## **1.0 SUMMARY**

The Century Limestone property is a potentially large tonnage, relatively untested, limestone deposit located on tidewater off Tlupana Inlet, northern Nootka Sound on the West Coast of Vancouver Island, British Columbia. The project is owned 100% by Doublestar Resources Ltd., whom is also the operator. Two distinct limestone deposits have been identified by Doublestar within the claim boundaries, the Century Limestone Project on the east (Tlupana Inlet), and the BCD Limestone project on the west (Hisnit Inlet). This report details and documents the results and interpretations from Doublestar's Geological and Geophysical evaluation of these deposits, conducted over 4 separate programs from May – December 2005.

The property evaluation program collected a total 475 rock chip samples from the Century and BCD projects. The CENTURY (321 Limestone samples and 16 mafic dyke samples) and the BCD claims (138 Limestone samples). These samples were collected on a grid with stations at 50 metre spacing, East-West and North-South. Sampling the limestone deposit in this fashion was deemed necessary to gain unbiased information on the quality, grade, extent and continuity of the limestone. The bulk of the geological sampling was conducted on the Century Project because it affords the easiest tidewater access. The average results of all 321 Limestone samples sampled within the Century Project are presented in Table 1.

**Table 1.** Average Whole Rock Analyses from the 321 CENTURY Project Limestone Samples

<b>SiO<sub>2</sub> %</b>	<b>TiO<sub>2</sub> %</b>	<b>Al<sub>2</sub>O<sub>3</sub> %</b>	<b>Fe<sub>2</sub>O<sub>3</sub> %</b>	<b>MnO %</b>	<b>MgO %</b>	<b>CaO %</b>	<b>Na<sub>2</sub>O %</b>	<b>K<sub>2</sub>O %</b>	<b>P<sub>2</sub>O<sub>5</sub> %</b>	<b>Ba(F) %</b>	<b>LOI %</b>	<b>Total %</b>
0.78	0.01	0.11	0.11	0.02	4.29	50.46	0.02	0.02	0.01	0.01	43.86	99.70

These results, coupled with a suite of additional geophysical, physical and chemical testing indicate a potentially economic limestone deposit on tidewater on the West Coast of Vancouver Island.

Once the results presented above were reviewed, the project was flown for new airphotos and topographic basemap control. Subsequently in December of 2005, a geophysical (Magnetometer) study of the Century deposit was conducted. The geophysical program consisted of 4.4 line kilometers of magnetometer survey, was designed to test the number and spacing of a series of mafic dykes noted during project sampling as well as to indicate a potential depth of limestone. The results of this program indicate the mafic dykes present on the property are spaced sufficiently far apart (~50 metres) so as to not preclude quarrying operations. The magnetometer study also indicated a possible depth of the deposit and helped constrain the attitude of bedding within the limestone on the property.

All field work was conducted under the guidance of the author, Paul D. Gray, P.Geo. Reports prepared by several independent contractors are included as appendices within this report, specifically, these include 1) Frontier Geoscience Magnetometer Study, Century Limestone Deposit; 2) Process Research Associate's Bond Work and Chemical Study; 3) Global Discovery Labs Whole Rock Analyses reports; and 4) Topographic basemap work from 2005 airphoto interpretation as produced by Eagle Mapping Inc.

Results from the 2005 Limestone Evaluation Program indicate the Century Limestone property hosts a potentially large tonnage limestone deposit of sufficient grade and quality to justify additional exploration work which includes geological and geophysical testing as well as diamond drilling.

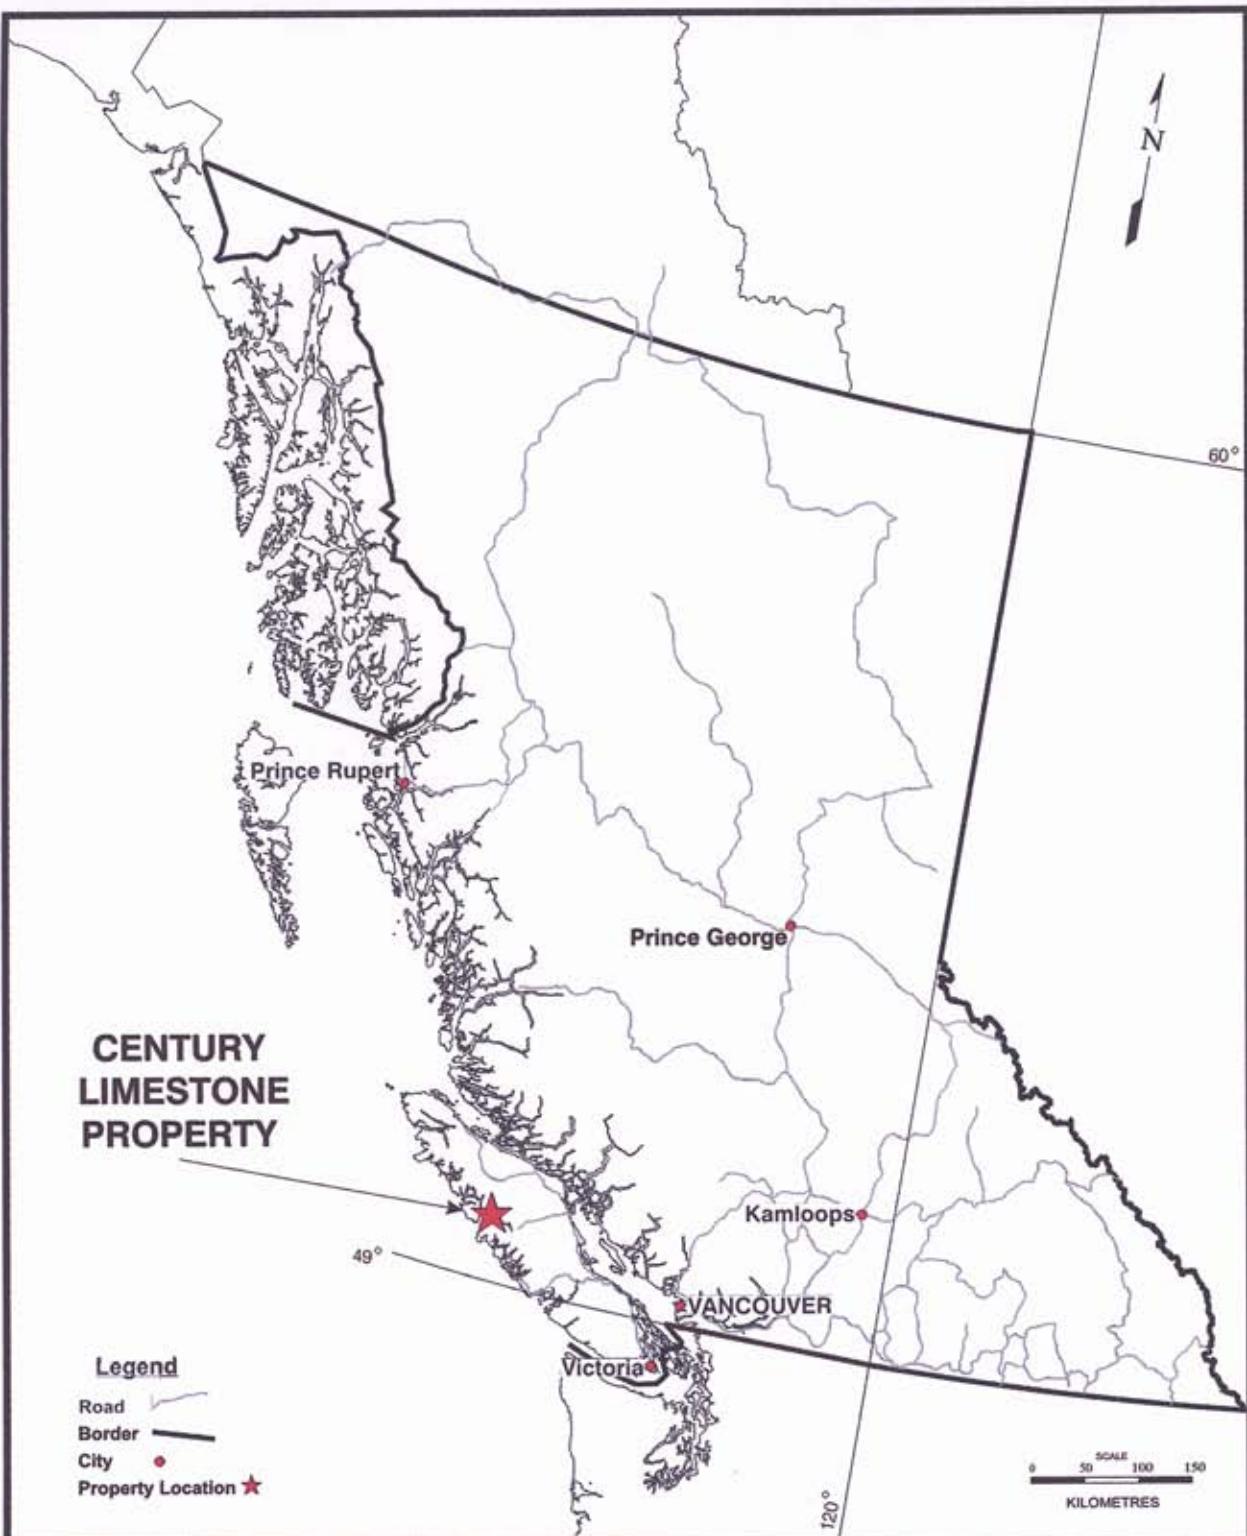

## **2.0 INTRODUCTION**

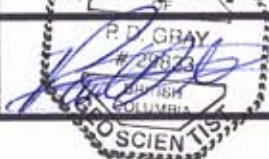

### **2.1 LOCATION AND ACCESS**

The Century Limestone property is located in Southwestern British Columbia, at tidewater, within Nootka Sound, Tlupana to Hisnit Inlets, on the extreme west coast of central Vancouver Island. The property lies approximately 40 kilometres southeast of Tahsis, British Columbia (Figures 1 and 2). N.T.S. map sheets 092E/15 and 092E/16 cover the project area, with the property centre at approximately  $49^{\circ} 52' 12''$  North latitude, and  $126^{\circ} 29' 24''$  West longitude (U.T.M. Zone 10 coordinates 681248 E.; 5515851 N; N.A.D. 83 datum).

Vehicular access to the property and area is afforded by a network of well maintained logging roads (INTERFOR and Western Forest Products). The main area access is the B.C. Highway Gold River – Tahsis road. The property itself can be reached by turning onto the Hisnit Main logging road at Head Bay (approximately 30 kilometers south of Tahsis). Approximately 7 kilometres up the Hisnit Main lies the project centre (See Figure 3). At kilometre 11, on the Hisnit Main lies the BCD property, which is traversed by a steep, switchbacked tributary logging road (Figure #3). Several deactivated and overgrown logging roads allow for trail like access across the Century property.

Food, fuel and accommodations are all readily available at Tahsis (Population ~ 500) or Gold River (Population ~ 2500). Both centres have deep water ports and are connected by three phase power transmission lines. These power lines pass within five kilometres of the Century project.

## **2.2 CLIMATE, TOPOGRAPHY AND VEGETATION**

The Hisnit peninsula of the Century Limestone Project is a rugged, heavily forested peninsula approximately 4 km wide and 6 km long with tide water access on each side. Historically and recently, significant areas of forest land have been harvested within the property boundaries and nearby areas, active logging will continue on the property in 2006 by Interfor. Property elevations range from sea level (0 metres) to 750 metres above sea level, with the Century side of the property peaking at 550 metres, and the BCD 750 metres.

The climate of the region can be classified as West Coast Marine, with mild but wet winter seasons and cool drier summers. Annual precipitation (snow) over 50 cm is normal, as well as significant rainfall. Due to the proximity of the project to tidewater, snowfalls are not considered to be severe. Temperatures may range from -15.0°C to +30°C.

## **2.3 OWNERSHIP AND CLAIM STATUS**

The Century Limestone Property is owned 100% by Doublestar Resources Ltd.

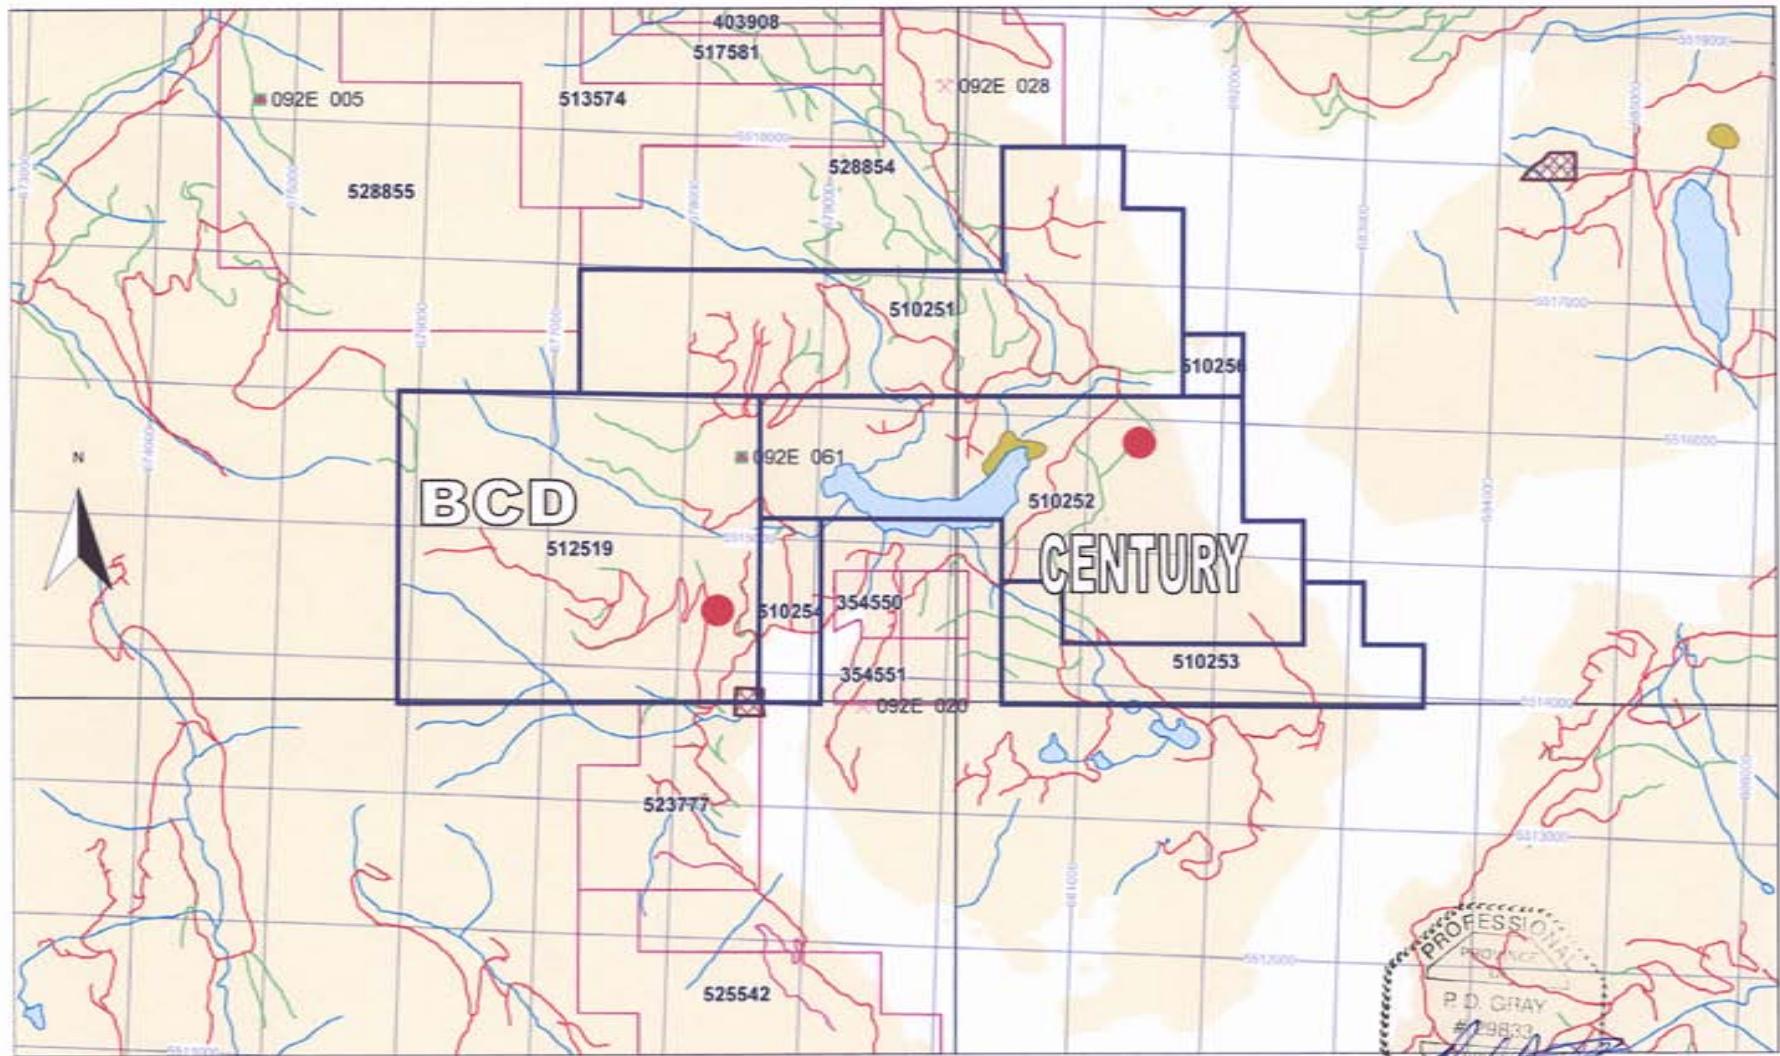

Doublestar completed the acquisition of a 100% interest in the property September 2005 in exchange for 210,000 Class "A" shares, a production royalty between 0.85% and 1.5%, and annual advance royalty payments of \$10,000. If production is not begun and the property is sold by Doublestar within four years of the agreement, the proceeds of the sale minus Doublestar's exploration costs would be split evenly between Doublestar and the vendors. Subsequent to this purchase, Doublestar added mineral claims to the package.

The property consists of six (6) MTO staked and/or converted mineral claims which in total, occupy an area of approximately 1,940.863 hectares (See Table 1 and Figure 3).

## **2.4 EXPLORATION HISTORY**

Limited limestone exploration has been conducted on the property to date. At the turn of the last century, small marble and limestone quarries were operated but not in any substantial amounts. A contemporary marble operation lies just to the south of the Century Limestone Property..

Skarnified contacts of local intrusions and Quatsino formation limestone have been prospected and worked for Cu, Au, and Ag. Several showings and workings are located to the north and west of the Century Claim Group which were explored for gold throughout the last century via adits and open cuts (likely because of the property's proximity to the historic mining centre of Zeballos).

Four known B.C. MINFILE occurrences are located within (or very close to) the Century Limestone property boundaries; 092E028, 092E020, 092E005, and 092E061 (See Figure 3).

*BC MINFILE 092E20 reports:*

***A deposit of recrystallized limestone at the head of Hisnet Inlet, a northwestward extension of Tlupana Inlet, was quarried for marble by Nootka Quarries Ltd. between 1908 and 1909, but no production figures are available. This occurrence is situated near the southeast end of a band of limestone of the Upper Triassic Quatsino Formation (Vancouver Group), extending northwest from Tlupana Inlet to Tahsis Inlet. The band continues for more than 1600 metres eastward from Hisnet Inlet. The limestone in this vicinity is more than 300 metres thick. Bedding strikes 060 to 080 degrees. A 3.5-kilometre wide stock of granodiorite of the Jurassic Island Intrusions intrudes the limestone a kilometre southeast of the quarry site.***

***The deposit is comprised of medium to coarse grained, white to light grey limestone (marble), occasionally containing some dolomitic bands. At the quarry site the limestone is intruded by basaltic dykes that make up to 55 per cent of the rock. Two samples of limestone from the quarry averaged 54.18% CaO, 0.78% MgO, 0.68% insolubles, 0.028% Al<sub>2</sub>O<sub>3</sub>, 0.095% Fe<sub>2</sub>O<sub>3</sub> and 0.013% sulphur (Canada Bureau of Mines Report 452, pages 167, 168, Samples 1424, 1425).***

And BC MINFILE 092E61 reports:

**At the Tlupana Arm occurrence northwest trending, Upper Triassic Vancouver Group, Quatsino Formation limestones and dolomites are exposed for over 1.5 kilometres along Deserted Creek. The Quatsino Formation hosts granitic plugs, dykes and stocks of the Jurassic Island Plutonic Suite.**

**About one kilometre southeast of a limestone quarry (Hisnit Inlet - 092E 020) on Deserted Creek are hard, dolomitic bands which contain numerous scattered "spots" up to 5 millimetres in diameter. The spots contain crystals or crystalline aggregates which appear dark on fresh surface. The material is more soluble than the host rock and weathers to a white fibrous residue which is left in cavities or pits on the dolomite surface (Open File 1987-13, page 51).**

**Goudge (1944) interprets the material to be brucite which is a common component in contact metamorphosed dolomites and which may be fibrous with anomalous birefringence in thin section. Parks (1917) reports similar characteristics for the Tlupana Arm mineral.**

## **3.0 GEOLOGY AND MINERALIZATION**

### **3.1 GENERAL REGIONAL GEOLOGY**

The Century Limestone property is hosted within sedimentary and volcanic rocks of the Late to Middle Triassic Vancouver Group (Quatsino Limestone and Karmutsen volcanics and Parson's Bay sediments). These lithologies are in fault contact with diorites of the Crystalline Westcoast Complex, all lithologies are intruded by the Eocene Catface Intrusions (Figures 4, 5, and 6).

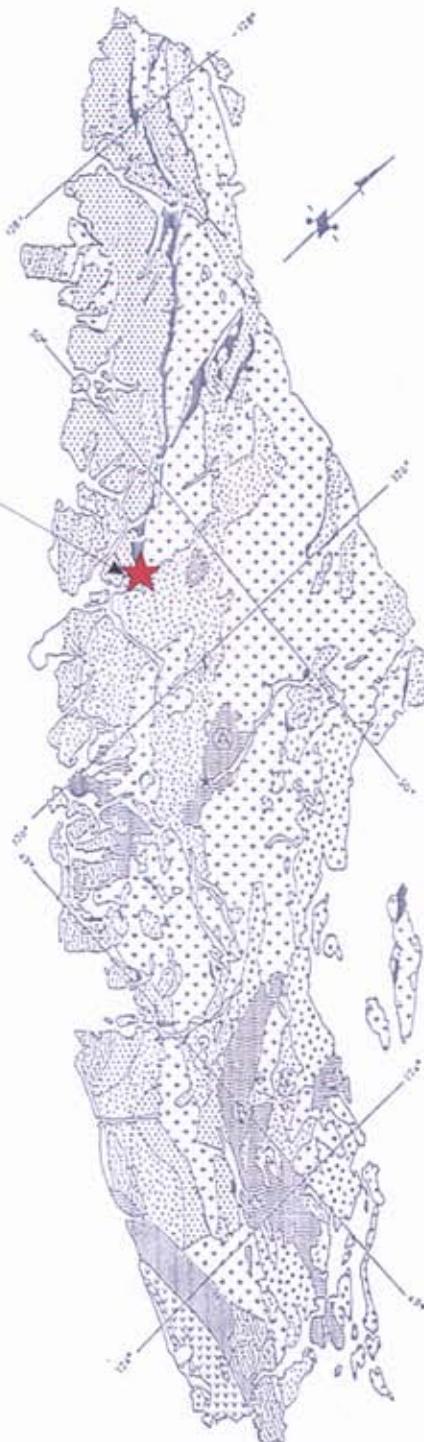

The most recent description of the regional geology of the Century Limestone area is presented by Nixon et al. (1994; 1997; 2000; 2006). The following summary is taken predominantly from Nixon et al.'s maps, papers and references. Figure 4 shows the bedrock geology of Vancouver Island.

Vancouver Island encompasses Upper Paleozoic to Lower Mesozoic rocks of Wrangellia – a tectonostratigraphic terrane that occurs intermittently northward as far as central Alaska. In the Late Carboniferous, this terrane was accreted to the Alexander Terrane forming the Insular Superterrane. Subsequently, this superterrane was rafted to North America sometime from the Middle Jurassic to the mid-Cretaceous (DeBari et al., 1999).

The pre-accretion history of Wrangellia is represented by the Paleozoic Sicker Group and the Middle Triassic Karmutsen Formation of the Vancouver Group. The Devonian to Early Permian Sicker Group is made up of marine volcanic and sedimentary rocks that host known VMS deposits such as at Myra Falls. The Karmutsen conformably overlies the Sicker Group and comprises basaltic and minor sedimentary rocks that underlie parts of Northern Vancouver Island. The Karmutsen unit can be up to 6000 metres thick. (DeBari et al., 1999). The Quatsino limestone Formation conformably overlies the Karmutsen.

The Bonanza Arc (DeBari et al., 1999) formed along the length of Vancouver Island during accretion of Wrangellia and is represented by the Bonanza volcanics. Later tectonic tilting preserved the Westcoast Crystalline Complex, Island Intrusions and the Bonanza Group volcanic rocks (Nixon et al., 1994).

### **3.2 LOCAL PROPERTY GEOLOGY**

The Century Limestone property is defined by the Upper Triassic Vancouver Group, Quatsino Limestone. The limestone is in general, massive to thickly bedded and well marbleized. The colour and texture of the limestone are variable from bright white to dark grey, and from fine grained to coarse grained, respectively. The latter is apparently due to variable recrystallization (marbleization). In general the texture can be described as cryptocrystalline. The Quatsino formation here is moderately dipping at approximately 45° and strikes northwest – southeast across the project (this structure is mirrored in the Parsons Bay exposures to the south, which do not appear on the government maps; Figure 5).

The marbleized limestone weathers grey to buff, but on fresh surfaces are typically white. These limestones are occasionally streaked with thin discontinuous grey interbeds. Extremely limited sulphide contamination was noted, with pyrite and massive sulphide mineralization seen in only near the skarnified intrusive contacts (to the north and west). No evidence for widespread silica, alumina or iron contamination of the limestone is noted within the Quatsino Limestone here. (Nixon et al., 2006)

Late, fine grained mafic intrusive dykes of andesite to trachyte, are noted throughout the property cross cutting the Quatsino Limestone. The dykes are dark grey-green to black, pale green-grey-weathering rocks of aphanitic to porphyritic textures with euhedral to subhedral phenocrysts of plagioclase. Contact relationships are complex and difficult to see in outcrop, but where visible (the shoreline), suggest a multi-stage emplacement history. These intrusive units are of concern to the otherwise pristine limestone deposit. (Nixon et al., 2006).

A shoreline traverse on the property indicates that mafic dykes account for approximately 25 percent of the total rock volume (although at higher elevations on the property these

dykes appear much less frequently). The dykes are generally less than 3.0 meters wide and have well developed chilled margins which do not invade the limestone hostrock more than a 10 centimetres. These dykes tend to be preferentially orientated subparallel to the bedding. Differential weathering with the limestone forms resistant ridges of dyke material within the project area. Interestingly, the BCD area is defined by significantly less exposures of mafic dykes than the Century area.

### **3.3 STRUCTURE**

A Northwest – Southeast structural grain is predominant within the project area. The Massive Quatsino bedding is typically difficult to measure on the limited well glaciated exposures the property offers. Roadcuts and drainages do afford structural measurable units. The Parson's Bay formations south of the limestone deposit are bedded on a much more fine scale and agree with the general  $110^{\circ}$  bedding attitude obtained over the Century area of the property.

The mafic dykes appear to follow bedding planes within the limestone. These zones of weakness may have offered channels for these intrusive units to impinge. The attitude of the limestone and mafic dykes was bolstered by the Magnetometer survey which indicated a general  $\sim 110^{\circ}$  attitude for these dykes.

## **4.0 ECONOMIC GEOLOGY**

### **4.1 Mineralization**

The sulphide mineralization noted on the Century Limestone property is best described as isolated and restricted, within pods of Skarn-style massive sulphides (Pyrite, Chalcopyrite, Galena and rare sphalerite) mineralization at or near the contact margins of intrusive bodies. Small “sweat zones” or concretions of massive sulphide were also noted in very limited numbers proximal to basaltic dyke – Limestone contacts. Generally speaking, the limestone deposit is clean and clear of sulphide mineralization.

The Economic target of this project is the limestone itself. The 2005 program began the process of qualifying the location, size, structure and grades of this potentially economic target.

## **5.0 2005 WORK PROGRAM**

### **5.1 SUMMARY**

The 2005 Century Limestone exploration program was designed as a first pass characterization study of the Century Limestone Project. The program tested the physical and chemical properties of the limestone on the property and also concentrated on the geological and geophysical aspects of the lithologies present. The program was successful in outlining a potentially large tonnage, high-quality limestone deposit.

The evaluation program of the Century/BCD limestone projects was conducted in 4 distinct programs from May-December 2005. Program 1: May 30 –June 7, sampled and mapped the Century Deposit while prospecting the entire claim area (4 personnel). Program 2: June 20 - June 24, sampled and mapped the BCD claims (2 personnel); Program 3: November 14 – November 25 cut line in preparation for geophysical study (2 personnel); Program 4: December 5 – 7, Geophysical program conducted (3 personnel).

In May and June of 2005 Doublestar workers, under the guidance of the author, collected a total of 475 rock chip samples over the two (2) main areas of interest on the property, the CENTURY (321 Limestone samples and 16 mafic dyke samples) and the BCD claims (138 Limestone samples). These samples were collected on 50 metre E-W grid centres on N-S lines separated by 50 metres (See Figures 7 and 8). All samples were selections of freshest rock available (which necessitated the need for grubbing and digging in some cases). Careful notes were taken during the program about the type of rock sample, the proximity of any dykes, the texture/colour, and other related lithological/descriptive information. In addition, introductory geological mapping (lithology and structure) was performed on the grid (tabulated results from these programs are presented in Appendix A).

All limestone and mafic dyke samples were collected from surface exposures on the property at regularly spaced intervals. The samples were bagged and tagged in the field and after the respective programs, were submitted to Global Discovery Labs of Vancouver, B.C. for Whole Rock Analysis. These analyses were intended to give an indication of the quality of the limestone over the deposits. The average results of all 321 Limestone samples sampled within the Century Project are presented in Table 1.

A suite of 6 samples scattered over the CENTURY project were collected and combined as a single “representative” sample for the project. This sample included all the types of limestone (colour, texture, grain size, etc.) encountered during the programs on the Century Project. This sample was analyzed for Bond Work Index at Process Research Associates Labs (PRA). This sample was to be an initial test of the hardness and crush/grindability of the limestone. The results of the PRA test work are attached with a descriptive report in Appendix B.

A selection of 17 pulps (12 from the CENTURY PROJECT and 5 from the BCD Project) from the first pass Whole Rock Analyses were sent to PRA for Total Sulphur and Chloride analyses. These samples were selected randomly from each of the projects to be utilized as representative indications for the respective deposits. No problematic Sulphur or Chlorides were noted from this work. The results of this test work are attached as Appendix B.

In December 2005, Doublestar initiated a 4.4 line kilometer Magnetometer study on the Century Deposit with a view to determining the number, attitude, and size of the noted mafic dykes which traverse the property. Selective mining of the limestone was not desired, and the existence of these dykes in any amount indicated a possible “fatal flaw” in the project that required additional evaluation prior to diamond drilling. The magnetometer study was designed in a 2 phase approach, Phase I; a small 4.4 line kilometer test program over the centre of the limestone deposit to determine if the project

would respond to a magnetometer survey, and if results warranted, Phase II; a ten (10) line kilometre extension to the Phase I grid expanding the magnetometer coverage substantially. The study uncovered “*at least 4 separate lineaments...[whose] response types are those expected of relatively steeply dipping source bodies. These lineaments are almost certainly of different mineralogical composition than the surrounding rock type [limestone] and likely represent mafic dykes.*” (Appendix C) The survey was therefore successful in that it identified the location and attitude of the mafic dykes, and further, that these dykes were spaced widely enough (approximately 50 - 100 metres) to not preclude a quarry operation. Attached as Appendix C is a copy of the Frontier Geosciences Inc. report on the 2005 magnetometer survey. A follow up, larger property survey is warranted to test the rest of the Century area of the property.

## **5.2 SAMPLING PROCEDURES**

Standard methods of sample collection were employed on this project. Surface samples were collected by chipping softball sized chips from bedrock exposures at regular 50 metre (North South and East-West) intervals along set traverse lines. Samples were taken from these predetermined sample sites, regardless of lithology. In almost all instances bedrock exposures were encountered, although grubbing and digging was required to access rock under moss and vegetated cover.

## **5.3 ANALYTICAL METHODS**

All chip samples obtained from the surface and sampling programs were analyzed by Global Discovery Labs by whole rock geochemistry methods for eleven oxides including CaO and MgO and for Loss On Ignition (LOI). In addition, Process Research Associates conducted various physical and chemical tests designed to evaluate the limestone characteristics and marketability. Details of the analytical methods and original assay certificates are presented in Appendix D.

## **5.4 GEOPHYSICAL SURVEY**

In December 2005, Frontier Geosciences Inc. conducted a 4.4 kilometre test Magnetometer program on the Century Deposit. The program was designed to determine the number and attitude of several mafic dykes cross cutting the project (noted during the sampling program on the project) as well as to establish a possible depth of limestone within the project area. Several days of line cutting were required to prepare a grid with adequate station and line spacing; this was accomplished in an 11 day program in late November, 2005.

Frontier Geoscience's report is attached as Appendix C, it summaries the program and its findings. In short, the program identified a number of mafic dykes on the project and determined their spacing to be on the order of 50-100 meters. Further, the program determined a potential depth in the shallowest Northeastern edge of the property to be approximately 100 metres.

The findings warrant a follow-up survey. For this program, the cut gridlines must be extended (~10 kilometres). A combination VLF/MAG survey is recommended during this next step.

## **5.5 AIRPHOTOS AND INTERPRETATIONS**

In July 2005, Eagle Mapping Ltd. was contracted to fly the project and take a number of airphotos from which a useable topographic basemap could be produced. It was decided to prepare two distinct project basemaps instead of one large one as a cost saving measure. At any time Eagle Mapping can produce topography for any of the areas which have been photographed. Appendix E shows the flightlines and area flown during this program, along with the two topographic maps produced from the program.

## **5.6 RESULTS**

The results of the whole rock and ICP analyses on the surface sampling programs are presented in raw and compiled forms in Appendices A and D.

Figures 7 and 8 show the results from the sampling and analytical program in numerical/range plots of CaO and MgO respectively. The mafic dykes and mafic dyke proximal rocks tend to show up as red due to their high MgO content. Post Magnetometer survey, it was found the areas of high MgO correspond well with areas of noted/sampled mafic dyke material.

## **6.0 RECOMMENDATIONS**

The 2005 Century/BCD project evaluation was successful in outlining a large, high-grade, potentially economic limestone deposit on tidewater on the west coast of Vancouver Island, B.C. From a geological perspective, this project warrants further expenditures to more accurately characterize the size and continuity of the deposits, both surficially and to depth. The most effective means of this characterization is by diamond drilling; however a series of steps should be taken before such a program is initiated:

- 1) Extend the exiting magnetometer grid to cover the entire area of Century sampled during 2005 (an additional 10 kilometers of cut grid will be required). Combine a VLF survey with this phase II magnetometer work to help better determine attitude of bedding, mafic dyke locations, and any structural lineaments which may be present;
- 2) Additional surface chip sampling and assaying of the BCD deposit (~350 samples up elevation and to the north) from the existing BCD grid followed by a MAG/VLF on the BCD Deposit to define the grade and continuity of the limestone here;
- 3) Detailed structural and geological mapping study of Century and BCD, combined with an on the ground determination of mafic dyke locations. This would amount to shore line traverses at low tide and detailed grid mapping up elevation (1:5,000 scale or less);
- 4) Diamond Drill Century Deposit. 30 holes, 100 metres each (3000 metres).

Dated: May 19, 2006

VANCOUVER, B.C.

## **8.0 STATEMENT OF QUALIFICATIONS**

I, Paul D. Gray, of #1 – 1081 West 8<sup>th</sup> Avenue, Vancouver V6H 1C3, in the Province of British Columbia, DO HEREBY CERTIFY THAT:

1. I am Vice President of Exploration for my employer, Doublestar Resources Ltd., with offices at 350 – 885 Dunsmuir Street, Vancouver, B.C.
2. I am a graduate of Dalhousie University, Halifax, in the Province of Nova Scotia, with a Bachelor of Science degree (Honours) in Earth Sciences.
3. I am a member in good standing of the Association of Professional Engineers and Geoscientists of British Columbia (APEGBC), license number 29833.
4. I have practised my profession as an exploration geologist in the mineral exploration industry continuously since 1997. I have worked on exploration projects in British Columbia, Northwest Territories, and Honduras, Central America.
5. I am the author of this report and the supervisor of the field work performed on the Century Limestone Property during the period May, 2005 – December 2005, as reported herein.

DATED at Vancouver, British Columbia this 19<sup>th</sup> day of May, 2006

May 19, 2006

Vancouver, B.C.

## **APPENDIX – B**

**PRA PHYSICAL AND CHEMICAL TEST WORK AND CONCLUSIONS**

## SUMMARY REPORT 0506408

To	Paul Gray		Company:	Doublestar Resources Ltd
From	Boja Grcic		Date	Aug 11, 2005
Project No	0506408	Send:	By e-mail	

### 1. OBJECTIVES

To determine the work index and mineralogy of 6 limestone samples.

### 2. RESULTS

The 6 rock samples were received on Aug 4, 2005 as per Sample Receiving Log attached. Samples were crushed to -6 mesh, blended and riffled into Composite AL-S 165-170 and splits were pulverized prior to XRD and whole rock analysis.

The grindability of Composite AL-S 165-170 was determined by standard procedures, as the Bond ball-mill index with a 200mesh closing screen size, to be **7.8kWh/ton** (**8.5kWh/tonne**). Comparative Bond index values for recent LeHigh limestone samples are presented below, but chemical analyses of these samples (performed by LeHigh) are not available. Composite AL-S 165-170 sample is slightly softer than LeHigh samples.

Table 1 - Bond Index Ranges for Common Limestone Samples

LeHigh Sample id	Bond Ball Mill Index	
	W (kWh/ton)	W(kWh/tonne)
AA03-7-4201	6.5	7.1
AA03-6-6006	10.0	11.1
TN04-4 26'-78'	8.9	9.8
TN04-3 21'-490'	6.6	7.2
DDH TN-04-02 5'-275'	6.2	6.9
DDH MB-04-1 14'-58'	9.9	10.9
Average	8.02	8.83

X-Ray Powder Diffraction (XRD) Analysis of Composite Al-S 165-170 indicated predominating calcite and dolomite mineralization, with minor brucite and traces of quartz, as presented in the Table 2. The X-ray diffractogram is attached, and the Whole Rock analytical results are listed in Table 3. The detailed test reports are included in the Appendix.

## SUMMARY REPORT 0506408

Table 2 - XRD Results

Mineral	Chemical Formula	%
Calcite	CaCO <sub>3</sub>	58.95
Dolomite	CaMg(CO <sub>3</sub> ) <sub>2</sub>	18.24
Brucite	Mg(OH) <sub>2</sub>	1.41
Quartz	SiO <sub>2</sub>	0.30

Table 3 - Whole Rock Analysis Results

Elements	Units	Sample id	
		Composite AL-S	Re-Composite AL-S

TiO <sub>2</sub>	%	0.01	0.01
LOI	%	26.70	25.13
Total	%	88.71	87.76

### 3. DISCUSSION

The results of Whole rock and XRD analyses reveal calcium : magnesium weight ratios on the order of 6:1, and the presence of minor impurities (<1% of quartz) in sample. The carbonate and any water of hydration are included in the LOI (loss on ignition), and less volatile sulphate and chloride anions are not yet accounted for.

From the bond ball mill index results Composite AL-S 165-170 sample has moderate hardness and grindability characteristics.

## BOND MILL GRINDABILITY TEST REPORT

Client: Doublestar Resources Ltd  
Test: BI-1

13 April, 2005

Dear Paul:

**RE: Inlet (#179842 & 179843) / G.D.L. Job V05-0214R**

Seven samples were submitted to Global Discovery Labs, a business unit of Teck Cominco Ltd. The samples were tested for limestone quality by analysis using x-ray fluorescence techniques. As well, mineralogy was established for two samples by analyzing them by x-ray diffraction techniques.

The whole rock chemistry (as determined by XRF analysis) is consistent with that of pure limestone except in the case of sample R05:3278 (#179842). This latter sample is consistent with good quality dolomite.

X-ray diffraction analysis of sample R05:3278 (#179842) indicates that the sample is a 90:10 mixture of dolomite and calcite. No other phases are present. The x-ray diffraction pattern of sample R05:3279 (#179843), deemed typical of all the limestone samples, indicates that it consists of 98% calcite, ~1% dolomite and less than 1% quartz.

Standards run with the samples include one certified National Bureau of Standards argillaceous limestone (NBS-1c) and one that is a dolomite (NBS-88b).

The mineralogical and chemical analysis of the two samples tested by the two x-ray techniques is in excellent agreement.

The chemistry and mineralogy of these samples is believed to be that of relatively high quality limestone (six) and one good dolomite.

Yours truly,

J.A. McLeod, M.A.Sc., P.Eng.  
Manager, G.D.L.

## 1. INTRODUCTION

On December 6, 2005, Frontier Geosciences Inc. carried out a total field magnetics survey for Doublestar Resources Ltd. at the Century Limestone property, near Nootka Sound, B.C. The site area is located near the town of Tahsis, midway up the west coast of Vancouver Island. A Survey Location Plan is shown at a 1:200,000 scale in Figure 1.

The objective of the survey was to identify mafic intrusive dykes within the Century Limestone unit. The extent to which mafic dykes exist is of immediate concern when attempting to assess the volume and quality of a potentially economically viable limestone deposit. The Gem Systems GSM-19 Overhauser magnetometer is ideal for this purpose; it is possible to identify magnetically anomalous trends within a large survey area in a short period of time.

In total, eight traverses, totaling 4.4 kilometers, were surveyed across the century limestone unit. The lines were spaced at 50 metre intervals and ran north to south.

## 2. THE MAGNETIC SURVEY METHOD

### 2.1 Instrumentation and Field Procedure

The magnetometer survey was carried out using a GEM Systems, GSM-19, portable, high sensitivity, Overhauser-effect magnetometer. The unit is a standard for measurement of the earth's magnetic field, having 0.01 nT (nanoTesla) resolution and 0.2 nT absolute accuracy over its full temperature range. In operation, a strong RF current is passed through the sensor head mounted on an aluminum staff. This creates a polarization of the proton-rich fluid in the sensor followed by a process of "deflection" whereby a short pulse deflects the proton magnetization (secondary magnetic field) into the plane of precession (earth's magnetic field). A slight pause in the process allows the electrical transients to die off, leaving a slowly decaying proton precession signal above the noise level. The proton precession frequency is then measured and converted into magnetic field units. Essentially, the data collected is a measurement of the earth's magnetic field plus any effect on the secondary magnetic field by ferrous objects and/or high concentrations of ferromagnetic minerals.

For each survey line, measurements were taken in "walk-mag" mode, where readings are taken at one second intervals between station markers.

To allow for correction of temporal variations in the magnetic field, a GEM systems, GSM-19 base station was set up in an area with a relatively uniform magnetic field. Quartz clocks in the two units were synchronized at the start of the survey and the data were combined at the end of the day via an RS232C interface. The built-in microprocessor in the GSM-19 base station automatically correlated the base station readings to the survey data to allow correction of diurnal variations in the survey data. The data were then dumped via the RS232C interface to a computer for processing purposes.

### 3. GEOPHYSICAL RESULTS

#### 3.1 General

A Site Location Plan showing the survey area's location relative to the nearby town of Tahsis is shown in Figure 1 at a scale of 1:200,000. The line locations and the total magnetic field response, presented in colour contour format, are illustrated at a scale of 1:2500 in Figure 2. Figure 2 also features a profile of the magnetic response taken through the line marked A-A'.

A variety of magnetic responses, including high intensity lineaments, high spatial-frequency dipoles, and a gradual strengthening in magnetic response in the northeast portion of the grid, are identifiable in Figure 2.

#### 3.2 Discussion

Of immediate interest with respect to the survey's objective; there appear to be at least 4 separate lineaments striking either northwest or southeast. The response types are those expected of relatively steeply dipping source bodies. These lineaments are almost certainly of different mineralogical composition than the surrounding rock type and likely represent mafic dikes. The lineaments themselves vary somewhat in their magnetic signature. Lineament 1, around 5775N and 5650N, has strong dipole behavior indicative of near-surface, high-intensity, possible skarn mineralization. Anomalies A and B, in the southern portion of the grid, exhibit magnetic signatures similar to lineament 1 and could possibly be connected either to each other, or to some other lineament located off the survey grid. The other identified lineaments (2-4), in the north part of the grid, do not feature a dipole signature and are therefore probably less concentrated, less intense sources than lineament 1.

Throughout the entirety of the surveyed grid, there appears to be a gradual strengthening of the magnetic response towards the northeast. Profile A-A', in Figure 2, shows the individual events associated with lineament 1, 3, and 4, as well as the magnetic response buildup discussed above. Based on the profile, it seems likely that the magnetic response change is caused by the presence of a deep basement-rock response, either due to a different mineralogical content than the southern portion of the grid, or due to a thinning of the limestone unit towards the northeast. To accurately estimate the depth of the magnetic source in the northeast portion of the grid it would be necessary to track the intensity back

to near the 54600 nT signal level seen in the southern portion of the profile. Capturing the full magnetic response event would enable the usage of the half-space method of determining source depth. With the data as presented, we estimate that the magnetic source depth is at least 100 metres, which represents a thickness of 100 metres for magnetically inactive lithologies in the northeast portion of the survey area. Of this 100 metre magnetically inactive section, the depth to which the Century Limestone extends is unknown. Similarly, the depth to which the limestone extends in the southern portion of the survey area cannot be determined, but it appears that the thickness of magnetically inactive material is greater than in the northeast portion of the grid.

I=insufficient sample X=small sample E=exceeds calibration C=being checked R=revised

If requested analyses are not shown, results are to follow

**ANALYTICAL METHODS**

FeO determined by acid digestion /volumetric. LOI determined gravimetrically

Other elements by Li borate fusion/XRF. Where no FeO value shown "Fe<sub>2</sub>O<sub>3</sub>" is total Fe as Fe<sub>2</sub>O<sub>3</sub>

---

Fred Lo, Chemist-Teck Cominco G.D.L.

**COMMENTS**

Rpt. Value = Repeated value of standard

Ref. Value = Reference value of standard

STD: NBS-88b = Certified Reference Material Standard

## ANALYTICAL METHODS

FeO determined by acid digestion /volumetric.LOI determined gravimetrically

Other elements by Li borate fusion/XRF. Where no FeO value shown "Fe<sub>2</sub>O<sub>3</sub>" is total Fe as Fe<sub>2</sub>O<sub>3</sub>*Paul G.J. Co*Paul G.J. Co,  
Analyst, Teck Cominco G.D.L.

## COMMENTS

Rpt. Value = Repeated value of standard

Ref. Value = Reference value of standard

STD: NBS-88b = Certified Reference Material Standard

Report date: 27 JUNE 2005

I=insufficient sample X=small sample E=exceeds calibration C=being checked R=revised

If requested analyses are not shown, results are to follow

#### ANALYTICAL METHODS

FeO determined by acid digestion /volumetric. LOI determined gravimetrically

Other elements by Li borate fusion/XRF. Where no FeO value shown "Fe2O3" is total Fe as Fe2O3

#### COMMENTS

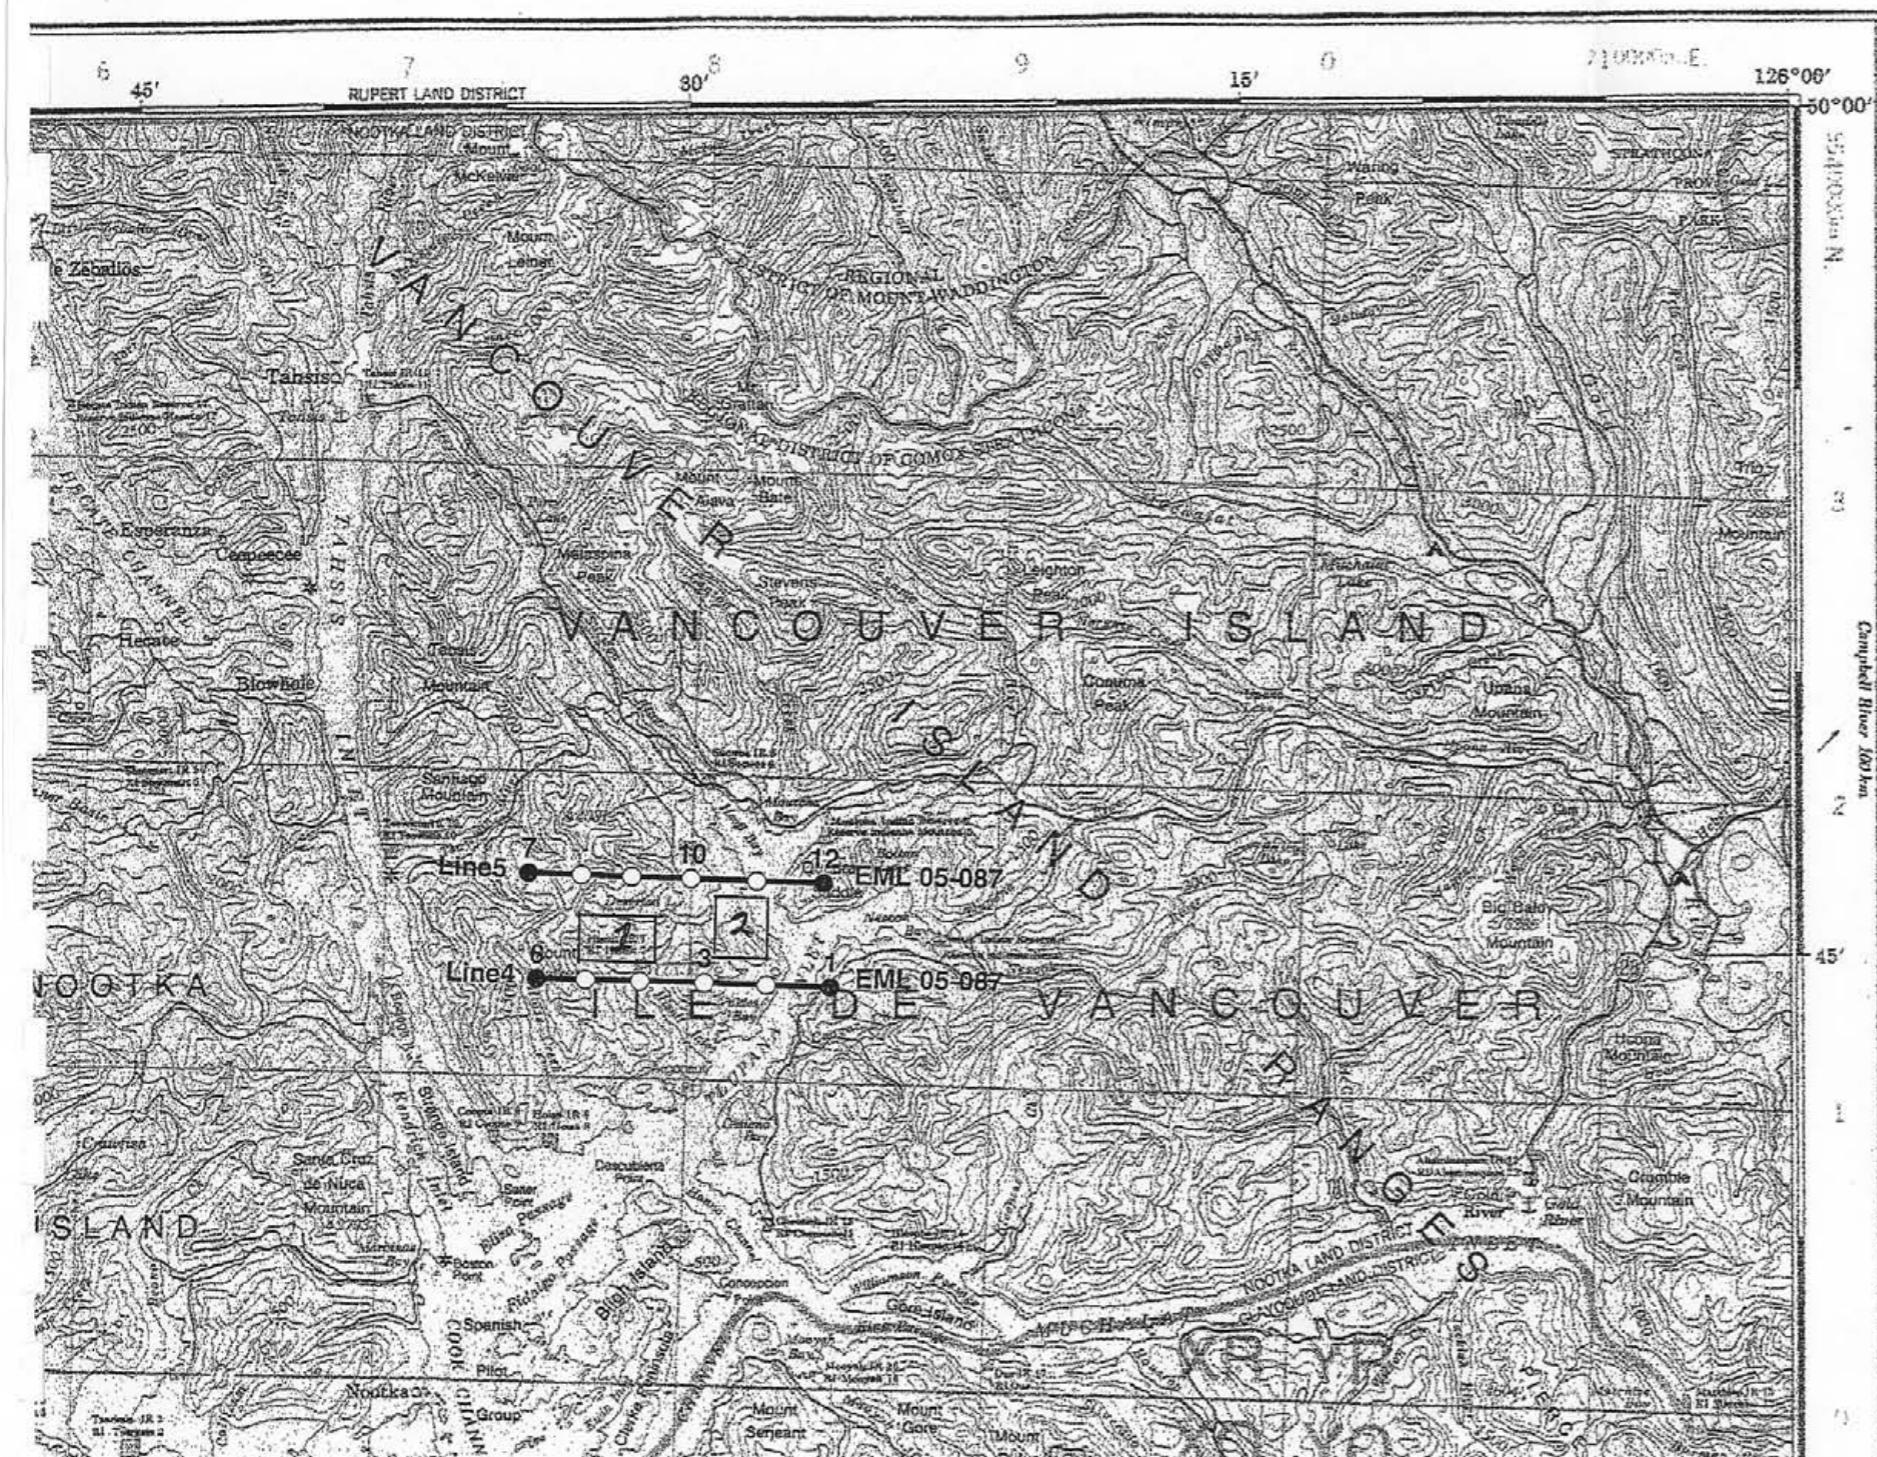

Rpt. Value = Repeated value of standard

Ref. Value = Reference value of standard

STD: NBS-88b = Certified Reference Material Standard
