyroxenite control the strike of sulfide mineralization. A "shattered zone" and minor quartz veining was plotted on the trench map, suggesting that there may have been brecciation and open space filling associated with the fracture system. Rhythmic layering was recognized in the clinopyroxenite. In the same report it was mentioned that Anaconda drilled a copper showing immediately south of Block "C", at a sulfide occurrence located along Arrastras Creek, near the very southern limit of the Tulameen ultramafic complex during this same period.

Inter Canadian Development Corp. optioned the Lode I, III and IV claim groups and earned in a 90% interest in the Lode II claim block (20 units). Allen (1987) collected 229 soil, silt and rock samples along three widely spaced reconnaissance lines. Soil samples were collected from B-Horizon soils from a depth of 20 to 40 centimeters every 50 meters. A Scintrex MP Proton magnetometer instrument was used to conduct a magnetometer survey along the same widely spaced lines. Allen (1987) noticed a broad general increase in magnetic readings towards the eastern margin of the complex. Allen and Brownlee (1989) conducted additional geophysical surveys over the area in 1988 and identified four VLF-EM-16 conductors within mafic to ultramafic rocks. Three of the four conductors are present on the BJP #1 claim block.

Two of the four conductors were spatially associated with elevated platinum, palladium, copper, nickel and chromium values in B-horizon soils that were collected during that program. During the next year follow-up B-horizon soil surveys confirmed the elevated and anomalous values that were obtained during the initial survey (Allen and Brownlee, 1989).

In late 1998 Aboriginal Investments acquired a 100% interest in claims BJP 1,2 and 3 which covered 53 units. Perry (1999) collected anomalous bedrock samples, mostly from outcroppings located within 200 meters of the overburden-covered VLF-EM-16 conductors. Values ranged up to 315 ppb Pt and 633 ppm Ni in fine-grained magnetite-rich hornblende pyroxenite. Some minor malachite staining was observed and sampled in the vicinity of the east-central conductor and slightly elevated Pt and Pd values were detected at the lab.

Lloyd Geophysics was hired to confirm the locations of the VLF-EM-16 anomalies and six trenches were demarcated in order to excavate and identify the cause for the electromagnetic anomalies. Thirteen B-horizon soils samples and 18 A-horizon humus soil samplers were collected and submitted for Pt-Pd-Au-Cu-Cr-Ni along with other elements which were analyzed by conventional fire assay, graphite furnace AA and multi-element ICP methods. Slightly elevated values of Pd and Cu in B-horizon soils were obtained in both the B-horizon soils and the humus samples in the vicinity of the east-central conductor. Highly anomalous Co and Ni values were obtained from A-horizon humus samples taken over the western conductor (See compilation map located in back pocket).

Trenches ranging in length from 35 to 80 meters in length and 0.5 to 5 meters in depth were excavated over the conductors using a JD 790 excavator. The east-central conductor was exposed in three separate trenches and a pyrite-bearing shear zone was exposed. Occasional malachite and a coarse grained cumulate pegmatite enriched in chalcopyrite was exposed. Sampling returned values up to 1.5% Cu, 50 ppb Au, 4600 ppb Ag and 30 ppb Pd in the cumulate pegmatite and in narrow, copper-rich quartz veins. Other anomalous Pt values were obtained within the excavated trench over the western conductor in magnetite-rich pyroxenite.

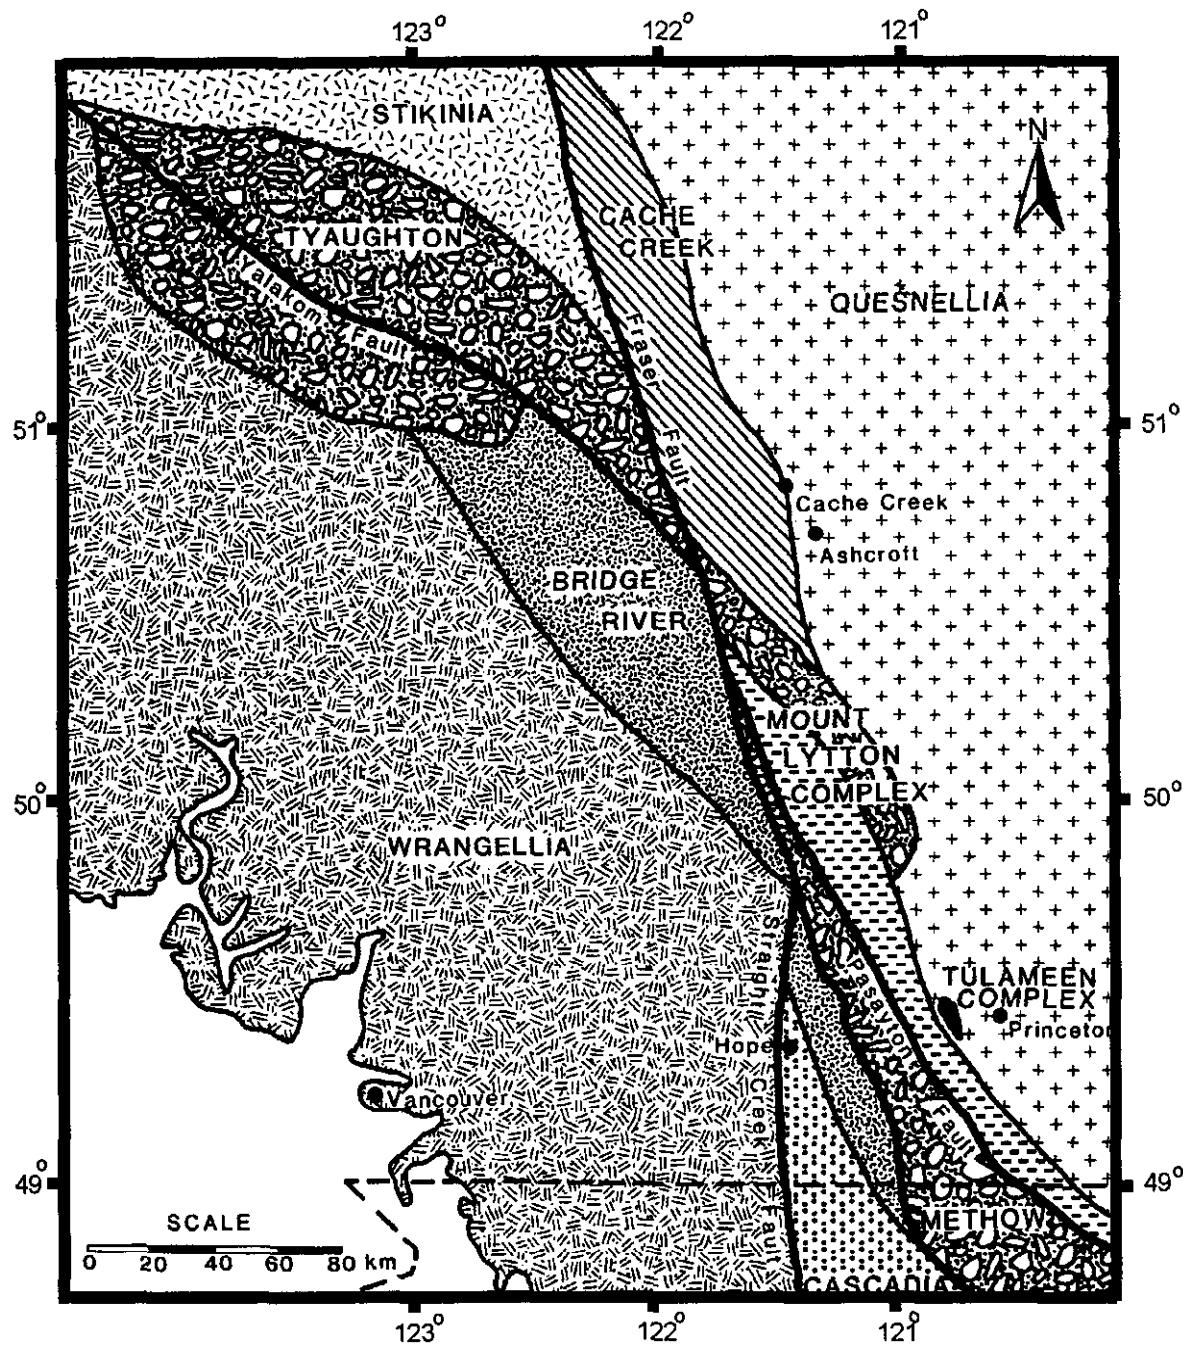

Figure 3. Geological setting of the Tulameen complex in relation to tectonostratigraphic terranes (modified after Kleinspehn, 1985). From Nixon and Rublee (1988)

4.0 Regional Geology

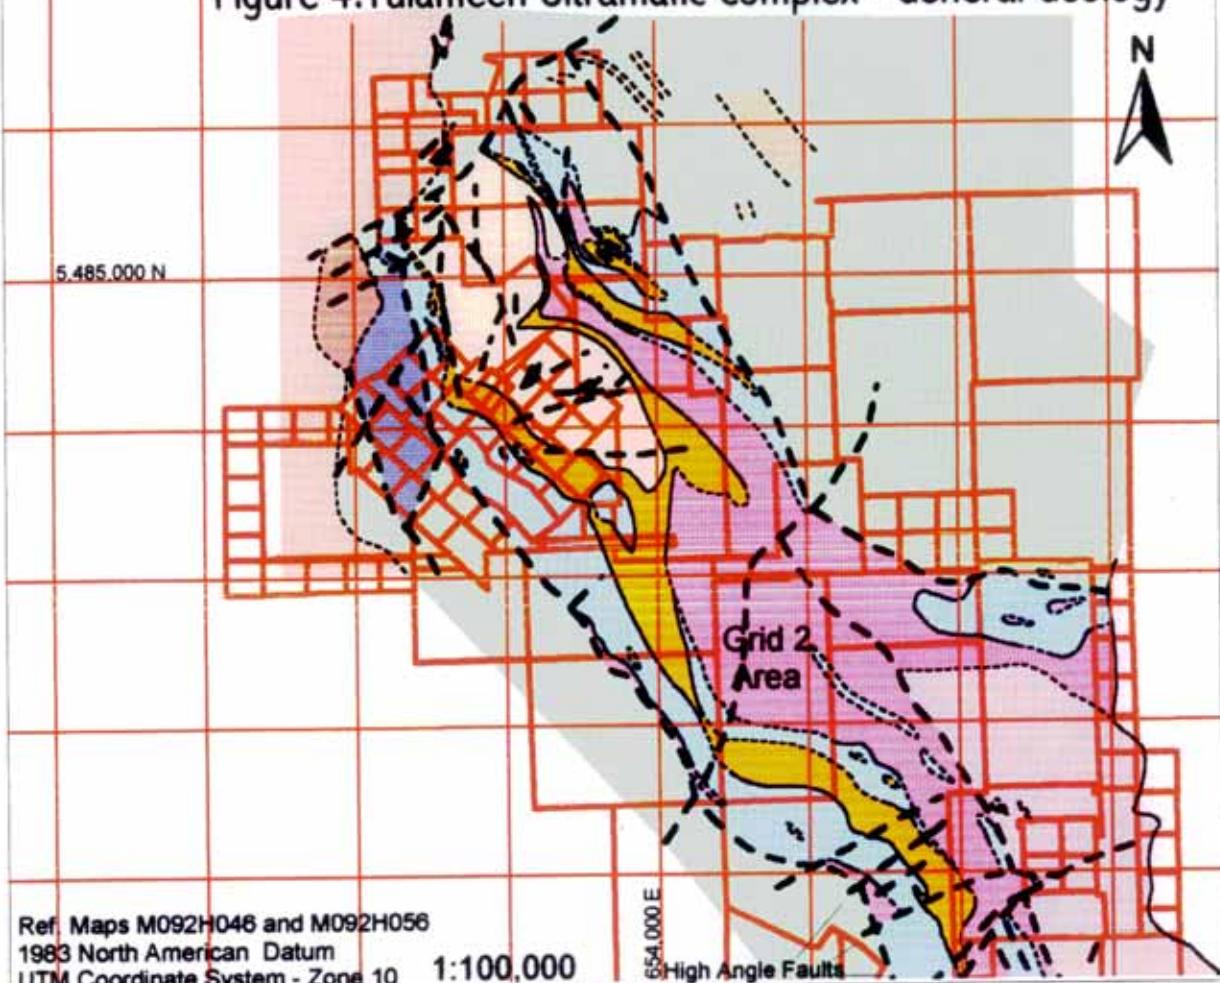

Nixon and Rublee (1988) have reported that Alaskan-type ultramafic complexes in British Columbia are potential hosts for exploitable deposits of platinum metals. The Tulameen ultramafic complex is situated immediately west of the juncture between the Quenellia tectonostratigraphic terrane with the Mount Lytton complex, and is situated within the southwestern Intermontaine Belt. Early tertiary “trans-tensional” block faulting related to regional right-lateral transform movement that has taken place along the Fraser River – Straight Creek fault system (Monger, 1985).

The Tulameen ultramafic complex (TUC) covers an area of 64 square kilometers, which makes it the largest of all Alaskan-type ultramafic complexes that occur within the Intermontaine Belt. The TUC extends north-northwest for 20 kilometers between Grasshopper Mountain and Arrastrada Creek in the south, parallel to the contact between Upper Triassic Nicola Group volcanics and metasedimentary rocks, and the granitic terrane of the Eagle Plutonic complex located to the west. The Nicola Group volcanic host rocks in this region are generally intermediate to felsic in composition and belong to the western facies of the Upper Triassic Nicola volcanic assemblage (Nixon and Rublee, 1988). This assemblage has undergone greenschist to amphibolite grade metamorphism.

The lithologies of the TUC are Early Jurassic, elongate ultramafic to gabbroic intrusive bodies. The Tulameen ultramafic assemblage was emplaced into the Upper Triassic Nicola Group during a late Triassic deformation event. During this time, Nicola group volcanics were folded along north to northwest trending fold axis (Findlay, 1969). Age dates for the complex yield a preferred age of 175 Ma (Mid-Jurassic), but this age may be erroneous due to argon loss during metamorphism. Preliminary age dates on the Eagle plutonic complex suggest an Early to mid-Cretaceous (97 to 120 Ma.) age of emplacement (Nixon and Rublee, 1988). The eastern margin of the TUC and its host Nicola volcanic assemblage are unconformably overlain by terrigenous metasedimentary and metavolcanic assemblages of the Early Tertiary (Eocene) Princeton Group along with Miocene plateau basalt flows.

Regional structures include major faults trending north-northwest and are characterized by a westward dipping foliation that parallels the eastern margin and extends into the Mount Lytton Batholith (also known as the Eagle Plutonic Assemblage) (Figure 3). The TUC displays a crude lop-sided concentric arrangement of a central dunite core surrounded by olivine clinopyroxenite, hornblende clinopyroxenite, and gabbroic rocks. The tectonic history during the implacement of the TUC intrusive assemblage was complex and a multiple stage event. Figure 4 is a map of the general geology of the Tulameen ultramafic complex, with major structures and geological units identified relative to Bright Star Ventures claims. The original version of this map was initially prepared by Findlay (1969) as part of his Ph. D. research, and was subsequently modified as a result of additional geological fieldwork completed by Nixon et. al.(1997). The digital work completed in this study has taken this map a step further through data aggregation and compilation of all the old surveys. All of the old exploration data is

Alaskan-Type Complex, by G.T. Nixon et. al., (1997)

being compiled and layered into GIS format for re-evaluation using digital maps and georeferenced orthophotos.

5.0 Property Geology—Alaskan-Type Ultramafic Complexes

The general structure of Alaskan-type ultramafic complexes is characterized by a crudely concentric outward zonation of rock types ranging from olivine-bearing to hornblende-rich or magnetite rich clinopyroxenites about a steeply dipping dunite core (Taylor, 1967). Typical cumulate minerals include forsteritic olivine, diopsidic augite, chromite and magnetite. Orthopyroxene is characteristically absent in Alaskan-type ultramafic intrusions, indicating an alkalic affinity. Gabbroic rocks are typically tholeiitic in composition, but in the case of the Tulameen, the gabbro complex is unique in composition since these rocks are classified as syenogabbros and syenodiorites Nixon et al., 1997). The property geology of the Tulameen ultramafic complex is similar to other well-documented Alaskan-Type ultramafic complexes located along the southeast coast of Alaska and in the Ural Mountains of Russia.

The Union Bay complex in Alaska is a concentrically zoned mafic / ultramafic complex with a dunite core and pyroxenite shells outward to a gabbro margin. High-grade PGE samples at Union bay contain significant amounts of iron, chromium and titanium oxides. PGE mineralization includes Pt-Fe alloys, native osmium and hollingworthite. Exploration work to date on the Union Bay complex favors the pyroxenite units as the most promising favourable host lithology for PGE mineralization.

5.1 – Mafic Intrusives

5.1a Gabbros

Large gabbroic intrusives occur throughout the TUC, proximal to the eastern margin of the complex. Major exposures are prevalent on the Grasshopper 1 and 2, Amy #1 and #2 and the BJP 1 and 2 claims. Findlay (1969) classified the gabbros as syenogabbros and syenodiorites. These gabbros are commonly in contact with olivine clinopyroxenite and only rarely come in contact with dunite. Syenodiorite is restricted to the southeastern margin of the TUC where it is unconformably overlain by Princeton Group lithologies.

The essential minerals within the syenogabbros include plagioclase (andesine), clinopyroxene, hornblende and potassium feldspar, with accessory minerals including apatite, opaque minerals, minor biotite and sphene. Most of the exposures of gabbro are saussuritized, are pale to dark grey in colour, and medium grained. Layered gabbros are common (Figure 4) throughout the TUC, and preserve a wealth of layering features, including modal grading of plagioclase and ferromagnesian phenocrysts in which the density grading may be normal or reversed in different layers (Nixon and Rublee, 1988).

Erosional tectonic unconformities transect earlier layers, indicating that magmatic activity occurred during crystal settling which disturbed the freshly precipitated cumulate crystal layers. Stratigraphic tops for magmatic layering are up to the west and dip steeply west towards the central dunite core in the TUC. Breccia zones have been observed in the gabbro in outcrops exposed along the Tulameen River, with rounded to sub-rounded blocks enclosed in a medium grained, uniform gabbroic groundmass. Net-textured sulfide mineralization (pyrite) has also been observed in the same section, and in this area the pyrite also lines fractures.

5.2 - Ultramafic Rocks

5.2a Dunite

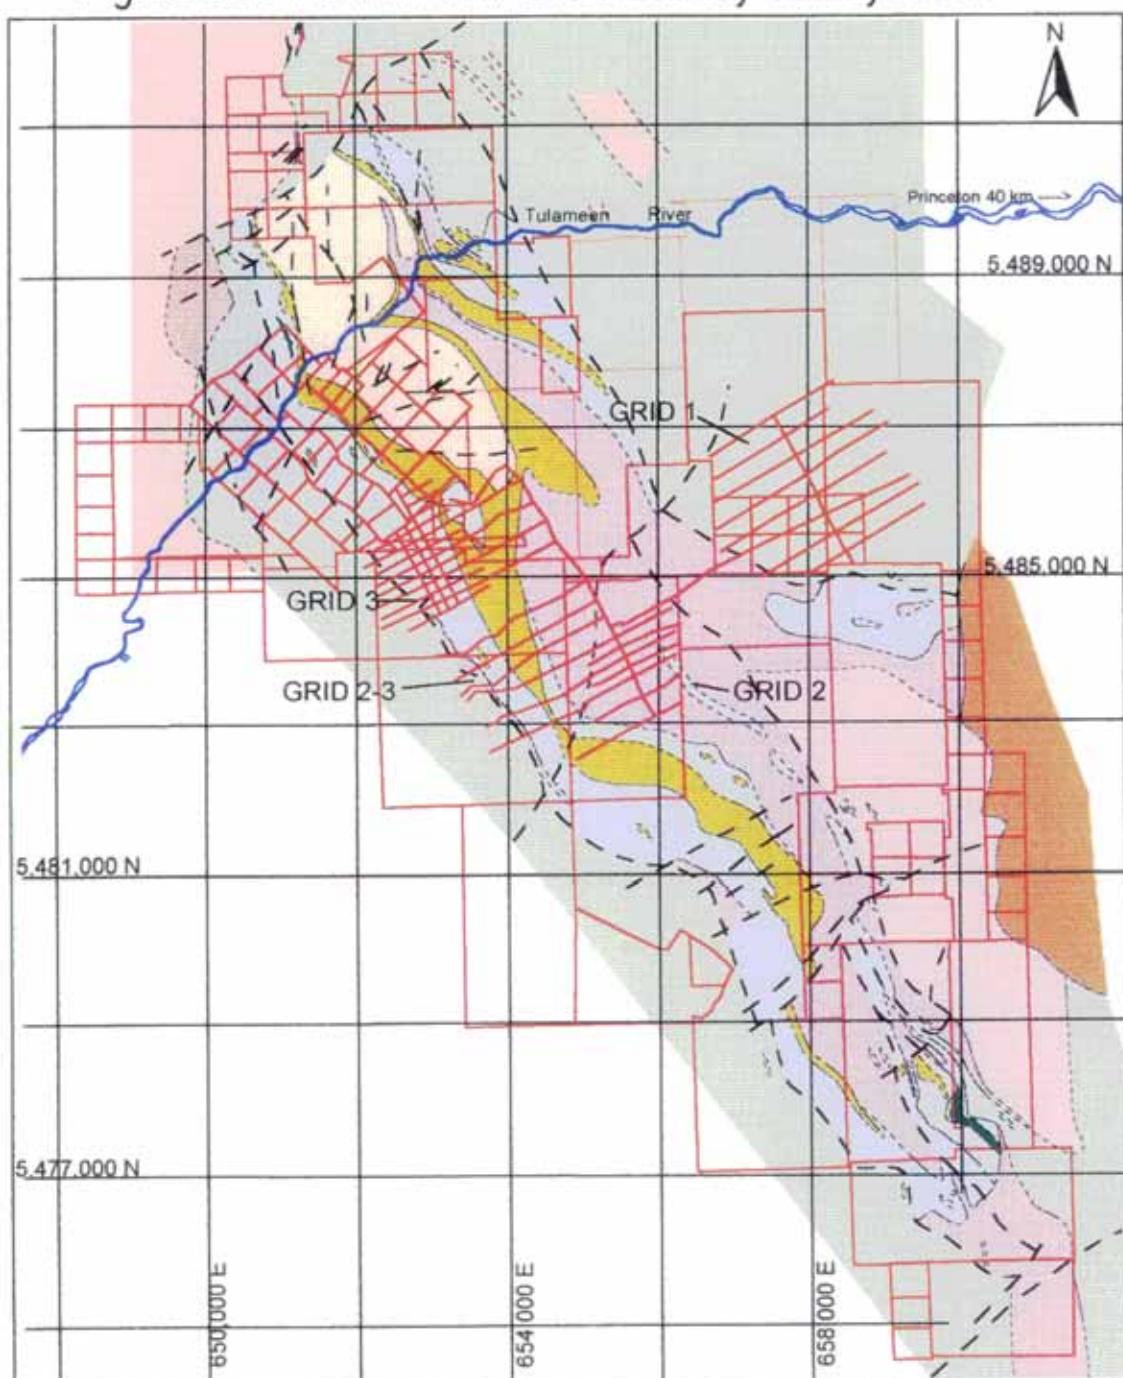

Outcrops of dunite within central core of the Tulameen complex are restricted to Grasshopper and Olivine Mountain, which is covered by the Grasshopper #1 and #2 claims. The dunite is generally medium to dark grey in colour when fresh. The primary mineralogy consists of up to 90% forsteritic olivine with accessory chromite and rare diopsidic augite. Alteration minerals occur along fractures, breccias and in shear zones, including serpentine, carbonate, magnetite and talc. The degree of serpentization varies from less than 20% to more than 80 % of the rock. The most intense areas of serpentization occur near the eastern margin of the complex. Chromitite and chrome spinel appear to be randomly distributed throughout the dunite as discrete layers, nodular masses and schlieren up to 1 meter in length and 6 centimeters in width. Microscopic platinum-iron alloy minerals associated with the chromite include isoferroplatinum, osmiridium, platiniridium and tulameenite (Hart, 1982).

Magnetite is disseminated throughout the dunite often forming thin, fine-grained bands or coarse aggregates. Generally the chromitite can be distinguished from magnetite by the difference in magnetic attraction, and the chromitite is generally coarser grained and has a granular sugary texture. High grade Pt mineralization was identified during the course of the Newmont exploration program on the Grasshopper claims in areas where the average Cr % ranged from 1.2 % to 17.42%

5.2b Olivine Clinopyroxenite

Olivine clinopyroxenite surrounds the dunite core of the TUC and is exposed on the Amy #1, Grasshopper #1, BJP1, BJP2 and BJP 3 claims. The fresh rock is medium to coarse grained and has a blotchy green and black appearance due to partially serpentized olivine and deep green clinopyroxene. Sporadic pegmatitic phases contain crystals up to 8 centimeters across and olivine crystals locally form schlieren (Nixon and Rublee, 1988). Olivine clinopyroxenite is present on the southern half of claim BJP1.

12 Kilometers

Scale 1:100,000

Within the contact zone, the dunite locally encapsulates the olivine clinopyroxenite while in other areas the reverse relationship is preserved in outcrop, and the olivine clinopyroxenite encapsulates the dunite. Breccias occur within the olivine clinopyroxenite near the western contact of the dunite between Britton and Champion Creeks. Angular to rounded blocks of dunite, pyroxenite and interlayered dunite-pyroxenite are enclosed in a serpentinized pyroxene-rich groundmass. A similar breccia occurs on the eastern margin of the dunite. Contacts dip moderately to steeply south.

5.2c Hornblende Clinopyroxenite

Hornblende clinopyroxenite generally occurs along the periphery of the Tulameen ultramafic complex and is present on the Grasshopper #1, Amy #2, and BJP 1,2 and 3 claims. Fresh rock is medium to coarse grained and contains diopsidic augite, hornblende, and relatively abundant magnetite with accessory minerals including biotite, sulfides and apatite. Mineral foliations are observable in medium-grained varieties and amphiboles may reach up to 3 centimeters in length in coarse-grained varieties. Accessory biotite and apatite occur in 6-meter thick magnetite-rich horizons on the southern slopes of Tanglewood Hill. The magnetite-rich horizons can also occur as schlieren and podiform masses. Mafic pegmatites are preferentially distributed near the margins of hornblende clinopyroxenite bodies (Findlay, 1969). One of the mafic pegmatites was sampled and identified as containing significant PGE values, with heavy pyrite and chalcopyrite mineralization exposed in the vicinity of Hines Creek along the sheared eastern contact zone between hornblende clinopyroxenites of the TUC with Nicola Group metavolcanic rocks (Zastavnikovich, 1988).

6.0 Soil Geochemistry Survey Results

Soil survey work on the Grid 2-3 area was completed on the Amy #2, BJP 2 and BJP 3 claims (Figure 5). It should be noted that the Amy #2 claim was under option to Bright Star at the time of the survey but has been subsequently dropped and returned to the claimholder in good standing. Approximately 17 kilometers of reconnaissance grid lines were flagged between grids 2 and 3 in order to obtain coverage of the western contact of Tulameen ultramafic complex. A total of 329 samples were taken on lines spaced between 150 and 400 meters apart, at 50-meter stations along the lines. Due to the highly magnetic nature of the hornblende clinopyroxenite units on the western half of the grid, lines tended to curve as a result of compass errors during traverses across this unit.

Figure 6a. is a map of B-horizon gold in soils, which indicates some minor sporadic gold distribution within the gabbro. Values range as high as 110 ppb Au over the gabbro, while near the sheared contact zone along the western margin of the Tulameen complex there is also a slightly elevated gold signature.

Figure 6a. Grid 2-3
B-Horizon Au (ppb)
in Soils

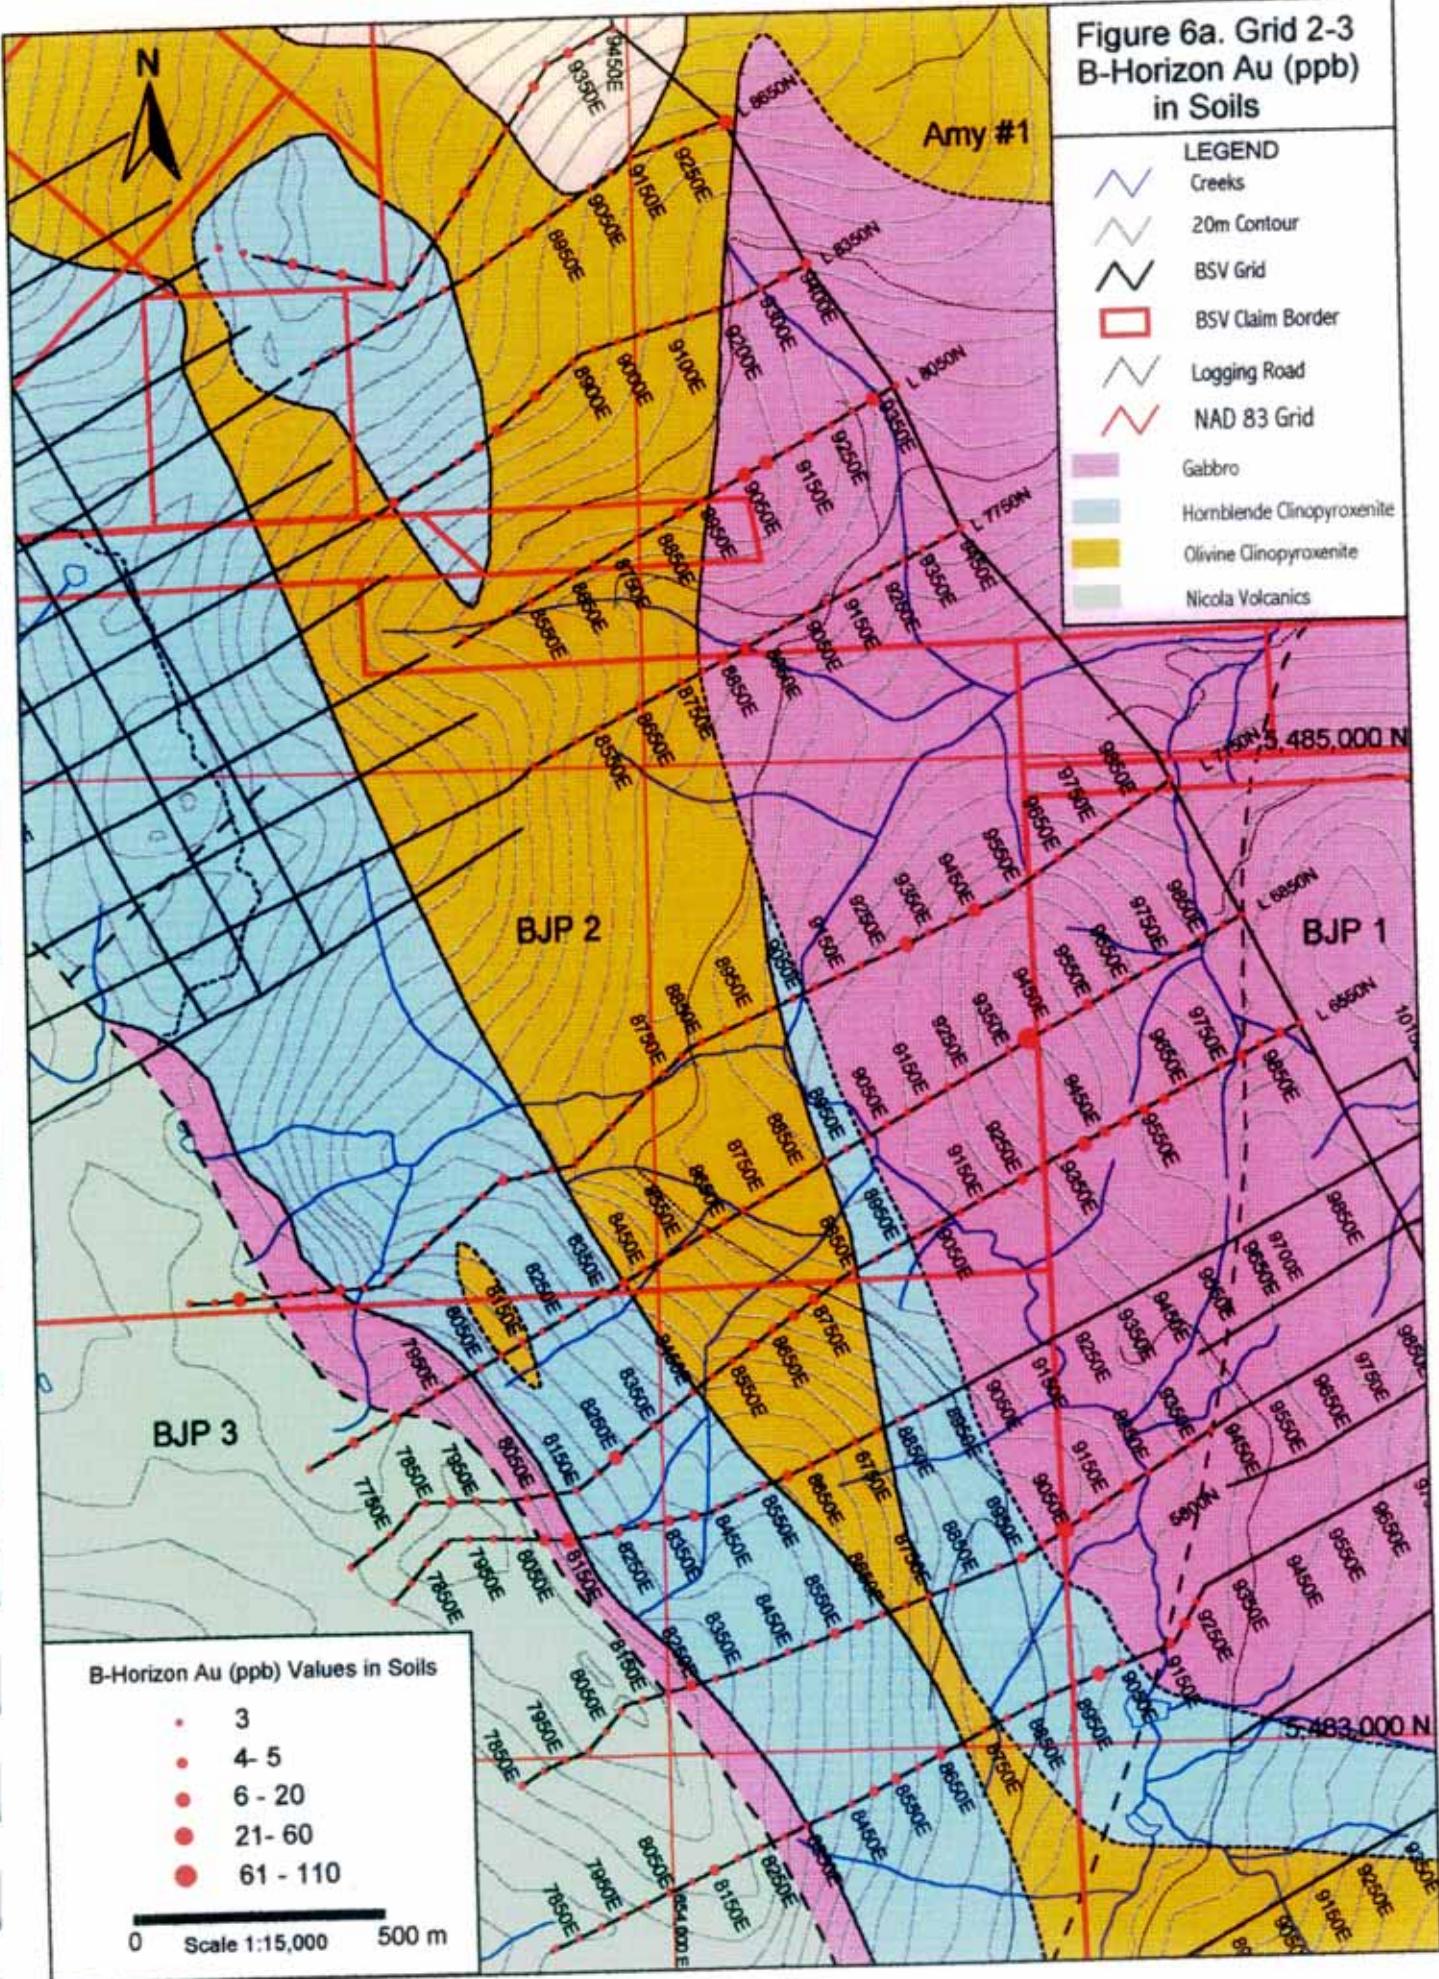

Figure 6b. Grid 2-3
B-Horizon Pd (ppb)
in Soils

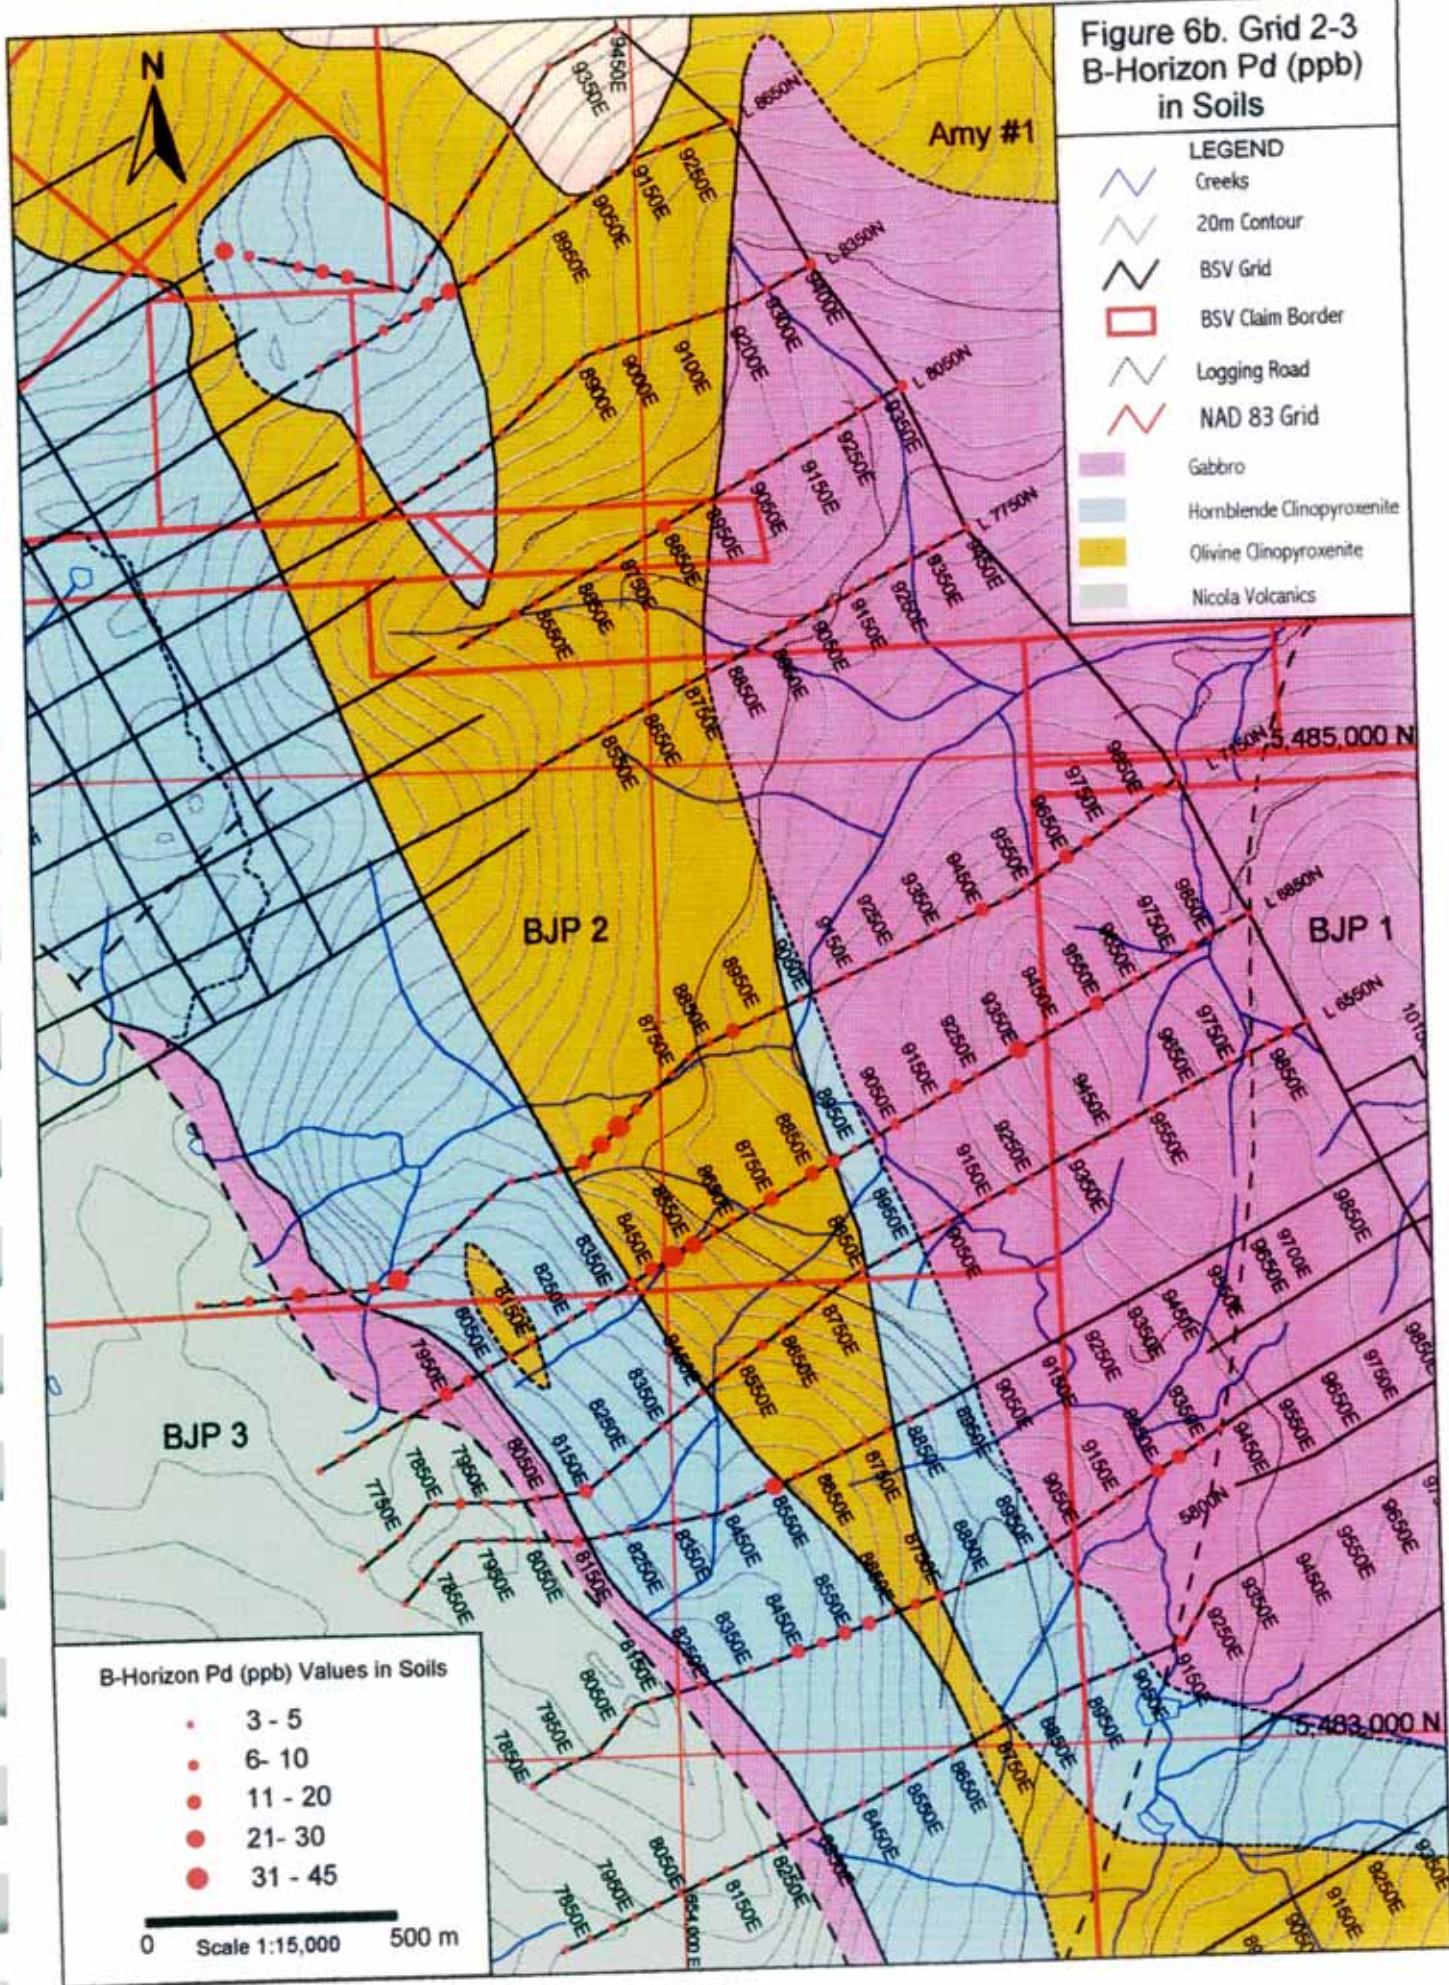

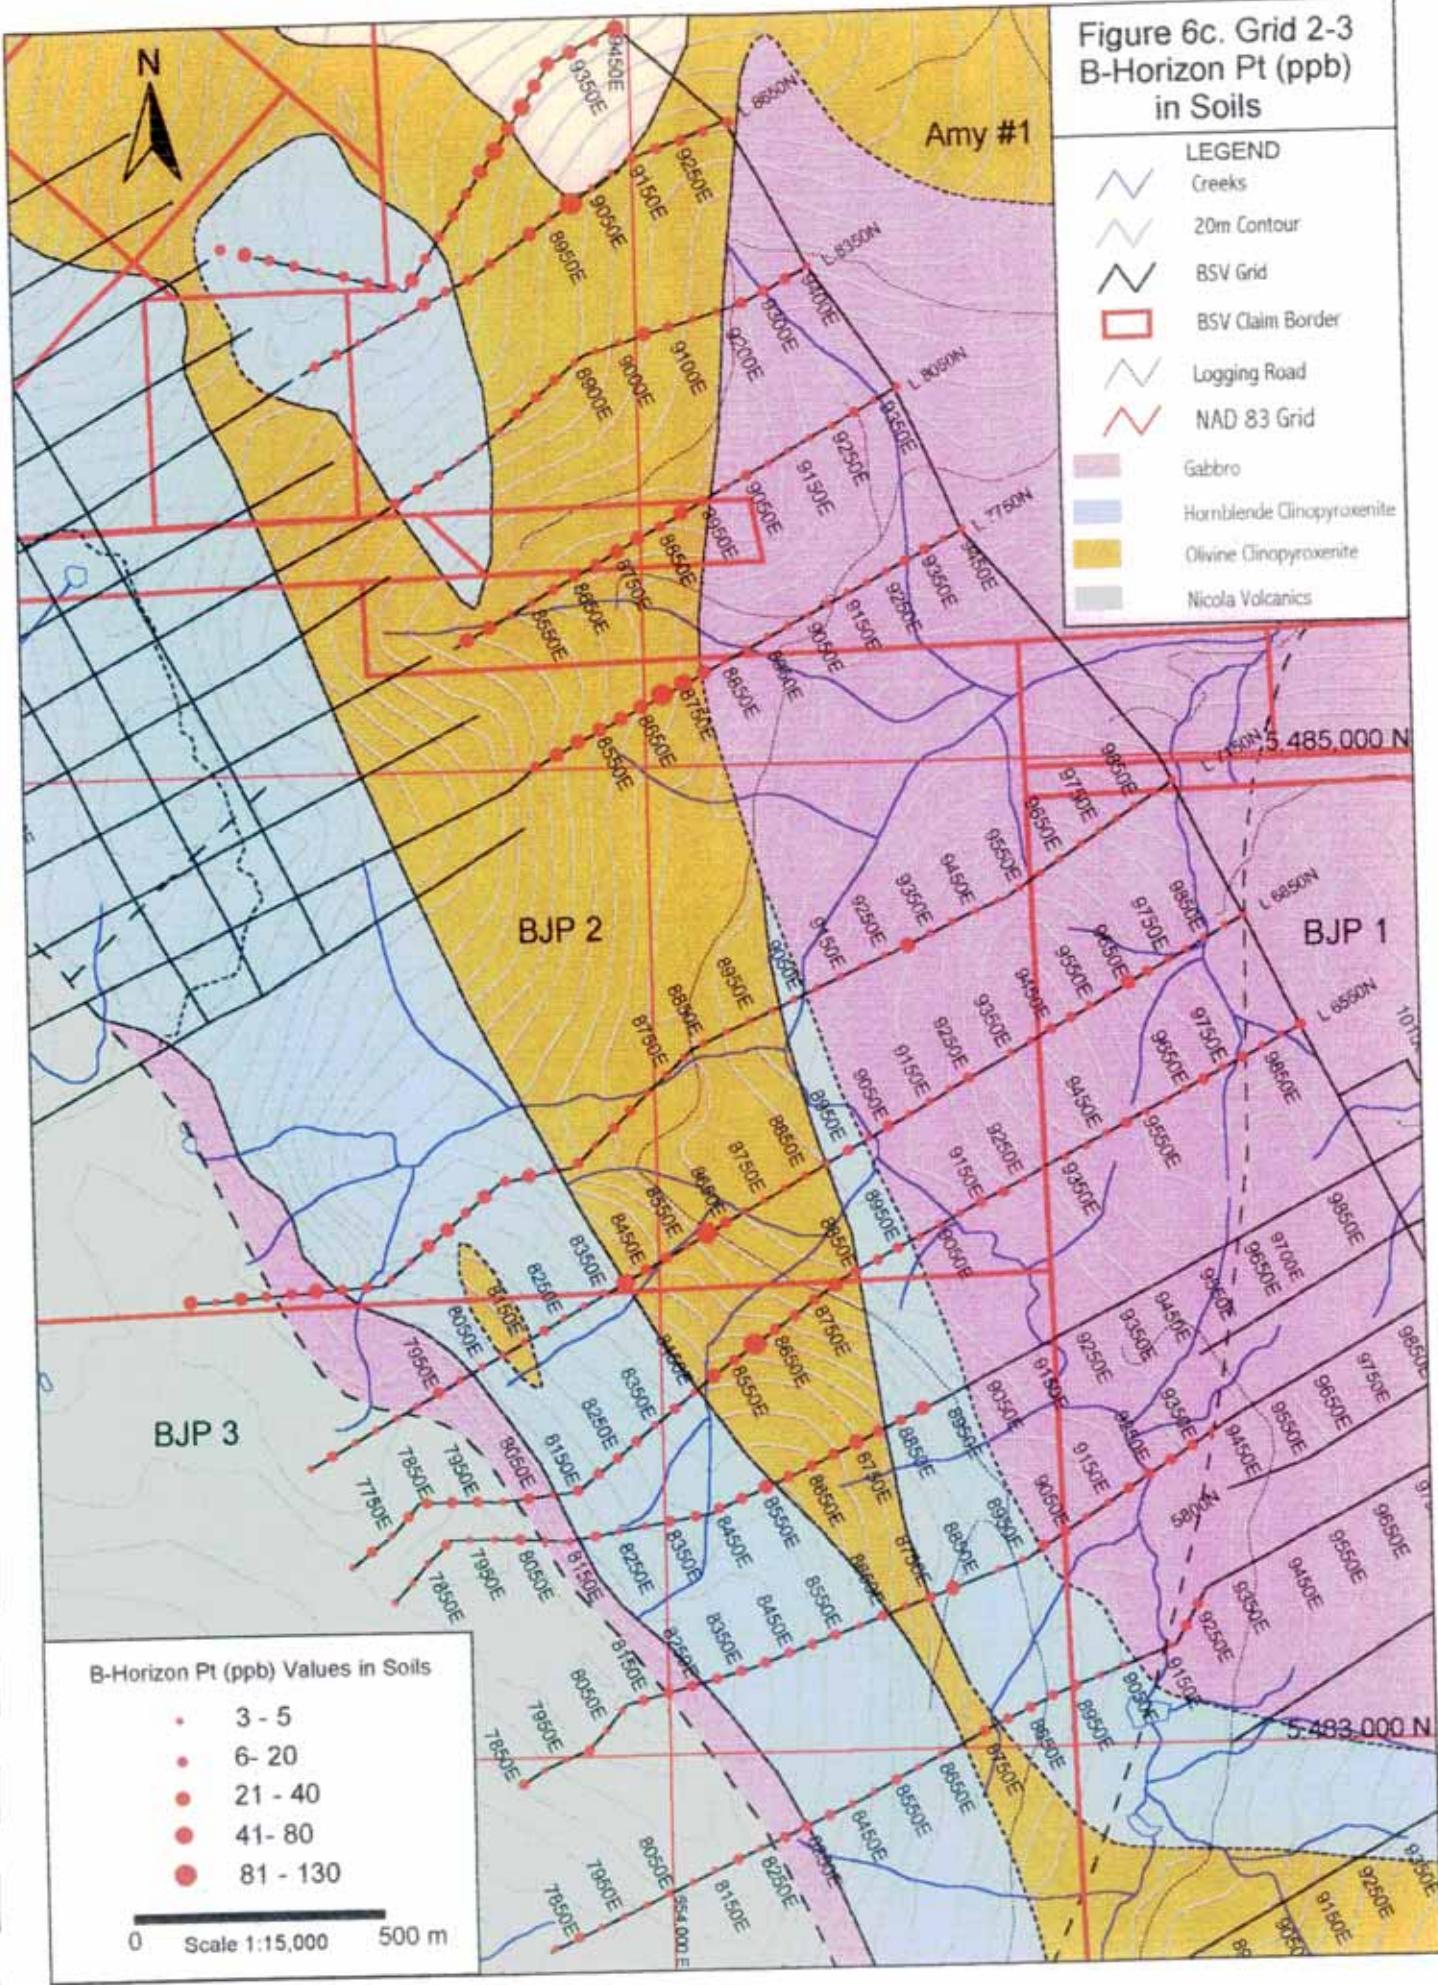

Figure 6c. Grid 2-3
B-Horizon Pt (ppb)
in Soils

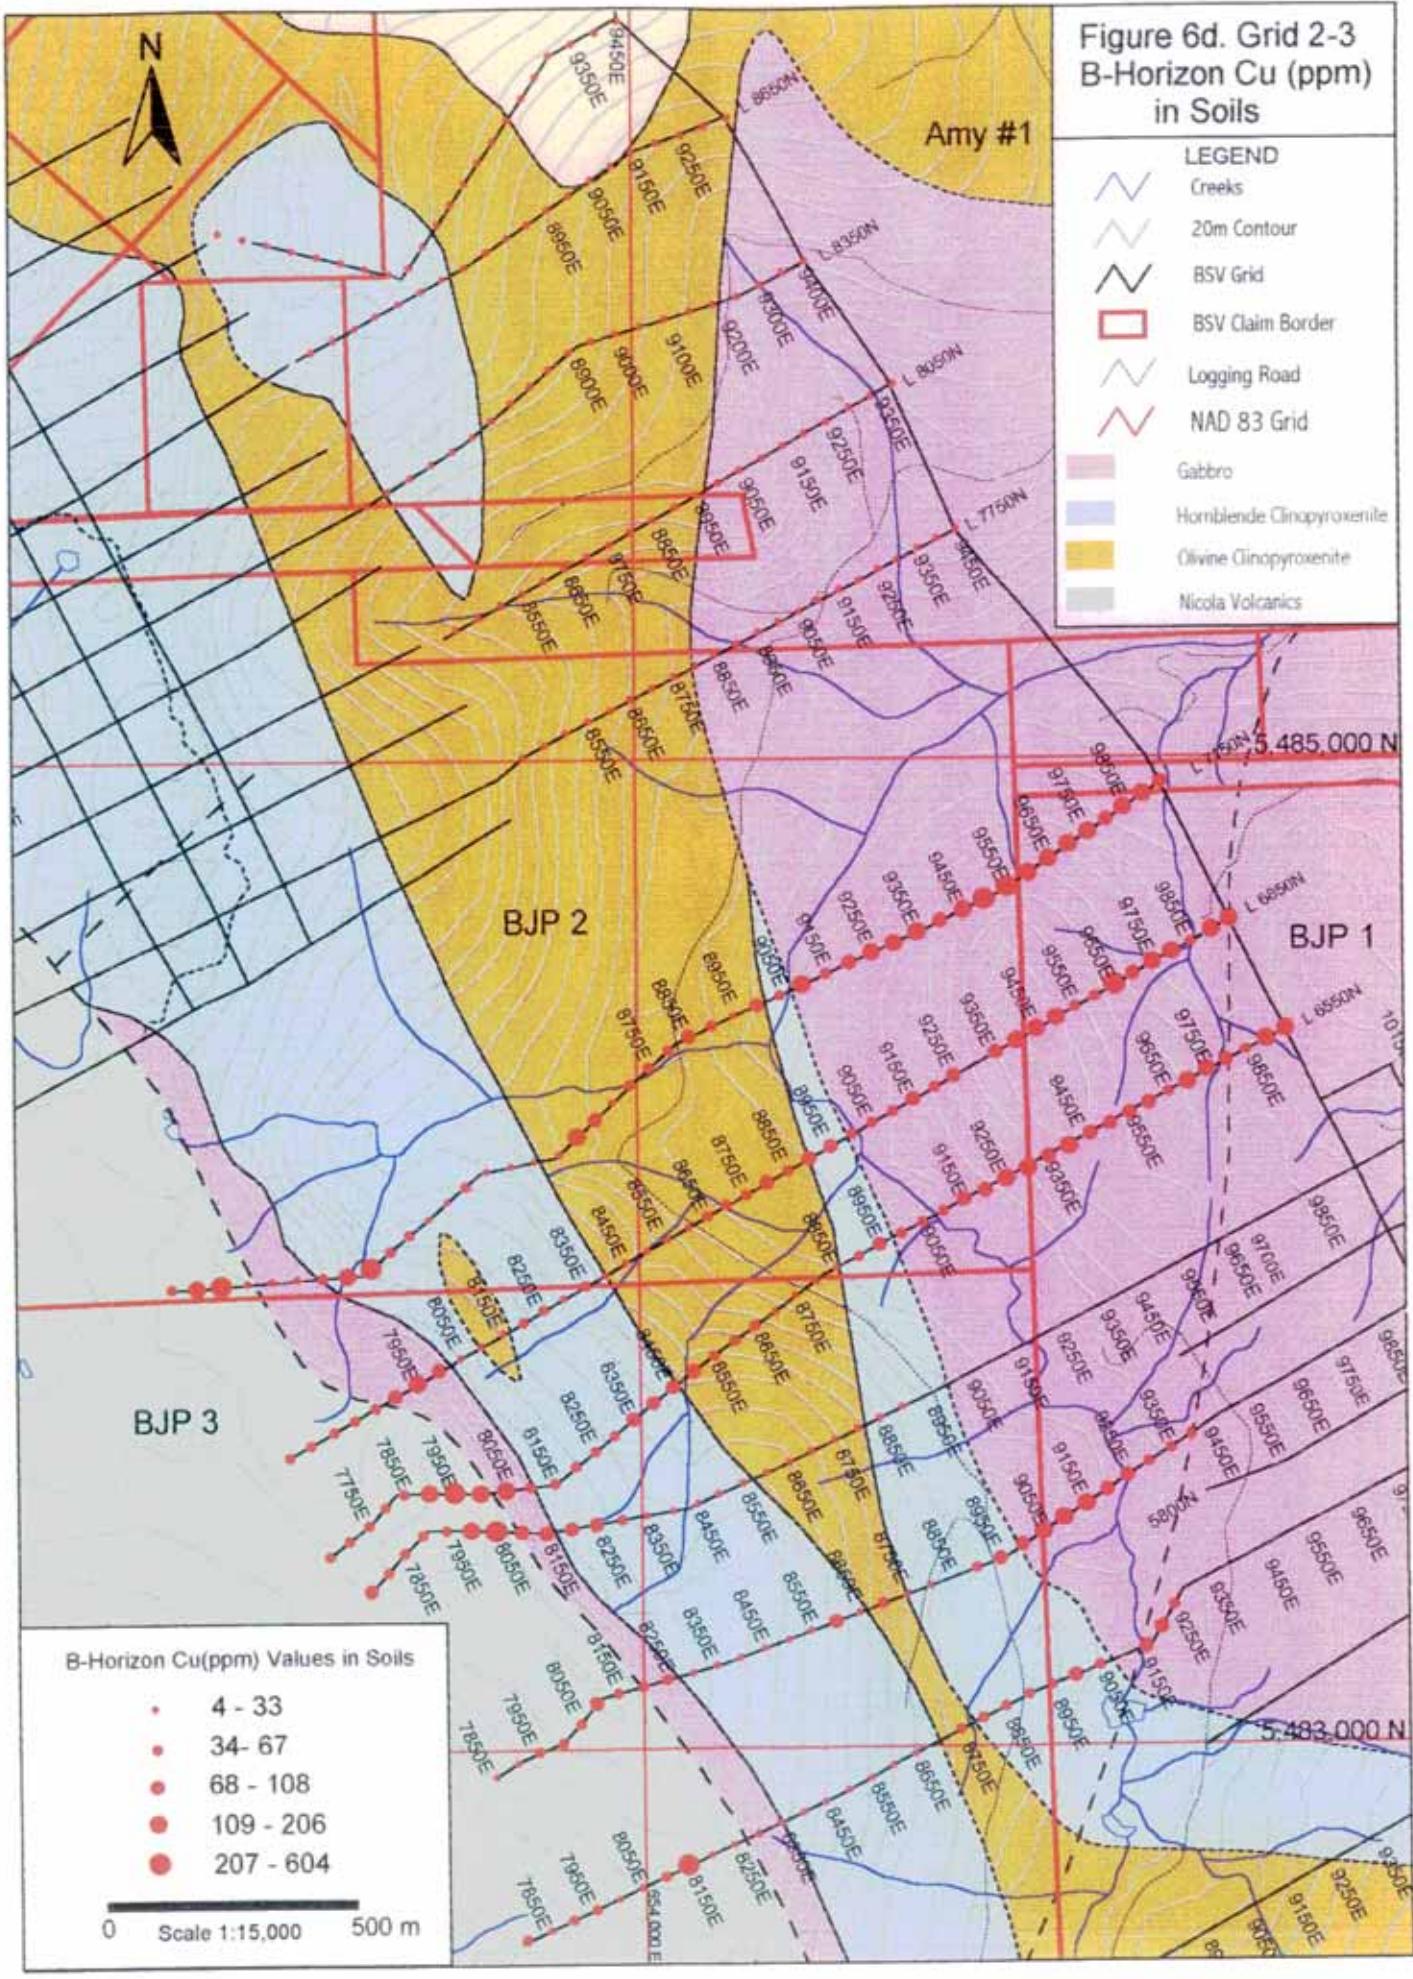

Figure 6b. demonstrates sporadic distribution of palladium in B-horizon soils throughout the gabbro, while in the olivine clinopyroxenite there is a well-defined soil anomaly on lines 6850N and 7150N between stations 8450E and 8650E, with values ranging up to 45 ppb Pd. This anomaly remains open to the northwest.

Figure 6c. indicates that the serpentized dunite is clearly anomalous as demonstrated on line 8950N. Several high soils values are present in the olivine clinopyroxenite as well, with soil values ranging as high as 130 ppb Pt. There is a good correlation with platinum and palladium in the olivine clinopyroxenite on lines 6850N and 7150N between 8450E and 8650E.

Figure 6d. indicates a NW extension of the Grid 2 copper anomaly in the gabbro, where a large area contains between 100 and 600 ppm Cu. Some of the highest copper values are also related to the sheared western margin of the Tulameen ultramafic complex.

8.0 Conclusions and Recommendations

Exploration costs for the soil survey are presented in Appendix A, while Assay certificates are presented in Appendix B. The soil geochemistry identified anomalous copper PGE values in B-horizon on the BJP 1,2 and 3 claims along the western margin of the Tulameen ultramafic complex. During the 2003 program, additional soil and rock sampling surveys, IP geophysics and diamond drilling will further test these anomalies. A 100,000. budget will be planned for additional work on the Grid 2_3 area in conjunction with the surrounding Bright Star Ventures properties.

APPENDIX A

Summary of Expenses – Grid 2_3 Survey

For Period August 8th – September 20th, 2002

Assay Costs – Eco-Tech laboratories	7,913.03
Room and board – 3 men 15 days @ 25.00/day	1,125.00
Food – 3 men 15 days @ 35.00 per day	1,535.00
Salaries – 3 men 15 days @ 160.00 per day	7,200.00
1 BSV Geotech 15 days supervision @ 175.00/day	2,625.00
1 BSV Geotech – 15 days truck rental @ 65.00 /day	975.00

For Period December 16th-21st, 2002

1 Geologist - 6 days data compilation, report @ 375.00/day	2,250.00
--	----------

Total =	\$23,623.03

APPENDIX C

STATEMENT OF QUALIFICATIONS – WILLIAM C. YEOMANS

I, William C. Yeomans, hereby certify the following:

1. I am an independent consulting geologist, employed by Yeomans Geological Services, with office at 3225 Oriole Drive, Westbank, B.C., V4T 1A4
2. I earned a Bachelor of Science (Hons.) in Geology in 1982 at Queen's University in Kingston, Ontario, Canada.
3. I am a Professional Geoscientist registered with The Association of Professional Engineers and Geoscientists of the Province of British Columbia, registration No. 27187.
4. I am a Qualified Person (QP) as outlined in National Instrument 43-101 of the Canadian Securities Administrators (CSA).
5. I have read National Instrument 43-101 and Form 43-101F1.
6. I have practiced my profession for 20 years, and I am experienced in mineral exploration throughout the Americas. I have managed exploration programs encompassing planning, setting up and supervising of the following: drilling; logging; sampling and laboratory protocols for reverse circulation, diamond drill core, planning and execution of regional and detailed geochemistry and geological surveys, database development and management in several countries. I have integrated geological, geochemical, and geophysical data modeling utilizing GIS and other software.
7. The geological report dated March 18th , 2003 and titled "Bright Star Ventures 2002 Summary of the PGE Exploration Program for the Tulameen Ultramafic Complex, Similkameen District, South Central British Columbia, Canada," is a compilation of data provided to me by Bright Star Ventures Ltd.
8. This report was prepared for Bright Star Ventures Ltd. and is based on data provided to me by the company, which are believed to be accurate. Although all reasonable care has been taken in the preparation of this report.
9. I am not independent should the issuer apply all of the tests in Section 1.5 of NI43-101. I own options to purchase 150,000 shares of Bright Star Ventures Ltd. I own no other interest in any company or entity that owns or controls an interest in the properties that comprise the Tulameen Ultramafic Project.
10. I hereby give permission to Bright Star Ventures Ltd. to use this report in its complete and unedited form. Permission must be obtained from me before publication of any excerpt or summary from this report. The author is not responsible for errors and inaccuracies arising from data that might not be accurate.

Dated the 26th day of June, 2003.

William C. Yeomans

William C. Yeomans, B.Sc. (Hons.) , P.Geo. (APEGBC)
(Association of Professional Engineers and Geoscientists of British Columbia)
