SUDHIR JAIN received M.Tech. in Exploration Geophysics from Indian Institute of Technology and Ph.D. in Geophysics from University of Liverpool. After working for twelve years for Mobil and sundry service companies in U.K., Libya, U.S.A., and Canada, Dr. Jain set up Commonwealth Geophysical, a service company for oil and mineral exploration in 1976. He developed innovative interpretation techniques for geophysical data which quickly became industry standards. He published over 40 papers and was honoured by European and Canadian professional societies.

Since 1974, Dr. Jain has explored for numerous companies in Canada and overseas as well as in Madagascar and Southeastern Alberta on his own account. He is also associated with ore exploration in British Columbia and diamond exploration in Saskatchewan. He is a registered Geoscientist in British Columbia, a member of Association of Professional Engineers, Geologists and Geophysicists of Alberta, and honorary member of Canadian Society of Exploration Geophysicists.

LORNE KELSCH graduated with B.Sc. from University of Manitoba in 1952. After working on seismic data acquisition, processing and interpretation for 22 years with Petty Ray Geophysical, Mr. Kelsch moved to PanCanadian where he worked in various capacities including Chief Geophysicist till his retirement in 1995.

Mr. Kelsch is a professional member of Association of Professional Engineers, Geologists and Geophysicists of Alberta, Canadian Society of Exploration Geophysicists.

INTRODUCTION

Claim Data

The B.T. Properties are presently held in the name of 26BT Resource Development Co. Ltd. They were originally staked by Brendan A. Gordon on behalf of Malcolm T. MacDonald, one of the principals of the Company.

<u>Claim Name</u>	<u>Tenure Number</u>	<u>Anniversary Date</u>
BT 1-4	313837-313840	October 8, 1993
BT 5,6	313845-313846	October 8, 1993

These were then sold to the company.

BT 7, 8, 9, 10 and 11 were acquired on behalf of the company in 1993. Details are as follows:

BT 8-10	323096-323098	December 21, 1994
BT 7,11	323202-323203	December 29, 1994

BT 12, 13, 14, 15, 16, 17, 18, 19 and 20 were acquired on behalf of the company by Brendan A. Gordon in June 1996. The details are as follows:

BT 12-17	346620-346625	June 09, 1996
BT 18	346941	June 10, 1996
BT 19	346626	June 10, 1996

On October 3, 2005, claims 1, 2 & 7 lapsed due to administrative error. These were reclaimed as follows:

BT 1-2	520728-520729	October 24, 2005
BT 7	520730	October 24, 2005

This report covers claims 1-6 and 8 only. Claims 7 and 9-20 were relinquished in the year 2000.

Location & Access

The property lies north of the Fraser River and south of the West Torphy River. The centre of the claims is about 6 kilometres N.N.E. of Sinclair Mills (Figure 1). Access to the claims is by old logging roads. The claims lie between the elevation of 700 meters and 1690 meters in generally rugged terrain. Devil's club and windfall trees make the claims difficult to traverse.

History

Two of the principals of the company entered the area north and east of MacGregor in 1989. This was based on projections of the trends seen in the configuration of the North American Continental mass as demonstrated by Government gravity and magnetic maps. Later, while studying reports and maps in the Provincial offices in Prince George, the magnetic feature shown on Aeromagnetic Map 1536 G of the Geophysics Division of Mines and Technical Surveys was noted. Subsequent sampling along creeks crossing the old logging road north of Sinclair Mills yielded unusually high amounts of magnetite. The decision to stake the area at the north west end of Bearpaw Ridge was then made and carried out in 1992. An aeromagnetic survey was flown, processed and interpreted in 1993. As a result of this survey, additional areas surrounding the claims were staked. 9 holes were drilled to the depth of 100' on the claims in October 1994. The chemical analysis from the cores showed that Fe₂O₃ content averaged between 10 - 20% in the holes and reached up to 35% in some zones. The magnetic separation in 20

samples from two of the holes showed that in samples with high Fe₂O₃ content (greater than 10%), magnetite is more than 75% of total Fe₂O₃ percentage.

Three holes were drilled to the depths of 300' in June 1995. Two of the holes confirmed the presence of magnetite in a variable amount to at least 300'. The third hole was mislocated and missed the anomaly. This hole does not appear to have any commercial significance.

Three holes were drilled in July 1996, two to the depth of 300' and one to 500'. One hole confirmed magnetic concentration while the other two were discouraging. Detailed surface geology was undertaken in 1997 together with mineral and chemical analysis of 60 stream samples and 109 chip samples. The report of professional geologist is included as Appendix 7 in Assessment Report Number 25280.

In the summer of 1998, ground magnetic and VLF-EM data was collected along eleven cut lines and four roads. 25 silt samples and 81 rock samples were also collected by E. R. Kruchkowski, P. Geol. and his crew. His report is included as Appendix 2 in Assessment Report Number 25664. Ground geophysical data results are discussed in a later section (Integration of Geology and Geophysics).

In the summer of 1999, ground magnetic data was collected along three extended and two new lines. 63 rock samples and magnetic data at 25' intervals were collected by E.R. Kruchkowski, P. Geol. and his crew. Two gravel samples were also collected for detailed analysis. Five cores from previous holes (94-4, 94-6, 95-2, 96-1, and 96-3) were analyzed in detail in 3.3 m (10') sections by Overburden Drilling Management for mineralogical content. Core for 94-4 was analyzed by MD Technologies of Perth, Australia for metallurgical analysis in July to October 1999.

In September 2000 two 92 m deep holes were drilled from the same location (surface sample R224, report no. 26336), one vertical and the other at 45° inclination. The cores were analyzed and selected samples were chemically analyzed Appendix 1 and 2, report no. 26336. The analysis of cores was inconsistent with surface geology and we suspect that the hole was mislocated. Its true location is not known. In 2001 gold was encountered in some silts samples and the focus of exploration shifted to gold from Titanium. Details of this work are described under current work - gold prospect.

Geology

Following summary of known geology of Bearpaw ridge closely follows the report by Pell (1994). The area is mapped as Silurian volcanoclastics, felsic and intermediate tuffs, agglomerates of Nonda formation over the ridge, foliated hornblende gneiss on the western slope and coarse grained massive pink syenites in the southwest (Figure 2). Pell notes sodalite syenite outcrop and two flanking syenite sills in southeast portion of the claim area which intrude the volcanoclastics whose southeastern extent is not defined. These volcanoclastics "largely comprise clinopyroxene crystal tuffs, calcareous tuffs and minor basaltic flows. Flow rocks contain clinopyroxene phenocrysts and altered phenocrysts (now chlorite) in a ground mass of opaque oxides, plagioclase and clinopyroxene microphenocrysts and chlorite". These may be classified as alkali basalts. Folded and foliated dioritic orthogneiss vary from a banded gneiss containing 5 - 10% magnetite-ilmenite to a mafic gneiss with 15 - 20% magnetite-ilmenite. Chemical analyses indicates Fe₂O₃ content of 6.9 and 14.5% in two volcanic samples and 1.5, 7 and 11.2% in three samples from mafic gneiss. Corresponding TiO₂ content is .59 and 2.06% in volcanics and .27, .80 and 2.01% in mafic gneisses.

Kelsch in an appendix to Kelsch and Jain (1994) reported that the accessible part of the terrain is generally covered by a thin layer of soil. The vegetation is thick. Devil's club and mosquitoes are plentiful and they make the work quite difficult. In spite of these problems, he obtained several surface samples. The majority of these samples were from glacial erratics which had not moved very far from

their original location. The magnetic susceptibility of these samples ranged from .001 to .250 S.I. units. Two of the samples were analyzed chemically by Terramin Research Labs Ltd. The analysis showed 22 and 25% Iron Oxide and 4.34 and 5% Titanium Oxide in these samples. These figures support more work on the prospect to define concentrations of magnetite and ilmenite which may have economic interest.

The magnetic data acquired by 26BT strongly suggest a magnetite rich intrusive of elliptical shape on the ridge. This is confirmed by the mineralogical analysis of samples from fifteen holes drilled so far which contain crystalline gabbro with high mafic content. The gabbro is quite heterogeneous laterally as well as vertically. Pell (1994) does not mention this intrusive. Incidentally, the sodalite body mapped by Pell was not encountered in hole 95-3.

Geophysics

Data Acquisition in 1993

26BT engaged Geonex Aerodat to conduct an aeromagnetic and electromagnetic survey over a 12 km X 13 km area including the company's claims. The data were acquired in February, 1993 by a helicopter with mean terrain clearance of 100 m for helicopter and 70 m for sensing equipment.¹ The survey comprises 321 line kilometres, with east-west traverse lines spaced 500 m apart and two north-south tie lines. In addition to the total field map with variable contour interval, Geonex also supplied maps for vertical gradient of the magnetic field and VLF-EM total field. The VLF-EM map is relatively quiet and indicates general absence of sulphide ores in the area. The vertical gradient measurements did not provide meaningful data probably because magnetic anomalies were very strong and very sharp. The details of acquisition and preliminary processing are contained in the report submitted by Geonex and included in Kelsch, and Jain (1993). Final processing and interpretation are described by Jain and Kelsch (1997) in Assessment Report Number 25280.

Data Acquisition in 1997

26BT engaged Dighem, A Division of CGG Canada Ltd. to conduct an aeromagnetic and multi-coil, multi-frequency electromagnetic survey over an approximately 62 sq km area. Total coverage amounted to 361 km including tie-lines. The survey was flown on February 8 and February 9, 1997. Dighem processed the data in their Mississauga, Ontario facility and final maps and their report was received by 26BT on April 8, 1997. For technical details of the Dighem report see Assessment Report Number 25034.

Interpretation of E-M Data

This is included in Assessment Report Number 25543 (D.R. Stevenson, P.Geo. electromagnetic data), Assessment Report Number 25664 (Appendix 2) and Assessment Report Number 25034 (Dighem maps).

DRILLING AND CORE ANALYSIS

9 holes were drilled to a depth of 30.46 m (100 ft) in October 1994, 3 holes to the depth of 91.38 m (300 ft) in June 1995 and three holes, two to the depth of 91.38 m (300 ft) and one to 152.29 m (500 ft) in July 1996. All holes were cored in hard rock. Location of the holes is shown in Figure 3. Core diameter was 43 mm (1 ¾"). Hole 7 did not hit the hard rock till it reached the bottom. Susceptibility

was measured at 1 ft intervals on the cores as an indicator of the magnetite content. Two boulder specimens collected in 1994 were analyzed. The holes were drilled to determine the source of magnetic anomaly and not for details of local geology. No obvious metals have been noted in the cores. Appendix 1 gives details of the drilling logistics. Core logs are given in Assessment Report Number 25034.

140 samples were selected from fourteen cores to include a wide variety of susceptibility and core type (grain-size, colour, rock type) and two from boulders picked up on the site. Magnetic susceptibility of the samples was measured several times at different locations on the sample and the average recorded.

The samples were chemically analyzed by Terramin Research Labs of Calgary in December, 1994, August, 1995 and October, 1996. The results of their analyses, measured susceptibility and rock type are given in Assessment Report Number 25664.

Cores from five holes, 94-4, 94-6, 95-2, 96-1 and 96-3 were cut in two halves along the diameter. One part was sent to Stu Averill, Overburden Drilling Management Limited, Napan, Ontario. His reports and analyses conducted by them are included in Assessment Report Number 26044. Overall results of this study are generally negative. The summary of Stu Averill's work is as follows:

1. The magnetite in the gabbro contains approximately 10% of its weight in TiO_2 in intercrystalline form. The titaniferous magnetite is of little commercial value.
2. There is no rutile contained in these cores.
3. Ilmenite content ranges from 2.5% to 5% in all holes except 96-4 where it is 10%. 94-4 also contained 2.5% P_2O_5 . However, apatite contained in the core is very fine-grained and may be deleterious to Ilmenite instead of being a by-product. As a result of this analysis, core from 94-4 was sent to MD Technologies in Perth, Australia for metallurgical analysis and review of commerciality of the core. Results from their analysis show that recoverable ilmenite is only 3.2% because substantial proportion of TiO_2 is contained in Pyroxenes as well as in magnetite and that calcium and phosphorus content makes it unsuitable for chloride feed stock but acceptable as sulphate feed stock. Two surface samples from northern part of the ridge had recoverable ilmenite exceeding 10%.

INTEGRATION OF GEOLOGY AND GEOPHYSICS

The geological study conducted in the summer of 1997, 1998 and 1999 by Ed Kruchkowski (see Assessment Report Numbers 25280, 25664 and 26044) provided encouraging results from silt and rock samples. Analyses of these samples generally supported the magnetic data interpretation and drill hole results of previous years. General conclusions from magnetic separation and petrographic studies are:

1. Recoverable magnetite is expected to be 60 - 75% of Fe_2O_3 content of the rock. However, this magnetite is of little commercial interest due to its TiO_2 content.
2. Recoverable ilmenite is expected to be about the same percentage as TiO_2 since pyroxenes and magnetite also contain TiO_2 .
3. Rutile is absent in all five holes analyzed in detail.
4. Apatite is present along the rims of zones with concentrated ilmenite. This apatite is very fine-grained, widely dispersed and probably not commercial.

Silt Samples

86 silt samples were collected in 1997 and 1998 from the stream beds. The chemical analyses showed Fe_2O_3 and TiO_2 content ranges of 5 - 36% and 0.5 - 14% respectively. Iron and titanium contents increased in tandem, TiO_2 being 20 - 40% of Fe_2O_3 . Generally the percentage was at the higher end of the spectrum when the Fe_2O_3 content was higher.

Higher concentrations were noted in streams which flowed through highly magnetic areas than in streams which bypassed such areas. The ground magnetic survey shows that many streams have moved since concentrating magnetite along several kilometres of their lengths. The data indicates the width of concentrated zones ranges from 100 - 200 m. It should be noted that string anomalies are also caused by sources other than streams.

Rock Samples

Rock samples were collected from accessible outcrops in 1997, 1998 and 1999. Chemical analyses of these samples showed that generally TiO_2 is 15 - 35% of Fe_2O_3 , its proportion increases when Fe_2O_3 concentration is high.

The chemical analysis done in 1997 did not include P_2O_5 and V_2O_5 . The analysis for these samples was repeated by Loring Lab in 1999 in Assessment Report Number 26044. This analysis indicates that ilmenite enrichment noted in 94-4 probably extends eastward and may be better than in 94-4. P_2O_5 content seems to be higher along the rims of high ilmenite zones. There is indication of local concentration of V_2O_5 but not to economic levels on its own account.

Ground Geophysical Survey

In June 1998 and 1999, total magnetic field data were collected along slashed lines and four roads. Station spacing was 25 m and line spacing averaged 1 km. The meter, ENVI MAG/VLF, S/N 9602230, was manufactured by and rented from Scintrex. This work is reported in Assessment Report No. 26044. To summarise, manually contoured map of magnetic field shows very strong (2000 -6000 nT) string like anomalies. When these strings follow the dips on topographic map, they indicate magnetite concentration in existing or old streams. When string like anomalies follow the trend of the topographic strikes, they may be due to the outcropping gabbro.

Composite Sample Separation and Analyses of Ilmenite and Magnetite

The crushed core for hole 94-4 was shipped to MD Mineral Technologies in Australia to determine the recoverable grade of ilmenite, magnetite and apatite, composition of ilmenite and magnetite and grain size of ilmenite and magnetite. The report of this analysis (Assessment Report Number 26336) can be summarised as follows:

1. Recoverable percentage of ilmenite totals only 2.9%. This could increase to almost 4.0% on optimum crushing.
2. Ilmenite is suitable for sulphate feedstock.
3. Magnetite contains approximately 15% TiO_2 .
4. Apatite, if any, is not recoverable.

These findings show that the hole itself is not commercial but the areas of higher TiO₂ content could be potentially commercial. Therefore, two crushed rock sample residuals from geochemical analysis for samples R65 and R222 located on the northwest slope of the ridge were sent to MD Minerals for similar analysis. The geochemical analysis had shown that TiO₂ content in these samples was approximately 10%. Unfortunately, fines (-45 micrometer) were 65.2% in R65 and 42% in R222. Even with this unfavourable ratio, the recoverable ilmenite was respectively 2.6% and 8.3% of the whole sample. This translates into maximum of 7.5% and 12.7% respectively. In R222, all of TiO₂ appears to be in ilmenite and magnetite and none in pyroxenes. Recovery of more than 10% ilmenite is probable in an optimally ground sample R222.

GOLD PROSPECT

In April 2001, 15 silt samples scattered over the area of the claims were sent to Loring Labs of Calgary for PGM analysis to review the prospects of gold, palladium and platinum. None of the samples had measurable platinum or palladium. However, two silt samples had gold content of 25 ppb and 1500 ppb. These samples are located on eastern side of the ridge, near an offshoot of the Tintina Regional fault and on the probable edge of the gabbro-rich intrusive. Seven rock samples were also analyzed for gold, copper, lead and zinc but they did not contain any of these elements in appreciable quantity,

Another 30 silt samples and one rock sample were analyzed for PGM elements and 32 element analysis in August 2001. The gold content in 30 samples was as follows:

Gold, ppb	Number of Samples
100 - 815	9
25 - 83	6
08 - 23	6
below 5	9

The only rock sample analyzed tested gold at 7 ppb. The gold values clustered around two good samples tested in the spring. 32 element analysis of these 30 silt samples and 7 rock samples confirmed that there was no other element of economic interest in appreciable quantity. These assays were included in Appendix 3 with the year 2001 report no. 26723.

In early October 2001, 26 stream silt, 14 rock and 166 soil (zone B) samples were collected in the general area of two good silt samples reported last year (Figure 2). The assay of these samples resulted in measurable gold in 8 rock, 4 silt and 37 soil samples. PGM and ICP analyses of these samples are given in Appendix 2. We also analyzed 6 samples from outcrops in this area (Appendix 2A). They showed no gold or other elements of any commercial interest thus setting eastern limit to prospective area.

Three samples from the core of hole 95-2 and one from hole 95-3 were processed by 30 element ICP analysis and also separately for gold. The results are given in Appendix 3. All four samples contained some gold but no other encouraging element. We had analysed five foot sections from hole 95-2 for magnetite and ilmenite in the year 2000. The remainders of these samples were now analysed for gold for the depths of 10 to 120 feet (Appendix 4). Although 8 of 21 segments had some gold, most encouraging was one located within five feet of the highly magnetic gabbro. It assayed 400 ppb of gold. This leads us to the hypothesis that highest concentration of gold occurs in less magnetic layer in contact with highly magnetic gabbro. We have not yet established this in other holes. However, silt

sample S105 which contained 800 ppb of gold was separated into magnetic and nonmagnetic parts. Nonmagnetic portion, 82.18% of the whole sample, assayed 700 ppb while magnetic portion, 17.82% of the sample, assayed 900 ppb (Appendix 4B). This shows that although gold may be concentrated in less magnetic rocks overlying gabbro, concentration of gold may not be related to magnetite content itself. Hole 96-3 is located southeast of the area outlined as gold prospect. The magnetic susceptibility in the core was very low to 275 feet and slightly higher for 275 – 300 ft. The core was split diametrically in two parts. One of the parts was further divided into two quarters. One quarter was assayed for gold, palladium, platinum and rhodium in five feet segments from 20 – 300 feet and the other into one foot segments from 250 – 284 feet (Appendix 4C). Small gold assays from 5 – 55 ppb were noted at scattered depth intervals but the values were not high enough to extend the area of commercial interest to the location of this hole.

139 rock and 34 silt samples in our claim area had been analyzed for other elements but not for gold. These samples were assayed for gold, palladium, platinum and rhodium to identify other areas of interest for precious metals on our claim (Appendix 5). Unfortunately, although isolated samples had some gold, no other area of commercial interest was identified.

Based on these results, we collected 563 soil samples (zone B) during August and September of 2002. These samples have been assayed. Location and gold content (when greater than 5 ppb) is shown in Figure 2. Following table summarises the content of gold in 729 soil samples collected so far.

Gold ppb	Number of samples
0 - 5	503
5 - 9	46
10 - 50	132
51 - 99	17
100 - 500	28
500 or more	3

The gold-bearing samples are grouped into three prospective areas totalling more than three square kilometres. We do not have enough data to be certain whether the areas are connected or not. The areas are open to the west and to the south. The silt sample with a 1500 ppb assay is located in this area. In addition, 30 samples out of 563 which were assayed for Palladium had it in varying amounts. One of these measured 140 ppb as well as 394 ppb of gold.

Hole 95-2 drilled in 1995 to evaluate the magnetite prospect was assayed for gold in 5 ft segments. The hole is located on Bearpaw Ridge just south of the prospective areas. 8 segments assayed gold as follows:

Depth range, ft	Gold ppb
10 – 15	20
15 – 20	10
25 – 30	5
70 – 75	10
75 – 80	35
80 – 85	30
85 – 90	400
90 – 95	25

Hole 96 – 3 located at the southern edge of the area of good soil samples showed measurable gold at following depth ranges:

Depth Range, ft	Gold ppb	Other metals, ppb
20 - 25	15	Pt 5
25 - 30	15	Pt 25
30 - 35	25	Pt 20
35 - 40		Pt 15
50 - 55		Pd 52
60 - 65	10	Pd 24
80 - 85	10	
125 - 130		Pt 5, Rh 5
130 - 135		Pt 15, Rh 15
135 - 140	5	
140 - 145	10	
145 - 150	55	
180 - 185	5	
190 - 195	35	
195 - 200	10	
200 - 205	5	
205 - 210	5	
210 - 215	15	
240 - 245	5	

Pt Platinum, Pd Palladium, Rh Rhodium

This hole was noteworthy for not encountering magnetic rock above 280 ft. While the assays are not exciting in themselves, they do suggest the possibility of a gold deposit nearby which could source the gold noted in silt and soil samples.

We discussed these results with two geologists, Ed Krutchkowski and Thomas Richards. Both were excited by the results. Thomas suggested that we should confirm these assays by getting another lab to do the analysis on some samples. Accordingly, we sent 10 samples with variable gold assays to Acme Lab in Vancouver for this analysis. Unfortunately, Acme results do not confirm previous results obtained by Loring Lab. This comparison is shown in the following table:

Sample ID	LORING LAB			ACME LAB			Sample Wt (Acme)
	Au	Pt	Pd	Au	Pt	Pd	
95-2 89-90	400			<2	<2	<2	30 gm
0+00N 39+50E	430	<5	<5	<2	2	2	30 gm
0+00N 41+25E	1585	<5	<5	2	7	7	30 gm
0+00N 43+00E	<5	<5	<5	<2	8	4	15 gm
3+00S 28+75E	110	<5	<5	8	<2	8	5 gm
3+00S 34+50E	<5	<5	<5	56	7	<2	5 gm
3+00S 48+75E	7	<5	<5	7	8	12	10 gm
5+00S 36+00E	<5	25	<5	<2	2	2	30 gm
5+00S 39+00E	13	22	<5	<2	<2	8	15 gm
5+00S 40+00E	13	42	<5	3	4	7	15 gm

If Acme results are correct, nine samples have negligible gold and one has higher gold content than Loring found.

These assays were included in Appendix 3 (report number 27021).

In order to resolve the anomalous results from different labs, Ed Kruchkowski collected 112 soil samples along the gaps in previous sampling during the summer of 2003. These samples were collected in duplicate, i.e. two samples were collected at each location. The samples were sent to Loring Lab in Calgary and Assayers Canada in Vancouver. The difference in two sets of assays was greater than expected in soil samples but the presence of gold was consistent. Based on all soil samples, and assays from Loring Lab we have delineated a 5 sq km area where gold is indicated and one sq. km where gold values are quite high (Figure 4).

Four trenches were dug in the best gold prospect at locations indicated in Figure 4. Trenches were dug approximately a meter into hard rock. 37 samples in rock and overburden were taken at 5 meters interval. Total length of trenches was 160 meters. The first trench encountered overburden of less than two meters and the bedrock was gabbro and anorthosite. Second trench was two meters to half meter deep and the bedrock was gabbro with and without anorthosite strings. A fault was identified in the bedrock by powdered rock. Trench 3 encountered tuff with anorthosite strings at one meter depth. Trench 4 had gabbro with pink anorthosite at the depth of 0.5 meter.

The chemical analysis of the samples was completed after the period covered by this report but the results are included here in view of their importance. The assays was most discouraging. There was no significant presence of gold in any sample. This lack of gold in the trenches means that finding the source of gold in soil samples is going to be an expensive proposition. The only positive in assays was presence of strontium in some samples which could indicate the presence of zinc nearby. However, there was no appreciable zinc anomaly in assays and this lead will not be followed for the present.

Current Work:

Although our gold prospect has dimmed in lustre, our Titanium prospect remains feasible. Therefore, the work in 2005 consisted of drilling two of the best locations for Ilmenite and magnetite which had been identified in 2000. Two holes, each 30 meter deep were drilled at each location, one vertical and the other slanted at 45 degrees. We encountered consistent high magnetic susceptibility zones in these holes (Figure 5). Unfortunately, the drilling was completed just a few days before the end of the financial year and core analysis has not been done yet.

Future Work:

The analysis of the four holes drilled in 2005 will be conducted in early 2006 and reported in our next report. The results will be crucial in determining the viability of Titanium/Magnetite prospect. Further action depends on these results.

Gold analyzed by Fireassay / A.A. finish.

"R" Denotes duplicate sample analyzed.

0.500 Gram sample is digested with Aqua Regia at 95 C for one hour and bulked to 10 ml with distilled water.

Partial dissolution for Al, B, Ba, Ca, Cr, Fe, K, La, Mg, Mn, Na, P, Sr, Ti, and W.

APPENDIX 4A

Sample No.	Au ppb
"Geochemical Analysis"	
95-2- 10-15	20
95-2- 15-20	10
95-2- 25-30	5
95-2- 30-35	< 5
95-2- 35-40	< 5
95-2- 40-45	< 5
95-2- 45-50	< 5
95-2- 50-55	< 5
95-2- 55-60	< 5
95-2- 60-65	< 5
95-2- 65-70	< 5
95-2- 70-75	10
95-2- 75-80	35
95-2- 80-85	30
95-2- 85-90	400
95-2- 90-95	25
95-2- 95-100	< 5
95-2- 100-105	< 5
95-2- 105-110	< 5
95-2- 110-115	< 5
95-2- 115-120	< 5

I HEREBY CERTIFY that the above results are those assays made by me upon the herein described samples :

 Assayer

Rejects and pulps are retained for one month unless specific arrangements are made in advance.
