1.0 EXECUTIVE SUMMARY

- This primary purpose of the 2005 Program included the creation of an integrated 3-dimensional model, a comprehensive geophysical survey and subsequent drilling campaign in support of completing and satisfying the terms of option agreement on the Craigmont Mine Property. In addition, this report includes details regarding all aspect of the aforementioned program along with recommendations for proceeding with exploration and development of the Craigmont Mine Property.
- At the start of the program, the claims that covered the Craigmont Property included 3222 hectares which comprised the group of claims under option to Christopher James Gold Corp. During the program the land position was increased by 264% to 8515 hectares. The previous Craigmont Holdings Ltd. land position along with the new and conversioned cells covers 19 titles and 10 leases.
- The requirement for completing the option on the Craigmont property was for the expenditure of \$500,000 by September 2005 and an additional \$500,000 by April 2006. As or December 2005, the approximate total spent on developing the property is \$1,020,000 which exceeds the commitment necessary for acquiring the property. Christopher James Gold now holds 100% of the rights to the base and precious metals on the property along with holding the fee simple rights.
- JDSemi of Kelowna, B.C. and Frontier Geosciences of North Vancouver, B.C. completed the geophysical survey that consisted of a comprehensive program that included a detailed surface magnetic survey, an induced polarization (IP) survey that also included a downhole IP component in addition to surface GPS surveying.
- Twenty eight survey lines were completed, each approximately 800 to 1700 meters in length. The lines ran from north to south on a local grid surveyed and marked by Amex Exploration Services of Kamloops, B.C. The time domain resistivity /IP was run using a pole-pole array as well as dipole arrays of 100 and 200 meters length and included current injection points in boreholes. Voltage measurements were made on 100 meter using two full waveform receiver of eight channel capacity each together with a multi-conductor potential cable with 100 meter take-outs connected to the ground through porous pots. The eight dipoles were tested for contact resistance before each reading was taken.
- Historic surface drillhole and selected underground drill data has been input from paper logs into a detailed database which includes collar, downhole survey, assay (i.e. Cu% and Fe%), lithology, into the processing and visualization software for analysis and for developing a complete 3D picture. In addition, topography, surface features (i.e. roads, pit, waste dumps, buildings), selected sections and plans, underground development and surface geology were input for spatial reference.
- All data was then transformed to UTM datum and passed through rudimentary quality control. Once completed a comprehensive 3D model of the main geological features was created to assist in the evaluation of geophysical targets.

CRAIGMONT MINE PROJECT

- In developing a complete exploration model and consequently opportunities for further investigation and drill targets, the most prospective areas would have more than one of the following characteristics:
 1. Magnetic trends and anomalies.
 2. IP chargeability highs and trends.
 3. Resistive lows.
 4. Favourable lithologic conditions and skarn occurrences.
 5. Zones of mineralization evidenced by Cu and Fe assay confirmation.
- The results produced by the geophysics program in combination with the exploration model produced 5 drill targets for the 2005 drilling campaign.
- The 2005 drilling campaign comprised 8 holes totalling approximately 4,500 feet. Two of the holes had to be abandoned due to bad ground, four of the holes hit favourable geology and two of the holes hit skarn mineralization that warranted analysis. Significant intersections included 0.45% Cu over 1.2 meters in Hole Ab-5 before the hole was lost and 0.36 % over 6 meters in Hole Ab-7 which included 0.53% over 3 meters.
- There was one lost time accident related to the drilling program.
- The final hole Ab-8 resulted in extensive water flow issues. Attempts were made to seal but these attempts failed. Water tests were taken and submitted to the Mines Inspector in order to secure an exemption. The exception was secured until spring however this will need to be addressed within the 2006 drilling campaign.
- It is recommended that a geophysical exploration program be carried out on the newly acquired ground and targets evaluated for future drilling.
- It is recommended that an underground exploration program be carried out on the historic Craigmont Mine area. This would include surface and downhole geophysics and potentially drilling from surface to identify the location and potential size of the remnant mineralization at the Craigmont Mine which is said to be 100,000,000 lb of Cu based on mostly anecdotal evidence. In support of this effort, a complete and comprehensive 3D model of the mine area is recommended which would include importing and georeferencing underground drillhole data and underground openings.
- It is recommended that an internal Scoping Study, performed by Beacon Hill and Knight and Piesold, be initiated which would form the basis for a Preliminary Assessment for the continuation of mining activities within the underground at the Craigmont Mine.

2.0 INTRODUCTION AND TERMS OF REFERENCE

Mr. Max Baker, President of Christopher James Gold Corp., retained the author to develop a comprehensive 3D model of the Craigmont Mine area focusing upon the area termed the Embayment block. The area lies adjacent to the Craigmont Mine proper and is thought to be perspective from the viewpoint of a new discovery. Should a new, potentially economic deposit be discovered within the Embayment Block, the reinvestigation and rehabilitation of the Craigmont Mine would be justified.

The Craigmont Mine is located on the 14 km. to the NW of Merritt, BC and is wholly owned by Christopher James Gold Corp. Garth Kirkham supervised the input of a sub-set of the historic data as it related to the investigation of the Embayment Block, integrated the data into MineSight Software and created the 3D exploration models, managed the geophysical program in addition to the 2005 diamond drilling program on the property.

3.0 PROPERTY DESCRIPTION AND LOCATION

The Craigmont Property is comprised of 10 original leases previously held by Craigmont Holding Ltd. and 97 Units staked on-line by Christopher James Gold Corp. The Craigmont Mine property is situated on Aberdeen Road in Lower Nicola - approximately 14 km to the northwest of Merritt, BC, Canada (Fig. 1). The property is centered upon latitude $50^{\circ} 12' 27''$ North, longitude $120^{\circ} 55' 29''$ West, on BCGS Map Sheets 092I016/09I026. This area is within the Nicola Mining Division.

Figure 1: Location of Merritt, BC.

The Craigmont Mine Property comprises 10 contiguous mining leases and 97 claim units. Lease details are listed in Table 1 with locations shown in Figure 2. Note that red outline denotes Blue Rock Resources Ltd. (formerly Better Resources) claim boundary under option by Christopher James Gold Corp. Table 2 and Figure 3 shows the new and converted cells (19 titles and 10 leases) as of December 10, 2005. This was performed by Amex Exploration Services on behalf of Craigmont Holdings Ltd. to insure tenure and avoid the loss or encroachment on existing claims, partials or surrounding areas. In addition, Christopher James Gold Corp. successfully staked on-line 3078 hectares (7 titles) on the northwest of the property which also encompasses the western boundary of the Highland Valley Copper property.

On January 31, 2006, Christopher James Gold notified Craigmont Holdings Ltd. of the satisfaction and completion of the commitments and expenditures thereby completing and exercising the option to attain all base and precious metals rights (with the exception of magnetite) for all lands as they occur on the properties listed above.

4.0 ACCESSIBILITY, CLIMATE, LOCAL RESOURCES, INFRASTRUCTURE AND PHYSIOGRAPHY

The property is 14 kilometers northwest of the City of Merritt with a population of approximately 100,000. Merritt is a full service community with all necessary facilities and infrastructure readily available. Access from Merritt is northwest via highway 97c (Merritt-Spences Bridge Highway for 9 km to the Aberdeen Road in Lower Nicola, then north on the Aberdeen Road for about 5.5 km to the old mill road north of the current Craigmont tailings operation, then on the old mine access roads to the north side of the east end of the abandoned pit.

Climate is moderately dry semi-continental with less than 1 meter of annual precipitation. Mild winters with moderate snowfalls and warm summer with modest amounts of rain characterize the climate. Temperatures range from +26°C to -11°C. Summary climate statistics are shown in Figure 4.

Annual Mean Total Rainfall	189.3 mm
Annual Mean Total Snowfall	99.6 mm
Hours of Sunshine	2,030 hours
Annual Mean Daily Temperature	6.7° C
July Daily Maximum Temperature	26.2° C
January Daily Minimum Temperature	-10.8° C
Average Frost Free Days	250 days
Average Growing Season	5 Months

Figure 4: Merritt, BC Climate Details

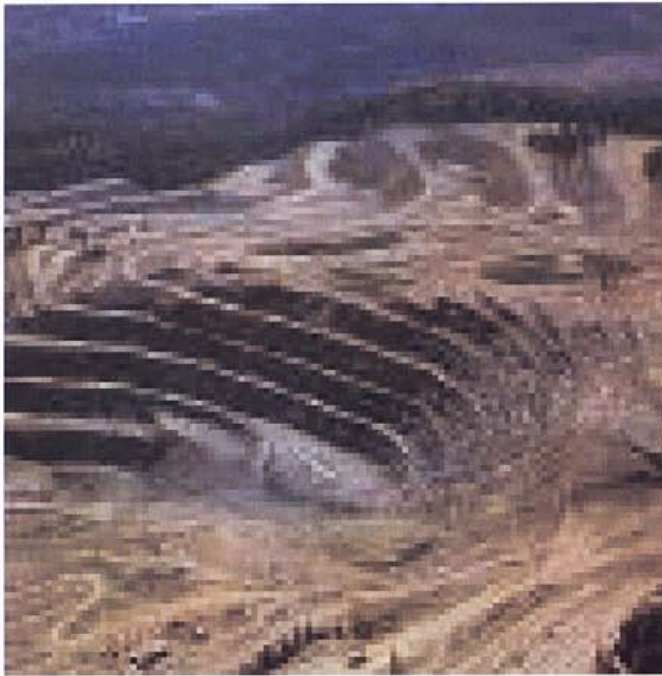

The terrain is typical of the area in the vicinity of Merritt, consisting of rolling hills separated by lakes, rivers, creeks, swamps. Most of the overburden is a thick alluvial till. Topography on the property ranges between 860 meters and 1633 meters above sea level. The upper elevations are covered by interior spruce and lodgepole pine which grade downward to ponderosa pine forest at about 900 meters.

5.0 HISTORY

5.1 Craigmont Mine

The written history of the Craigmont mine and orebodies is detailed in Murphy Sewchuk's book titled "The Craigmont Story" dated 1983 in addition to J.F. Bristow's summary of the early history dated 1968;

Figure 5: Craigmont Mine Pit Area

"The Eric showing situated one mile to the east of the present open pit, was diamond drilled and trenched during or before 1935. In 1954, the fourteen key mineral claims which form the core of the present property were acquired. Prior to 1957, most of the geological and geophysical work was concentrated in the vicinity of Jackson Lake on the Payston showing approximately one mile north-west of the present open pit. Much of the initial work consisted of the investigation and the evaluation of magnetic anomalies of low magnetic intensity similar to the anomalies obtained in the Bethlehem property in the highland valley area 20 mile to the north. It is interesting to note that the anomaly obtained above the Craigmont No. 1 orebody was one of the high magnetic intensity".

"Diamond drilling during late 1957 and 1958 outlined up to 640 feet (195 meters) averaging over 4.4% copper. Open pit mining commenced

in 1962 and underground production in 1967. From 1977 to early 1979 a comprehensive multidisciplinary property wide exploration program was undertaken to search for additional ore grade mineralization (Morrison 1979). Although several existing zones were examined and others discovered, they were considered to small and/or low grade to warrant developing as feed for the 5000 ton per day milling complex. When the mining stopped in 1982, over 34 million tonnes of ore had been mined. Magnetite however, has been mined from stockpiles, dumps and tailings which are operations that continue today. Since 1991, Craigmont Holdings Ltd. has been reprocessing material for magnetite that is used for the cleaning of metallurgical coal. In addition, there is a large hematite component which is a product typically used for pigment. Annual production is 60,000 tonnes per year (although current production is within the 80,000 tonne range due to increased demand) of clean metallurgical grade magnetite. Recent exploration on the mine property has focused primarily upon relatively high grade magnetite mineralization and specifically that material related to the low grade copper mineralization only found on the peripheries of the mined out ore body. These bodies were likely left as crown pillars and were deemed uneconomic for copper mill feed.

"During Craigmont's lifetime as a copper producer, it added over 947 million pounds (426 million kilograms) of copper to the world's marketplace. The mine grossed over CAN\$450 million in sales. Production costs included approximately CAN\$112 million paid in wages to employees. Craigmont had net earnings over its two-decade lifetime of CAN\$115 million and paid shareholders CAN\$107 million in

dividends. The federal and the provincial governments received CAN\$74 million in direct taxes and royalties. In addition to the direct taxes, the company paid sales taxes on goods and services while its employees paid income taxes on wages and salaries.” Considering the multiplier effect that such an operation has on the community and local economy, for every job created, 3 to 5 supporting jobs are created. Therefore the impact of Craigmont on Merritt was very significant and instrumental in its early growth.

In addition, Craigmont can take credit for innovations in mining such as being the first large scale open pit mine in British Columbia and being one of the pioneers for using underground bulk mining techniques such as sub-level block caving which is considered state-of-the-art even today. Both methods are currently the desired method of extraction for surface and underground mining. Craigmont was also an innovator when it came to mining equipment. In an era where underground mining was only achieved by tracked equipment, Craigmont was at the forefront of utilizing diesel, trackless and hydraulic machinery and when the necessary equipment did not exist, the Craigmont personnel modified the on-site stock.

5.2 Craigmont Mine Area - Previous Exploration

Economic copper mineralization was discovered at Craigmont in 1957 through drill testing of various geochemical and geophysical targets adjacent to the Guichon Creek Batholith. Between 1957 and 1961, when the mine commenced production, an airborne magnetic survey and various ground magnetic surveys were carried out by Craigmont on the surrounding properties. Various other geophysical techniques were tested until 1972 such as Self Potential, SLINGRAM, Ronka MK4 horizontal loop and Induced Polarization. In addition, geologic mapping and extensive prospecting was performed. A total of 85 surface drillholes had been drilled during this period on a variety of targets.

Between 1972 and 1977, the only exploration work that was completed was a proton magnetometer survey over the eastern portion of the property and Noranda-Cressy Block. Ten additional surface drillholes were completed totaling 4,919 feet which tested various magnetic highs. Although a substantial amount of skarn was discovered, none contained any significant copper mineralization.

Up to this point, no underground exploration had been carried out apart from the drilling focused upon the definition of the No. 3 type ore west of the 7015E Section. From 1977 through 1979, as the reserve base became severely depleted, a CAN\$1.6 million program of exploration was spent in a quest for more ore. This included:

- 24 additional surface drillholes totaling 35,824 feet
- 11 underground drillholes totaling 12,670 feet
- Geological mapping of the entire property at 1" = 200' scale
- Relogging of approximately 200 surface and underground production drillholes along with approximately 50 surface exploration drillholes
- Total field magnetics totaling 37,100 line-feet
- Vertical field magnetics totaling 57,500 line-feet
- Inverse polarization totaling 18,500 line-feet
- Pulse electro-magnetics totaling 150,500 line-feet
- VLF (Very Low Frequency) totaling 67,500 line-feet

The geophysical surveys focused on specific areas of the property. The consensus was that magnetics best reflected the presence of mineralization and should be included in any future geophysical surveys or exploration programs.

In total, Placer Dome investigated the areas adjacent to the mine and surrounding areas spending over \$8 million in the 1970's and 1980's which would be much more in today's dollars. Sadly for Placer but perhaps opportune for CJG, a significant orebody has not been found although there is a wide belief that one exists. It is thought that, by using current technology and by integrated all historic data, a new orebody may be discovered which would justify attempting to economically exploit the reserves and resources left in place.

6.0 GEOLOGY

6.1 Regional and Local Geology

The Promontory Hills area is underlain by a complex east- northeast trending, steeply dipping volcanic pile of Upper Triassic Nicola Group rocks, bounded to the north by the multistage Early Jurassic-Late Triassic Guichon Creek batholith and unconformably overlain by the Middle and Upper Cretaceous Spences Bridge Group. Most of the area is covered by extensive gravel overburden.

In the vicinity of Craigmont mine, the Border phase of the Guichon Creek batholith varies in composition from quartz diorite to granodiorite. These rocks intrude the Nicola Group, a thick volcanic and sedimentary series of agglomerate, breccia, andesitic flows, limestone, argillite and greywacke. Attitudes parallel the intrusive contact zone. Sediments immediately adjacent to the batholith are hornfelsed quartzofeldspathic greywackes. Spences Bridge Group agglomerates and flows dip approximately 15 degrees to the south and outcrop in the areas south and west of the mine.

The mine lies adjacent to the southern margin of the Guichon Creek batholith. Host rocks to the mineralization are calcareous sedimentary rocks of the Nicola Group comprised of limestones, limy tuffs, greywackes and argillites.

The gross structure at the mine is a large anticline with ore-bearing drag folds on the north limb. These folds plunge 60 to 70 degrees eastward and are often occupied by diorite dykes. The anticline is cut off by a northwest trending fault on the west and an east trending fault on the south. Orebodies lie within a block bounded by these regional faults and the Guichon Creek intrusive.

Alteration mineralogy indicates thermal zoning. Within the hornfelsed zone, greywackes contain biotite and actinolite and limestone is altered to marble. Immediately to the south is a massive actinolite skarn which, in places, is further altered to epidote and garnet (grossularite, andradite).

Three types of alteration are present. First is a zone of potassic alteration with a related (second) distal hornfels. Third is skarn alteration which overprints the potassic alteration and some of the hornfels. The skarn is garnet-epidote-amphibolite in composition with some chlorite, tourmaline and sericite.

Semi-continuous ore is found over a strike length of 900 metres and a vertical depth of 600 metres. The five main orebodies are confined to the limy horizon between walls of greywacke and andesite.

Mineralization consists of magnetite, hematite and chalcopyrite and occur as massive pods, lenses and disseminations extending through the calc-silicate horizon. The body is roughly tabular, trends east and dips near vertically. Minor folding and faulting is present but do not significantly distort the

mineralization. Chalcopyrite is associated with, but post-dates the magnetite and commonly encloses the magnetite.

Chalcopyrite is the principal ore mineral and occurs as veins, streaks, patches and coarse disseminations. It was first deposited with magnetite during the development of the actinolite skarn and later with specularite as fracture-fillings and veins. Bornite is present in small amounts. Pyrite is confined to areas of heavy garnet alteration. Approximately 20 per cent of the ore (by weight) is comprised of magnetite and hematite and along with actinolite, epidote, grossularite, andradite, pyrite and minor diopside, occur in the skarn. Supergene minerals, native copper and chalcocite, occur in a narrow oxidized zone immediately above the orebody. The apparent ore controls are favourable host rock, folding and brecciation of host rock, and proximity to the batholith.

The original Craigmont copper mine went into production in 1962, with underground mining ceasing in February 1982 as a result of the falling price of copper. The concentrator remained in operation processing the iron ore stockpiles until November 1982, when it was also shut down.

From the commencement of its operation in 1962 until 1970, Craigmont Mines Limited did not recover the magnetite in its milling process, and on a material-balance basis there is estimated to be in the order of 5 million tonnes of magnetite in the tailings deposit. The company reports that exploration completed in 1991 proved the presence of in excess of 1 million tonnes of magnetite in the southerly one-quarter of the tailings.

Since the cessation of production in 1982, magnetite has been shipped from the stockpiles at Craigmont to western Canadian and United States coal producers, to be used as an essential component in their heavy media separation process.

Magnetite remaining in the original stockpiles as of 1992 represents approximately three years of industry requirements, based on the current level of usage. In order to replenish the stockpiles, in 1991 the company applied for the necessary government permits to construct a facility to recover the magnetite from the old tailings deposit. Production from the plant is scheduled to commence in the fall of 1992 (J. Harris (Yorkshire Resources), personal communication, 1992).

Seven Industries Inc. continues to produce about 60,000 tonnes per year of magnetite by processing the Craigmont tailings. The quality of the product has improved and the company is supplying most coal mines in western Canada (except Manalta and Line Creek). The company has filed a conceptual design to create a new tailings storage dam (on top of the old one) which would allow the operation to continue for at least another 15 years (Information Circular 1996-1, page 10).

6.2 Property Geology

The Craigmont Cu-Fe skarn deposit is adjacent to the southern margin of the lower Jurassic Guichon Creek Batholith, near Kamloops in British Columbia, Canada. For details of the geological setting see the Highland Valley record.

The host to ore are the sedimentary and volcanic rocks of the upper Triassic Nicola Group. In the mine area this group is represented by a complex sequence at least 600 m thick which has been subdivided into Basalt, Rhyolite, Carbonate and Clastic Sediments Units. All strike and dip parallel to the contact of the batholith, and are within the batholith contact aureole. Only the Clastic Sediment Unit however, is in contact with the batholith. The majority of the skarn and ore is within facies that comprise lime sandstone,

lime siltstone, quartzo-feldspathic siltstone and argillite. The first stage of development of the ore is magnetite rich, with actinolite-epidote-magnetite skarn developed within basaltic rocks and Fe-bearing siltstones of the facies listed above, while barren grossular garnet-epidote-calcite-pyrite skarns are found in Fe-poor rhyolitic bands of the same facies and the Carbonate Unit. In the second stage massive barren grandite garnet skarn replaced mineralised first stage skarns in the vicinity of diorite plugs and specularite ore formed in brecciated first stage skarn and clastic rocks away from the plugs. While the first stage skarn requires no addition of the main rock forming elements, only a redistribution and concentration of the elements already present, Cu was apparently added, or was subjected to a better process of redistribution and concentration compared to the other elements. The second stage similarly requires only redistribution and recrystallisation of first stage skarns and ore (Morrison, 1980).

Cu and Fe are the only elements in economic concentrations and chalcopyrite is the only significant Cu mineral. The chalcopyrite is disseminated and is interstitial to magnetite in the first stage mineralised skarns, and is interstitial to the second stage specularite in the matrix of the breccias of that stage. Chalcopyrite also occurs with pyrite as stringer ore in bleached sediments and rhyolite tuffs in the stratigraphic footwall of the main orebodies. The Craigmont deposit has more in common with Cu-Fe deposits found in meta-sedimentary and meta-volcanic rocks than with those generally associated with porphyry copper deposits (Morrison, 1980). Morrison (1980) considers Craigmont to be more likely a product of concentration of metals already within the Nicola Group by the Guichon Creek Batholith, than of the mineralising event that produced the porphyry Cu deposits of the central Guichon Creek Batholith. This is reinforced by the identification of Cu-Fe rich units within the host rocks which extend away from the batholith, and apparently control the distribution of much of the ore within the sequence which is restricted to the aureole. Published reserve and production figures comprised 33.7 Mt @ 1.77% Cu, 19% Fe (Prod. 1961-82, Dawson, et al. 1991).

7.0 MINE GEOLOGY

Sections 7.0 through 10.0 have been extracted and/or paraphrased from a variety of reports as listed in Section 18.0 References however the primary sources are the reports by C.F. Staargaard (1995) and J.E.L. Lindinger (2004).

7.1 Structure

In the Mine Block, the Nicola Group rocks strike and dip parallel to the contact of the Guichon Creek Batholith. All Nicola Group rocks drilled within the Mine Block have partly developed granoblastic texture and mineral assemblages indicative of the hornblende hornfels facies of contact metamorphism (Drummond 1966). The batholith contact aureole is at least 1500 feet wide in the Mine Block. Mapping within the major units suggests that changes in lithology along strike and down dip are better explained by interfingering of facies than by drag-folding of a single unit of uniform thickness.

This interpretation is more consistent with mapping in the Promontory area and with stratigraphic relationships in present day volcano-sedimentary environments. A major anticlinal fold comparable to that at Promontory Hills may have its axis in the basalt unit south of the mine workings, but there is insufficient data to support such a hypothesis. Minor folding within the Mine Block is restricted to the Carbonate unit, where measured axes have no consistent orientation. An antiform interpreted from the distribution of a distinctive grit band on section 7415 and minor folds observed on the 3060 level drift. These minor structures may be the result of plug emplacement. Fault sets recognized within the open pit and underground are consistent with trends recognized at Promontory Hill. The two best developed sets,

striking 0800 with steep south dip and 280 degrees with near vertical dips, are parallel to the margin of the Guichon Creek Batholith and to bedding, foliation and pervasive shearing in the Nicola Group rocks. Two other sets, striking 030 degrees and dipping 65 degrees east are parallel to the faults that controlled deposition of Kingsvale volcanic rocks nearby.

7.2 Basalt Unit

In the mine, the Basalt unit is at least 300 feet thick. It consists of the interbedded plagioclase porphyritic flows, tuffs and derived sandstones and siltstones. The pyroclastic and epiclastic rocks are derived from the flow rocks. Several fine grained basalt flows also occur within the Carbonate unit in the central and eastern part of the mine.

7.3 Rhyolite Unit

The Rhyolite Unit includes up to 800 feet of white, grey and buff lapilli tuff, lithic tuff, crystal tuff and tuff. All the fragments and crystals are derived from quartz-feldspar porphyritic rhyolite and the matrix is normally aphanitic rhyolite tuff with minor muscovite and chlorite. However, locally the matrix contains biotite and calcite and the fragments and crystals are rounded, suggesting reworking of the tuffs.

7.4 Carbonate Unit

The Carbonate unit has been subdivided into three facies that are gradational in composition and locally interbedded. In the western part of the mine, there are two discrete lenses of the Massive Limestone facies that are separated by and grade down dip into rocks of the Interbedded and Grit facies. Farther east in the mine, the two lenses merge and eventually grade out completely. The Interbedded facies consists of thin-bedded, light grey to black impure lime siltstone, thin-bedded to laminated dark brown to black quartzo-feldspathic siltstone; and thin-bedded to laminated dark grey to black argillite. The pure sandstone contains mostly quartz and feldspar as impurities but the other three lithologies contain banded and disseminated biotite, pyrite, chalcopyrite and carbon. The grit facies consists of medium- to thick-bedded, grey sandstone, grit and conglomerate. The massive Limestone facies consists of several lensoid bodies of nearly pure limestone with few interbeds of rhyolite tuff, argillite or siltstone near margins.

7.5 Clastic Sediment Unit

The Clastic Sediment unit is approximately 500 feet thick in the mine area. It consists of variably recrystallized massive to thick-bedded, brown to grey, quartzo-feldspathic sandstone and siltstone. A few beds containing relict pyroxene phenoclasts, magnetite, hornblende and andesine may be recrystallized basalt tuff. Much of the sandstone in this unit is recrystallized to a rock of dioritic texture. In hand specimen, it can only be distinguished from adjacent quartz diorite by the presence of siltstone interbeds. However, in thin section the recrystallized sandstone can be distinguished by its total mafic content, the association of hornblende with biotite, chlorite and muscovite rather than clinopyroxene, the presence of volcanic rock fragments and the presence of metamorphic as well as detrital feldspar grains.

7.6 Guichon Creek Batholith

The contact of the Guichon Creek Batholith is irregular and difficult to define because of the similarity between the Border phase quartz diorite and the recrystallized sandstone of the Clastic Sediment unit. The

Border phase is mainly grey, medium-grained, weakly foliated biotite-hornblende-quartz diorite, although near its margins it ranges from hornblendite to granodiorite and contains numerous partly digested inclusions of Nicola Group rocks. The Border phase is pervasively saussuritized, sericitized and chloritized, but is unmineralized in the mine.

7.6 Diorite Plugs

Diorite Plugs, similar to the batholith Border phase, occur as bulbs and fingers that are elongated parallel to the stratigraphy, but which cut all the units in the mine. The plugs are light grey, coarse grained diorite, occasionally with a core of quartz diorite or granodiorite. Fractures in the diorite have haloes up to 1 inch wide of saussurite and chlorite, and veins with epidote, chalcopyrite and chlorite have epidotized haloes. Late prehnite-calcite and laumontite veinlets are common.

8.0 SKARN TYPES

Several characteristics of the skarn, not emphasized previously, have important consequences for the interpretation of ore genesis at Craigmont:

- Only about two-thirds of the Craigmont ore is developed in skarn while the balance was developed within brecciated and veined, hornfelsed clastic rocks.
- Even massive skarns contain abundant relics of the silicate and carbonate rocks within which they have developed.
- Some of the skarn assemblages are comparable to hornfels assemblages in the wall rock.
- There is no obvious zoning of skarn assemblages away from the contact of the Guichon Creek batholith. Zoning takes place along strike within the Carbonate unit, which is elongated parallel to the batholith contact.

Two distinct stages of skarn development are recognized; Stage I skarns contain only relics of the host rocks and Stage II skarns contain relics of both Stage I skarns and host rocks.

8.1 Stage I Skarns

Stage I skarns are characterized by abundant bleached and unaltered relics of the host rocks as well as by the following associations:

- Magnetite with chalcopyrite in ore-bearing magnetite-rich and actinolite-epidote-magnetite skarns.
- Epidote with garnet in barren banded epidote-garnet skarn
- Barren massive garnet-epidote-calcite-pyrite skarn.

8.2 Stage II Skarns

Mineralized Stage II skarn is characterized by the presence of specular hematite that either co-exists with or replaces magnetite in Stage I skarn. Barren Stage II skarn is composed of massive garnet which replaces Stage I skarn in the vicinity of diorite plugs. Stage II skarns include:

- Specularite-Rich Skarn
- Massive Garnet Replacement Skarn

9.0 ORE TYPES

Three major ore types at Craigmont have chalcopyrite associated with magnetite, specular hematite and pyrite, respectively. Chalcopyrite, magnetite and specularite are the only significant ore minerals in the mine, and only Cu and Fe are recovered in mill concentrations. Minor supergene native copper, chalcopyrite, malachite and azurite occur at the paleo-erosion surface beneath the Kingsvale volcanic rocks at the west end of the open pit and in limonite-stained fractures in Nicola Group rocks. Bornite and covellite occur locally in fractures in chalcopyrite and intrusions of pyrrhotite, marcasite and mackinawite locally coats fractures in marble, garnet skarn and diorite plugs.

The overall shape of the orebody is like a giant Pterodactyl flying east. The head (No. 1 East) and body (no.2) are composed of magnetite-rich and magnetite bearing ore, the dorsal fin (No. 1 Main) is specularite-magnetite and specularite ore, the wings (North Limb, Wing, No. 1 South and Northwest) are magnetite ore with specularite ore tips, and foot is stringer ore.

10.0 GENESIS OF SKARN AND ORE

In the Craigmont deposit, two stages of skarn and ore development can be distinguished. In Stage I, host rock strata controlled the distribution and composition of barren garnet-epidote skarn and of the mineralized magnetite and actinolite-epidote-magnetite skarns. In Stage II, diorite plugs controlled the distribution of barren garnet skarn, which replaced Stage I actinolite-epidote-magnetite skarn and gave rise to the specularite-rich ore of the No. 1 Main, No. 1 South, Northwest and Wing orebodies.

11.0 RESOURCE AND RESERVE ESTIMATION

Since 1961 (Table 5), the mine produced 887 million pounds (402 million kilograms) of copper, 925 million pounds (420 million kilograms) of magnetite, 981 million pounds (445 million kilograms) of iron. Surprisingly, 77,851 grams (2,503 ounces) of gold and 242,510 grams (7,797 ounces) of silver have been historically produced from the property. At today's (March 2006 metals prices at approximately US\$2.50 per pound Cu, US\$80 per tonne magnetite, US\$54 per tonne iron, US\$550 per ounce gold and US\$10 per ounce silver), the net present value of the mine would equate to the combined revenue of \$2.2 billion for the copper, \$33 million for the magnetite, \$24 million for the iron and \$2 million for the gold and silver combining for a total of approximately US\$2.3 billion NPV, 96% of which is attributed from the copper content.

Current and/or remaining reserves and resources are unknown. Estimates have been extracted from internal memos and anecdotal data derived from personnel that worked at the site prior to shutdown. The most solid data is that from an internal Craigmont Mines Ltd. memo dated October 30, 1985 authored by J.F. Bristow regarding the ore reserves within the No. 3 Orebody. Figure 6 illustrates the typical longitudinal section of the mine with the surface topography, pit, main haulage levels, orebodies (i.e. No. 1, No. 2 and No. 3) along with an outline of the potentially caved area within the the underground area. The geological ore reserves for the No. 3 Orebody, calculated using a polygonal method, are estimated to contain the following:

Table 4: Production Details: Craigmont Mine

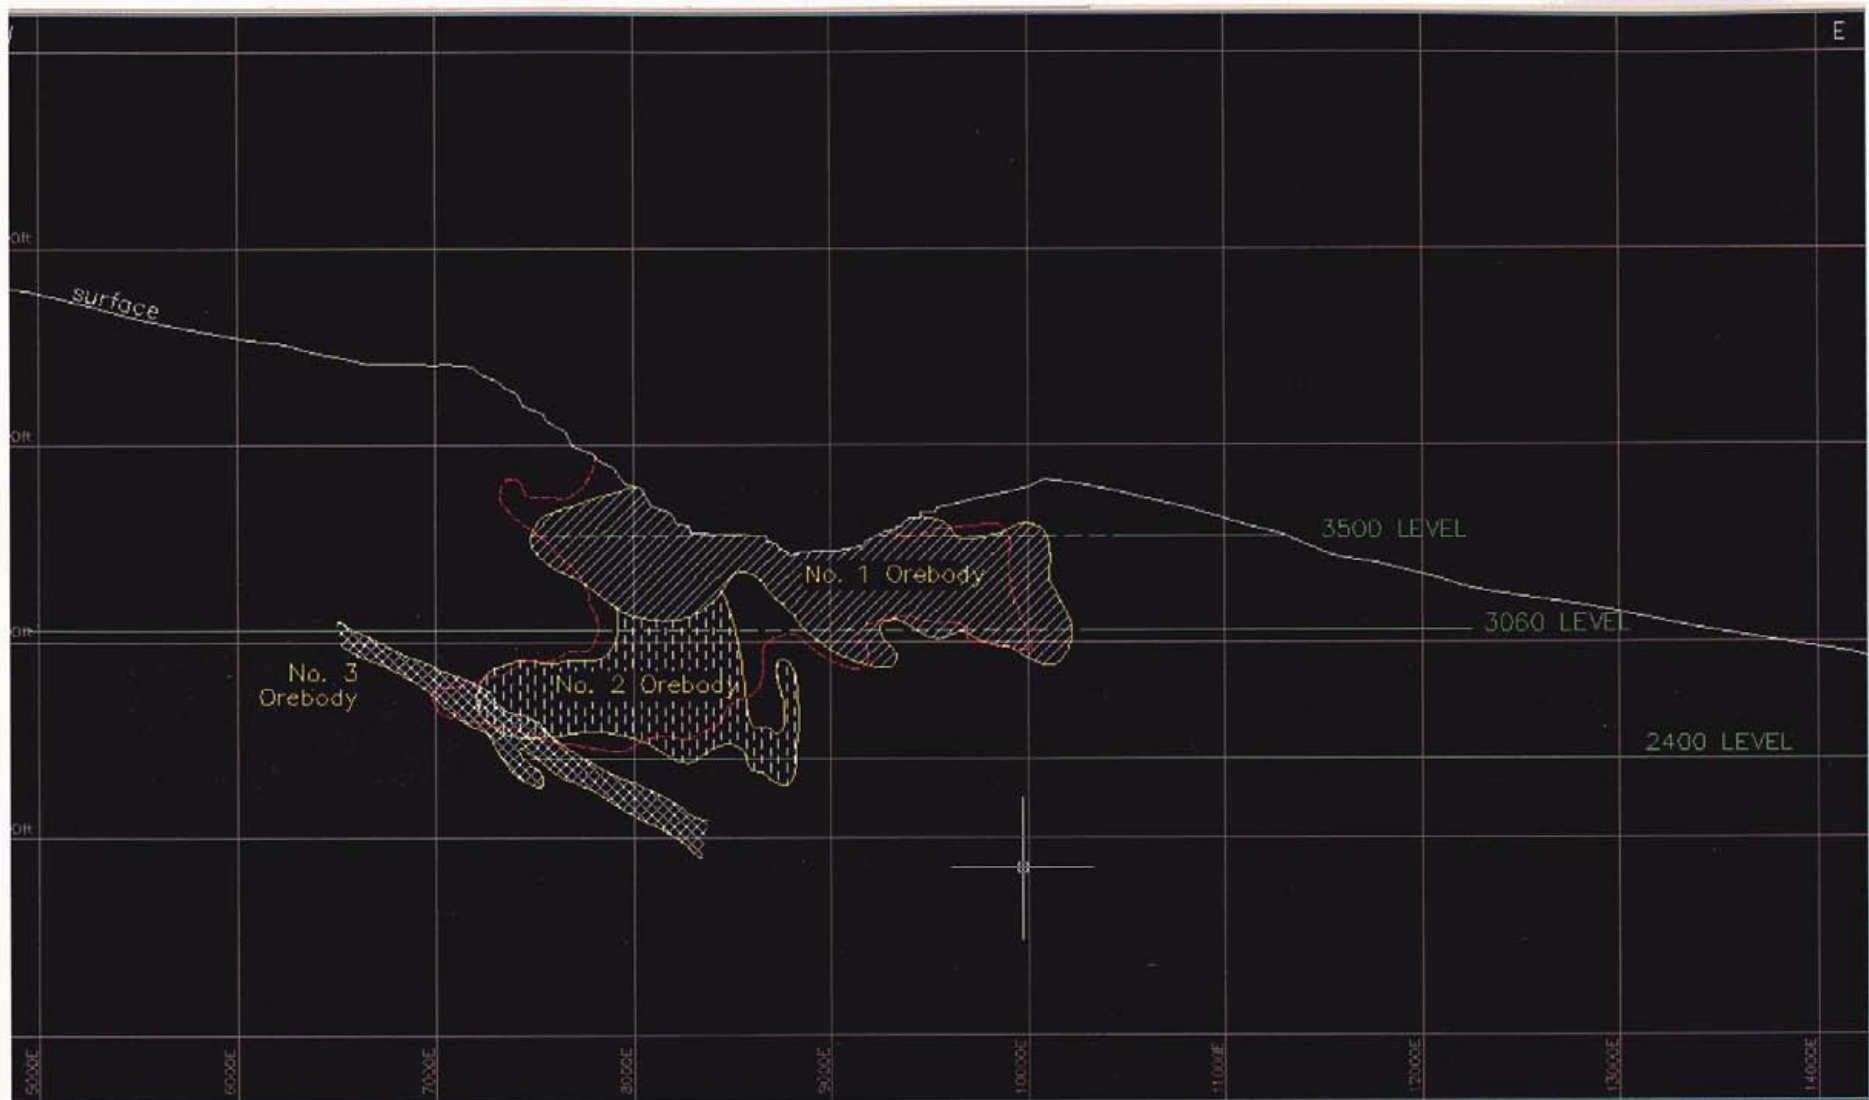

Category	Tons	% Copper
Probable	401,000	1.71

CRAIGMONT MINE PROJECT

Possible	889,000	1.45
Total Probable + Possible	1,290,000	1.53

It should be noted that it has been acknowledged that the No. 3 Orebody is very poorly defined which may enhance the possibilities for expanding the resource. These reserves were estimated assuming a 0.7% cut-off grade, a 20 foot minimum width, a tonnage factor of 12 cubic feet per ton and no allowance for dilution or recoveries.

In addition, it is thought that extensive remnant mineralization within the sub-level cave exists within the hangingwall of the mined out orebodies. These are primarily within No. 1 and No. 2 orebodies. This material is believed to grade approximately 0.4% copper. There is no practical way to estimate the amount of this type of material remains however inputting the underground drillhole data and creating grade contours from the copper values may give an indication. In addition, if we assume that the average cut-off grade for the underground sub-level cave was 0.7% with a calculated recovery of 130% and 6% to 10% ore loss then based on the original 1961 ore reserve estimates of 27,754,000 tons grading 1.79% Cu indicate that there may be in the range of 1.6 million tons of +1.5% Cu (60,000,000 pounds of Cu) material remaining within the cave.

12.0 2005 INTEGRATED 3D MODEL

12.1 Introduction

The following sections detail the methods, process and strategies employed in creating the computer models for the Craigmont Mine Project. Table 6 lists some conventions and abbreviations that are encountered throughout the modelling sections of this report.

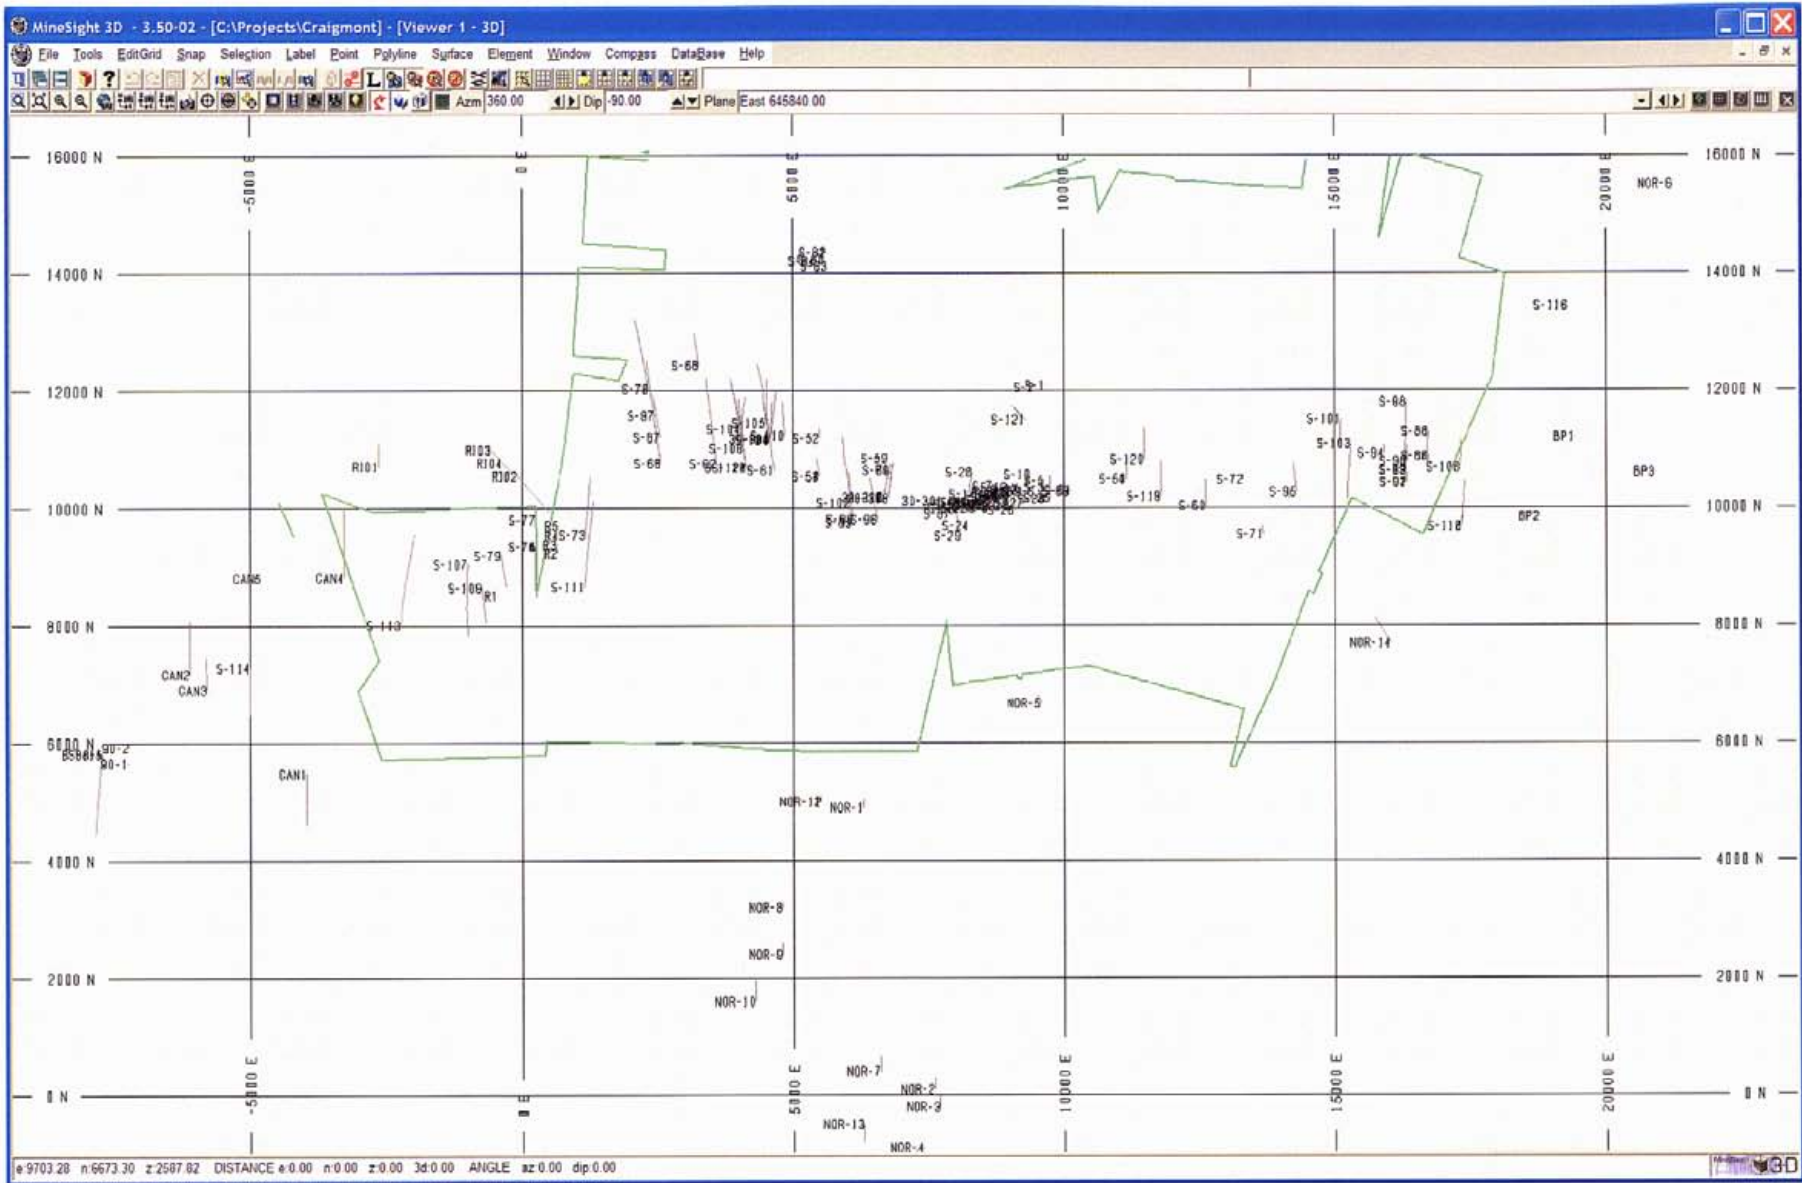

<i>Abbreviation</i>	<i>Description</i>
<i>GPS</i>	Geographical Positioning Systems
<i>UTM</i>	Universal Trans-Mercator
<i>Cu</i>	Copper
<i>Fe</i>	Iron
<i>%</i>	Percent metal content
<i>m</i>	Meters
<i>QA/QC</i>	Quality Assurance / Quality Control
<i>X, Y, Z</i>	Cartesian Coordinates, also "Easting", "Northing", and "Elevation"
<i>DDH</i>	Diamond Drill Holes.
<i>N, S, E, W</i>	Cardinal points, North, South, East, and West, respectively, and combinations thereof.
<i>JDSemi</i>	JDSemi and/or Jeff Stibbard
<i>Frontier</i>	Frontier Geophysics Ltd.
<i>Christopher James and/or CJG</i>	Christopher James Gold Corp.
<i>Craigmont</i>	Craigmont Holdings Ltd.

Table 6: Report Conventions and Abbreviations

12.2 Coordinate System

Prior to proceeding with the modelling of the property, it was decided to transform all data including drillhole data, surface features and geology along with underground coordinate data from the drift development to the NAD83 UTM coordinate system. The standardization of the grid and coordinate system was necessary for laying out the geophysical survey lines and line cutting as current technology is more reliant upon GPS instrumentation. In addition, going forward it is more desirable to be able to utilize GPS technology and not be limited upon historic mine grid systems.

The surveying was performed by JDSemi and the coordinate transformations were calculated by Frontier Geophysics of Vancouver, BC utilizing a detailed GPS survey supplied by Craigmont Holdings personnel. This translated data was supplied for the use and purpose of this comprehensive model. Figure 7 illustrates the drillhole data as defined in the original mine grid whilst Figure shows the same data transposed to the UTM NAD 83 mine grid system. Figure 9 shows the geophysics grid superimposed upon the UTM NAD 83 grid for reference purposes.

12.3 Assay Database

The data integration exercise consisted primarily of inputting data manually as most data existed only in paper format. The data itself was sourced from Christopher James directors, Cliff Rennie of Better Resources, Craigmont Holdings head office in Vancouver and the Craigmont Holdings minesite offices. Appendix 1 lists all surface drillhole collars and select underground holes used within this study. Note that the holes drilled in 2005 are not included within this subset however collars and surveys are listed in Appendix 2.

Figures 10 through 12 summarizes statistics for the Cu% and Fe% for the database which has 909 Cu and 820 Fe values with a minimum value of 0.00 and maximum values of 10.2% Cu and 100% Fe. The average overall Cu grade for the surface holes is 0.6% Cu and 11.2% Fe, with standard deviations of 1.04 and 10.76, respectively resulting in a reasonable coefficient of variation (CV) of 1.745 and 0.942, respectively.

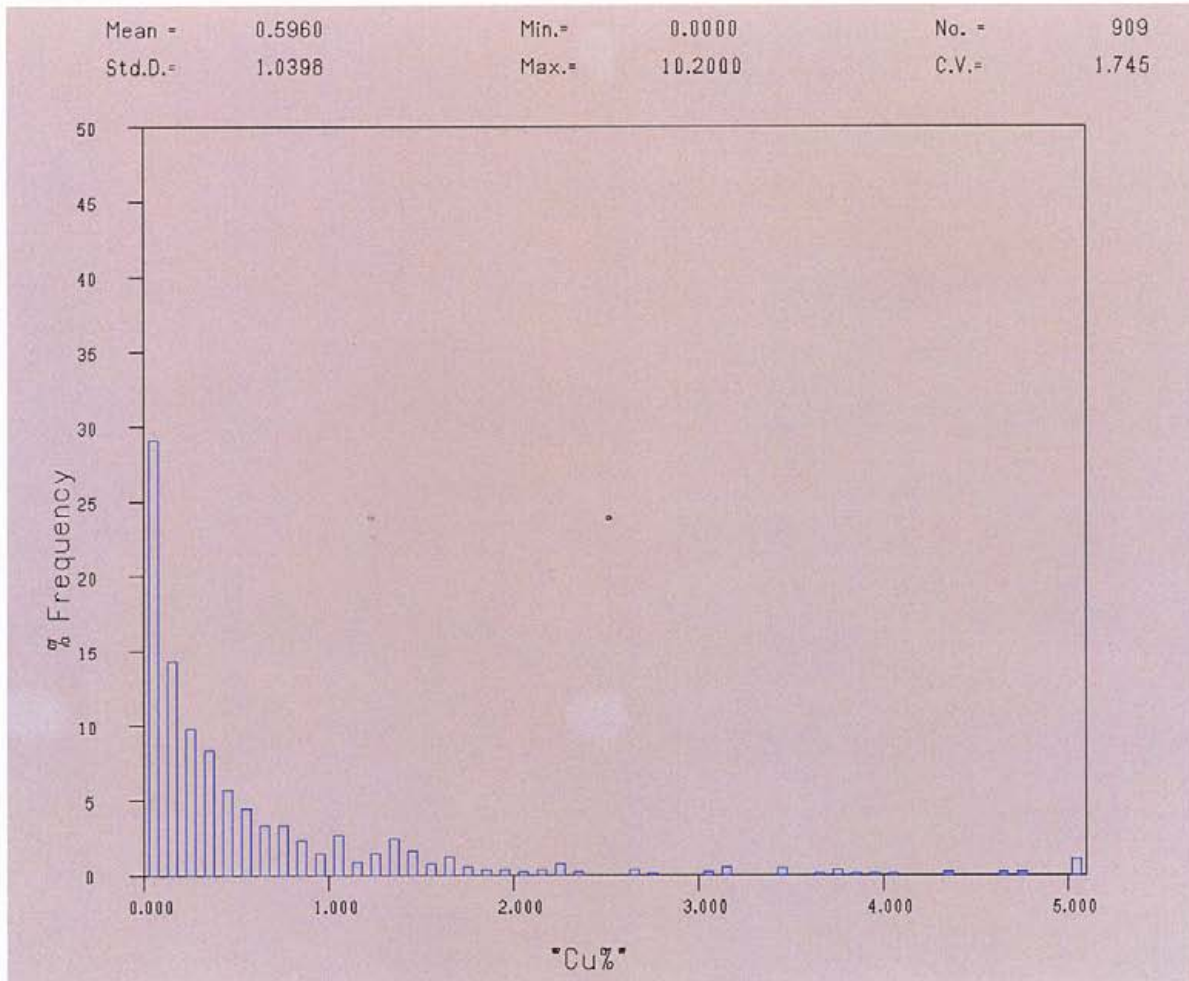

Figure 10: Histogram and Basic Statistics of all Cu% samples.

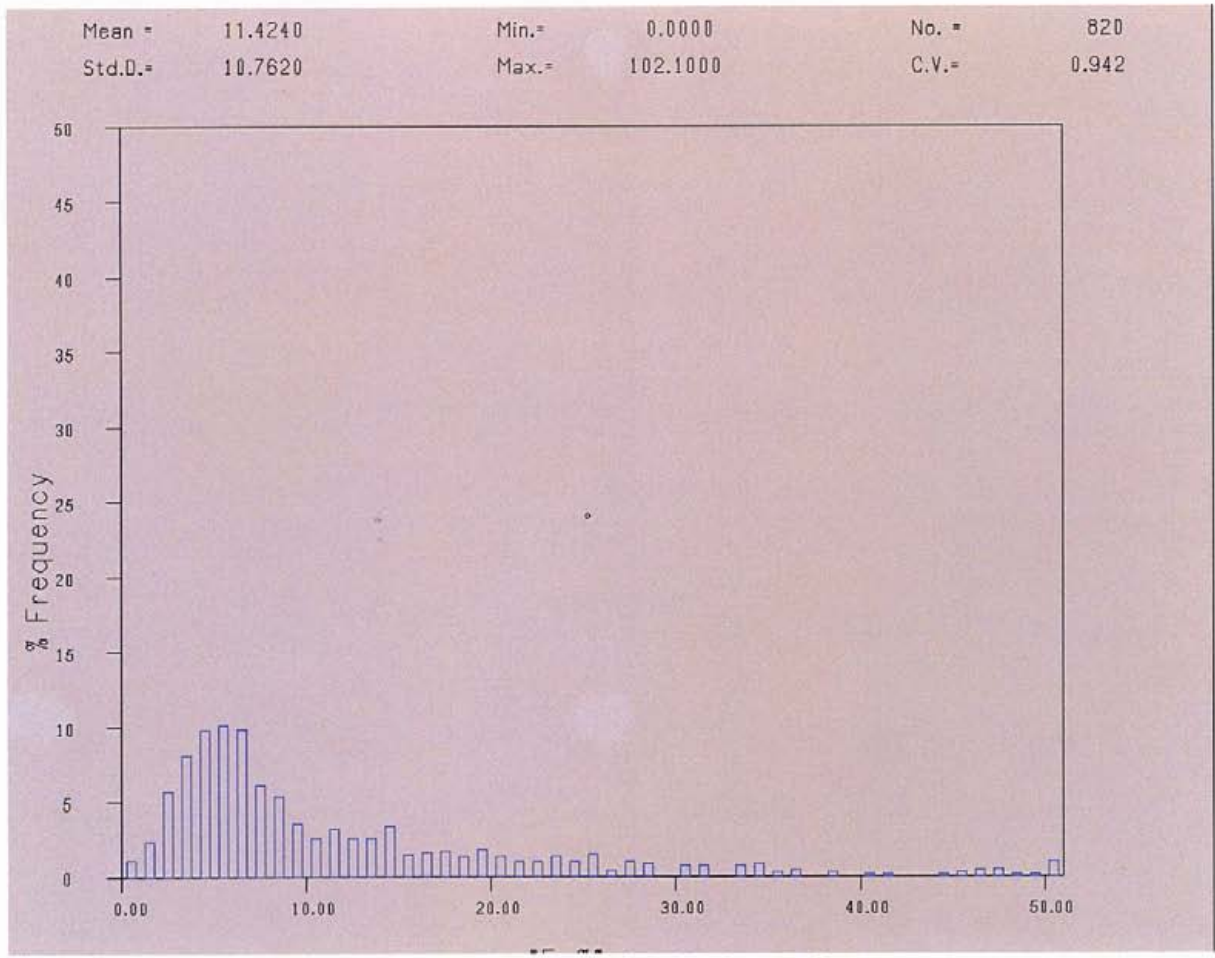

Figure 11: Histogram and Basic Statistics of all Fe% samples.

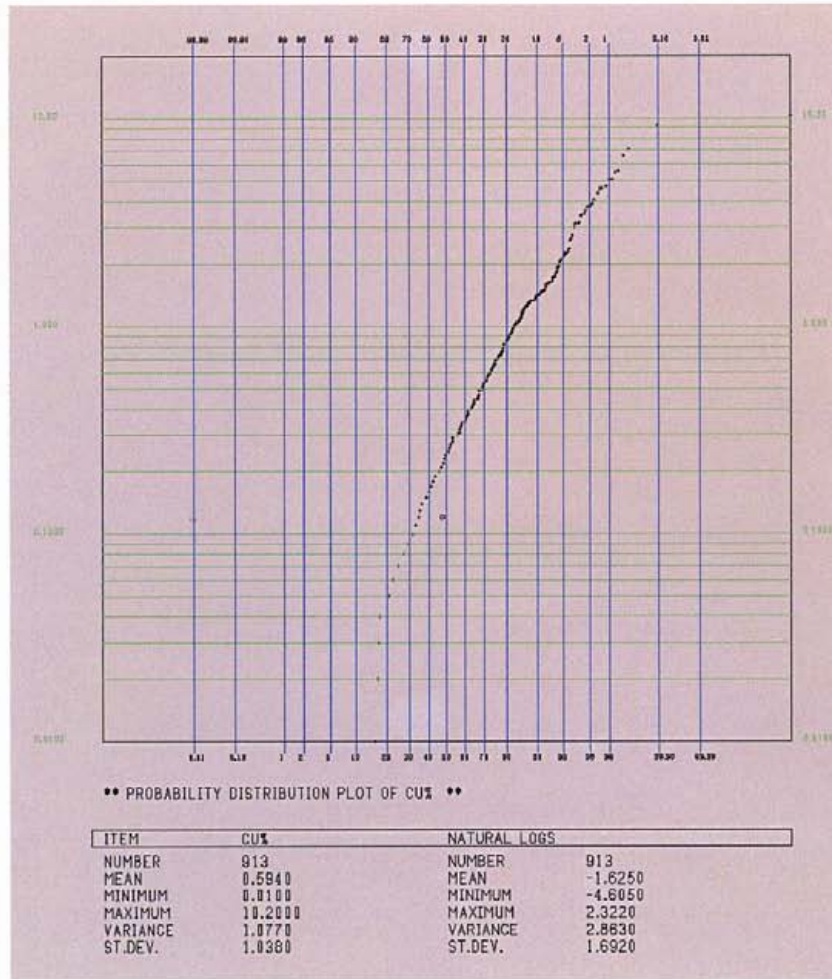

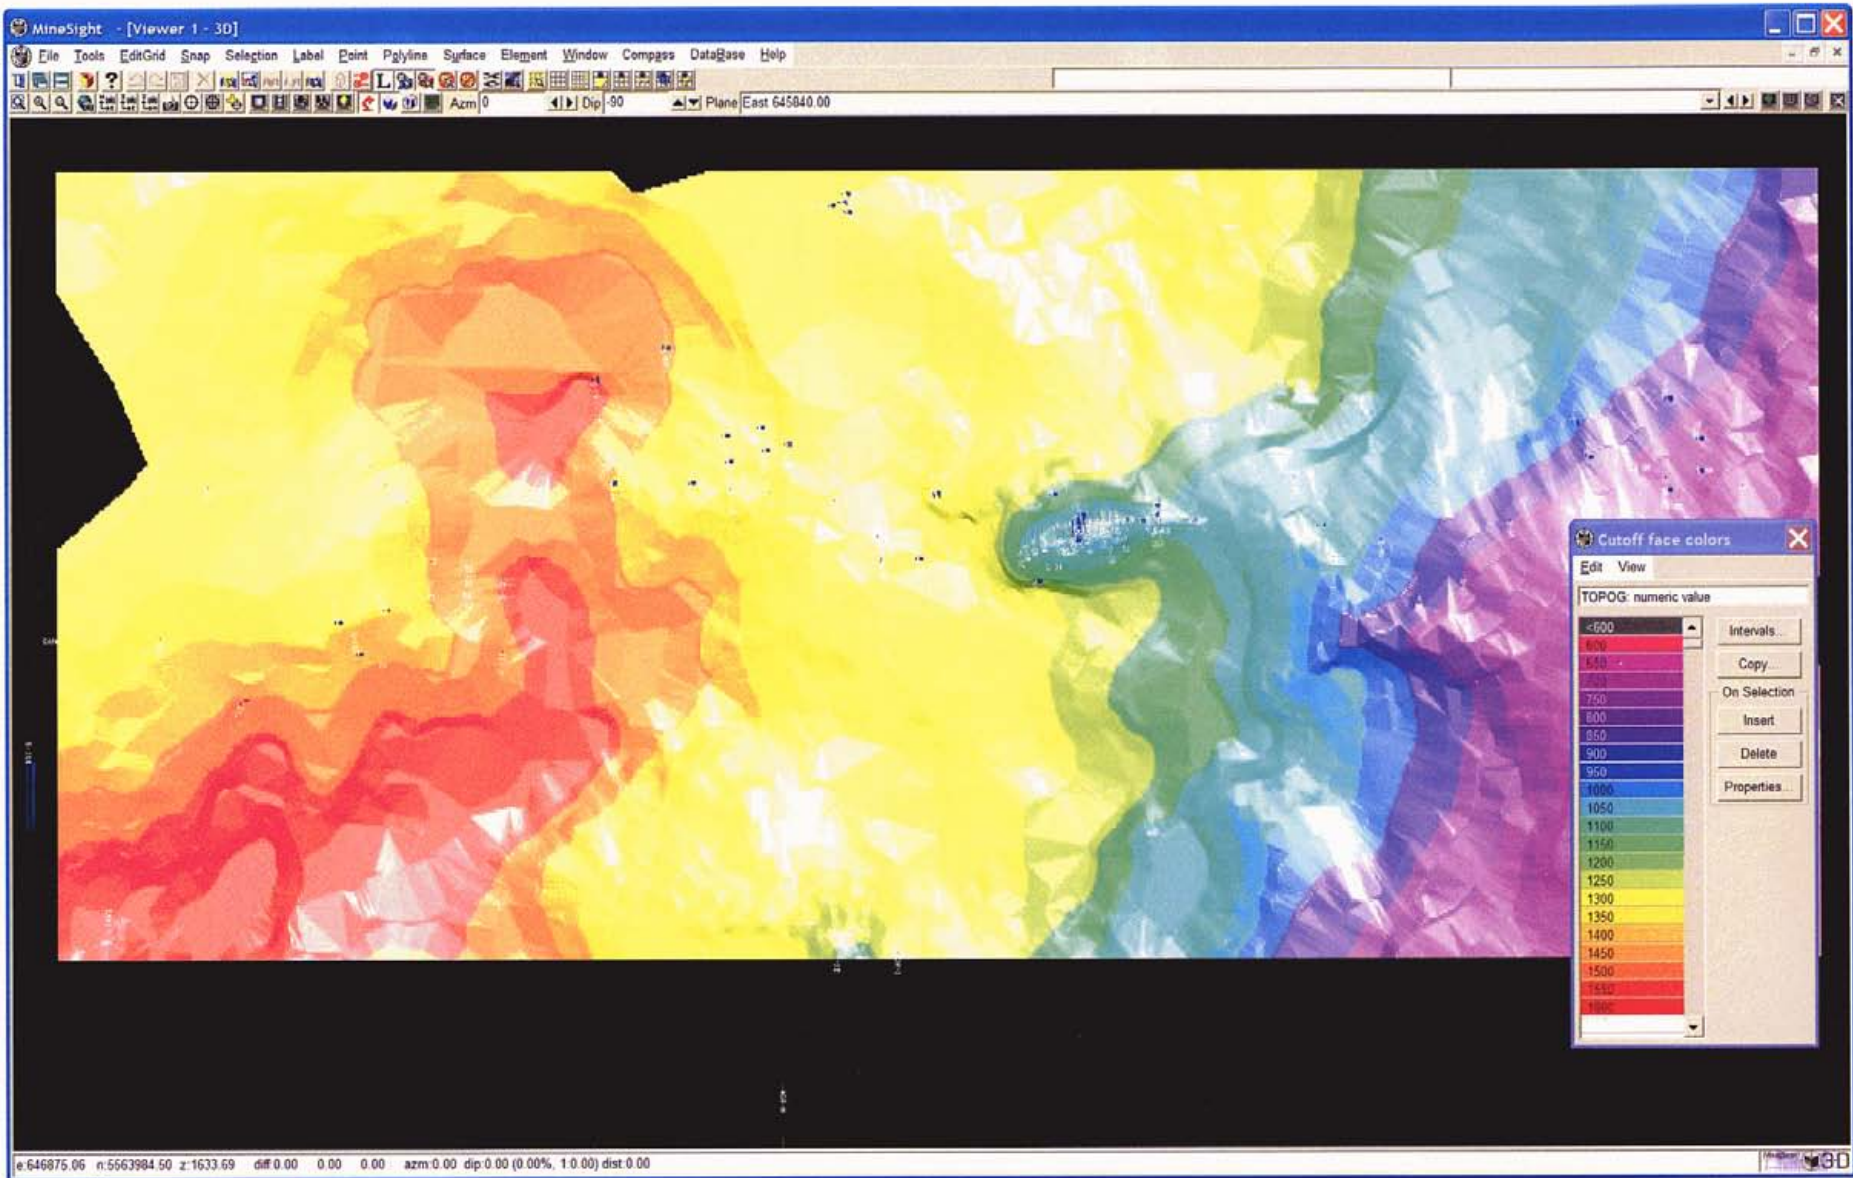

Figure 12: Probability Plot of all Cu% samples.

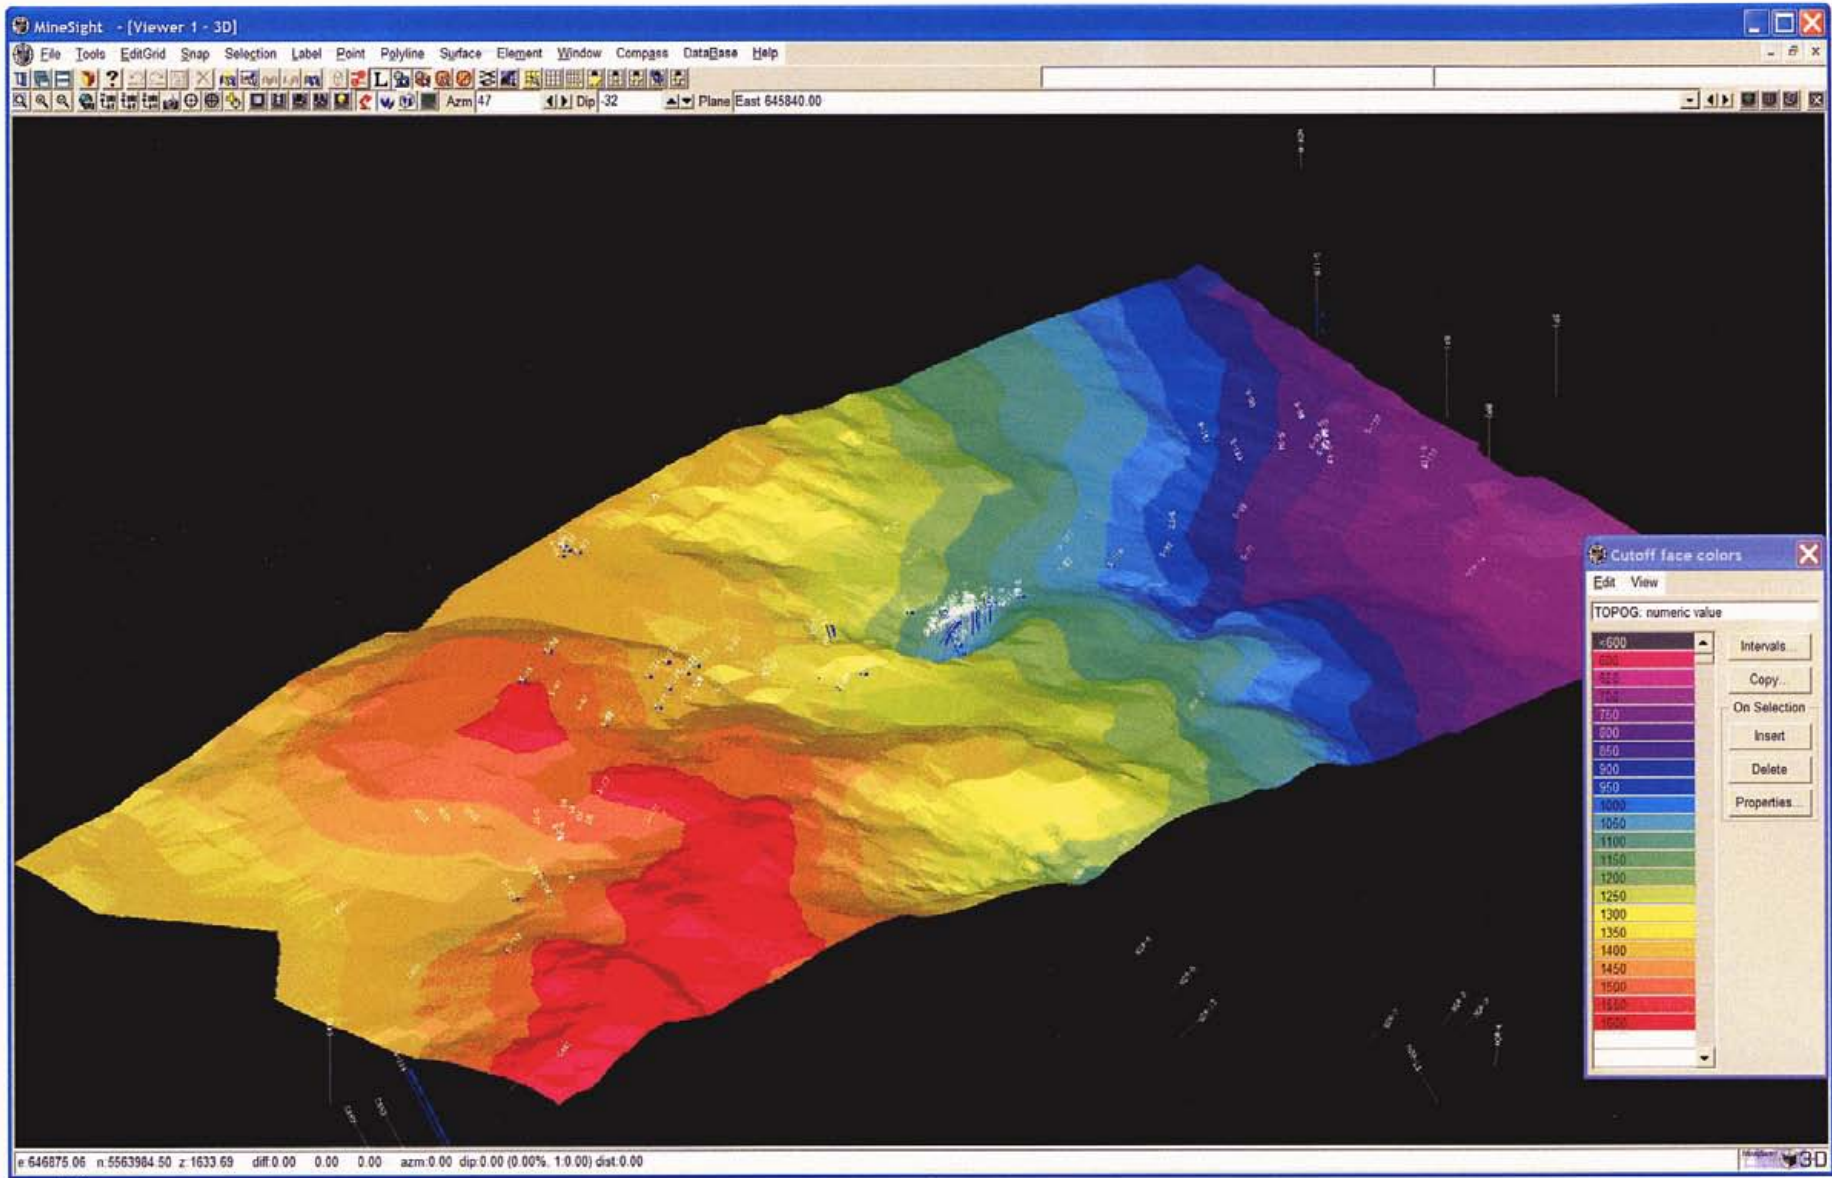

12.3 Topography.

Topography was imported from an AutoCAD topographic map supplied by C.F. Staargaard in DXF format. Figure 13 shows a plan view of the topographic map and Figure 14 illustrates a three-dimensional rendition of the topography used, looking Northeast. Figure 15 illustrates a digital terrain model derived from the contour data.

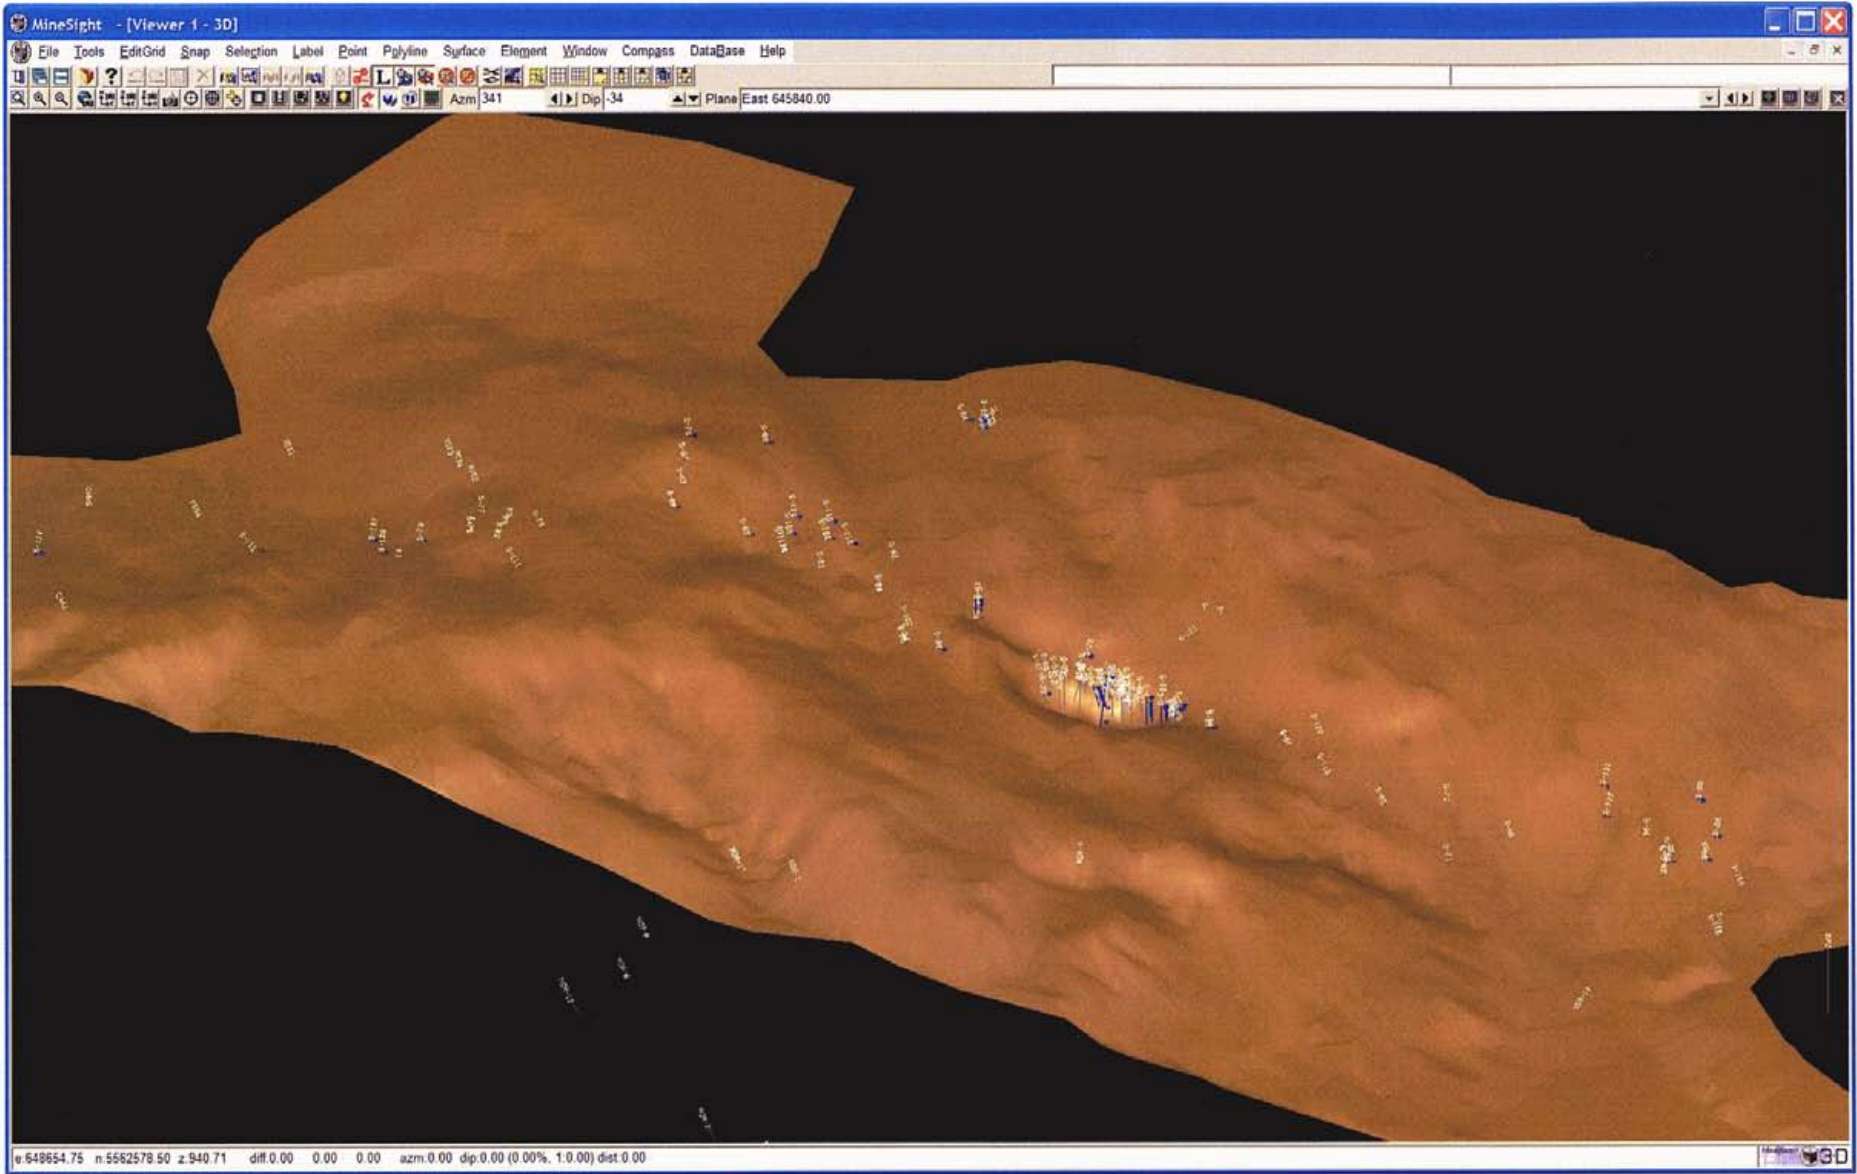

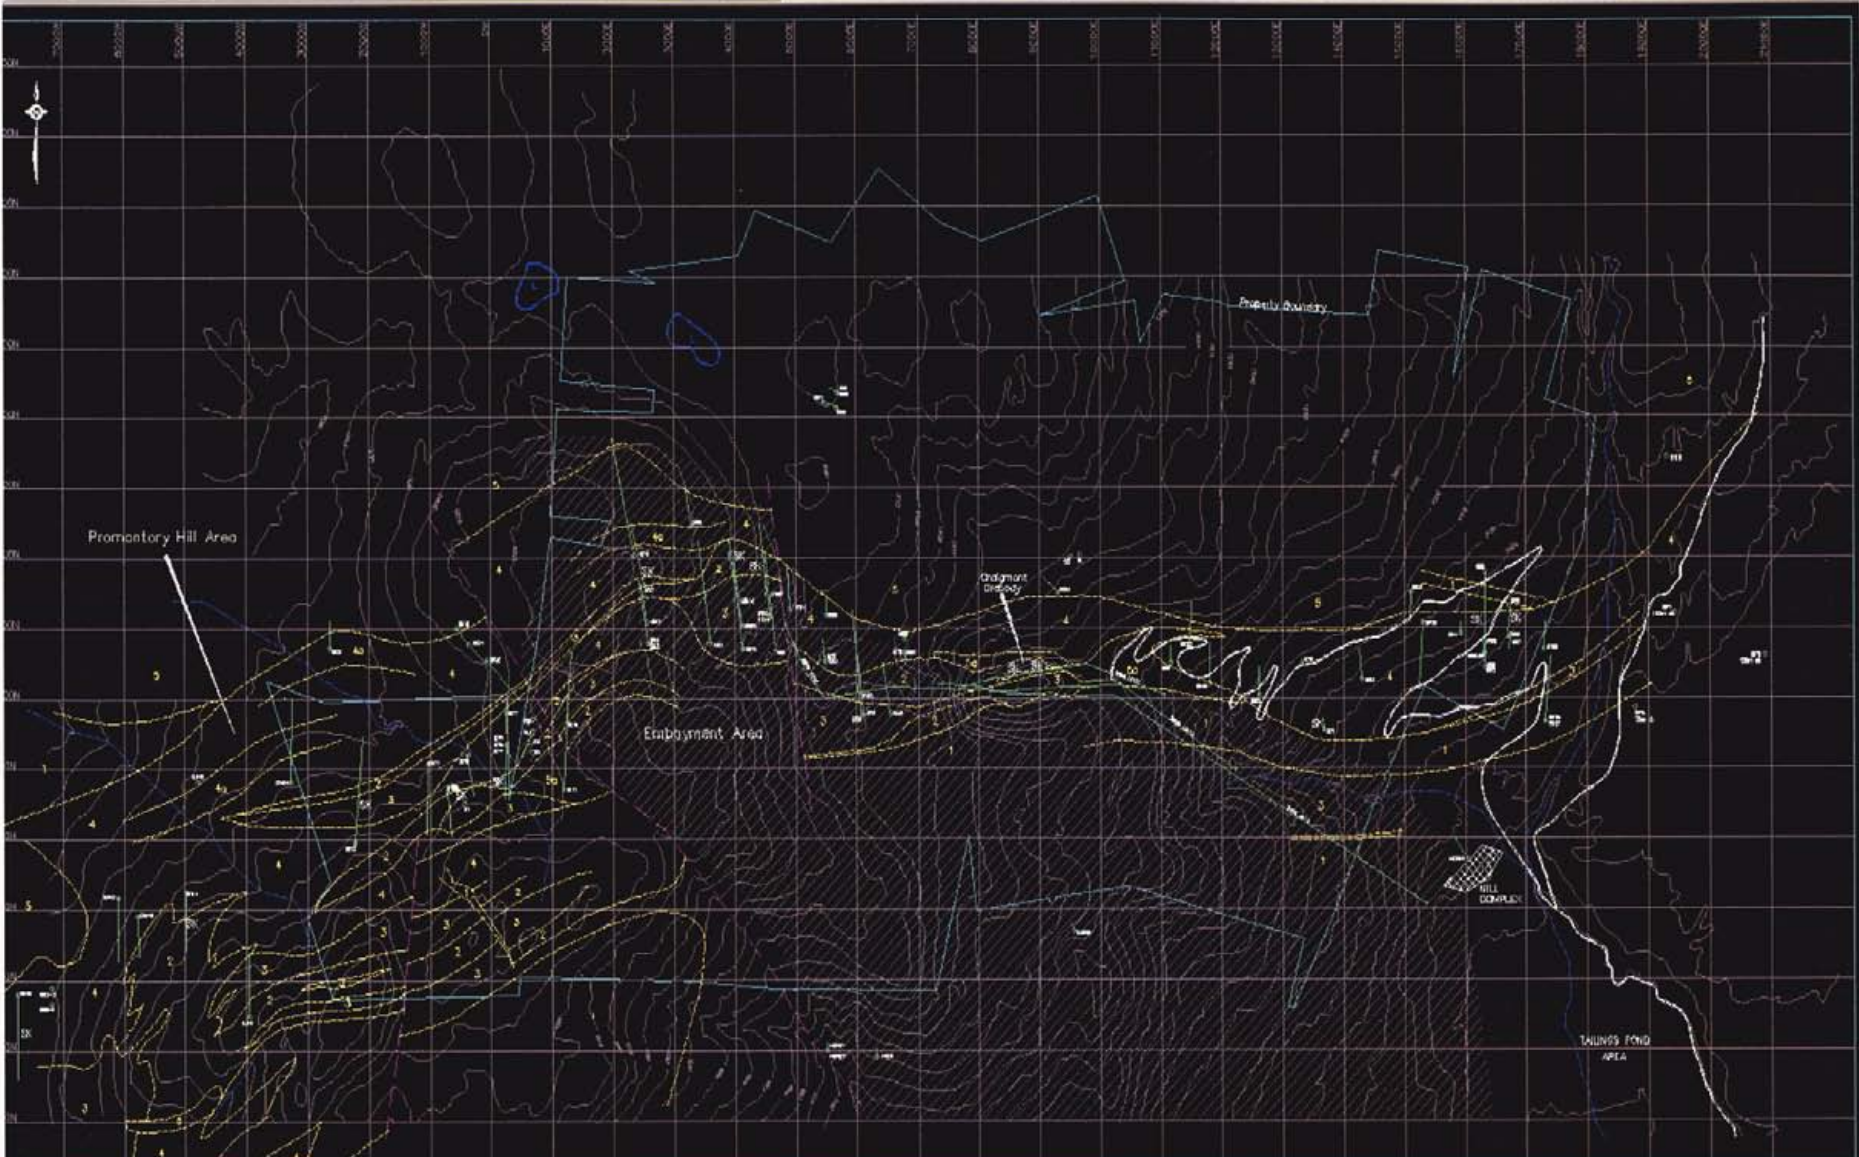

Figure 15: Digital terrain model of triangulated topography in 3D perspective view looking northwest.

12.5 Computerized Geologic Modeling.

Surface geology was projected from a detailed geology map supplied by C.F. Staargaard in AutoCAD DXF format as shown in Figure 16. This map was then draped upon the 3D topographic DTM (digital terrain model) as shown in Figure 17. These geological outlines which existed in the file as polylines were then gridded or digitally coded directly into the gridded surface model created for surface geology as shown in Figure 18 and 19. These figures illustrate the major geologic units as mapped during various exploration campaigns projected upon 3D topography which was used as a guide for the 2005 geophysics and drilling program. The colour coded units are red being the Guichon Creek Batholith, yellow is the Nicola Group Clastic Sediments, light blue the Nicola Group Rhyolite Fragmental, dark blue the Nicola Group limestone and magenta the Nicola Andesitic Volcanics.

CRAIGMONT MINE PROJECT

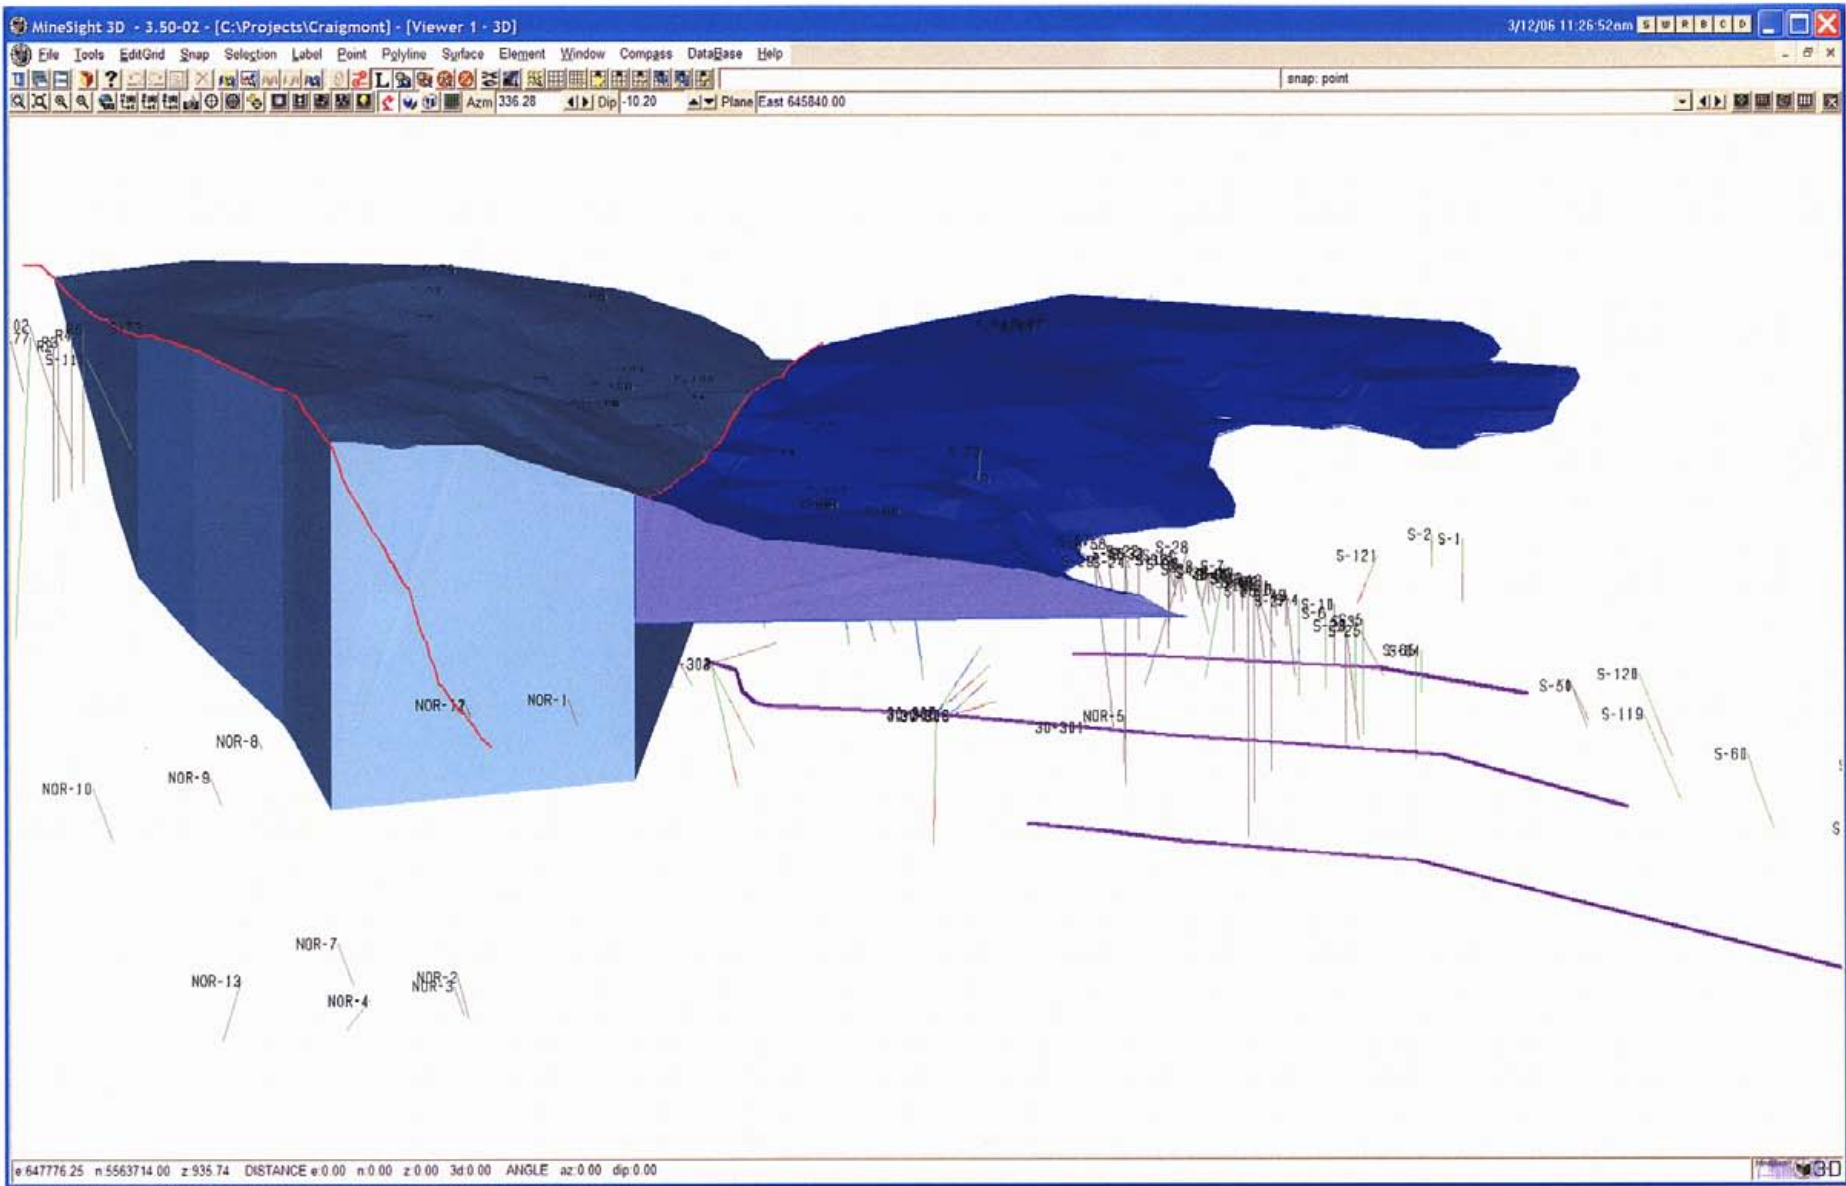

Figure 19: Plan view of surface geology, as described above, projected upon 3D topography.

The next step was to create 3D solids of the major units such as the Kingsvale volcanic member as shown in Figure 20 and 21. In addition, solids models of the main limestone and clastic units were created from the surface geology extruded from the surface geology map and from downhole intercepts as shown in Figure 22 and 23. Figure 23 illustrates a perspective view looking from below (in the area of 4700 Section) with limestone unit extruded below Kingsvale and the 3060 underground haulage drift. This is the location of the Embayment Block target where the drillholes are shown piercing the limestone with mineralized skarn and Cu mineralization shown in red (490 feet of 0.41% Cu see Figure 35). It is clear that there is a great potential for a large potentially economic orebody within the wallrock of the limestone unit.

13.0 2005 EXPLORATION PROGRAM (GEOPHYSICAL SURVEY)

13.1 Embayment Block

As a first step, it was determined that the best approach would be to investigate the Embayment Block as it would be the best perspective territory for a new discovery. At the time that the program was initiated, copper prices were still in the \$1.00 to \$1.50 US range however at the time of this report prices have spiked to high not seen since the 1980's and currently are within the \$2.50 range. It was determined that without a new discovery, the mine would not be able to sustain a long term mining strategy especially if the operation was to rely solely upon the remaining and remnant reserves and resources. In addition, there are concerns with respect to the quantification of the historic reserves and resources as the data appears to be primarily internal memos, personal communications and anecdotal information.

It was decided that the best approach, based on past exploration techniques used successfully on the deposit, the terrain and the nature of the mineralization (i.e. copper rich, magnetite skarn), that a combination of magnetics and induced polarization would be the most effective in identifying a potentially economic deposit. Therefore, JDSemi of Kelowna, B.C. and Frontier Geosciences of North Vancouver, B.C. were contracted to complete the geophysical survey that consisted of a comprehensive program that included a detailed surface magnetic survey, an induced polarization (IP) survey that also included a downhole IP component in addition to surface GPS surveying.

Twenty eight survey lines were completed, each approximately 800 to 1700 meters in length. The lines ran from north to south on a local grid surveyed and marked by Amex Exploration Services of Kamloops, B.C. The time domain resistivity /IP was run using a pole-pole array as well as dipole arrays of 100 and 200 meters length and included current injection points in boreholes. Voltage measurements were made on 100 meter using two full waveform receiver of eight channel capacity each together with a multi-conductor potential cable with 100 meter take-outs connected to the ground through porous pots. The eight dipoles were tested for contact resistance before each reading was taken.

The magnetometer survey was carried out using a GEM Systems, GSM-19, portable, high sensitivity, Overhauser-effect magnetometer. The unit is a standard for measurement of the earth's magnetic field, having 0.01 nT (nanoTesla) resolution and 0.2 nT absolute accuracy over its full temperature range. In operation, a strong RF current is passed through the sensor head mounted on an aluminium staff. This creates a polarization of the proton-rich fluid in the sensor followed by a process of "deflection" whereby a short pulse deflects the proton magnetization (secondary magnetic field) into the plane of precession (earth's magnetic field). A slight pause in the process allows the electrical transients to die off, leaving a slowly decaying proton precession signal above the noise level. The proton precession frequency is then measured and converted into magnetic field units. Essentially, the data collected is a measurement of the earth's magnetic field plus any effect on the secondary magnetic field by ferrous objects and/or high concentrations of ferromagnetic minerals.

In addition, state-of-the-art geophysical processing techniques were employed, namely 3-dimensional inversion which is an enabling technology that allows the company to not only identify prospective

drilling targets but also to develop a 3D picture of the nature, extent, orientation and character of the anomalous zones.

Station spacing in the field was measured using slope distances. Grid position and topography information was obtained using GPS measurements carried out by Amex Exploration, together with the digital elevation model in the old Imperial Mine Grid coordinates. In addition, the NTS TRIM map information was used to determine the exact coordinate transformation from Mine Grid to NAD83 UTM coordinates. The Mine Grid map proved to be more detailed than the TRIM map and, once converted to NAD83, was used as the base for the work. The resistivity and IP measurements were converted to the input format of the 3D Loke RES2DINV inversion program from Geotomo Software. The inversion routine employed by the program is based on the smoothness-constrained least-squares method (deGroot-Hedlin and Constable 1990, Sasaki 1992). Output from the inversion program may then be sliced vertically or horizontally, and input into a 3D visualization program such as Mayavi and Minesight 3D.

In addition, historic surface drillhole and selected underground drill data has been input from paper logs into a detailed database which includes collar, downhole survey, assay (i.e. Cu% and Fe%), lithology, into the processing and visualization software for analysis and for developing a complete 3D picture.

In developing a complete exploration model and consequently opportunities for further investigation and drill targets, the most prospective areas would have more than one of the following characteristics:

1. Magnetic trends and anomalies.
2. IP chargeability highs and trends.
3. Resistive lows.
4. Favourable lithologic conditions and skarn occurrences.
5. Zones of mineralization evidenced by Cu and Fe assay confirmation.

A surface plan of total field magnetics (Figure 21) was created in addition to profiles of inverted IP (chargeability) and resistivity were produced at 10m intervals in plan (1050 meters through 1650 meters), section and long section as shown in figures 22 through 25.

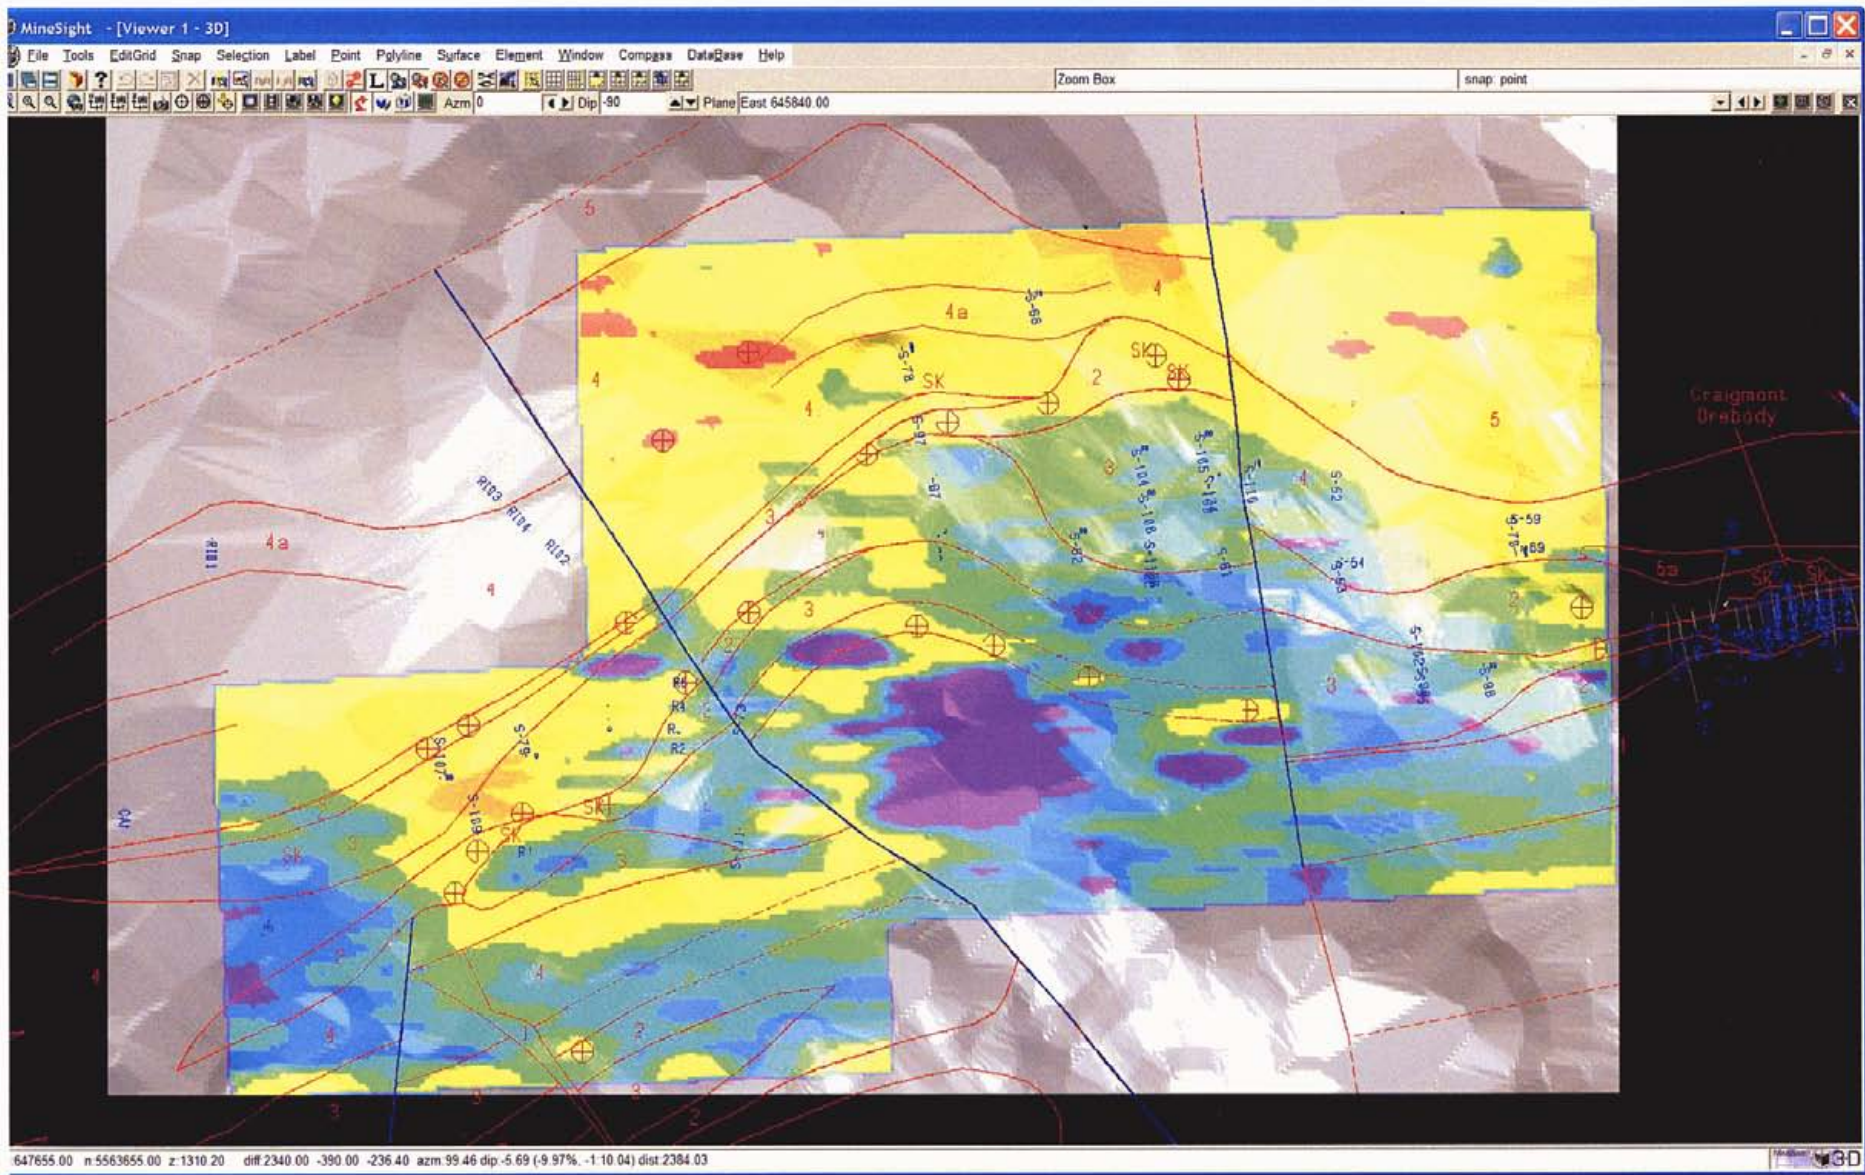

Figure 24: Total field magnetics with surface geology overlaid along with historic surface drillholes. Trends and target anomalies denoted by O with +.

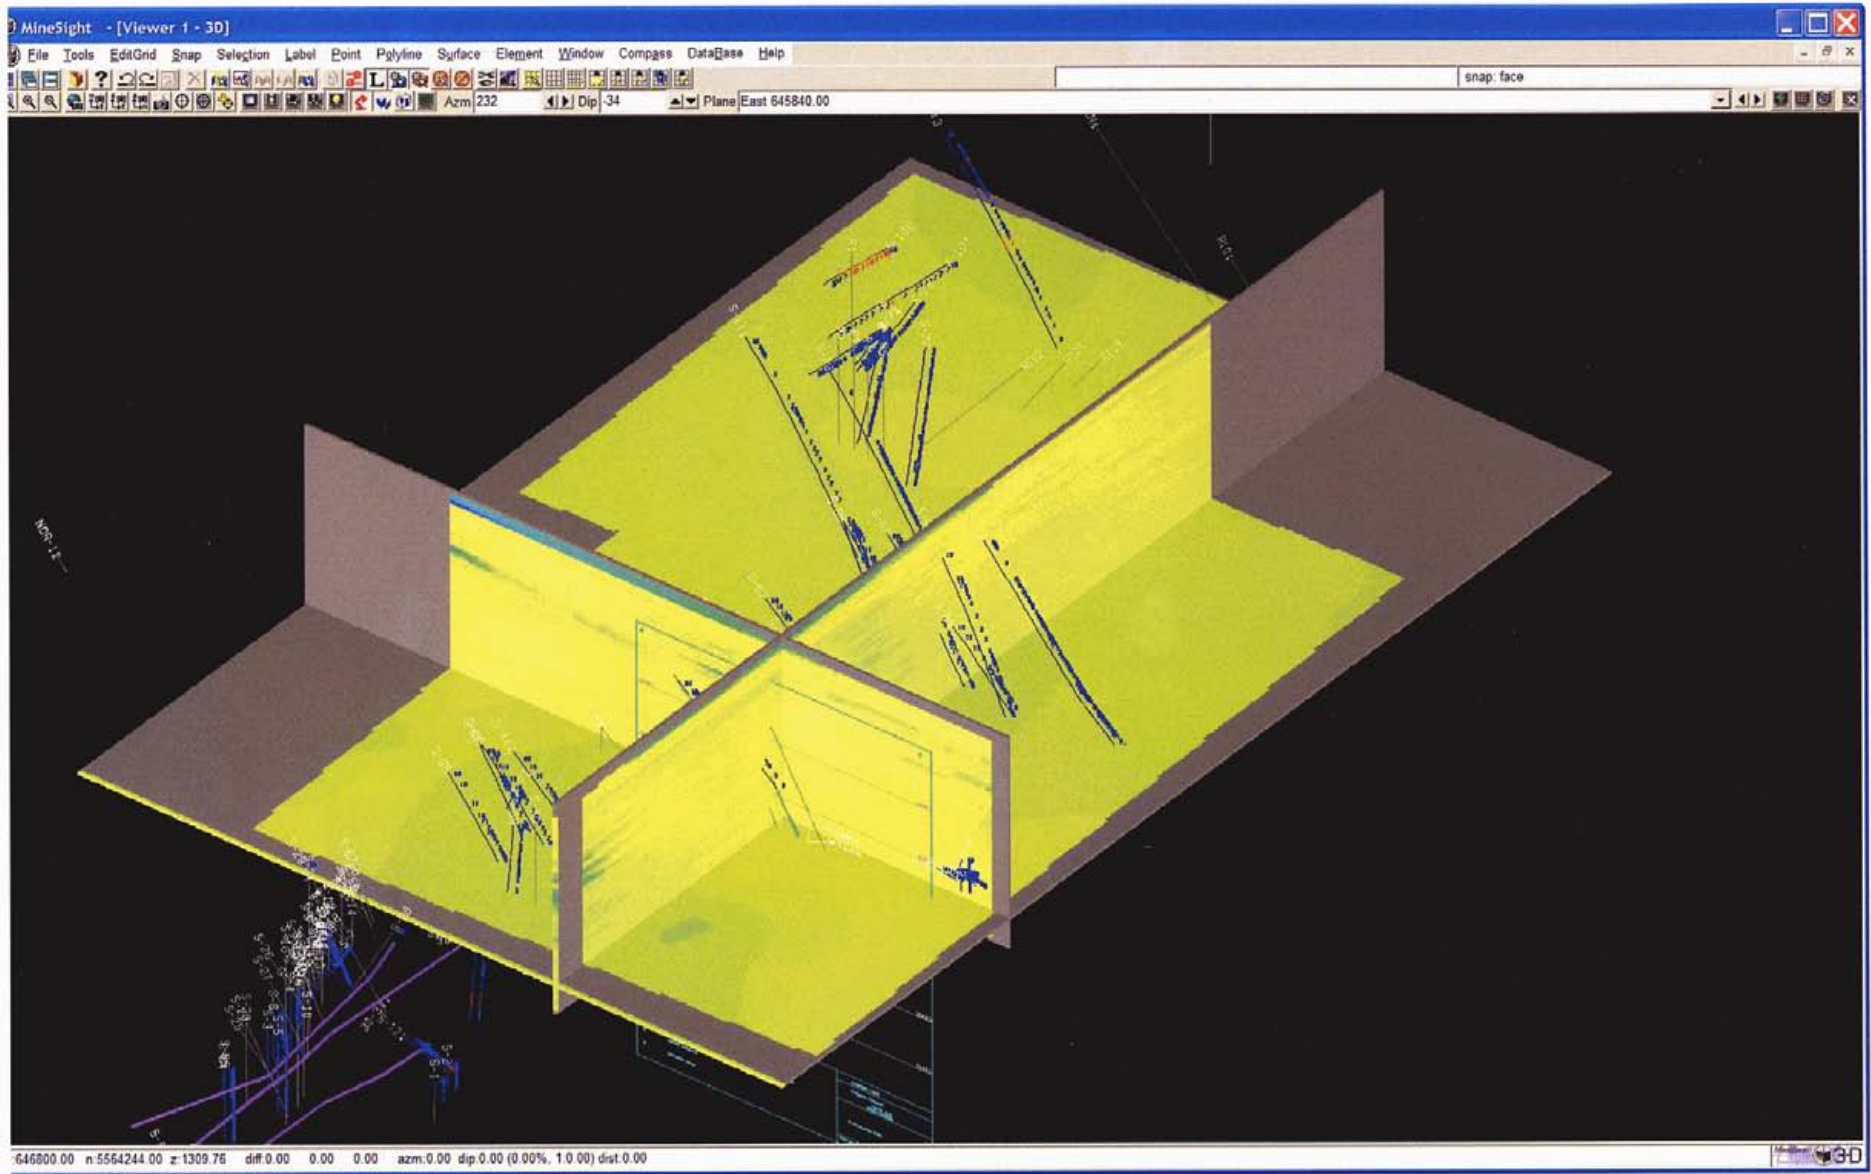

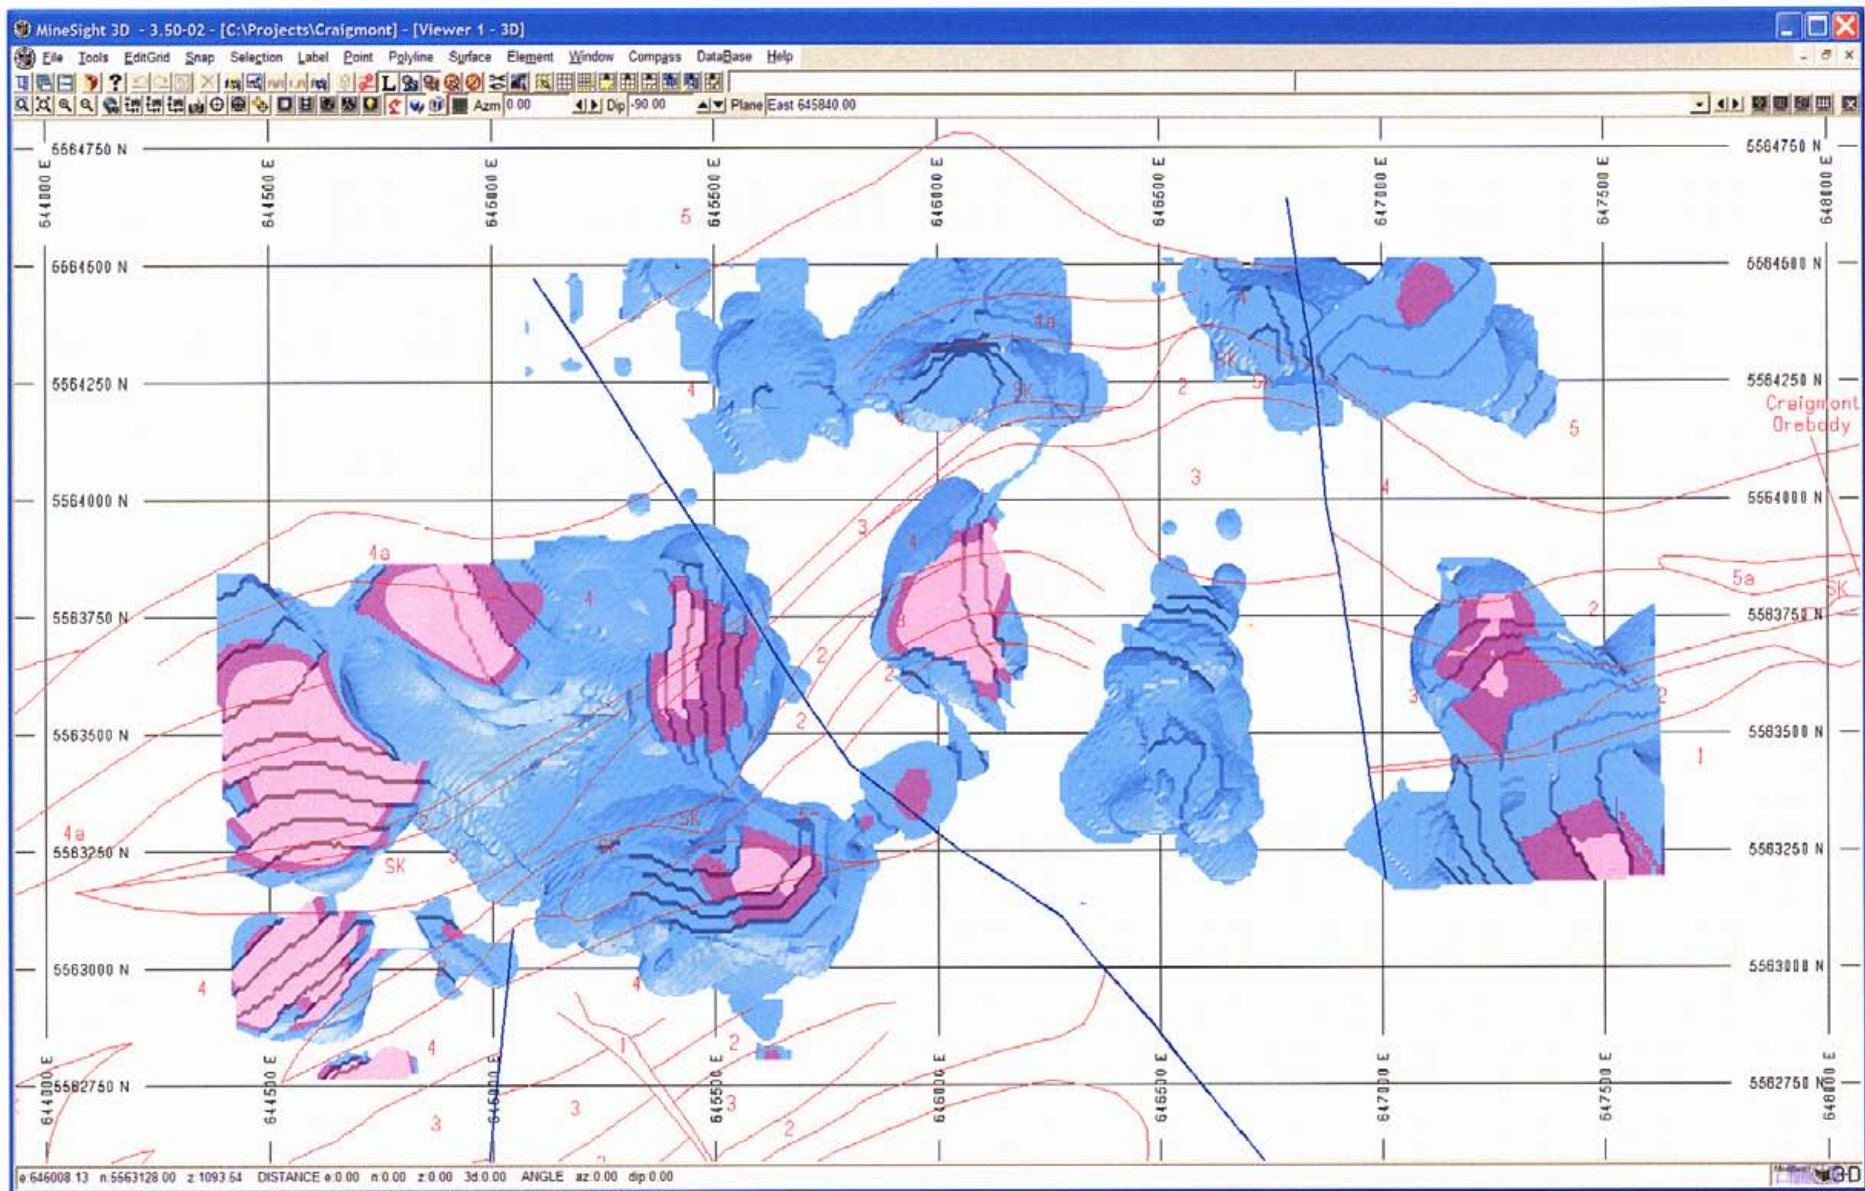

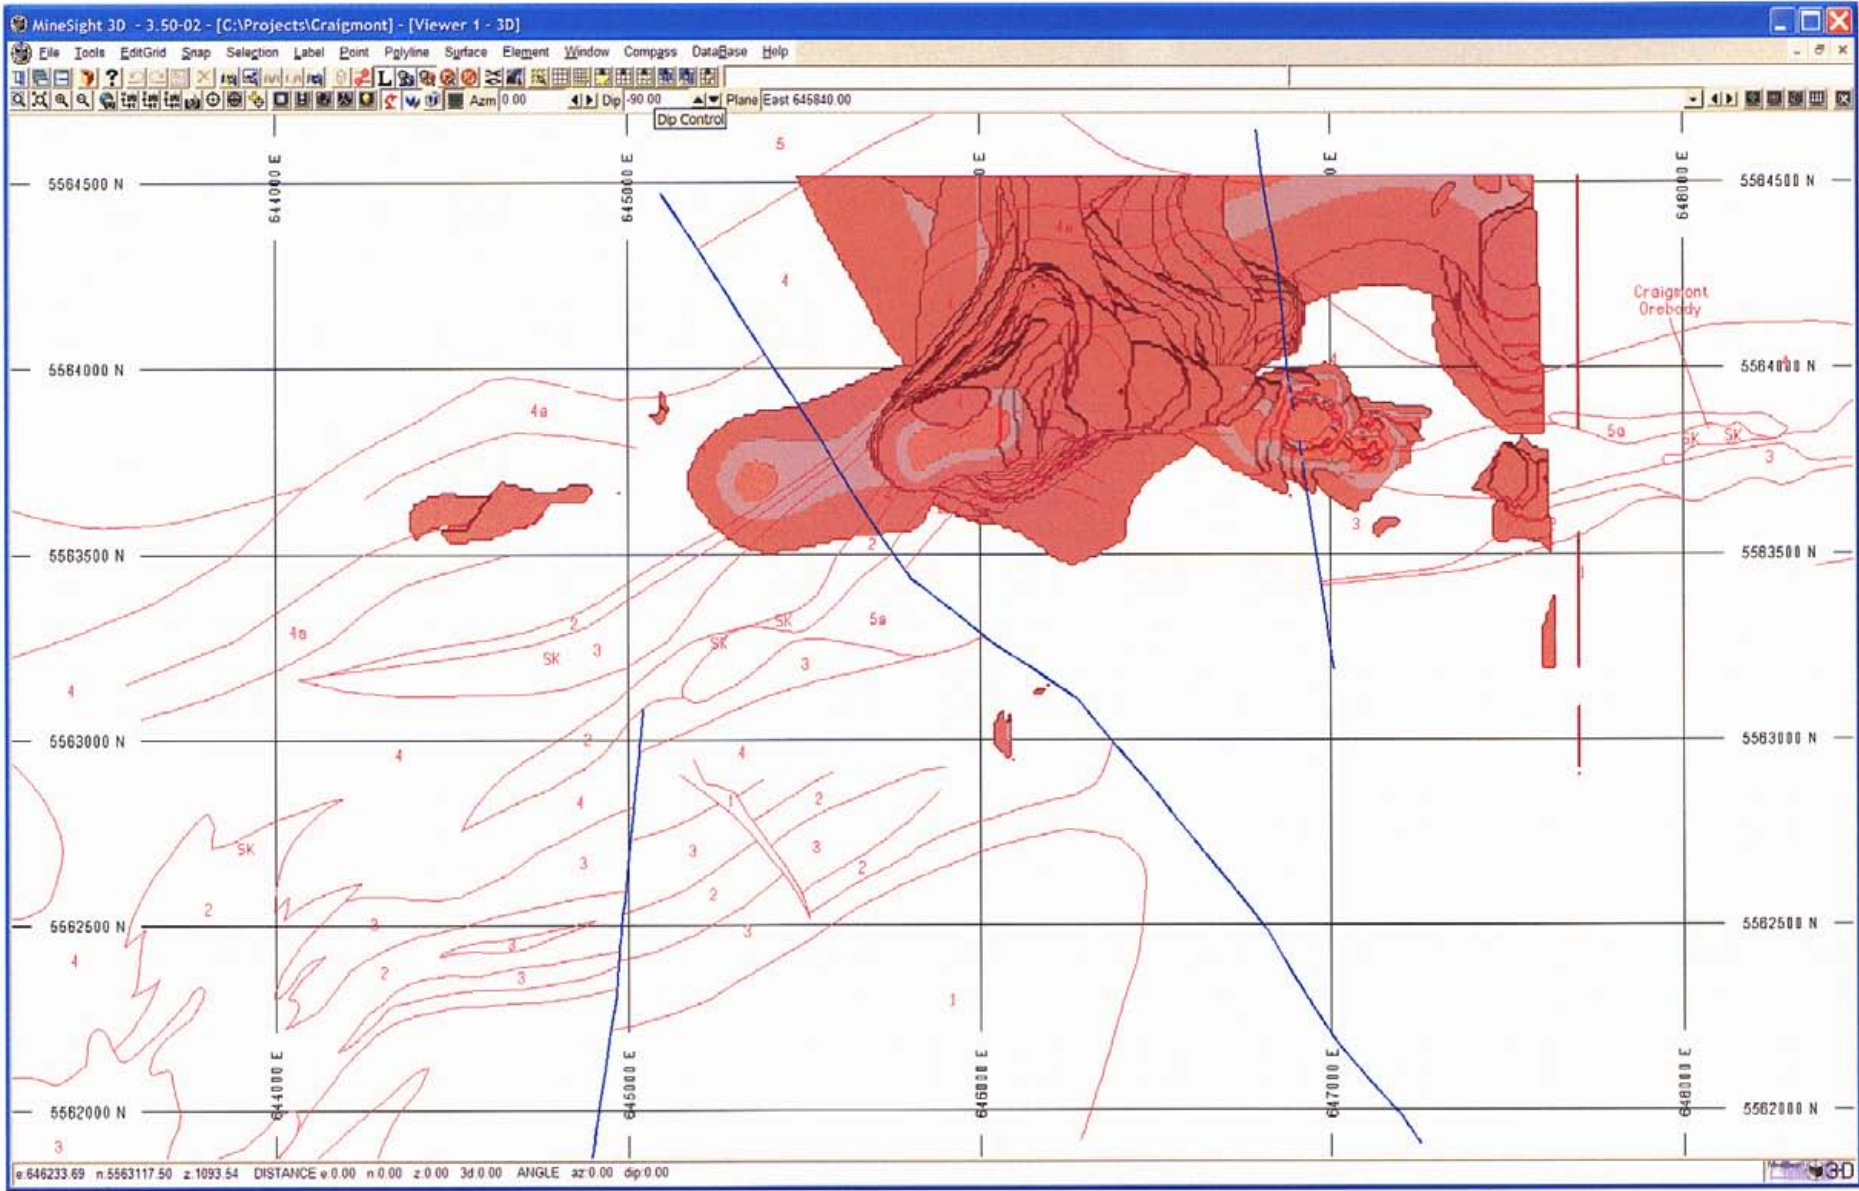

Figure 28: IP Chargeability highs and trends within target areas.

CRAIGMONT MINE PROJECT

Figure 29: Plan view of IP Chargeability highs and trends within target areas.

CRAIGMONT MINE PROJECT

Figure 30: Plan view of IP Resistivity lows and trends within target areas.

The data has delineated a large discrete body of low resistivity and high chargeability trends (Figures 2 and 5) within the Embayment Block (shown bounded by the faults in blue in Figure 21). In addition, this area has been intersected by historic drilling that has intersected actinolite-epidote scarn along with Cu and Fe mineralization.

The second chargeable body is defined on the western end of the study area which is evidenced by a chargeability high, resistivity low along with a magnetic anomaly (Figures 21, 23 and 24). Again, this area has intersected favourable lithology and mineralization by historic drilling activity.

High chargeability bodies are commonly associated with economic sulphides and, as these bodies are spatially related to elevated values of Cu and Fe, these bodies identified by the survey represent high priority targets. Additionally the resistivity data model, in the embayment block defines a large highly resistive body. This resistive body is juxtaposed to the chargeable features, and may be a large scarn. In addition, as the Cu mineralization is commonly associated with the existence of magnetite, it is safe to assume that magnetic anomalies offer a good indication of highly prospective areas.

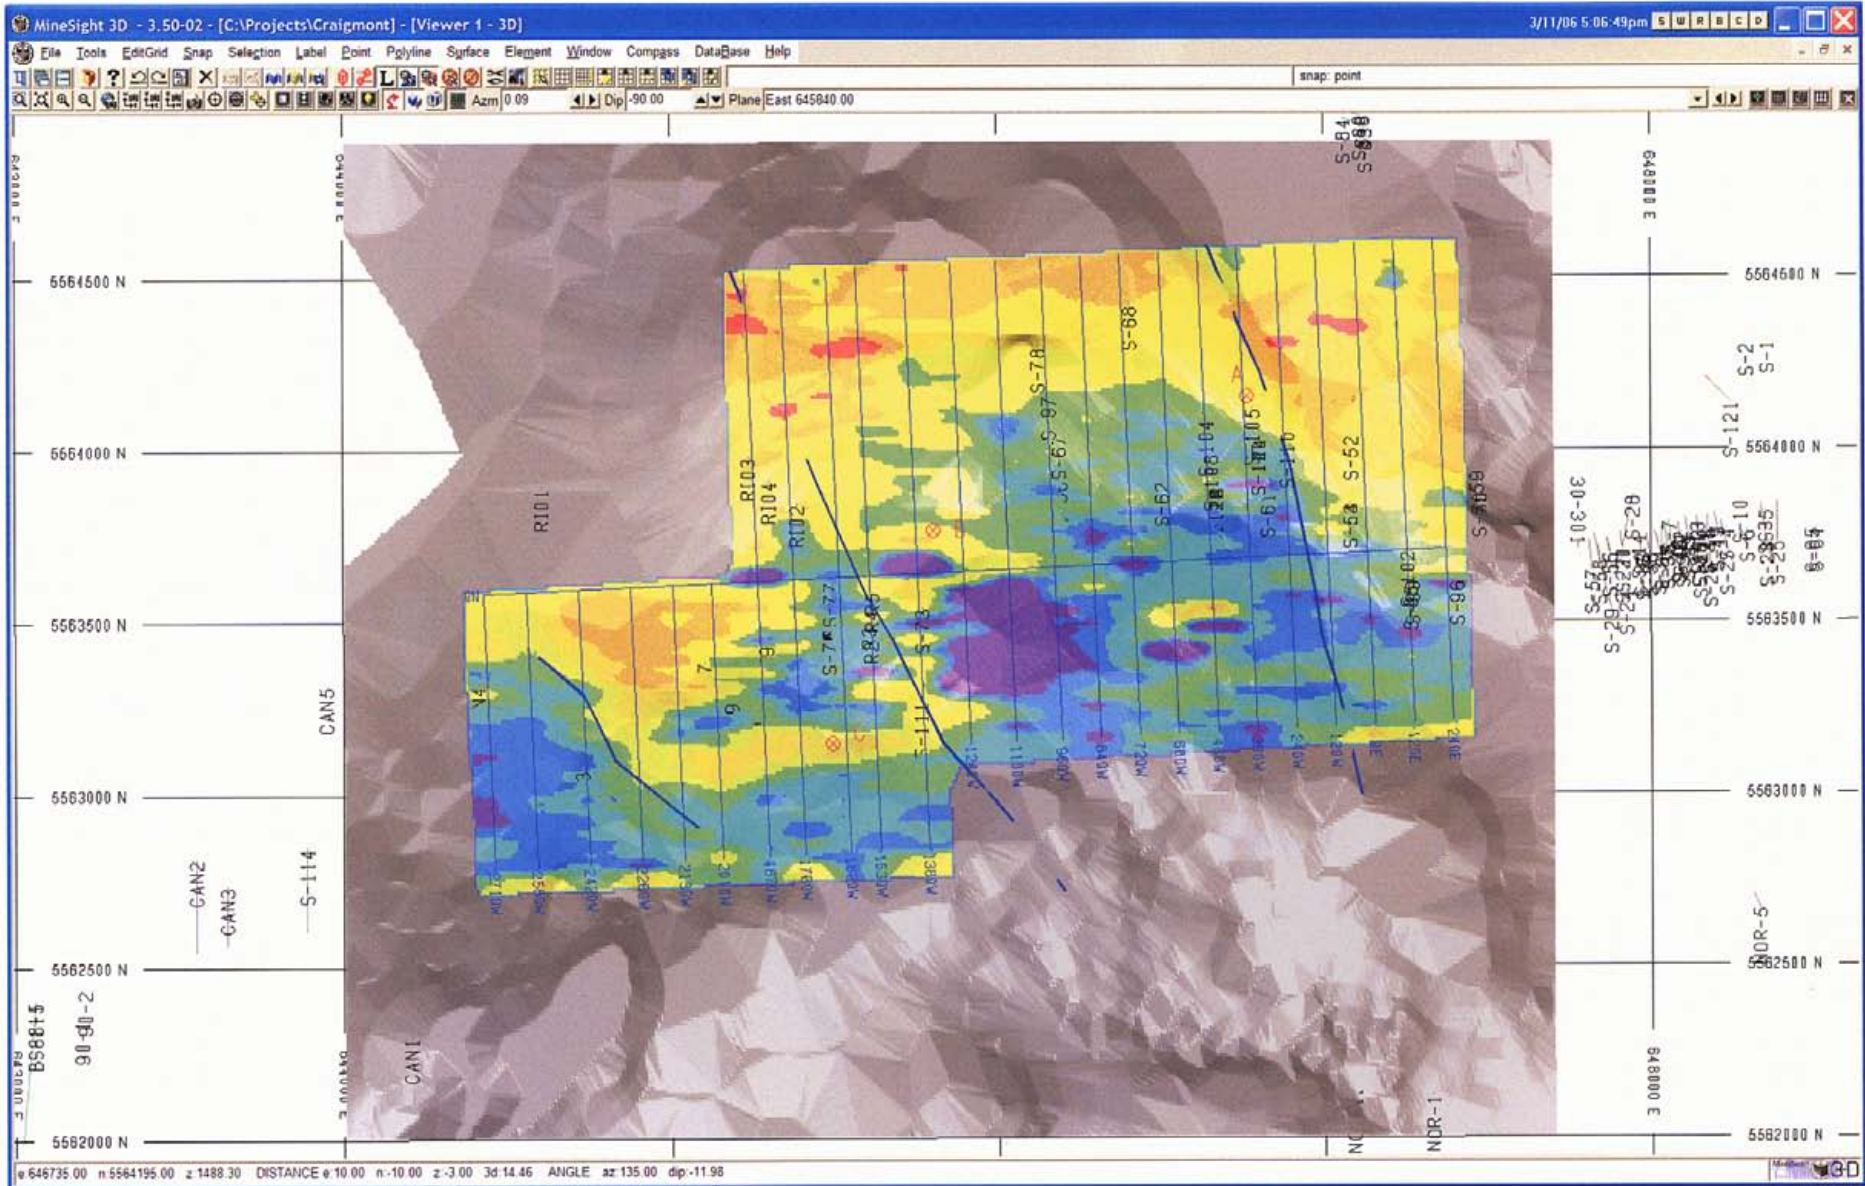

All of the geophysical targets will require drill testing along with the anomalous copper areas previously reported. The Company is currently applying for the necessary drill permits and is sourcing a drill contractor.

14.0 2005 EXPORATION PROGRAM (DRILLING)

14.1 Embayment and West Block

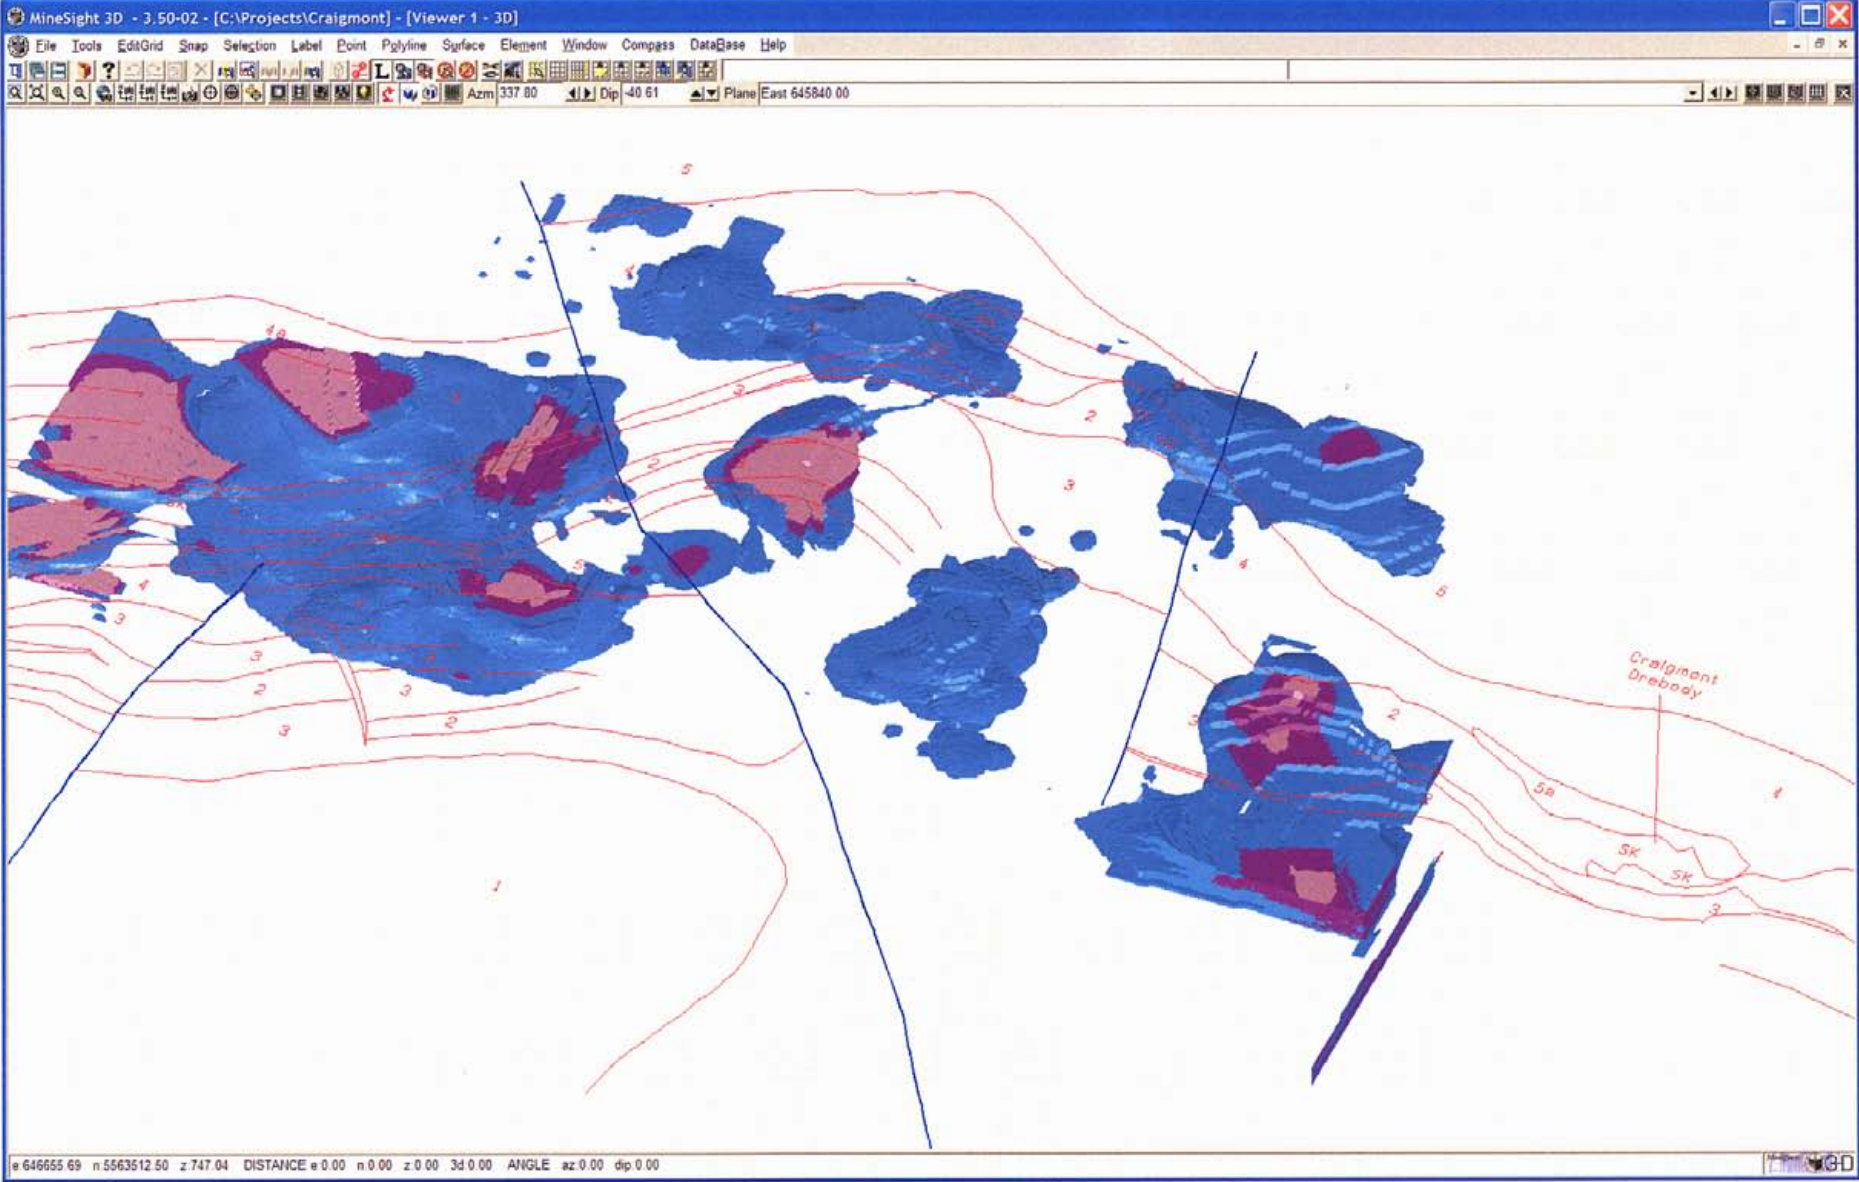

The 2005 drilling campaign comprised 8 holes totalling approximately 4,500 feet. Two of the holes had to be abandoned due to bad ground, four of the holes hit favourable geology and two of the holes hit scarn mineralization that warranted analysis. Significant intersections included 0.45% Cu over 1.2 meters in Hole Ab-5 before the hole was lost and 0.36 % over 6 meters in Hole Ab-7 which included 0.53% over 3 meters.

This drilling program at Craigmont tested 3 drill targets identified by an extensive geophysical program that included magnetics, surface and downhole IP. In addition, the geophysical data was processed using state-of-the-art 3-dimensional inversion which is an enabling technology that allows the company to not only identify prospective drilling targets but also to develop a 3D picture of the nature, extent, orientation and character of the anomalous zones. Figure 31 illustrates the target areas denoted by A, B and C while Figure 32 through 34 shows the 3D IP is volumes which indicate the areas of high conductivity and potential mineralization. It was interesting to note that the magnetic highs coincided with the edges of high conductivity however the resistivity models were not indicative of areas with potential for mineralization. Review of previous reports throughout the area point to magnetics as being the only meaningful geophysical method for indicating areas of potential copper mineralization.

Figure 34: IP Chargeability highs and trends within target areas at a threshold of 13.417.

1. Craigmont Extension (Embayment Block); Magnetic Anomaly “A”

A series of 3 holes were slated to test the extension of a previously identified zone of skarn mineralization that had historic grades of 490 feet of 0.41% Cu and including an intersection of 184 feet of 0.88% Cu in addition to 30 feet @ 2.56% Cu as shown in Figure 19. However, the first hole was lost and the second was cased and abandoned due to poor ground conditions within the holes. The third was not attempted. The reader is cautioned that these values were reported prior to NI43-101 while the mine was still in production, have not been verified and therefore should not be relied upon and are for reference only. This zone has been shown to be coincident with a modest magnetic trend in addition to being in proximity to a chargeable and resistive anomaly.

Holes AB-1 and AB-2 appear to have been very close to the Kingsvale Group – Nicola Group unconformity and may have ended in a basal tuffaceous bentonitic layer overlying the Nicola Group rocks. No new information was therefore obtained about the Nicola Group rocks or the mineral potential to alter the geological model used to select the target originally. Unless new information becomes available to alter the model, the target remains viable. The casing was left in AB-2 to allow re-entry to complete the hole to the planned depth of about 425 metres. Due to the bad ground conditions, it will be necessary to ream and case the hole through the clay seams. As this was the process being undertaken on AB-1 when the hole was lost, there is a similar risk involved in re-entering AB-2, but not necessarily greater risk than drilling a new hole with HQ and stepping down to NQ once into the Nicola Group rocks.

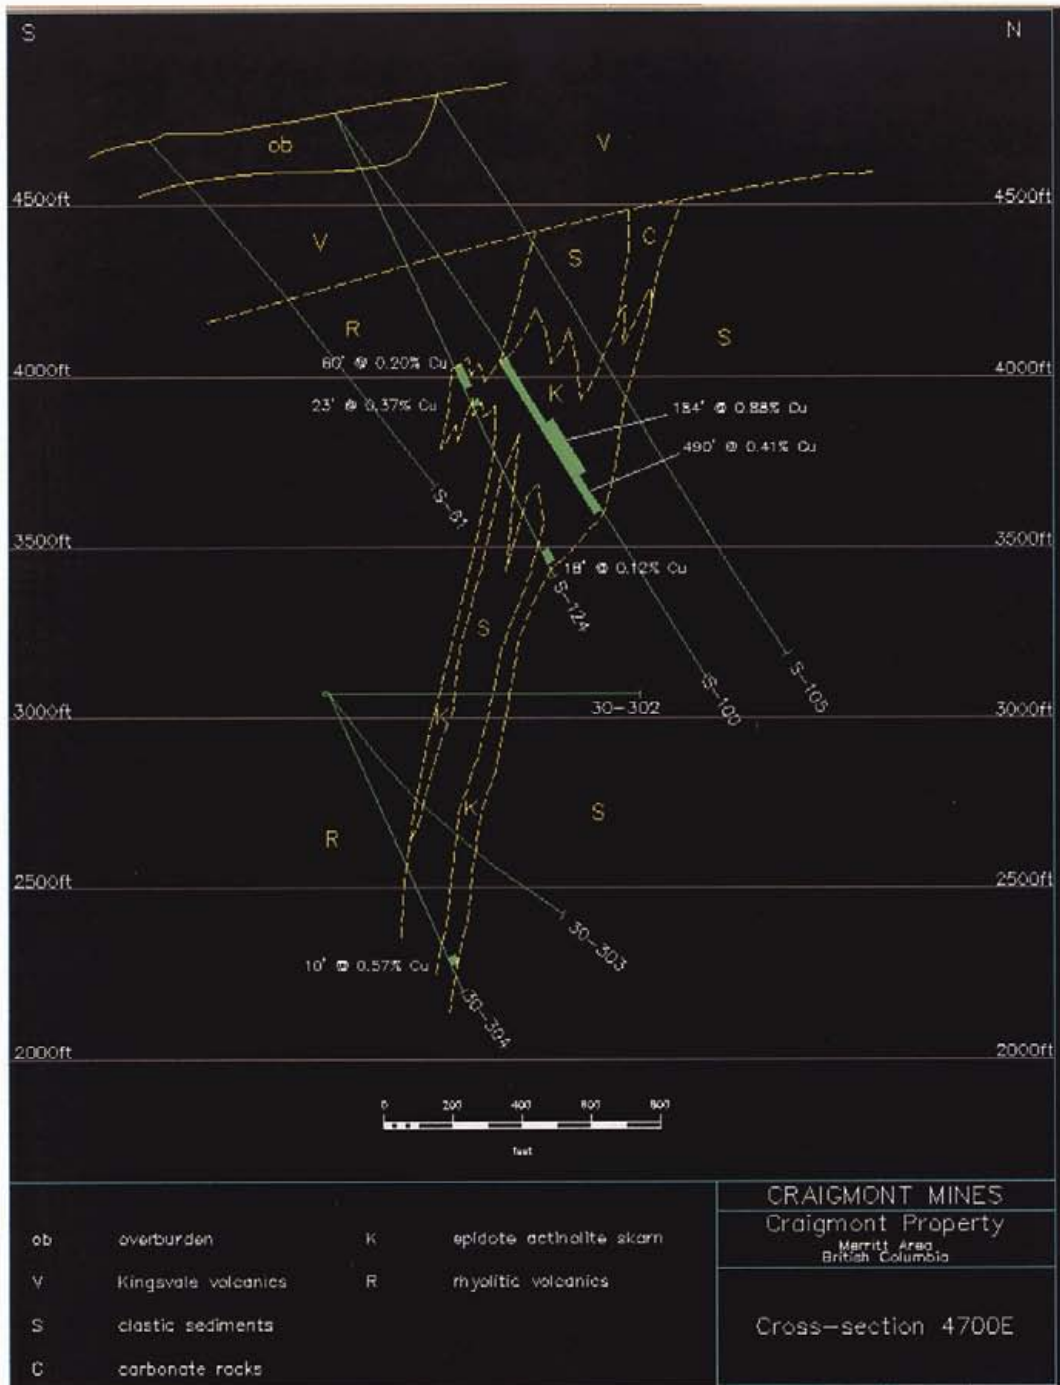

Figure 35: 4700E Cross-section considered to be the primary target for mineralization within the Embayment Block.

2. Magnetic Anomaly "B"

Hole AB-3 encountered weakly to moderately magnetite altered rocks near surface, but not a body of

high grade magnetite skarn in the projected target depth of 40 to 45 metres. It appears that the hole was drilled in Kingsvale Group rocks. No further drilling is recommended on this anomaly.

3. Magnetic Anomaly "C"

The magnetic anomaly appears to be caused by the magnetite bearing (~3% magnetite) plug of diorite that underlies the anomaly area drill tested. The diorite also appears to be the cause of the skarn alterations and minor associated occurrences of chalcopyrite in the limy and non-limy rocks of the underlying Carbonate unit. In general, the skarn alterations diminish in intensity and frequency with increasing distance from the diorite. Skarn mineralogy generally reflects the protolith composition (garnet more common in more limy units). There are examples, however, of compositional changes with depth within individual skarn horizons (e.g. magnetite dominant skarn grading to specularite rich skarn) that support the interpreted geometry of the diorite as a sill-like body dipping northward subparallel to Carbonate Unit strata, as opposed to a crosscutting, dyke-like body. There appear to be sufficient favourable host rocks underlying the diorite (e.g. impure limestone, limy volcaniclastic rocks) to host a significant skarn deposit. The fact that the alterations and mineralization are not more extensive indicates that the diorite was not an adequate source of heat and fluids to effect the alterations at the structural level investigated. This does not, however, eliminate the possibility of a deep target where steeply (70-80°) northward dipping Carbonate unit rocks are closer to the Guichon Batholith. No further drilling is recommended on this anomaly.

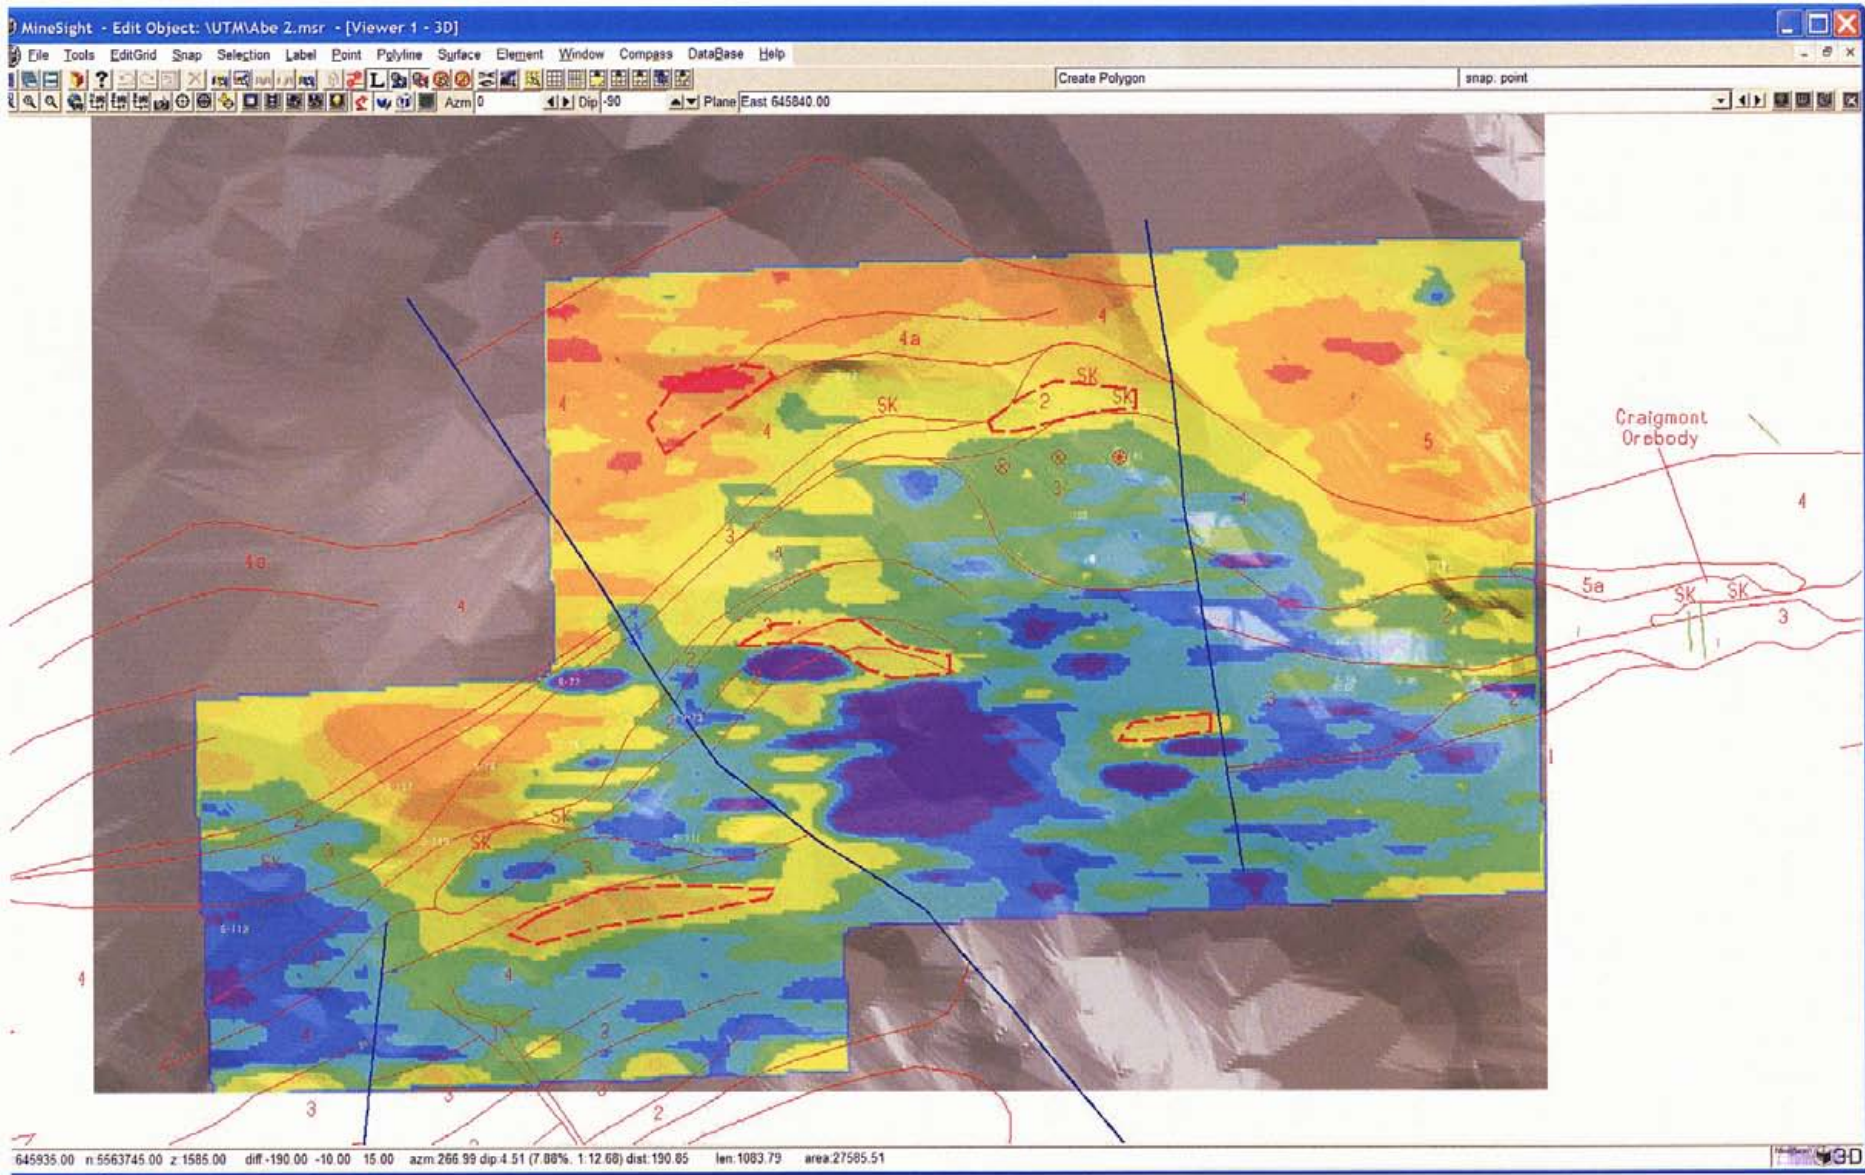

Figure 36: Plan view total field magnetic data with geology denoted by red solid lines, faults as blue solid lines and anomalous zones identified with bold red dashed areas.

Four additional shallow drill targets, untested by previous programs and studies, identify prospective areas for a follow-up program. The length of the drill holes are expected to vary from about 100 metres to more than 500 metres in this eastern zone.

Jeff Stibbard of JDSemi (Kelowna, B.C.) coordinated drilling activities and logistics in the field and Spence Coutlee of SCS Drilling (Kamloops, B.C.) is provided drilling services.

Drill core from the program was sampled and prepared for analysis according to industry standards and sent to EcoTech Laboratories of Kamloops, BC, Canada for 30 gram fire assay with AA finish and 28 element ICP analysis with Aqua Riga digest. EcoTech is a certified laboratory as required by Canadian National Instrument 43-101.

Drill Holes AB-1 and AB-2 (Craigmont Extension)

Holes AB-1 and AB-2 were collared within the Embayment block close to the fault defining the boundary between the Embayment and Mine blocks. The holes were drilled at a bearing of 355° with dips of -60° and -55° , respectively, to intersect the southward dipping sequence of mineralized Nicola Group volcanic and sedimentary rocks underlying a thick cover of volcanic rocks of the Cretaceous-Tertiary Kingsvale Group. The holes each penetrated about 2 metres of overburden, were collared in Kingsvale Group volcanics and remained in these rocks to their respective lengths of 145.4 and 159.4 metres. Both holes encountered strongly sheared and phyllosilicate / argillic altered rock in the bottom 5-10 metres with seams of sand, mud and clay in the last 5 metres. Drill hole AB-1 was abandoned when casing broke in the hole in an attempt to ream through the bad ground. Hole AB-2 was stopped in the bad ground and the casing (6.1 metres / 20 feet) was left in the hole to allow re-entry at a later date.

The Kingsvale Group in the area was most recently mapped in the late 1970s (McMillan, 1978a, b; Morrison, 1980) and earlier described by J.M. Carr (Mines and Petroleum Report, 1960, 1961). Up to about 200 metres of unmineralized andesitic to rhyolitic flows, breccias and basal tuffs unconformably overlie the Nicola Group rocks in the mine area. Carr (1960) noted a basal bentonitic flow about 10 metres thick resting partly on Nicola rocks. This may relate to the bad ground with swelling clay seams encountered at the bottom 5 to 10 metres of holes AB-1 and AB-2. Hole S-105 (-55° / 353°) located northeast of holes AB-1 and AB-2 intersected the Kingsvale-Nicola contact at approximately 144 metres depth in the hole. Hole S-104 (-51° / 349°) collared about 100 metres to the west of AB-1 and AB-2 intersected Nicola rocks at about 150 metres depth in the hole. Both holes encountered sheared and altered rocks at these depths. This correlates very closely with the depths to the bad ground in the current holes and suggests that the holes ended close to the contact and that the clay seams may be related to the bentonitic unit described by Carr.

The Kingsvale Group rocks intersected in AB-1 and AB-2 are multi-coloured, multi-lithic, variably altered felsic volcanic breccia, conglomerate, lesser agglomerate and lapilli / ash tuffs, and (probable) andesitic flows. Fragments are poorly sorted, sub-angular to rounded, generally 1-10 cm in diameter to a maximum of about 1 meter, and edge packed with generally 25% or less lapilli and ash matrix. Rock is moderately porous with voids common in the upper part of the hole. There are some textural and compositional variations with depth. These variations do not appear to correlate between AB-1 and AB-2, however, suggesting rapid lateral variations.

Fragments appear to be volcanoclastics (crystal tuffs, ash tuffs, banded tuffs) of felsic composition and generally fine-grained. Darker varieties may be more basaltic in composition. A medium to light grey volcanic with 10% or more black amphibole (hornblende) needles and fragments in a fine grained to aphanitic matrix occurs in lengths of 0.5 metres or more. The amphiboles commonly have red hematite alteration rims or are weakly magnetite altered. Sharp planar contacts of the unit coupled with some layering of the phenocrysts suggest these are flows, likely the equivalent of units called "hornblende needle amygdaloidal flow or andesite flow" in previous drilling (1970s).

Fragments are typically red, dark green-grey, light grey, tan and orange altered. Red hematite alteration is common in the upper part of the holes affecting about 20% of the fragments and decreases with depth. There is minor epidote in vesicles, no carbonate, sparse (<1%) pyrite and weak, disseminated magnetite in the breccias, tuff and flows. Concentric, light grey, tan and green, soft, phyllosilicate alteration rims on dark to medium grey fragments to complete alteration are common. Chlorite-sericite alterations generally increase with depth, with argillic alterations in the bottom parts of the holes in the sheared rock.

AB-3 (Magnetic Anomaly "B")

Hole AB-3 was collared within the Embayment block close to the projected fault defining the west side of the block. The hole was drilled with bearing of 000° and dip of -55° to investigate an east-west trending magnetic dipole with an interpreted target depth of about 50 m.. The hole intersected bedrock at about 1.5 metres and collared in a massive, dense, blue-grey, porphyritic mafic aphanite (basalt) that extended to a down-hole depth of about 8 metres.

Underlying this unit to a down-hole depth of about 58 metres was mixed weakly to strongly tan (serpentine?) altered, weakly to moderately magnetic, weakly amygdular porphyritic mafic aphanite (basalt) similar to the above unit and moderately to strongly tan altered to bleached tuff breccia. Some banding of feldspar phenocrysts suggest the dark volcanic rocks are flows. The breccia fragments are mainly composed of the dark volcanic rock and locally resemble crackle breccias rather than rotational breccias or lapilli tuffs. From about 58 metres to the end of the hole at 90.5 metres, the hole intersected multi-coloured (purple, red, green and tan), multi-lithic volcanic conglomerate and intercalated thin-bedded sandstone and siltstone. The conglomerate fragments are mainly sub-rounded to rounded altered dark (basaltic) volcanics, felsic ash tuff, white altered clasts (dacitic) and weakly magnetite altered felsic phanerite (dioritoid). Fragments range in size from about 2-6 cm and are generally tight packed in a multi-lithic pebble- to sand-size matrix. Bedding where present ranges from about 45° to 65° to the core axis.

The rocks intersected in this hole appear to closely match rocks of the Basalt Unit most recently described by Morrison (1980) as consisting of red to purple, massive to weakly bedded agglomerate, tuff and lapilli tuff with intercalated volcanic conglomerate and sandstone, porphyritic basalt flows and hematized flow breccia. This hole, however, is located well north of the known basalt unit in the core of the anticline underlying Promontory Hills, and is an area within the projected cover of Kingsvale Group rocks. This alone would not necessarily relegate the units to the Kingsvale Group. The magnetite altered felsic phanerite (dioritoid) fragments in the conglomerate, however, may be derived from the Guichon Creek Batholith, and as such would eliminate these rocks as part of the older Nicola Group.

The hole was drilled to intersect a near-surface magnetite-rich target. The volcanic rocks intersected have a weak to moderate magnetic susceptibility due to disseminated magnetite, but no strong, near-surface magnetite rich body was encountered. The hole was stopped at 90.5 metres.

AB-4 to AB-8 (Magnetic Anomaly "C")

Five holes bearing 000° and with dips of -50° (AB-4, -5) and -45° (AB-6, -7, -8) were drilled over an east-west strike length of about 500 metres on the south slope of Promontory Hill to test magnetic anomaly "C" for possible related copper-skarn mineralization. The anomaly extends about 700 metres east-west between lines 13+80W and 21+30W and from east to west was projected to transect rocks of the Nicola Group Clastic Sediment, Rhyolite and Carbonate units. Some plugs of Guichon diorite intruding the Nicola rocks were projected to underlie the western end of the anomaly. The target was interpreted (Frontier report, 2005) as occurring at a depth range of less than 50 metres below surface. Overburden cover intersected in the holes ranged from about 10 to 15 metres thick (true thickness), generally thinning from west to east and down-slope to the south.

Hole AB-4 was drilled on line 18+70W being about one-third the length of the anomaly from its western end. The hole intersected a weakly magnetite altered, salmon-pink, light orange to light green, medium grained granitoid about 10 metres thick directly beneath the overburden. The rock is composed of abundant medium-grained eggshell-white feldspar phenocrysts (+ k-spar?) and lesser subangular to subrounded and broken quartz phenocrysts and weakly chlorite+/-magnetite altered mafics in a pinkish to light green aphanitic matrix. A similar unit was intersected directly beneath the overburden cover in holes AB-8 and AB-6 located about 250 metres and 350 metres to the east of AB-4, respectively. The unit appears to be wedge-shaped increasing in thickness to about 25 metres in drill hole AB-8 and to about 45 metres thick in AB-6. The top of the wedge is defined by the subcrop surface and the bottom by a contact with an apparent dip of about 35° to the north. Hole AB-5 and AB-7 did not intersect the unit. The weak magnetic susceptibility of the unit and near surface position showed that the unit is not the cause of the strong magnetite anomaly, but could be reflected in the weaker part of the north flank of the anomaly. The unit is likely a phase of the diorite found below this unit in holes AB-6 and AB-8 as well as in holes AB-5 and AB-7. At the Craigmont Mine (Morrison, 1980) diorite plugs occasionally had a core of quartz diorite or granodiorite.

Intercalated massive to weakly bedded, felsic ash, lapilli, crystal and lithic tuffs, thin-bedded to laminated, black, quartzofeldspathic siltstone, limy siltstone, carbonaceous siltstone, limy sandstone, grit, impure limestone and lenses of crystalline limestone (marble) and limy breccia underlie the granitoid. These are interpreted to be part of the Nicola Group Carbonate unit. Most of the rocks are weakly to moderately chlorite and/or epidote altered, with epidote more common in the limy units and chlorite after mafics in the non-limy tuffs. There is only trace to minor amounts of magnetite through the sequence - not enough to explain the magnetic anomaly. Pyrite is ubiquitous and increases on average from 1-2% above about 90 metres depth to 2-3% below with concentrations of to 3-5% from about 111 to 124 metres in limy breccias and felsic tuffs immediately above epidote+/-garnet+/-magnetite+/-earthy hematite skarn altered tuff and marble at 124-127 metres depth. Very minor amounts of chalcopyrite as spots on margins of clasts were intersected in a narrow thin specularite-hematite-amphibole skarn at 96.3-97.6 metres and from 115.2-116.4 metres in a limy, brecciated tuff.

Hole AB-5 was drilled approximately 230 metres east of AB-4. It encountered massive, medium grained, moderately magnetite altered diorite from the subcrop surface to a down-hole depth of 57 metres. The diorite is characterized by abundant pyroxene phenocrysts with ragged edges generally with magnetite in the rims of the phenocrysts. Magnetite composes about 2-3% of the rock (based on Davis Tube test). Thin section work done in the 1970s on very similar rocks intersected in drill hole S-111 identified the rock as a pyroxene diorite with interstitial k-spar and quartz. Alteration of the pyroxene phenocrysts was

identified as serpentine. Alterations are weak chlorite-sericite and weak to locally moderate epidote. Pyrite content of the diorite is generally low to 1-2%. Below the diorite are skarn-altered limy and non-limy felsic volcanoclastic rocks. Skarn alterations are mainly magnetite-actinolite-chlorite-pyrite+/-epidote. From about 79 metres to the end of the hole earthy hematite and specularite are common alteration minerals and where strongest in the skarn, magnetite is less prominent. Garnet occurs in two of the limy units with associated moderate to strong epidote along bedding. Pyrite varies in amount from about 3-10%. Some of the skarn units are cut by quartz+/-magnetite veins and these are cut by white calcite+/-zeolite+/-epidote veins. From 91.6-92.8 m, chalcopryite (1-2%) occurs as blebs and thin veinlets in white calcite veins that crosscut intense actinolite-magnetite-chlorite-pyrite skarn altered breccia. The hole was abandoned at 95.4 metres in unmineralized skarn when the core barrel separated from the drill string.

The strongly magnetically altered skarn was encountered at a depth of 91.5 meters to 93 meters within an interbedded impure limestone unit. It should be noted that significant chalcopryite was discovered and will be assayed for copper content along with other elements. Unfortunately the hole was lost directly following this interval due to drill failure. However, the company is stepping out 100 meters to the east in an effort to extend the continuity of the structure and to investigate to depth.

Hole AB-8 was drilled approximately 40 metres to the north of hole AB-5 to follow up on the skarn and copper mineralization in that hole and to push past the depth at which hole AB-5 was lost. It intersected pink granitoid from the subcrop surface to a down-hole depth of 42 metres and coarse grained, magnetite-bearing diorite to 144 metres. The increase in apparent thickness of the diorite to about 100 metres from less than 30 metres in hole AB-5, and an equivalent thickness in hole AB-6 to the northeast, suggest that the root of the plug lies to the north. The overall moderate magnetite alteration (~3% magnetite) of the diorite coupled with the lateral extent of the unit and its position overlying the magnetite-skarn altered units indicates that magnetic anomaly "C" primarily reflects the magnetic susceptibility of the diorite.

Below the diorite in AB-8 is an approximately 25-m-thick sequence of variably skarn altered limy and non-limy, generally felsic volcanoclastic rocks. Skarn minerals vary between units depending on the carbonate content and also vary within units. In general, red-brown andradite garnet and specularite are more common and magnetite-actinolite less common than in AB-5. This may reflect a higher heat gradient with increased thickness of the diorite plug to the north of AB-5. Pyrite is generally more abundant (3-5%) in the limy skarn units than in the non-limy units (1-2%). A few spots of chalcopryite were intersected in a specularite-rich skarn in a very limy unit. Underlying the skarn units from about 170 metres is light to medium grey impure crystalline limestone (marble) and interbedded limy and felsic sandstone alternating with medium grey, weakly magnetic, hornblende needle porphyritic felsic (andesite?) flows. The limestone units are weakly garnet+/-epidote (no magnetite) altered with the skarn alterations following the bedding in the limestone, contain 1-2% disseminated pyrite, and are cut by scattered crystalline calcite veins to cm thick and narrow multilithic breccia dykes. The limestone displays distorted bedding with bedding varying from 0-45° to the core axis. The porphyritic volcanic rocks have weak colour banding and alignment of fresh hornblende needles indicating they are probably flows. Multilithic breccia dykes that include fragments of skarn occur at top and bottom contacts and within the unit. The hole was stopped at 188.4 metres due to the weak skarn alterations in the limy units and lack of copper mineralization.

Hole AB-6 was drilled on line 15+30W, about 100 metres east of AB-5 to follow up the mineralization encountered in that hole and test the anomaly along strike to the east. This was the deepest hole of the program having been drilled to 305.1 metres to test the skarn potential at depth in the carbonate unit. The

hole intersected the pink granitoid from subcrop surface to about 60 m, but unlike AB-8, encountered about 15 metres of breccia (with minor chalcopyrite) and 4 metres of limy, magnetite-actinolite skarn above the diorite. The diorite has an apparent thickness of about 90 metres in AB-6. From the bottom contact of the diorite at 169 metres to the end of the hole, AB-6 intersected a thick sequence of massive white crystalline limestones, banded grey, impure limestones, limy and non-limy felsic volcanoclastic (and /or epiclastic) tuffs, sandstones, greywackes(?), quartzofeldspathic and limy siltstones of the Nicola Carbonate unit. Skarn alterations are generally weak, follow the thin-bedded impure limey horizons and are mainly andradite-epidote+/-actinolite with little magnetite and extend to about 200 metres down hole. Beyond that depth, skarn alterations are very weak to absent. Pyrite, however, occurs through to the bottom of the hole in amounts of 2-3% and locally to 5%. The hole was stopped at 305.1 metres due to the lack of skarn alterations of the carbonate unit rocks. The skarn alterations and weak copper mineralization encountered in the holes drilled into magnetic anomaly "C" appear to be related directly to the diorite plug underlying the area with strongest alterations occurring in the units close to the diorite.

Hole AB-7 was drilled off the eastern end of the magnetic anomaly. It was spotted there on the basis that the end of the anomaly could reflect structural changes and/or deformation of the underlying limy units and enhanced development of skarn and mineralization, and/or that the diorite was thinner or had pinched out south of drill hole S-111. The diorite was, however, encountered from the subcrop surface to 45-m depth. From 45 to 95 metres the hole intersected several thin (< 2 thick) horizons of garnet-epidote-pyrite and magnetite-specularite-hematite skarn horizons in a sequence of limy and non-limy fine-grained felsic volcanoclastics, minor breccia, and diorite or dioritized(?) rocks. From 75.0 to 79.2 metres a magnetite-andradite-specularite-hematite-pyrite skarn in a limy host rock contains chalcopyrite blebs (estimated 1% over 5 m) with minor disseminated chalcopyrite below that to about 87 metres depth in a weakly magnetite-epidote altered felsic rock. From about 95 to 116 metres depth, the hole intersected interlayered porphyritic and amygdaloidal felsic (andesitic?) volcanic (flow?) rocks. These units may correlate with the andesitic flow intersected at depth in hole AB-8. The hole was stopped at a depth of 126.8 metres due to the general lack of skarn alterations below 88 metres depth. It ended in a light grey quartzofeldspathic rock that may be part of the Nicola Rhyolite unit.

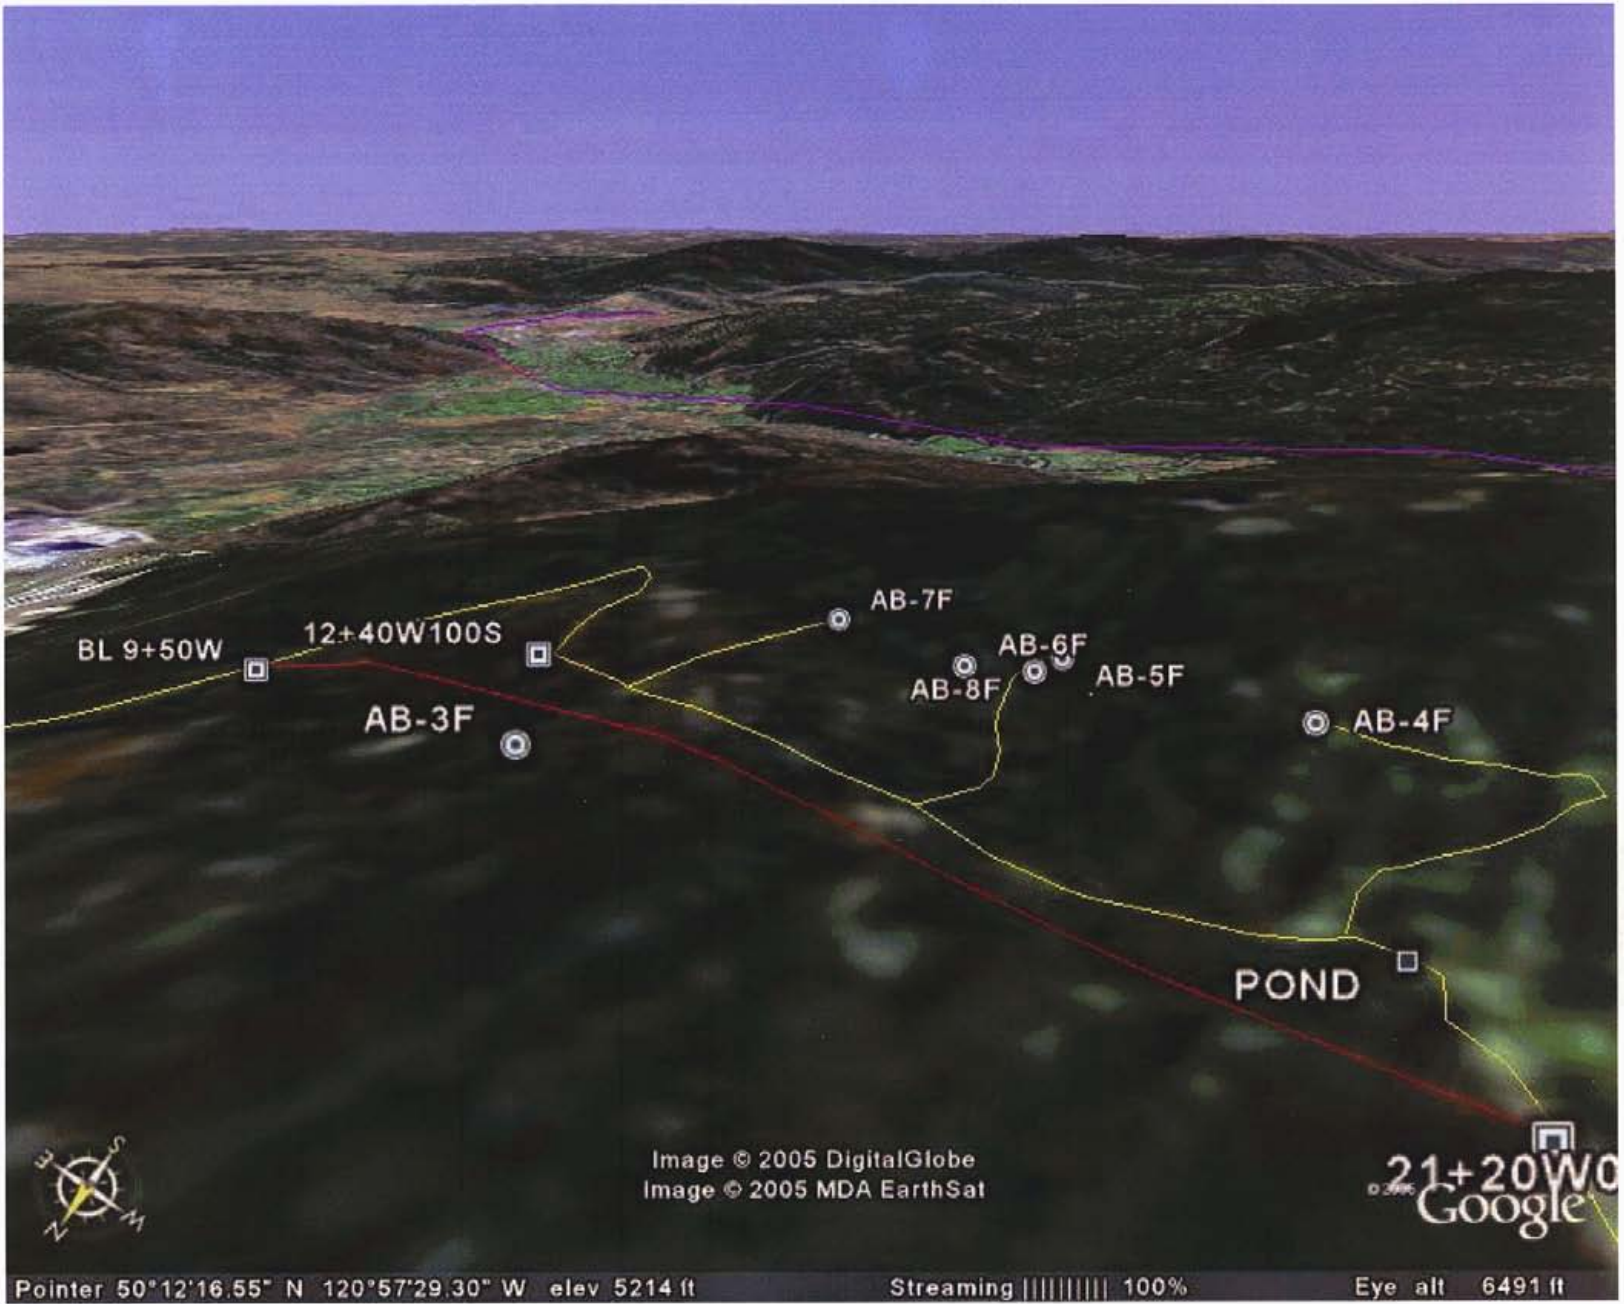

Figure 37: Perspective view using Google Earth to illustrate the location of the drillholes and the access roads.

15.0 OTHER RELEVANT DATA AND INFORMATION

15.1 Site Roads

There are roads in place for access to all areas of the Craigmont Mine site and surrounding claims. It is necessary to utilize a bulldozer to clear spurs to drill pads in addition to the creation of drill pads. Due to previous geophysical activity, a well defined grid has been created over the deposit extending over the Embayment Block to the Betty Claims.

15.2 Underground Development

The portals for the haulage drifts are still in place on-site however the condition of the haulage drifts is unknown. Information derived by historic reports and descriptions of the construction give insight into the methods used and quality of construction. The main haulage drifts were constructed using concrete and steel however the secondary drifts were likely limited to support using timbers. During the 2005 program, a secondary drift was breached from surface while building a sump and a view into the development showed timbers in relatively good condition coated by creosote.

15.3 Surface Facilities

There are some of the historic mill facilities that remain on-site not to mention the existing magnetite mill facility owned by Craigmont holdings. In addition, Craigmont Holding has office and storage facilities along with supporting infrastructure for their magnetite operation. Extensive core storage facilities exist on-site however their condition is poor.

15.4 Labour

There is a large and experienced labour force in and around the Merritt area; proximity to Vancouver (3 hours), Kamloops (1 hour) and the Okanagan Valley (1.5 hours).

15.5 Environmental Issues

CJG has no known environmental liability other than a commitment to stem the water flow within Ab-8 that could not be cased and completed at the end of the 2005 campaign. However, it is unknown whether Craigmont Holdings Ltd. will be subject to extensive reclamation and remediation on the site, tailings, dumps and pit.

15.6 Permitting

Mining permits are in place as a result of the existing and continuing magnetite mining activities at the site. This is an extremely advantageous situation and it is to the best interest of all that these permits stay current and operations continue on the site.

16.0 RECOMMENDATIONS

It is recommended that all data be transferred and transposed to electronic format and the database be completed. In addition, a QA/QC program should be established.

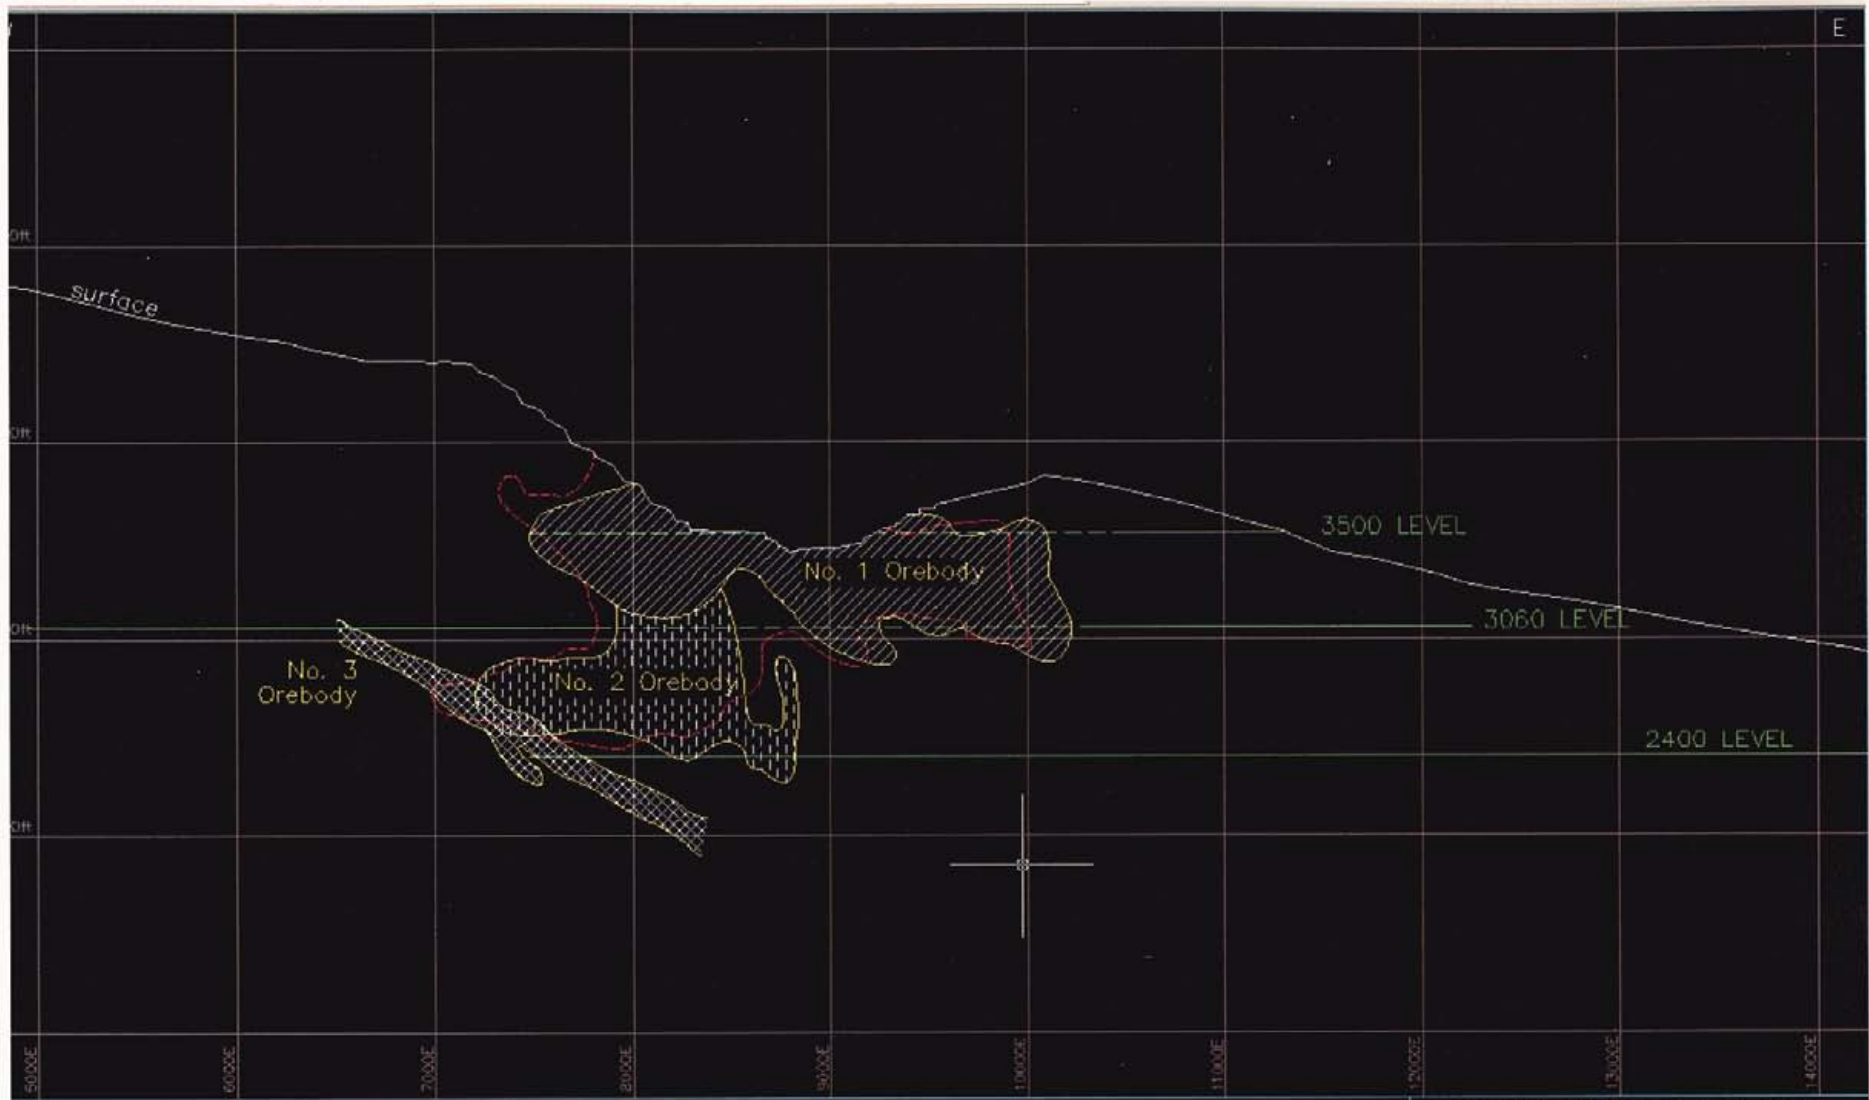

Review all data and results from previous programs, both surface and underground and establish models, sections/plans on which a potential mine plan can be devised. Estimate a potential mineable tonnage and grade from historic data and calculations.

It is recommended that a geophysical exploration program be carried out on the newly acquired ground and targets evaluated for future drilling.

It is recommended that an underground exploration program be carried out on the historic Craigmont Mine area. This would include surface and downhole geophysics and potentially drilling from surface to identify the location and potential size of the remnant mineralization at the Craigmont Mine which is said to be 100,000,000 lb of Cu based on mostly anecdotal evidence. In support of this effort, a complete and comprehensive 3D model of the mine area is recommended which would include importing and georeferencing underground drillhole data and underground openings.

It is recommended that an internal Scoping Study, performed by Beacon Hill and Knight and Piesold, be initiated which would form the basis for a Preliminary Assessment for the continuation of mining activities within the underground at the Craigmont Mine.

It is recommended that a 3,000 meter drill program be undertaken on the Craigmont Deposit. This program should be focused on identifying and extending the areas of historic production that have been theorized to be still in-situ. Also, the further work should be dedicated to identifying areas of potential economic mineralization within the Embayment Block, Northwest Claims area and the Betty claims.

DRILL COLLARS FOR 2005 DRILLING CAMPAIGN

CRAIGMONT MINE PROJECT

<p>HOLE NO.</p>	<p align="center">CRAIGMONT DRILLING PROGRAM – FALL 2005 CHRISTOPHER JAMES GOLD CORP. DRILL HOLE COLLAR DATA</p>
<p>AB-1</p>	<p>UTM Coordinates (GPS - corrected): Zone 10 646725.8E 5564115.5N (NAD83) Local Grid Location: 3+70W; 4+31N Collar Elevation: 1466.0 m Bearing: 355° Dip: -60° Length: 145.4 m Core Size: NQ Date Collared: August 10, 2005 Date Completed: August 18, 2005 Dip Tests: -65° @ 100m Logged by: J.A. Fleming, P.Geo. Comment: Casing broke in hole – hole abandoned</p>
<p>AB-2</p>	<p>UTM Coordinates (GPS uncorrected): Zone 10 646725E 5564095N (NAD83) Local Grid Location: 3+70W; 4+07N Collar Elevation (approx.): 1462 m Bearing: 355° Dip: -55° Length: 159.4 m Core Size: NQ Date Collared: August 18, 2005 Date Completed: August 22, 2005 Dip Tests: -60° @ 100 m Logged by: J.A. Fleming, P.Geo. Comment: Hole stopped due squeezing in clay seams– 20' casing left in hole.</p>
<p>AB-3</p>	<p>UTM Coordinates (GPS uncorrected): Zone 10 645747E 5563703N (NAD83) Local Grid Location: 13+93W; 0+62N Elevation: 1600 (approx.) Bearing: 000° Dip: -55° Length: 90.5 m (297') Core Size: NQ Date Collared: August 23, 2005 Date Completed: August 27, 2005 Dip Tests: -60° @ 84 m Logged by: J.A. Fleming, P.Geo. Comment: Stopped due to lack of mineralization</p>
<p>AB-4</p>	<p>UTM Coordinates (GPS uncorrected): Zone 10 645293E 5563196N (NAD83) Local Grid Location: 18+70W; 4+32S Elevation (approx.): 1550 m Bearing: 180° Dip: -50° Length: 151.2 m (496') Core Size: NQ Date Collared: August 28, 2005 Date Completed: Sept. 2, 2005 Dip Tests: -55° @ 105.5 m Logged by: J.A. Fleming, P.Geo. Comment: Stopped due to lack of mineralization</p>
	<p>UTM Coordinates (GPS uncorrected): Zone 10 645534E 5563205N (NAD83) Local Grid Location: 16+40W; 4+40S Collar Elevation (approx): 1550 m</p>

CRAIGMONT MINE PROJECT

<p>AB-5</p>	<p>Bearing: 180° Dip: -50° Length: 95.40 m (313') Core Size: NQ Date Collared: September 10, 2005 Date Completed: September 17, 2005 Dip Tests: None Logged by: J.A. Fleming, P.Geo. Comment: Hole abandoned - core barrel separated from drill string.</p>
<p>AB-6</p>	<p>UTM Coordinates (GPS uncorrected): Zone 10 645603E 5563270N (NAD83) Local Grid Location: 15+30W; 3+58S Elevation (approx.): 1550 Bearing: 180° Dip: -45° Length: 305.10 m (1001') Core Size: NQ Date Collared: September 20, 2005 Date Completed: October 3, 2005 Dip Tests: -50° (100 m); -50° (EOH) Logged by: J.A. Fleming, P.Geo. Comment: Attempts to plug hole unsuccessful</p>
<p>AB-7</p>	<p>UTM Coordinates (GPS uncorrected): Zone 10 645758E 5563260N (NAD83) Local Grid Location: 13+80W; 3+88S Elevation (approx.): Bearing: 180° Dip: -50° Length: 126.8 m (416') Core Size: NQ Date Collared: Oct. 6, 2005 Date Completed: Oct. 14, 2005 Dip Tests: None Logged by: J.A. Fleming, P.Geo. Comment: Stopped due to lack of mineralization at depth</p>
<p>AB-8</p>	<p>UTM Coordinates (GPS uncorrected): Zone 10 645540E 5563250N (NAD83) Local Grid Location: 16+22W; 3+98S Elevation (approx.): 1540 m Bearing: 180° Dip: -45° Length: 188.36 m (618') Core Size: NQ Date Collared: Oct. 19, 2005 Date Completed: Oct. 27, 2005 Dip Tests: -50° @ EOH Logged by: J.A. Fleming, P.Geo. Comment: Stopped due to lack of mineralization.</p>

APPENDIX 3

DRILL LOGS FOR 2005 DRILLING CAMPAIGN

CRAIGMONT PROJECT 2005 Christopher James Gold Inc.		
HOLE # AB-1		
UTM Coordinates (GPS - corrected): Zone 10 646725.8E 5564115.5N (NAD83) Local Grid Location: 3+70W; 4+31N Collar Elevation: 1466.0 m Bearing: 355° Dip: -60° Length: 145.4 m Core Size: NQ Date Collared: August 10, 2005 Date Completed: August 18, 2005 Dip Tests: -65° @ 100m Logged by: J.A. Fleming, P.Geo. Comment: Casing broke in hole – hole abandoned		
FROM- TO (m)	ROCK UNIT	DESCRIPTION
0 2.1	99	Casing to 3.0 m (10 feet) – hit bedrock at about 2.1 m (7 feet)
2.1 52.0	10	Multi-coloured felsic volcanic breccia and conglomerate, agglomerate and lapilli tuff. Bombs, block and lapilli are dark to light grey and light orange to brick red in colour being variably altered felsic volcanic rocks (andesite). Fragments mostly have about 10%+ amphibole (hornblende) euhedra and crystal fragments in fine grained feldspathic matrix. The amphibole fragments plus occasional lithic clasts and lack of layering of phenocrysts suggest the volcanic fragments are pyroclastic rocks rather than flows. Magnetite is weakly disseminated through most of the rock fragments (with or after mafics) even in the lightest altered bombs, blocks and lapilli. Very sparse disseminated pyrite and no carbonates. Some minor epidote developed in small vesicles in the fragments. Light grey to tan concentric alteration rims are common on fragments with partial

CRAIGMONT MINE PROJECT

			to complete alteration -- argillic or sericitic -- Fragments poorly sorted, generally edge to long packed, with mostly less than 25% lapilli & ash matrix. Voids common in upper part of hole. Some of the light altered fragments look like granitoid (i.e. dioritic). Broken and rubbly core from about 50 to 60 m plus some finely broken core.
52	63	10	Amygdaloidal felsite (andesite) with inclusions of felsic phanerite (dioritoid).
63	98.5	10	<p>Increased proportion of medium-grey volcanic with broken amphibole (hornblende) crystals with red hematite alteration rims and honey coloured altered feldspar laths.</p> <p>Sections of the volcanic rock are longer (0.5 m) than the rest of the breccia fragments and contacts are sharp implying flows, but no banding or fining of grain size at contact. The units are likely logged previously as “hornblende needle amygdaloidal andesite flow” and “andesite flows”. Increased proportion of bomb and block fragments vs. the lapilli and ash-sized matrix. About 20% of fragments are red (hematite) altered.</p> <p>At 95 m note some bluish alteration on fractures, very fine grained minor disseminated pyrite and minor epidote. Some layering, possibly bedding at 50°C.A.at 98-99 m.</p>
98.5	139.3	10	<p>Multi-coloured volcanic breccia as from 7-52 m but with fewer red coloured fragments and increased green chlorite-sericite alterations of pebble and ash matrix</p> <p>At 101 m is a shear at 20° C.A. with chlorite-sericite on slickensided shear surfaces. Volcanic breccia fragments (rounded) increased in size to 1 m with less than 10% lapilli-pebble matrix. At 99 m is a dark f.g. rock with abundant feldspar phenos (basalt?). Possible tuff beds from 106 to 109 m.</p> <p>113 -121 m: increased porosity - vuggy with fine drusy crystals – after lapilli or glass shards?</p> <p>124-127 m: fractured sections with friable, sheared and broken core.</p>
139.1	145.4	10	<p>Intense fracture zone with highly broken core and seams of sand, mud and clay.</p> <p>About 80% core less than 1 cm in size with abundant orange coating plus soft soapy film (sericite or talc) on fractures to ~140 m. From 140-141 m ~95% core in pieces less than 5 mm in size in fine grained greenish soft matrix (sericite or talc).</p>

CRAIGMONT MINE PROJECT

		<p>At 141 m a 10-cm length of pink, medium grained granitoid with about 20% quartz, 10% hornblende, 40% soft argillized feldspar in fine grained matrix.</p> <p>From 141 to EOH ~50% of core is in lengths < 1 cm long with seams of sand, tan mud and clay.</p>
145.4 m		<p>Casing broke off in hole while being reamed through fracture / clay zone. Hole was abandoned.</p>

CRAIGMONT MINE PROJECT

		<p>CRAIGMONT PROJECT 2005 Christopher James Gold Inc.</p> <p>HOLE # AB-2</p> <p>UTM Coordinates (GPS uncorrected): Zone 10 646725E 5564095N (NAD83) Local Grid Location: 3+70W; 4+07N Collar Elevation (approx.): 1462 m Bearing: 355° Dip: -55° Length: 159.4 m (523') Core Size: NQ Date Collared: August 18, 2005 Date Completed: August 22, 2005 Dip Tests: -60° @ 100 m Logged by: J.A. Fleming, P.Geo. Comment: Hole stopped due squeezing in clay seams – casing left in hole.</p>
FROM- TO (m)	ROCK UNIT	DESCRIPTION
0 6	99	Cased 6.1 m (20 feet). Hit bedrock at about 1.5 m
6 11	10	Lost and broken core.
11 12	10	Multicoloured, volcanic breccia and agglomerate with medium green-grey felsic-intermediate (andesitic) reddish tuff, lapilli, bombs and cobbles.
12 14.3	10	Medium grey ash, crystal and lapilli tuff with 5% bronzy subhedral crystals (altered amphibole?). Slight brown alteration of matrix (biotitic?).
14.3 106.5	10	Multicoloured, porous, agglomerate and conglomerate with red, dark green-grey, light grey, tan and orange bombs, cobbles and lapilli. Fragments poorly sorted, generally 1-10 cm in diameter and tightly edge packed. Rock moderately porous in upper sections. Composed (likely) of basalt, andesite and dacite tuffs and flows. Some of the clasts are dark to medium grey, weakly altered (concentric bands) to completely tan-green altered (v-soft). Some clasts are medium grey tuff with black amphibole needles and white feldspar subhedra to 2 mm in fine grained to ash size matrix. Amphibole needle rich bands 10-30 cm thick with v.f.g. to aphanitic matrix. Sharp contacts

CRAIGMONT MINE PROJECT

			<p>and weak banding suggest may be flows. At 90-95 m sheared tuff with 5-10% dark weakly magnetite altered amphibole crystals in feldspathic fine ash matrix. Weak banding.</p> <p>Broken core 15 m; at 31 m is 6 cm of brown mud and breccia; at 41 m is 0.4m soft brown gritty mud, at 43.6 m a 5 cm mud & clay seam. At 86-88 m sheared; at 92.3 m 0.4 m friable and chloritized; 93-97 m shears at 0-30° C.A Sharp contact at 106.5 m</p>
106.5	121.4	10	<p>Multicoloured, poorly sorted finer grained variety of above agglomerate and conglomerate.</p> <p>Same fragment composition but average size is < 1cm with about 80% of clasts < 5 mm and minor amounts of 1-5 cm size. Fragments comprise about 30% light grey (rhyodacitic) tuff, 30% medium grey (andesitic) and 5 -10% dark (basaltic). Matrix is sand sized to aphanitic, locally grit size, generally light grey and felsic. Alterations are chlorite+/- magnetite, sericite, red hematite, minor epidote and minor disseminated pyrite. Sheared contact at 121.4 at 0-10° C.A.</p>
121.4	129.0	10	<p>Medium grey amphibole (hornblende) crystal tuff -ash tuff (possibly andesitic flow rock - same as at 90 m)</p>
129.0	141.0	10	<p>Intercalated agglomerate-conglomerate, hornblende crystal-ash tuff (0.5-m sections) and fine grained - gritty unit (0.5-1 m sections).</p>
141.0	148.4	10	<p>Multicoloured conglomerate similar to 106.5-121.32 m but with stronger chlorite-sericite alteration.</p> <p>Up to 40% of lithic-lapilli fragments strongly altered to soft light green sericite.</p>
148.4	151.5	10	<p>Sheared and strongly sericite+talc(?) altered version of above unit. Shears at 0-30° C.A. Note: short pieces of medium grained hornblende granitoid (diorite?) in the sheared and broken section.</p>
151.5	159.4	10	<p>Intensely fractured and friable, greenish sericite-talc(?) altered rock with mud and clay seams.</p> <p>Remnant altered tuff fragments through to 158 m. Soft soapy mineral coating slip surfaces plus orange zeolite on fractures. Soft green clay from 157.6-159.4 m.</p>

CRAIGMONT MINE PROJECT

		Hole abandoned due to clay seams. Casing left in hole.

CRAIGMONT PROJECT 2005 Christopher James Gold Inc.		
HOLE # AB-3		
UTM Coordinates (GPS uncorrected): Zone 10 645747E 5563703N (NAD83) Local Grid Location: 13+93W; 0+62N Elevation: 1600 (approx.) Bearing: 000° Dip: -55° Length: 90.5 m (297') Core Size: NQ Date Collared: August 23, 2005 Date Completed: August 27, 2005 Dip Tests: -60° @ 84 m Logged by: J.A. Fleming, P.Geo. Comment:		
FROM- TO (m)	ROCK UNIT	DESCRIPTION
0 2.7	99	Casing 3.1 m (10') -- hit bedrock at about 1.5 m
2.7 8.0	10	Blue-grey, massive, dense, feldspar porphyry mafite (basalt). Composed of 30% medium grained (< 5 mm) white altered feldspar, in dark, v.f.g. to aphanitic matrix. 1-2% subhedral phenocrysts to 2 mm of chlorite-sericite altered pyriboles. Crosscut by 1-2 mm thick dark to light green and white chlorite-sericite altered material. Dendrites at 3.3 m with bluish trace under purplish-black (red-brown streak) mineral (manganite?).
8.0 15.0	10	Tan, greenish to orange, strongly altered weakly magnetic mafite breccia. Alterations (serpentine?) create crackle breccia texture with sub-angular to sub-rounded fragments of dark volcanic rimmed with light tan to greenish rims. Rock friable where alteration strongest. Contacts between breccia and dark volcanic (possibly flows) at 10-30° C.A.
15.0 50-3	10	Mixed weak to moderate magnetite altered, dark, fine-grained volcanic rock and minor tan-altered breccia. Dark volcanic rock similar to 2.7-8.0 m. 1-2% pyribole phenocrysts altered to translucent amber mineral. Green variety may be olivine. Very weak alignment of fine grained feldspar laths at 90° C.A. Pyribole subhedra 1-2 mm altered to chlorite and sericite. Scattered

CRAIGMONT MINE PROJECT

			<p>small amygdular looking ovoids ($\leq 1\text{mm}$) occur with alteration rims and bleached alteration halos. Pyrite $<1\%$ occurring in altered phenocrysts or amygdules. Minor epidote on fractures (drusy, f.g. yellowish-green) and minor amphibole. Fractures coated with light green, white, and bluish to reddish orange minerals - probably hydroxides (brucite?) and zeolites (laumontite?). Light green mineral is massive and finely botryoidal and comes with black to red-brown spots and dendrites (manganite or goethite?). Brownish silt and sand seams with rock clasts to $\pm 2\text{mm}$ at 30.3-30.5 m and 39.0-39.4 m.</p>
50.3	52.0	10	<p>Mixed dark, weakly magnetic, volcanic (basalt) and amber-tan altered tuff breccia.</p> <p>Subrounded fragments 2-5 cm diameter, mostly dark, weakly magnetite altered volcanic (basalt) in matrix of finer grained sub-angular clasts and very soft, amber-tan, finely banded v.f.g. and waxy matrix (serpentine?). Thin alteration rims on dark volcanic fragments.</p>
52.0	58.0	10	<p>Strongly altered and bleached (basalt) breccia with partial to complete light-tan alteration of volcanic fragments.</p> <p>Very broken core at 53.9-56.7 m - breccia fragments loosely bound by soft matrix. Mislatch at 171' - lost 6' of core.</p>
58.0	72.0	10	<p>Weakly magnetic, multicoloured volcanic conglomerate.</p> <p>Red, orange, tan, grey, white altered rounded to sub-rounded volcanic fragments 2-6 cm in diameter mixed with subangular to subrounded sand-size fragments ($< 2\text{mm}$) in finer grained matrix. Larger fragments are dark grey altered to white volcanics similar to above dark (basaltic) volcanic rocks, weak to moderately magnetite altered and with or without light alteration rims. Red (hematite?) alteration occurs in irregular patches to strong pervasive alteration of matrix - appears to post-date tan alteration. Note: white and clear crystals in voids with honey-coloured minerals. Amount of matrix decreases with depth with fragments tight packed. Sharp contact at 45°C.A.</p>
72.0	77.5	10	<p>Multicoloured, multilithic, purple, red, green and tan volcanic conglomerate and intercalated thin-bedded sandstone and siltstone.</p> <p>Fragments $> 2\text{-}3\text{cm}$ generally well rounded and composed of felsic to intermediate composition ash tuff, weakly porphyritic, red, feldspathic tuff with epidote altered pyribole crystals and red alteration of aphanitic matrix, medium grained, and weak to moderately magnetite bearing dioritoid (diorite or dioritized) with irregular mafics (biotite or pyribole) in light green, qtz-feld. matrix, and white altered (dacitic)</p>

CRAIGMONT MINE PROJECT

			clasts. Matrix composed of pebble to sand sized, rounded to subrounded multilithic, multicolour clasts. Thin bedded sandstone and siltstone beds / lenses to 1 m thick & oriented at 45° C.A. at 72 m and 65° C.A. at 77 m.
77.5	84.4	10	Coarser conglomerate with light grey, weakly magnetic diorite fragments to 10 cm in fine pebble matrix.
84.4	87.0	10	Reddish-brown, weakly bedded volcanic conglomerate and sandstone (lapilli-ash tuff) with scattered greenish diorite clasts to 6 cm. Bedding at 65° C.A. at 85 m; conglomerate is tight packed. Grit size clasts (about 2 mm dia.) compose >80% of rock.
87.0	88.0	10	Thin bedded volcanic sandstone and siltstone with bedding at 60° C.A.
88.0	90.5	10	Purplish-red volcanic conglomerate and breccia with dioritic clasts and white (dacitic?), soft altered tuff. Clasts cobble size and tight packed and come with light alteration rims as seen in above units
90.5			EOH – hole stopped as no high grade magnetite source for the ground magnetic anomaly was found within 100 m. The weak magnetite alteration of the basalt(?) would appear to be the source for the anomaly.

CRAIGMONT MINE PROJECT

		<p>CRAIGMONT PROJECT 2005 Christopher James Gold Inc.</p> <p>HOLE # AB-4</p> <p>UTM Coordinates (GPS uncorrected): Zone 10 645293E 5563196N (NAD83) Local Grid Location: 18+70W; 4+32S Elevation (approx.): 1550 m Bearing: 180° Dip: -50° Length: 151.18 m (496') Core Size: NQ Date Collared: August 28, 2005 Date Completed: Sept. 4, 2005 Dip Tests: -55° @ 105.5 m Logged by: J.A. Fleming, P.Geo. Comment: Stopped due to lack of mineralization</p>
FROM- TO (m)	ROCK UNIT	DESCRIPTION
0 23.2	99	Casing 23.5 m (77 feet). Hit bedrock at about 21 m (70 feet)
23.2 32.0	91	Salmon-pink, light orange and light green medium grained granitoid (granite/ granodiorite). Composed of ~40% feldspar, ~20% quartz and ~10% mafics in pinkish to light green aphanitic matrix. Feldspar subhedra generally eggshell white to pinkish and weakly altered, quartz subangular to subrounded and broken. Mafics have ragged outlines and are weakly altered to chlorite +/- magnetite. Minor calcite, no visible pyrite, weak magnetite, thin coatings of white to orange mineral (zeolite) on fractures. Moderately to strongly fractured. Sharp contact at 32.0 m.
32.0 38.4	21	Dark grey to black, medium to light grey and light green, thick- to thin-bedded, interbedded limy sandstone / impure limestone and felsic ash tuff. Pyritic, medium to dark grey (andesitic) and light to medium grey (rhyodacitic) thin-bedded tuffs (possibly sandstone and siltstone). Limy beds generally 1-4 cm thick, grain size 0.5-1 mm with +50% carbonate. Moderate epidote altered +/- magnetite. Minor pyrite. Thin dark grey to black beds are fine sandstone to siltstone and carbonaceous with 2-3% pyrite both disseminated and as lenses along bedding planes. Non-limy beds generally hard and compose about 80% of rock vs. limy beds at 20%. Thin pyrite veins have thin (< 2 mm) dark chlorite alteration envelopes cut by thin (1-2 mm) calcite+/-mafic (amphibole?) veins. Greasy brown alteration in dark

CRAIGMONT MINE PROJECT

			beds (biotite hornfels alteration?). Some coarse ash tight packed and cut by tan quartz veins with green sericite plus dark green mineral around fragments, plus 1-2% pyrite.
38.4	46.7	21	<p>Medium to light grey, weakly bedded, felsic, ash-lapilli tuff.</p> <p>Clasts to >1 cm in diameter, generally 2-3 mm. Some brecciation. Weakly chlorite altered, some brown biotite(?), minor magnetite, no epidote, pyrite 1-3%. Bedding at 50° C.A.</p>
46.7	52	21	<p>Black, thin-bedded, laminated, carbonaceous, quartzofeldspathic siltstone (i.e. hard) and thin inter-bedded grey quartzofeldspathic siltstone.</p> <p>Weakly limy with lenses of calcite. Pyrite 2-3% aligned along bedding planes. Crosscut by calcite-zeolite healed fractures. No magnetite and minor epidote. Some limy, light green beds at 50-51 m. Bedding at 50° C.A. @ 48m and 45° C.A. @ 50 m. 1.0 m of strong sericite-pyritic mud @ 50.6 m.</p>
52	54	21	<p>Thin-bedded, white to light grey, oolitic limestone and limy siltstone (80%) and dark, weakly limy, black, carbonaceous siltstone (20%).</p> <p>Abundant white 1-2 mm long ovoids 1-2 mm in length aligned along beds in thin-bedded sections. Some fractures healed with calcite with minor displacements of less than 1 cm and deformation of beds. Pyrite less than 1% and weak epidote alteration.</p>
54	57.9	21	<p>Medium grey-green ash tuff</p> <p>Mottled, sub-rounded clasts with corroded margins in light green aphanitic felsic matrix. Highly fractured with zeolite+/-calcite on fractures. Very weak chlorite alteration, 1-2 % disseminated pyrite and no magnetite. 1-m-thick mud seam at 56.7 m plus 1 m of finely broken core.</p>
57.9	64.5	21	<p>Mottled green, white, silicified, chlorite altered, coarse ash feldspathic tuff.</p> <p>Rock composed of 60-75% white feldspar subhedra, sub-angular to subrounded tight packed with minor quartz clasts. Intergranular chloritic altered mafics compose 5-10 %. Matrix is aphanitic and pinkish in colour. About 25% of section composed of pinkish- grey quartz veins generally 5-10 cm thick with associated strong chlorite-</p>

CRAIGMONT MINE PROJECT

			sericite alteration envelopes. Moderate chlorite-sericite altered, minor epidote and hematite. Pyrite 1-2%. Trace magnetite. Moderately fractured. Some brecciation, shearing and strong silic alteration.
64.5	68.0	21	Thin, inter-bedded, light- to medium-grey to greenish, impure limestone/ limey sandstone and dark grey-black, quartzofeldspathic siltstone and cherty beds. Bedding defined by grain size, colour and compositional variations. Bedding is 50° C.A @ 60 m, 55° C.A. @ 67 m. Pyrite 1-2 % as disseminated euhedra and fine-grained clusters. Increased to 3-5% in dark beds. Alterations: weak epidote, weak chlorite. Scattered crystalline calcite veins. Note: black, weakly acicular mineral infiltrated in greenish-altered cherty beds (e.g. 66m).
68	72.0	21	Greenish, coarse ash, feldspathic tuff similar to 54-57.9 m. Weak to moderate chlorite alteration, no magnetite or epidote, 1 -2 % pyrite. Moderately to highly fractured with stockwork of zeolite and calcite healed fractures. 20 cm of mud, clay and broken core at 71.9 m.
72	81.1	21	Thin-bedded, limey sandstone and black qtz-feld siltstone similar to above limy sections. Tight fold at 75 m with fold axis along core. Also syndepositional breccia and cross-bedding. Bedding at 57° C.A @ 73 m, 0° @ 75 m, 57° @ 77 m and 55° @ 78 m. Pyrite generally 1-2%, locally 3-5% as disseminations, lenses along bedding planes and in crosscutting calcite veins.
81.1	87.2	21	Highly fractured, brecciated, chlorite-epidote altered coarse ash tuff with black sooty core from 82-83 m. Tuff clasts resemble accretionary lapilli. Weak to moderate epidote and chlorite, locally strong sericite alterations. Pyrite 1-2 %, trace magnetite. Black carbonaceous, sooty material coating fine grain to silt size loose clasts.
87.2	91.5	21	Dark to medium green, chlorite+/-epidote altered feldspathic (andesitic) coarse ash, crystal and lithic tuff. Tuff clasts close packed; some look sutured (welded tuff?). Moderate

CRAIGMONT MINE PROJECT

			chlorite alteration, weak epidote, and minor magnetite. Pyrite 1-3% as disseminations and thin veinlets with spots of epidote.
91.5	94.0	21	Thin-bedded, grey-green, epidote altered, impure limestone / limy sandstone and dark quartzofeldspathic (i.e. hard) siltstone. Syn- and post-depositional deformation with grey limy sandstone as sedimentary breccia matrix. Weak to moderate epidote alteration - strongest in grey-white limy beds. Pyrite disseminated in limy sandstone and as v.f.g. clusters along bedding in finely laminated limy sandstone.
94.0	96.3	21	Mottled green, greenish-grey, pinkish and orange weakly chlorite and epidote altered feldspathic (andesitic to dacitic) ash, crystal tuff. Scattered quartz tuff clasts. Pyrite 2-3% occurring as disseminations, fracture fillings and replacing mafics.
96.3	97.6	1	Specularite-earthy hematite-amphibole skarn in weakly limy felsic ash tuff with minor chalcopyrite. From 97.3-97.5 m several spots 1-2 mm of chalcopyrite on margins of light felsic tuff clasts and dark green actinolite(?) veins and patches.
97.6	104.0	21	Greenish-grey-black, weak to moderate, patchy epidote altered limy sandstone / impure limestone. Fragments of banded limy rock and distorted beds with weak to moderate epidote alteration and white crystalline calcite breccia matrix. Some remnant bedding at 45° C.A. Pyrite 2-3% both as euhedra to 2mm and fine grained in fractures and veinlets.
104	108	21	Moderately chlorite-sericite altered mixed limy sandstone and weakly limy ash tuff. Rock highly fractured and broken. At 105.5 a 20 cm section of soft mud and finely broken core. Weak, patchy epidote alteration. Pyrite 2-3% fine disseminated to coarse euhedra. Locally 4-5% pyrite.
108	111	21	Medium greenish-grey and patchy light brown chlorite-biotite?+/- epidote altered weakly bedded andesitic coarse ash tuff. Non-limy, non-magnetic. Brown alteration possibly biotite. 5-10%

CRAIGMONT MINE PROJECT

			chloritized mafics. Narrow chlorite-pyrite veinlets with 1-2mm-thick bleached envelopes. Few quartz veins 1-2 cm thick with pyrite +/- epidote. Weak bedding at 30° C.A. Cut by 1-2 mm-thick zeolite veinlets locally with associated light green alteration (sericite).
111	117	21	<p>Weakly limy, brecciated, chlorite, epidote, and biotite(?) altered tuff with section of breccia with minor chalcopryrite.</p> <p>Breccia with fragments of white limestone and limy rocks, pinkish-grey vein quartz vein and thin-banded light grey volcanic (hyalite?)</p> <p>Moderate epidote along limy beds with chlorite and up to 5% pyrite. Some brownish (biotite?) altered tuff sections. Generally 3-5% pyrite disseminated to 3-4 mm euhedra and along beds.</p> <p>Spots of chalcopryrite occur from 115.2-116.4 m in breccia fragments, breccia matrix and as veinlets cutting quartz veins.</p>
117	124	21	<p>Medium to light grey-green felsic (andesitic-dacitic) coarse ash and lapilli tuff.</p> <p>Poorly sorted ash and fine grained lapilli in fine-grained to aphanitic light-green altered matrix. Weak to non-limy; non-magnetic; weak chlorite altered mafics; minor epidote in cross-cutting pyrite veins. Pyrite 3-5% as fine disseminations and euhedra to 2-3 mm in veinlets with chlorite.</p>
124	127	21	<p>Medium green-grey felsic lithic-lapilli tuff and medium grained grey-white marble.</p> <p>Patchy dark and light green, tan and pinkish colours. Volcanic rock is chlorite-epidote+/-garnet+/-magnetite+/-earthy hematite altered. Marble has minor epidote and garnets to 1-2 mm size. Some narrow bands of amber, yellowish-green and brownish garnets with pyrite, white crystalline calcite and minor earthy hematite. At 126.8 m rock cut by 2-3 cm thick, tan, finely banded felsic dyke at 0° C.A.</p>
127	144	21	<p>Complex limy sedimentary breccia with medium grained marble matrix and bands / beds.</p> <p>Fragments consist of medium-dark green felsic lithic-lapilli tuff, purple-pinkish hard aphanitic rock (rhyolite?). Up to 30% of rock consists of soft, patchy light green altered rock with dark green mafic (amphibolitic?) matrix. Marble has minor spots of magnetite,</p>

CRAIGMONT MINE PROJECT

			<p>epidote, disseminated pyrite, and is cut by calcite veins. Marble increases in % with depth and as discrete bands / beds to 10 cm. From 133-139 m the breccia is finer grained with abundant dark, fine grained to aphanitic fragments in generally limy matrix. About 50% of rock from 133 m is limy or is marble. Pyrite is 1-3 % as disseminations and in veins to 2-3 mm with chlorite+/-sericite. From 142-144 m white, medium to fine grained marble with contorted bedding at 10-45° C.A.</p>
144	149.5	21	<p>Medium to dark green-grey, limy, poorly sorted, weakly bedded, limy volcanic sandstone and pebble conglomerate (grit unit?).</p> <p>Clasts to 2 cm in diameter; most are less than 5 mm. Composed of ash tuff and fine grained to aphanitic quartzofeldspathic (rhyolitic) rock. Soft, black silicate in matrix and clasts compose 5-10% of rock - not chlorite or sericite Weak to locally moderate epidote alteration as spots. Pyrite 2-3% disseminated and fine grained. Rock cut by white calcite veins to 1 cm.</p>
149.5	151.2	21	<p>Medium to light green, grey, weakly banded, hard, non-limy, non-magnetic, quartzofeldspathic (rhyolitic) lithic-lapilli tuff (greywacke?) and/or flow breccia.</p> <p>Poorly defined subrounded to subangular fragments to 1 cm in cloudy, light green, aphanitic, hard, quartzofeldspathic matrix. Banding defined mainly by colour variations and texture (fragmental, fine-grained, laminated). Bands vary from < 1 mm to >1cm thick. Minor amounts of pyrite (< 1%) . EOH at 151.18 m.</p>

CRAIGMONT MINE PROJECT

<p>CRAIGMONT PROJECT 2005 Christopher James Gold Inc.</p> <p>HOLE # AB-5</p> <p>UTM Coordinates (GPS uncorrected): Zone 10 645534E 5563205N (NAD83) Local Grid Location: 16+40W; 4+40S Collar Elevation (approx): 1550 m Bearing: 180° Dip: -50° Length: 95.40 m (313') Core Size: NQ Date Collared: September 10, 2005 Date Completed: September 17, 2005 Dip Tests: None Logged by: J.A. Fleming, P.Geo. Comment: Hole abandoned - core barrel separated from drill string.</p>		
FROM- TO (m)	ROCK UNIT	DESCRIPTION
0 15.2	99	Casing 15.24 m (50 feet) – no core
15.2 23.0	8	<p>Massive, medium grained, green, white, pale orange, moderately magnetite altered pyroxene diorite.</p> <p>(Note: this rock is very similar to one identified in hole S-109 by thin-sections (t/s) as an augite diorite with interstitial k-spar and quartz. It was logged prior to t/s work as a hornblende diorite, and in other holes (e.g. S-111) as a dioritized greywacke or dioritized arkose. In this hole it was logged as a dioritized volcanoclastic - but it is clearly also a variety of diorite - the original description in this log is retained (below). The dark, ragged altered clusters referred to are altered pyroxenes - in S-109 the alteration was identified in t/s as sperpentine).</p> <p>Spotted texture with about 40% medium green and black, ragged-edged, small (average 1-2mm) chl-amp-mag altered clusters (a.k.a. pyroxenes) in (apparent) matrix of translucent, grey, white and pale green feldspar ash-size clasts and microlites in white, frosted, aphanitic matrix, along with (apparent) sub-angular to rounded lithic clasts to about 5 mm diameter. Some chl-amp-mag clusters to 5 mm. Faint clastic texture of lapilli to 3 cm defined by alterations (e.g. white alteration rims around the darker clasts /patches). Matrix stained pinkish-orange zeolite (laumontite), hematite, and/or k-spar. Magnetite occurs 5-10% (Davis tube = 3.1 % magnetite) as f.g.</p>

CRAIGMONT MINE PROJECT

			crystals and in clusters to 2-3 mm, generally in the darker material, but also disseminated. Only minor amounts of pyrite (<1%).
23.0	57.0	8	<p>Massive, equigranular, green, white, pale orange very coarse grained pyroxene diorite.</p> <p>(See above note) Similar to above unit but with coarser (80% 2-10 mm) chl-amp-mag clusters and occasional coarse banding defined by colour and grain size.</p> <p>The rock consists of about 30-40% chl-amp-mag clusters, 30% tight-packed, light green altered, ash size feldspar clasts and grey translucent clasts (microlites/glass shards?) and some sub-rdd lithic clasts, and 30% aphanitic matrix. Some grey quartz clasts to 3 mm (e.g. @ 30 m). Magnetite runs 3-5%, pyrite <1% and white to pinkish zeolite and calcite veinlets (1-3 mm thick and low angle to C.A.) 1-2%. Minor epidote, generally as spots in rims of the chl-mag-amp clusters, but also in the light volcanoclastic material. Epidote and pyrite increase in intensity with depth to 1-2% pyrite and moderate amounts of epidote by 38 m.</p> <p>At 38.7-40.2 m broken and crushed rock with coarse calcite crystals including a 3-cm-thick band of calc-chl-spec-hem at 30° to C.A. Some light green, sericite alteration envelopes developed on zeolite-calcite veins plus spots of bright green material. Also, from about 42 m some strong epidote development in calcite-zeolite veins and in the wallrock. The light grey aphanitic matrix looks albitic or silic. Scattered quartz crystals and some quartz veins with epidote alteration envelopes. The light to sea green (sericite?) alteration of the feldspar clasts and matrix increases with depth. At about 45 m a 2 cm clast occurs with tan, dark and light green banding (siltstone clast?). Abrupt rock change (contact not preserved) at 57.0 m..</p>
57.0	58.0	21	<p>Pale green, dark green and pinkish, thin-bedded, fine grained felsic volcanoclastic rock (fine ash and cherty tuff).</p> <p>Chlorite-sericite altered; moderately pyritic (5%) and cut by thin calcite veinlets.</p>
58.0	60.4	1	<p>Thin- to thick-bedded, light to dark green and black, actinolite-magnetite-epidote+/-garnet skarn altered volcanoclastic rock (ash tuff)</p> <p>Light brown to orange (andradite) garnet, epidote and pyrite bands follow bedding. (55-60° to C.A.). Chl-act alteration locally very</p>

CRAIGMONT MINE PROJECT

			strong and massive (e.g. 59.6-60.0 m) with 3-5% pyrite, some calcite, specularite and hematite. Magnetite occurs in spots and patches to 1 cm and crosscutting veinlets. Chalcopyrite spots (1-2 mm) occur (<1%) from 59.6-60.4 m with about 3% pyrite. Rock very broken at 57-59 m with chlorite, sericite and pyrite on fractures and slip surfaces. A strong shear occurs at 30° to C.A.
60.4	66.8	1	Thin- to thick-bedded, weak to moderately limy, magnetite-pyrite+/-epidote+/-actinolite skarn altered felsic volcanoclastic rock. Rock is grey, greenish grey, tan feldspathic ash+/-lithic+/-lapilli tuff. Magnetite preferentially alters lapilli and amounts to 5-10%, and pyrite also 5-10%. Epidote and actinolite alterations are weak. Very broken core to 68 m with abundant chl-zeo+/-pyr coated fractures and locally sericite mud. At 61.3 is 10 cm of gritty mud.
66.8	68.0	1	Dark grey to black, weakly bedded, weakly limy, magnetite-actinolite-chlorite+/-pyrite+/-hematite skarn in felsic volcanoclastic rock. Similar to above unit. Magnetite runs 10-15%, pyrite 5-10%.
68.0	69.2	1	Thin-bedded, magnetite-chlorite-actinolite-pyrite skarn altered volcanoclastic rock similar to above unit. Magnetite composes 10-15%, pyrite 5-10%, chlorite and actinolite are moderate in amount and epidote is weak. Scattered white chlorite-zeolite veins with minor associated epidote.
69.2	70.5	1	Black, magnetite-actinolite-chlorite skarn altered volcanoclastic rock (looks like ash tuff) Magnetite composes 15%+ and pyrite about 3% of rock. Chlorite and actinolite alterations are moderately strong. Cut by scattered, thin calcite+/-epidote veins.
70.5	73.0	8	Medium dark green, non-limy, spotted black to dark green magnetite-amphibole-chlorite+/- epidote altered pyroxene diorite. Similar rock and alterations to unit at top of hole (see note at top of log). Magnetite runs about 10% and pyrite 3%. Minor hematite present on fractures and slip surfaces. Actinolite and chlorite are moderate in intensity and epidote is weak but increasing with depth.
73.0	75.0	1	Light green and orange, weak to moderate magnetite-actinolite-chlorite-epidote skarn altered volcanoclastic rock.

CRAIGMONT MINE PROJECT

			Probably ash-lithic-lapilli tuff, but possibly volcanic sediment (sandstone - conglomerate). Magnetite runs about 5%, and 1-2 mm chlorite and actinolite clots about 10-15% evenly distributed through rock. Epidote is locally strong and occurs interstitial to the volcaniclasts. Note: some scattered quartz patches. The orange mineral pervasively stains clasts and matrix and is probably the laumontite found on fractures and in veinlets.
75.0	78.0	21	<p>Bedded light green, dark green and black, poorly sorted magnetite-actinolite-chlorite-epidote altered quartzofeldspathic volcaniclastic rock.</p> <p>Looks more like a volcanic sediment or reworked ash-lapilli tuff. Bedding (?) at about 60° defined by colour variations, weak alignment of larger clasts and thin v.f.g. silic bands. Magnetite runs 5-10% and chl-act-epi alterations are weak to moderate. Rock is non-limy.</p>
78.0	79.0	21	<p>Strong chlorite-sericite altered, weak to moderate magnetite altered sheared rock.</p> <p>Soft, gritty silt seam 0.5 m thick at 67.3 and a 4 cm seam at 30° to C.A. Rock fragments are granule size in a silt size matrix</p>
79.0	80.4	21	<p>Dark grey to black, moderate to strongly magnetite altered, weakly limy feldspathic volcaniclastic rock (crystal ash tuff).</p> <p>About 60% sand/ash size (1-2 mm) feldspar clasts tight packed in fine grained to aphanitic felsic matrix. Magnetite composes about 10% of rock and occurs interstitial to the clasts. Pyrite is weak (1-3%). Some sericite alteration of feldspars. Hematite (1-3%) occurs on fractures. Traces of epidote. Cut by thin calcite veins (5%).</p>
80.4	81.0	21	Fault/shear zone with very soft, strongly sericite altered core with 1-3 cm diameter fragments in soft sericitic mud. Hole produced water at ~81 m (267').
81.0	83.0	1	<p>Thick-bedded, quartz-veined, moderately magnetite-specularite-hematite+/-actinolite+/-chlorite skarn altered, weakly limy volcaniclastic rock.</p> <p>Magnetite runs 3-5% with some coarse magnetite in a vein with specularite in with strong sericite wallrock alterations. Specularite and hematite each compose about 3-5% of rock. Some coarse specularite</p>

CRAIGMONT MINE PROJECT

			has crystals to 2 cm. Quartz-magnetite veins compose about 30% of the rock. Original rock texture largely obliterated. Some bedding preserved at about 60° to C.A.
83.0	90.5	1	<p>Brecciated, weak to moderately limy, patchy tan, dark and light green, grey and reddish magnetite-actinolite -epidote-garnet+/-specularite skarn.</p> <p>Protolith probably volcanoclastic sedimentary rock. Breccia fragments are subrounded to subangular and average <1 cm with some 2-3 cm. Strong (20%) tan-yellow garnet (andradite) alteration in top part of section with strong epidote and no garnet beyond 85 m depth. Chloritized actinolite is pervasive through the rock. Some specularite in patches of crystals to 5 cm in sericite and hematite altered rock. Magnetite alteration intensity increases from generally moderate (3-5%) from 80-90 m to moderate to strong (10-15%) from 90 to 95 m. Actinolite alteration intensity increases from weak to moderate in this section to strong to very strong below to 95 m. Epidote alteration intensity decreases from moderate to strong in this section to weak to very weak below to 95 m. Some scattered, irregular - patchy quartz veins 2-3 cm thick cut by white calcite veins. A spot of chalcopyrite occurs in the dark skarn.</p> <p>At 86 m is a 30-cm-section of magnetite (20%)-chlorite+actinolite (20%)-specularite (5%) skarn in grey quartz + hematite and epidote.</p> <p>Specularite (2-5%) and hematite (3-10%) occur to 90.2 m. Hematite occurs on slips at 10-20° C.A. at 87 m depth. Sections of magnetite-actinolite skarn 30-50 cm thick occur through section. Rock laced with thin (1-2 mm thick) calcite-zeolite veins.</p> <p>At 87.7-89.0 m strongly fractured and broken breccia with abundant chlorite and sericite on fractures. Fragments are multilithic breccia. Rock very soft and friable, pyritic and limy at 89.1-89.3 m. with a soft, pyritic, chlorite-sericite seam at 30° C.A. at 89.0 m.</p>
90.5	91.6	21	Quartz-rich breccia with strong magnetite-pyrite alteration. Some massive pyrite veins to 3 cm thick. Scattered calcite veins to 1 cm thick
91.6	92.8	1	<p>Dark green to black, strong actinolite-magnetite-pyrite chalcopyrite-bearing skarn altered breccia.</p> <p>Actinolite is felted and massive (30-50%) with chlorite after actinolite.</p>

CRAIGMONT MINE PROJECT

			<p>Magnetite runs 10-15% and pyrite 5-10%. Chalcopyrite occurs as blebs and thin (<1mm) veinlets in amounts of ~2-3% through the dark green felted actinolite-magnetite skarn. Chalcopyrite mineralization is late-stage with some occurring with calcite in the matrix. Patches or fragments of grey quartz are common.</p>
92.8	95.0	1	<p>Dark green to black very strong amphibole-magnetite-chlorite-pyrite+/-hematite skarn without visible chalcopyrite.</p> <p>Magnetite runs 10-15% and pyrite 5-10% disseminated as clots to 2 mm diameter.</p>
95.0	95.4	1	<p>Very finely broken sericite altered specularite-hematite-pyrite-magnetite skarn altered silic volcanoclastic rock.</p> <p>Fine grained specularite occurs to 10% as does pyrite. Magnetite and hematite both compose about 5% of rock.</p>
95.4			<p>End of hole - hole lost when rods seized in hole due to silty seams - the core barrel broke off in hole when pulling rods.</p>

CRAIGMONT PROJECT 2005 Christopher James Gold Inc.		
HOLE # AB-6		
		UTM Coordinates (GPS uncorrected): Zone 10 645603E 5563270N (NAD83) Local Grid Location: 15+30W; 3+58S Elevation (approx.): 1550 Bearing: 180° Dip: -45° Length: 305.10 m (1001') Core Size: NQ Date Collared: September 20, 2005 Date Completed: October 3, 2005 Dip Tests: -50° (100 m); -50° (EOH) Logged by: J.A. Fleming, P.Geo. Comment: Attempts to plug hole unsuccessful
FROM- TO (m)	ROCK UNIT	DESCRIPTION
0 9.1	99	Casing 9.1 m (30 feet) - no core
9.1 59.5	91	Pinkish-grey to tan, equigranular, medium grained granitoid (granite/granodiorite) Composed of about 40-50% plagioclase, 20-30% k-spar, 10-20% quartz and 10-20% mafics. No magnetite or pyrite present. Subhedral feldspar to 5 mm across, quartz is anhedral and occurs interstitial to the feldspar. Salmon-pink k-spar evident from about 22 m. Mafics (biotite or amphibole) are finer grained at about 1 mm across on average but also occur in clusters to 2-3 mm. Weak alteration of mafics to chlorite, feldspar to sericite with some strong sericite alterations on fractures. Core strongly fractured with fracture sets at 45 and 60° C.A. with calcite, pink zeolite and orange-tan (hydroxides?) coatings. Contact at 59.5 m has 10 cm of broken core in soft sericitic mud.
59.5 74.0	21	Complex breccia of above granitoid, a light grey, felsic volcanoclastic(?) rock and black, limy fine grained rock. Minor chalcopryrite (<1% cpy) disseminated. in the black and felsic rocks to about 65 m. Some fragments have chlorite-amphibole alteration. Light grey, strongly fractured and sheared, weakly magnetite altered, pinkish granitoid +/- felsic volcanic prevalent from about 65-74 m. Rock generally strongly fractured with calcite and tan (ankerite?) on fractures. A 20-cm-thick clay/mud seam occurs at

CRAIGMONT MINE PROJECT

		about 65 m. At 69-73 m the breccia is strongly fractured with moderate to intense sericite alteration to sericite mud.	
74.0	78.0	1	<p>Intermixed limy magnetite-amphibole (actinolite) skarn, altered felsic rock (rhyolite tuff?), pink granitoid and remnant impure limestone.</p> <p>Limy skarn from 76-77.5 m with 10-15% magnetite and 3-5% pyrite. About 50% of rock is remnant limestone. A few spots (~1 mm across) of cpy occur from 77-77.5 m in very strong magnetite altered skarn. From 74.5-77 m are short sections of weak mag-chl-amp altered pink granitoid with brecciated contacts. A fault contact occurs at 77.5-78. m with about 30 cm of black, chloritic, weak magnetite and <1% pyrite, non-limy mud seam at ~ 55° C.A.</p>
78.0	83.0	8	<p>Dark grey to black, fine grained, massive, weakly to moderately magnetite altered (3-5%) rock cut by coarse grained pyroxene diorite.</p> <p>Dark rock has 2-3% scattered clusters 2-3 mm across of crystalline epidote and amygdular looking clots of quartz (?) and chlorite. Diorite is sericite altered with xenoliths of limestone and the limy felsic (tuff?) unit. Calcite and orange zeolite veinlets cut all units. The dark rock composes about 30% of the section.</p>
83.0	168.0	8	<p>Weak to moderately magnetite altered, weakly epidote altered, coarse grained pyroxene diorite.</p> <p>(Same rock as identified in S-109 in thin sections as a two-pyroxene diorite with plag. laths and interstitial k-spar (10%) and quartz. This unit is also found in holes AB-4 and 5 and is generally weak to moderately (~3%) magnetite altered. The macro texture is of apparent clusters of medium grained pyriboles in an apparent volcanoclastic or coherent volcanic rock with fine grained shards / laths of feldspar in a aphanitic frosty looking matrix.).</p> <p>The pyroxene phenocrysts are ragged-edged and up to ~ 8 mm across, compose ~ 30% of rock, and are generally serpentized (identified alteration in S-109) and magnetite altered around inner edges. Feldspars are weakly to moderately altered to sea green to light green sericite plus bleached envelopes on thin quartz veins. Locally, bright red hematite occurs in cores of phenocrysts. Pyrite is disseminated in amounts of mainly <= 1%; locally to 2% over 2-3 m, and generally in the feldspar. Core cut by 1-2% thin (1-3 mm thick) calcite and orange zeolite (laumontite) veinlets. Scattered veins to 1 cm thick.</p>

			<p>At 140-143 m is a soft, very limy, sericite altered shear zone with breccia and a 30- cm-seam of pebbly sericite mud. Abundant orange zeolite and calcite veins and patches below shear zone along with moderate red hematite alteration.</p> <p>At 146.5-147.5 m is a light green-orange coloured felsic rock with apparent texture of tight-packed, sand-sized light grey grains (quartz/feldspar) in an aphanitic matrix (no pyriboles).</p> <p>A sharp contact at bottom at 30° C.A. with soft black rock and abundant quartz veins.</p> <p>One spot of chalcopyrite was found in the felsic rock.</p> <p>From about 160 m to bottom of unit the grain size is finer (chilled contact) and increased sericite alterations. Magnetite alteration is increased to ~5% in last metre above contact with ~10 cm of silty gouge at abrupt contact at 168 m.</p>
168.0	168.6	91	<p>Bright orange-pink equigranular quartz and feldspar rich rock (granitoid dyke?)</p> <p>Composed of sericite altered feldspar laths and interstitial grey (quartz) material. Rock is non-magnetic and contains no visible pyrite. Sharp bottom contact.</p>
168.6	170.1	1	<p>Garnet-epidote-pyrite+/-specularite skarn in medium to fine-grained, weakly limy banded rock (volcaniclastic?).</p> <p>Garnet is red-brown in colour and with epidote follows the banding (bedding). Garnet-epidote alteration is moderate to strong; pyrite runs 3-5%, specularite 1-2%. No magnetite.</p>
170.1	182.5	21	<p>Brecciated, matrix supported, medium to dark grey, weakly magnetite-epidote altered felsic rock (volcaniclastic?).</p> <p>Fragments (~40%) mainly 5-10 mm across with some to 3-4 cm in moderately limy, sand to granule size matrix (~60%). Some arrowhead-shaped magnetite patches 2-3mm long with sharp edges scattered though rock (e.g. @ 175 m). From 178.5-182.15 m breccia includes (~60%) fragments of the pink-orange (granitoid?) rock from 168 m. Rock is moderately porous (note: artesian H₂O at ~178 m depth). Core generally finely broken through the section (RQD = 3-</p>

CRAIGMONT MINE PROJECT

1	<p>193.9-194.5 m: Pyritic (3-5%) rock with fine grained clasts in a weakly epidote altered, moderately limy felsic sandstone(?).</p>
2	<p>194.5-199.0 m: Epidote-pyrite-andradite-amphibole (actinolite) skarn altered thin-bedded to laminated weakly limy rock with contorted bedding, intercalated, tan, quartzofeldspathic siltstone, grey limestone beds 1-3 cm thick, and grey silic beds. Moderate to strong epidote, plus tan garnet (~2-3%) and dark chlorite-amphibole (~3-5%) follow siltstone beds.</p>
1	<p>199.0-200.6 m: Banded light grey and white crystalline limestone/marble with 5-10% pinkish, non-limy felsic clastic beds. Some flame-ups (tops up) and bedding at ~50° C.A.</p>
1	<p>200.6-207.3 m: Weakly epidote+/-andradite garnet skarn altered dark grey sandy / pebbly limestone. Very similar to 183.8-184.7 m. with 30-40% rounded to subrounded, dark green chlorite altered clasts in +50% grey limestone matrix. Clasts average 1-2 mm across and from 184 m are up to 3 cm across and include dark, laminated, non-limy felsic rock and weakly magnetite altered dark felsic fine grained rock. Light green phyllosilicate alterations enhance clastic texture of dark rock. Pyrite disseminated 2-3%. Epidote alteration strong at bottom contact.</p>
1	<p>207.3-222.8 m: Massive, light green-grey, fine grained, non-limy, felsic volcanoclastic(?) rock (andesitic ash+/-crystal+/-lapilli tuff?). Vague clastic texture with subangular to rounded 5-10 mm diameter chlorite-epidote altered fragments plus quartz and k-spar patches. Some subhedral feldspar crystals 1-2 mm long tight packed in aphanitic felsic matrix and scattered poorly defined patches (lapilli). Weak epidote alteration. Pyrite 1-2%. Scattered tan calcite+/-zeolite veins. Sharp bottom contact at 20-30° C.A. with some coarse conglomerate /breccia above contact with rounded clasts to 5 cm across.</p>
1	<p>222.8-224.6 m: White-grey, coarse bedded (~50° C.A.) crystalline limestone with scattered dark subangular debris 1-5 mm.</p>
1	<p>224.6-225.9 m: Same as 183.8-184.7 m with subangular to rounded tan siltstone clasts and dark grey felsic clasts.</p>
1	<p>225.9-227 m: Light green-tan, weakly limy, thin-bedded to laminated quartzofeldspathic volcanoclastic(?) siltstone and sandstone. Weak</p>

CRAIGMONT MINE PROJECT

			epidote-chlorite alteration along beds with minor pyrite. Bedding at ~50° C.A. Rock brecciated at bottom with scattered quartz fragments. Bottom contact at 30° C.A.
228.0	236.5	21	Medium green-grey, massive to banded, non-limy, chl-epi-amp+/-bio altered felsic volcanoclastic(?) similar to 207.3-228.0 m. Better defined clasts than above unit, but clast edges still somewhat indistinct. Minor matrix. Scattered rounded clasts to 2-3 cm across. Some crackle/pseudo breccia at 236-236 m (clasts close together - with subangular, altered clast edges).
236.5	245.7	21	Light to medium green-grey, weakly limy, amphibole+/-epidote-pyrite (2-3%) altered felsic volcanoclastic(?) rock. Composed of tight-packed, 40%, 1-2 mm feldspar subhedra with indistinct edges in fine grained to aphanitic felsic matrix. Amphibole (actinolite) composes about 20 - 30% of rock and occurs interstitial to the feldspar subhedra. Some scattered coarse patches of limestone and bands to 0.6 m thick of limy and non-limy laminated siltstone.
245.7	262.1	21	Limy, poorly sorted felsic volcanoclastic(?) sandstone - similar to 183.8-184.7 m, banded grey-white limestone and quartzofeldspathic siltstone clasts. Composed of 50-60% light grey silic subrounded clasts <1 mm in diameter in ~50%+ limy matrix. Some lensoidal, aligned silic clasts look like welded rhyolitic ash fall or flow texture. Includes fragments of thin-bedded, quartzofeldspathic siltstone. Weak to moderate epidote altered with 2-3% disseminated pyrite. A 0.3 m soft limy, sericitic shear zone occurs at 251 m.
262.1	274.6	21	Interbedded grey-white impure limestone (20-30%) with limy, tan quartzofeldspathic siltstone (40-50%). Abundant dark felsic clasts (10-20%) to 5 mm in the grey limestone (similar to 189 m). No epidote alteration. and <1% pyrite. Soft, limy broken core over 0.6 m at 268 m. - H2O aquifer. A 5 cm limy, polymictic sandstone - pebble dyke occurs at 271.2 m at ~50° C.A.
274.6	284.7	21	Interbedded impure, grey, banded limestone, tan-grey quartzofeldspathic and limy siltstones, volcanoclastic sediments and dark felsic rock. 274.6-275.8: Mixed brecciated tan, patchy biotite altered siltstone

CRAIGMONT MINE PROJECT

			and grey sandstone / greywacke(?) with 3-10 cm thick layers of volcanoclastic rock with compact light-grey shard-like clasts with white rims (vitric ash tuff?) and 0.6 m poorly sorted breccia / conglomerate with dark grey rounded to subrounded clasts to 2cm in medium grained felsic matrix. Pyrite 2-3%.
284.7	290.2	21	Impure grey sandy limestone with 40-50%, mainly 1-2 mm, subangular to subrounded, medium- to dark-grey fine grained to aphanitic felsic rock and 10-20% interclast dark phyllosilicate matrix. Clasts mostly light altered and have a weak porphyritic texture (rhyolite?). Also clasts of very fine grained mostly light altered from medium dark green mafic (basalt?) rock. Pyrite 2-3%, locally to 5%.
290.2	291.7	21	Dark grey-green, weakly limy volcanoclastic (greywacke?) with tight-packed light-grey quartz and feldspar clasts and irregular shards. Clasts have indistinct boundaries in chloritic matrix. Some tuff beds with flattened-oriented clasts (welded vitric tuff?). Some sections have more sandstone/grit texture with 1-2 mm rounded dark and light clasts (~60%) in limy (~20%) chloritic (~20%) matrix. Light alteration envelopes on chlorite-pyrite veins reveal the tight-packed 1-2 mm clasts and shards not readily visible in the dark rock.
291.7	296.6	21	Same as 284.7 - 290.2 m. Pyrite runs 2-3%.
296.6	305.1	21	Interbedded, thin-bedded, grey-white medium-grained limestone, limy, tan siltstone, spotted limestone (same as above unit), dark felsic rock (as in above unit), felsic sandstone / grit beds and breccia with calcite matrix. End of Hole at 301.5 m. Stopped due to lack of skarn alterations and mineralization. Casing (60 feet) left in hole and capped to hold water (estimate ~300 gpm water flow from hole).

		<p>CRAIGMONT PROJECT 2005 Christopher James Gold Inc.</p> <p>HOLE # AB-7</p> <p>UTM Coordinates (GPS uncorrected): Zone 10 645758E 5563260N (NAD83) Local Grid Location: 13+80W; 3+88S Elevation (approx.): 1590 m Bearing: 180° Dip: -50° Length: 126.8 m (416') Core Size: NQ Date Collared: Oct. 6, 2005 Date Completed: Oct. 14, 2005 Dip Tests: None Logged by: J.A. Fleming, P.Geo. Comment: .Stopped due to lack of mineralization at depth</p>
FROM- TO (m)	ROCK UNIT	DESCRIPTION
0 18.3	99	Casing 18.3 m (60 feet) - no core
18.3 45.7	8	<p>Massive, medium green-grey, medium- to coarse-grained, weakly to moderately magnetite+/-epidote altered pyroxene diorite.</p> <p>(Same rock as identified in S-109 in thin sections as a two-pyroxene diorite with plag. laths and interstitial k-spar (10%) and 18.3-45.7 m cont.: quartz. This unit is also found in holes AB-4, 5 and 6 and is generally weak to moderately magnetite altered.)</p> <p>The macro-scale texture is of apparent clusters of medium grained pyriboles in an apparent volcanoclastic or coherent volcanic rock with fine-grained shards / laths of feldspar in an aphanitic frosty looking matrix.</p> <p>Mafic (pyroxene) subhedra compose 10-30% of the rock and range from 2-8 mm across and average 2-3 mm across. Crystal forms are better defined than in AB-5 and AB-6. Feldspar crystal sizes vary suggesting possible different phases of the intrusive. Local granular texture and weak banding defined by colour and texture variations suggest a dioritized sedimentary protolith (sandstone / greywacke). Magnetite alteration is weak to moderate (1-3%) +/- hematite and mainly associated with alteration of the mafics. Epidote alteration is weak and occurs as spots through diorite and as envelopes on quartz-calcite veins. Mafics are weakly altered to chlorite; feldspar locally altered to light-green sericite. Pyrite runs 1-2% to about 40</p>

CRAIGMONT MINE PROJECT

			m and increases to 3-5% below with clusters of fine-grained pyrite to 2-3 mm across. Some endoskarn developed in the diorite at 43 m over 0.6 m with coarse-grained brown garnet+epidote+pyrite (3-5%) in light altered rock.
45.7	46.6	1	Thin-banded (40° C.A.), light green, dark green, reddish-brown and pinkish garnet-epidote-pyrite skarn. Includes coarse (2-3 cm across) orange-brown to purple garnet, bands and patches of epidote, salmon-pink (k-spar?) alteration of matrix plus interstitial grey quartz and lenses of pyrite. Some possible remnant pyroxene phenocrysts. suggest this may be altered diorite.
46.6	47.5		Fault / shear (cuts core at 10-20° C.A.) with clay gouge of plasticene consistency with rock clasts 1-3 mm across composing about 20%. Some breccia adjacent to fault with a 3-mm-spot of chalcopyrite in matrix with calcite and quartz fragments.
47.5	50.0	8	Medium-grained, medium grey diorite similar to 18.3-45.7 m. Weak magnetite alteration (<1%) and 2-3% disseminated pyrite. Displays an apparent clastic texture.
50.0	51.8	21	Strongly fractured, medium to light grey, aphanitic, quartzofeldspathic rock (rhyolite?). Mottled alterations; 2-3% disseminated pyrite; no magnetite. Spots of light brown may be biotite.
51.8	54.3	1	Reddish-brown, light to dark green, banded (~45° C.A.), non-limy, garnet-epidote-amphibole(?) skarn. Coarse grained (to 2 cm) reddish-brown garnets 30-40%, epidote 10-20%, chlorite-amphibole altered host rock 30-40%. Pyrite fine grained and disseminated at <1%. Epidote alteration after garnet (retrograde) and chlorite-amphibole veins cut garnet.
54.3	62.8	21	Light green-grey felsic volcanoclastic(?) rock and minor breccia. Apparent texture of tight-packed, weakly aligned feldspar prismatic subhedra (>60%) in aphanitic matrix (crystal tuff?). Very minor

CRAIGMONT MINE PROJECT

			garnet alteration; patchy light brown alteration (biotite?); no magnetite; pyrite <1%. Short section (0.6 m) at 54.2 of possible pinkish granitoid with >60% feldspar, ~20% interstitial quartz and ~20% chloritic mafics.
62.8	67.7	81	<p>Strongly fractured, brecciated and altered granitoid – possibly altered variety of the overlying dioritoid.</p> <p>Medium grained bronzy mafics (phlogophite?) compose ~30%, feldspar subhedra 2-3mm long compose >30%. Minor greenish to yellow-brown (andradite) garnet alteration; patchy minor epidote; disseminated pyrite 1-2%. Strong shatter breccia at 64.0-65.8 m with jigsaw fit clasts to 5 mm across. Finely broken core at 67.0-67.7 m.</p>
67.7	75.0	81	<p>Medium to dark grey, fine grained, weakly porphyritic, weakly magnetite altered dioritoid.</p> <p>Mafic (pyroxene) phenocrysts generally < 1 mm across, but scattered phenocrysts > 5 mm across. Includes a 0.6 m section at 71.9 m of garnet (yellowish)-epidote skarn in limy breccia with fragments of diorite and dark limestone. Note thin black needles (tourmaline?) in the breccia. Seam of medium to light green, limy, pyritic clay with specularite and red hematite at bottom contact.</p>
75.0	79.2	1	<p>Chalcopyrite-bearing, magnetite-andradite garnet-specularite-hematite-pyrite skarn in limy host rock</p> <p>Chalcopyrite occurs as blebs to 10 mm long in late-stage white calcite veins up to ~1%/5.5 m including ~3%/0.3 m. Magnetite and pyrite vary in amounts up to 10% each over short sections (< 1 m). Pyrite averages 3-5% over section.</p>
79.2	86.6	81	<p>Light grey, non-limy, weakly epidote and magnetite altered fine grained, equigranular felsic rock (diorite?)</p> <p>Minor disseminated chalcopyrite to 80.5 m. Pyrite 2-3%.</p>
86.6	88.4	1	<p>Magnetite-specularite-hematite-epidote skarn altered, mottled, light green to tan, weakly limy, siltstone.</p> <p>Magnetite (3-5%), specularite and hematite occur in distinct bands (beds) and crosscutting veins to 1 cm thick. Epidote ~5%, pyrite 3-5%. Fractures in slst filled with chlorite+/-amphibole.</p>

CRAIGMONT MINE PROJECT

88.4 95.1	81	<p>Medium green-grey, massive to weakly banded medium to fine grained felsic volcanoclastic(?) – possible altered fine-grained diorite.</p> <p>Composed of >60% tight-packed feldspar subhedra 1-2 mm long and 20-30% chloritic mafics in fine grained to aphanitic matrix. Feldspar typically have indistinct edges similar to the main diorite. Some feldspar are rounded. Also some rounded quartz grains. The unit is somewhat similar to unit in S-111 at ~185 m (609') logged previously as a “dioritized feldspar greywacke”.</p> <p>Weakly to moderately chlorite-epidote altered. Pyrite runs 3-5%. Some 3-5 cm thick basalt dyklets(?) with scarce black pyroble phenocrysts in medium green, fine-grained matrix. Some weak banding at ~40° C.A.</p>
95.1 115.8	7	<p>Dark grey, massive, fine grained, porphyritic and amygdular, felsic (andesitic?) volcanic flow (possible volcanoclastic tuff).</p> <p>Three main varieties of the rock alternate through the section – a weakly porphyritic and amygdular unit (95.1-98.1 m and 105.8-110.9 m) a strongly amygdular unit (98.1-103.6 m and 112.8-115.8 m) a strongly porphyritic unit (103.6-105.8 m and 110.9-112.8 m).</p> <p>Generally, magnetite alteration is weak to moderate (1-3%) and pyrite mineralization is weak (<1%). The reoccurrence of the units suggests zoning in flows wrt tops and bottoms. No flow banding observed, however.</p> <p>95.1-98.1 m: Composed of >60% fine grained (<1mm) subangular to subrounded feldspar with indistinct edges and 10-20% f.g. chlorite. Rock is not hard (i.e. not silic). Contains 1-2% scattered black subhedral pyroble crystals (phenos) and white calcite filled amygdules. Light alterations at 96.3 m reveal an apparent volcanoclastic texture of >50% dark green subangular to subrounded clasts and elongated shards with light alteration rims – possible vitric/ash/crystal tuff. Also scattered large, dark green subrounded clasts to 5 mm.</p> <p>98.1-103.6 m: Similar to above unit but with up to 5% pink, orange and white feldspar, calcite and zeolite filled amygdules.</p> <p>103.6-105.8 m: Similar to first unit but with 5-10% black euhedral</p>

CRAIGMONT MINE PROJECT

		<p>pyribole phenocrysts. Looks somewhat like a finer grained version of the pyroxene diorite.</p> <p>105.8-110.9 m: Similar to the first unit – minor hematite on fractures.</p> <p>110.9-112.8 m: Similar to the third unit but with light patches to 1 cm diameter with irregular edges (alteration effect?).</p> <p>112.8-115.8 m: Similar to second unit with 5-10% amygdules, some elongated to 5 mm. Some light alterations give an apparent breccia or banded texture.</p> <p>Sharp contact at 60° C.A. at 115.8 m with minor brecciation at contact.</p>
115.8 126.8	Rhyolite Unit?	<p>Medium to light grey, strongly fractured quartzofeldspathic volcaniclastic(?) rock.</p> <p>Composed of apparent tight packed clasts generally <1 mm of feldspar with light grey interstitial wormy quartz. Scattered poorly defined larger clasts (lapilli?) to 8 mm. Cut by grey to pinkish quartz veins 2-3 cm thick with associated light green sericite alteration cut by chlorite-pyrite veins. Some structural breccia with chlorite (after amphibole?) and pyrite in matrix. Also crackle breccia with chlorite rimmed quartz fragments. Minor specularite in the breccia matrix.</p> <p>Hole stopped at 126.8 m due to lack of mineralization at depth or strong skarn alteration.</p>

CRAIGMONT MINE PROJECT

		<p>CRAIGMONT PROJECT 2005 Christopher James Gold Inc.</p> <p>HOLE # AB-8</p> <p>UTM Coordinates (GPS uncorrected): Zone 10 645540E 5563250N (NAD83) Local Grid Location: 16+22W; 3+98S Elevation (approx.): 1540 m Bearing: 180° Dip: -45° Length: 188.36 m (618') Core Size: NQ Date Collared: Oct. 19, 2005 Date Completed: Oct. 27, 2005 Dip Tests: -50° @ EOH Logged by: J.A. Fleming, P.Geo. Comment: Stopped due to lack of mineralization.</p>
FROM- TO (m)	ROCK UNIT	DESCRIPTION
0 13.7	99	Casing 13.7 (45 feet) - no core
13.7 42.0	91	<p>Strongly fractured, light, pinkish-orange and light green-grey, medium grained granitoid (granite / granodiorite). (Unit is very similar to pin-orange granitoid in AB-6 at about 38 m.)</p> <p>Composed of about 30% grey quartz phenocrysts, generally subhedral to rounded, about 60% feldspar laths, of which about 30% is orange zeolite altered (or is k-spar, or both), and about 10% interstitial chloritized mafics. Generally poorly defined crystalline texture – has a shattered appearance. On the core surface the quartz appears fine-grained (<1 mm) and subangular resembling clasts. The feldspar laths are white and partly to completely pink-orange altered or light green sericite altered. No magnetite, and minor pyrite (<1%).</p> <p>From start to about 38 m abundant fractures with moderate to strong sericite coatings along with probable hydroxides and iron oxides. Locally some breccia with subangular fragments 0.5-3 cm composing about 60% in matrix of finer grained rock of same composition. Scattered thin white calcite and red zeolite veins.</p>
42.0 144.0	8	<p>Massive, medium- to coarser-grained, green, white, pale orange, weak to moderately magnetite, weakly epidote altered diorite.</p> <p>(Note: this rock is very similar to one identified in hole S-109 by</p>

CRAIGMONT MINE PROJECT

		<p>thin-sections (t/s) as an augite diorite with interstitial k-spar and quartz. It was logged (prior to t/s work) as a hornblende diorite and in other holes (e.g. S-111) as a dioritized greywacke or dioritized arkose. The dark, ragged altered clusters are altered pyroxenes - in S-109 the alteration was identified in t/s as sperpentine).</p> <p>Spotted texture with ~ 60% feldspar, ~29% ragged-edged pyriboles and ~20% interstitial quartz. Feldspars mainly shades of light green sericite altered in light green to white feldspathic groundmass. Some white sericite alteration / bleaching of feldspars in alteration envelopes along narrow calcite-zeolite healed fractures. Minor epidote alteration as spots through the rock (<1%).</p> <p>Pyroxenes increase in size to +8 mm from about 50 m. Pyrite disseminated at <1% in upper part of unit and magnetite is moderate (~2-3%) as alteration rims on pyroxenes. In strong sericite altered sections, pyrite is more abundant (2-3%) and magnetite is reduced to <1%. Pyrite clusters increase in size to 5 m.</p> <p>From 66-86 m the magnetite is weak (<1%) and pyrite increased to 2-3%. Some light reddish-brown fine-grained mafics (mica?). Very broken sericite altered core at 91-94.5 m and runs of broken core from 98 m with narrow (20-30 cm) clay/silt seams at 102 and 104m. Shear with strong sericite alteration at 105-106 m with a few spots of chalcopyrite in the diorite.</p> <p>106-112 m: mafic phenocrysts increased in size to 1 cm with magnetite and amphibole altered rims and lighter-coloured interiors. Scattered epidote-calcite veins with light alteration envelopes and cut by calcite-zeolite veins (2-3%) at 0-30° and 50-70° C.A. By 112 m, magnetite alteration increased to 1-2% magnetite; pyrite <1% and weak epidote. Calcite-zeolite veins to 2 cm thick at 10-30° C.A. Some sections to >0.5 m of epidote-quartz-calcite veins at low angle to core axis (~5°). Calcite-zeolite veins increase in frequency with depth, magnetite alteration is weak (~1%) and pyrite is <1%. The size of the mafic phenocrysts decreases to 2-3 mm across close to the bottom contact at about 144 m.</p>
144.0 146.5	81	Contact zone breccia with magnetite-altered diorite (50%) and light green felsic weakly banded rock (volcaniclastic?)

CRAIGMONT MINE PROJECT

		<p>Diorite has bleached mafics, increased mafics - banding, more distinct feldspar laths and increased pyrite (2-3%) as disseminations. The felsic rock has thin white alteration rims around grains (clasts / crystals?).</p>
146.5 148.6	1	<p>Red-brown garnet-chlorite-epidote-pyrite skarn grading to yellow-brown garnet-epidote-amphibole skarn with depth.</p> <p>Host is weakly limy, felsic fine-grained rock with 3-5% disseminated pyrite and cut by white, crystalline calcite healed fractures. Red-brown garnet is in streaks/bands and patchy to coarse grained. Epidote is locally strong after garnet and chlorite. Light tan mineral after garnet. Little magnetite alteration.</p>
148.6 151.8	1	<p>Weakly banded, very limy, magnetite-amphibole-chlorite-pyrite+/-garnet skarn grading to specularite-rich skarn at bottom with minor chalcopyrite.</p> <p>Magnetite alteration is strong (>10%) as disseminations of fine grains and patches. Pyrite amounts to about 5%, as disseminations of fine grains to larger clusters to 1 mm. Epidote alteration is weak. Some orange k-spar (?) patches. Banding is at ~45° C.A. Skarn changes to coarse-grained specularite (~5%) rich variety by 149.9 with a few spots of disseminated chalcopyrite. Probable contact of the limestone unit at ~149 m at top of skarn represented by increased limy content and skarn change.</p>
151.8 160.9	21	<p>Medium green-grey, non-limy, weakly magnetite and weakly chlorite-sericite altered felsic fine-grained rock (volcaniclastic?)</p> <p>Indistinct, fine-grained texture, with scattered larger (2-3 mm) grains with indistinct edges. Pyrite amounts to 1-2%. Some pinkish quartz veins at 156.4 m. At 154.5 m is 1 m of broken, rubbly core with <50% recovery of dark grey, fine grained, weakly magnetite altered, possibly detrital rock. Some rounded to subangular grains with very irregular boundaries in fine-grained / aphanitic matrix.</p>
160.9 168.0	1	<p>Very limy, magnetite-specularite-garnet-epidote-pyrite+/-k-spar skarn.</p> <p>Magnetite amounts to 2-3%, garnet 3-5%, pyrite 3-5%, specularite 5-10% and epidote locally strong (164-168 m). Very</p>

CRAIGMONT MINE PROJECT

		broken core with poor recovery. Specularite occurs as disseminations and seams/veins.
168.0 169.0	21	<p>Poorly sorted to weakly-graded, epidote altered breccia with fragments of limestone and skarn in a limy matrix.</p> <p>Fragments matrix supported with 60% fragments > 3 mm in diameter and graded to finer size to sharp contact with underlying limestone. Some post-skarn sericite alterations. Rock generally porous and friable.</p>
169.0 174.2	2	<p>Light to medium grey, light green and dark grey, thin-bedded impure medium grained crystalline limestone (marble).</p> <p>Bedding is at 0-20° C.A. at contact to ~45° C.A. at 173 m. Some red-brown garnet alteration along and across bedding, some tan garnet along bedding, weak to moderate epidote. No magnetite. Moderate pyrite (2-3%) and epidote altered with yellow-tan garnet at 172-174.2 m. Epidote and garnet generally in different beds.</p> <p>Some breccia dykes (phreatic?) to 1 m thick with subangular limestone fragments in fine-grained limy matrix. Breccia dyke at 173.3 m is 20 cm thick at 45° C.A. and cuts garnet skarn beds. Breccia is tight packed (>90% fragments) with subangular to rounded, multilithic breccia clasts (dark and light felsic and limy clasts).</p>
174.2 179.2	7	<p>Medium grey to pinkish grey, weakly magnetite altered, hornblende needle porphyritic banded felsic (andesitic) volcanic flow(?)</p> <p>Brecciated contacts at top and bottom of unit. Weakly banded with darker bands to 1-2 cm thick composes, 30% of rock. Hornblende needles are euhedral and fresh, compose ~10% or greater, average 1-2 mm long to maximum of 1 cm, weakly aligned in fine-grained feldspathic groundmass of feldspar laths < 1 mm long (30-50%) in fine grained to aphanitic matrix. Matrix is locally pinkish (k-spar?). No pyrite. Minor magnetite. Cut by thin (1-2 mm) which calcite veinlets.</p> <p>Phreatic(?) breccia dykes at top and bottom and narrow (2-5 cm thick) dykes within unit. Cut by calcite veinlets. Breccias are tight packed and clast supported in thin dykes and matrix supported in</p>

CRAIGMONT MINE PROJECT

		breccia at top and bottom of unit. Clasts are multilithic and include dark and light volcanics, quartz, quartz-feldspar porphyry, dacite, skarn and flow rock. Small fragments are rounded and larger are subangular to near source. Banding at ~50° C.A. at 178 m.
179.2 185.0	21	<p>Interbedded grey, dirty, crystalline limestone, thin-bedded to laminated tan-grey limy sandstone and weakly limy, dark, felsic sandstone.</p> <p>Minor garnet skarn in felsic sandstone. Some light green sericite alterations. Crosscutting crystalline calcite veins to 2 cm thick. Some garnet-epidote-pyrite (1-2%) skarn along some beds. At 182-185 increased red-brown garnet and moderate to strong epidote. Some coarse breccia with white calcite veins and in breccia matrix and fragments of dark grey, weakly limy felsic rock and bleached, light grey version.</p>
185.0 188.4	7	<p>Hornblende needle porphyritic, weakly magnetite altered, felsic (andesitic) volcanic rock (as above.)</p> <p>Medium grey and dark grey bands. Near contacts, rock is reddish and dark. Abundant (50%) white, 1 mm-long subhedral feldspar.</p>
188.4		End of hole. Hole stopped due to lack of mineralization and lack of amphibole (actinolite) skarn alterations.
