1.0 INTRODUCTION

The Ranch property (also known as Alberts Hump) covers six main zones of gold+/-silver mineralization, consisting of the BV, Thesis, JK, Bonanza, Mickey and Ridge. All six mineralized zones exhibit alteration and mineralization characteristic of high-sulphidation epithermal systems, with high-grade gold mineralization hosted within zones of vuggy silica centered on north-northwest trending extensional faults and subsidiary northeast and northwest trending tensional faults. Mineralized zones on the property form the central core of a larger zone of hydrothermal alteration, which covers a 10-km2 area. Past exploration on the property has outlined an estimated 226,775 tonnes grading 10.28 g/t gold in the Bonanza zone and a probable 121,551 tonnes averaging 8.5 g/t gold within the Thesis zone.

Exploration to date for the most part, has focused on delineating high grade mineralized zones within the central feeder structures of the Thesis, JK, Bonanza and Ridge zones. With the exception of limited work in 1997, the potential for lower grade bulk mineable mineralization was not evaluated. The geological setting of mineralization on the Ranch property suggests exceptional potential for the unearthing of zones of semi-conformable, lower-grade, bulk mineable precious metal mineralization adjacent to presently defined high-grade feeder zones.

2.0 LOCATION/ACCESS

The Ranch property is situated in the Toodoggone Area of the Liard & Omineca Mining Divisions. The property lies in North Central British Columbia approximately 300 kilometres north of the town of Smithers, 500 kilometers northwest of Prince George and 925 kilometers north-northwest of Vancouver. {Fig.1}

Vehicle access to the property is by way of a series of paved and gravel roads from Prince George to the Baker Mine, then by the use of ATV-passable decommissioned roads to the property. Driving time from Prince George is approximately nine hours. Access by air can be achieved by several routes, the simplest of which is via a regularly scheduled flight by fixed wing aircraft from Prince George or Smithers to the Kemess airstrip, then by means of helicopter or vehicle to the property.

3.0 CLAIM STATUS

The Toodoggone claims lie within the Swannel ranges of the Omineca Mountains. The property straddles extensive alpine ridges and open, U-section valleys including those of McClair and Moosehorn Creeks. The Ranch Camp, on the western segment of the claims, is situated at an elevation of 1,570 meters.

The Ranch claims are 100% owned by Guardsmen Resources Inc. On June 20, 2006, Christopher James Gold Corp. acquired an exclusive option to purchase Guardsmen Resources Inc.

The property includes 39 Mineral Tenures comprising 13,122 hectares. The property is positioned on NTS map sheet 94/6E at Latitude 57°25 N- Longitude 127°23' W and falls within the Liard/Omineca Mining Division. ~~{Fig.2}~~

4.0 PHYSIOGRAPHY

The area underlain by Toodoggone volcanic rocks is characterized by rounded mountains and ridges. Along the northern periphery the landscape changes abruptly to more rugged jagged peaks of the Takla Volcanic Ranges.

At lower elevations, open sedge meadows and forests of pine, hemlock predominated with alders constrained to steeped slopes or in avalanche scars. Outcrop on the property is sparse and limited predominantly to ridges and valleys. Open stands of spruce and fir along the upper edges of the Toodoggone River gradually thin out to tree line at approximately 1,500 meters. The vegetation on the property consists for the most part of alpine meadow grasses, heather and shrubs

The overriding continental feature that affects the climate of the region is the Arctic air mass, which brings frigid temperatures, clear skies and low humidity in the winter months. Nearly all rainfall occurs amid the months of June and September. Snowfall between November and April accounts for nearly as much precipitation as does rainfall the rest of the year. The relative contribution of snow to total precipitation increases with elevation.

5.0 BRIEF SUMMARY OF OWNERSHIP AND EXPLORATION HISTORY

The following is a summary of exploration and development activities on and around Guardsmen's Ranch property:

- 1973: Surface exploration aimed at the identification of copper-molybdenum porphyry mineralization, was conduced by Newconnex Exploration in and around the current Ranch property
- 1979: Energex Minerals Ltd. ("Energex") optioned a group of four claims (the original AL property) over part of the current Ranch property
- 1980: The AL property, along with the nearby Moose and JD properties were optioned to Texasgulf Canada Ltd. ("Texasgulf"), who completed reconnaissance geochemical surveys, geological mapping and staking of additional ground south of the current Ranch property
- 1981: Texasgulf conducted more extensive grid-controlled geochemistry, along with trenching, VLF-EM/magnetometer orientation surveys; results were positive and additional ground was acquired
- 1982: Texasgulf conducted additional geological mapping, rock and soil geochemistry, IP surveys, trenching, diamond drilling and a legal survey of corner posts. Drilling and trenching focused on the Bonanza and Ridge zones; drilling was considered a technical success in that the target was intercepted, however results were variable, perhaps reflecting nugget effects which are a common occurrence in high-grade precious metal vein systems
- 1983: Texasgulf conducted surface exploration, including trenching, geological mapping and soil sampling, which lead to the discovery of the "Verrenas" zone (a very high-grade portion of the Bonanza zone) and the Thesis II zone.
- 1984: Texasgulf conducted extensive trenching and diamond drilling of the Bonanza, Ridge, Thesis II zones, as well as the newly discovered high-grade Thesis III and BV (Barite Vein) zones. The property was subsequently returned to Energex by Texasgulf
- 1985-1986: Energex conducted a surface program consisting of trenching, geological mapping, geophysical and geophysical surveys, followed by drilling of in excess of 14,500 m, mainly in the Bonanza, BV and Thesis zones
- 1986: Energex constructed a pilot plant with a 5.5 tonnes/day capacity to process high-grade ore from the Thesis zone; a total of 209 tonnes of ore was processed. A geological resource of 1,900,000 tons of 0.16 oz/ton (1,723,490 tonnes of 5.5 grams of gold per tonne; 304,000 contained ounces), including a higher grade portion of 374,680 tons of 0.28 oz/ton (339,872 tonnes of 9.6 grams of gold per tonne; 104,910 contained ounces) (uncut, undiluted, with a 0.12 oz/ton cutoff) was reported for several zones on the AL and Mets properties.
- 1987: Energex drilled 8,600 m in 122 holes, directed towards proving up reserves in the Bonanza and BV zones. Writers of Assessment report 17655 concluded that "an insignificant amount of drilling inadequately tested the depth potential of the Bonanza zone"

• 1988: Energex completed 6,800 m of drilling on the Bonanza West, Thesis, Ridge and low grade Cu-Au Bingo zone. By the end of 1988, a total of 19 surface showings had been discovered on and around what is now Guardsmen's Ranch property
• 1987-1988: Energex carried out a feasibility study and heap leach tests funded by flow through financing and aimed at a self-financed development. Changes in the structure of flow through funds in 1989 precluded Energex's ability to continue to raise money and carry out this plan
• 1990: Cheni Gold optioned the Al property and completed an access road from the Lawyer's deposit to the Bonanza zone. Reserves of 226,775 tonnes of ore with an average grade of 10.28 g/t gold (69,993 contained ounces) was reported for the Bonanza zone (George Cross Newsletter #95, May 16, 1990)
• 1991: Cheni Gold mined high grade from the Bonanza zone and trucked it approximately 40 kilometers to the south to process at the Lawyer's mill. Assessment Report 25707 states that about 10,000 ounces of gold was recovered from 38,000 tons at an average grade of 0.30 oz/ton mined from two small pits, whereas the BC MINFILE reports 60,000 tons of an unspecified grade was mined.
• 1997: a 18.5 line km IP survey was conducted on the AL and Mets properties by new owner AGC Americas Gold Corporation Corp. ("AGC") and joint venture partner Antares Mining and Exploration Co.
• 2001: the AL property had lapsed; a portion of this ground, covering the Bonanza, Thesis, Bingo and JK zones was staked by Guardsmen as the Ranch property

In 2001, Guardsmen had hired Andrew Kaip, MSc., to work one day on mapping and prospecting the Ranch property with Michael Renning, propspector. At this time representative samples were collected from all mineralized zones on the property. A total of nine rock samples were collected for geochemical analysis.

Samples AWK01-067 to -070 were collected from subcrop and float material along the trace of the Thesis zone and comprise a suite of representative styles of mineralization in this zone.

Samples AWK01-067 and -070 represent zones of oxidized vuggy to massive silica, whereas samples AWK01-068 and 069 represent silica+barite+pyrite mineralization.

Samples AWK01-068 and –069 returned values of 30.5 and 11.0 g/t Au, respectively, indicating a strong correlation between silica+barite+sulphide mineralization and gold concentrations in this zone.

Samples AWK01-067 and –070, comprised of vuggy to more massive silica with no visible barite or sulphides, returned 12.8 and 0.7 g/t Au; the inconsistency in gold content may in part be due to the their relative location within the zone and/or proximity to feeder structures within the hydrothermal system, although this has yet to be demonstrated.

Below is a summary of gold and silver grades for samples collected from the Ranch property:

Sample #	Zone	Length (m)	Gold (g/t)	Silver (g/t)
AWK01-067	Thesis	n/a	12.8	8.4
AWK01-068	Thesis	n/a	30.5	10.8
AWK01-069	Thesis	n/a	11.0	8.0
AWK01-070	Thesis	n/a	0.7	0.3
AWK01-071	JK	n/a	2.9	1.4
AWK01-072	Bonanza	n/a	4.2	17.8
AWK01-073	Bonanza	n/a	29.9	47.1
AWK01-074	NW of Bonanza	5	0.5	3.4
AWK01-075	Ridge	5	1.2	47.9

Sample AWK01-071 was collected from strongly hematitic and brecciated silica subcrop along the trace of the JK zone. The sample returned up to 2.9 g/t Au, which is considered strongly anomalous. Breccia textures within the silica range from crackle to milled breccias with rounded fragments within a matrix of silica rock flower. At this location, the JK Zone appears to intersect the newly recognized Mickey Zone.

In addition to anomalous gold concentrations, sample AWK01-071 is anomalous in molybdenum. Sample 7881 collected July 2006 from this exact site ran 1257 g/t Au and 32ppm Mo confirming earlier results by Kaip and Renning. This location, now part of the 'Mickey Zone', was subject to recent news releases (November 1, 2006 and February 15, 2007) by Christopher James Gold "A 780 metre-long north - south trending structure located between the Thesis III and Bonanza Zones. Mineralized outcrop is limited, with preliminary sample results ranging between 0.44 g/t Au and 80.56 g/t Au."

Samples AWK01-072 and -073 were collected from mineralized dump material adjacent to the Bonanza pit, where Cheni Gold mines extracted and milled approximately 38,000 to 60,000 tonnes of ore in 1991. Mineralization comprises vuggy silica with disseminated to locally massive pyrite and fine-grained grey sulphides. Based on this limited sampling, there appears to be a strong relationship between sulphide concentration and gold content.

Sample AWK01-073, which was comprised of dark grey coloured, vuggy silica with >20% disseminated, pyrite and grey sulfides returned 29.9 g/t Au, whereas sample AWK01-072 which was comprised of vuggy silica with significantly less pyrite returned 4.2 g/t Au.

Sample AWK01-074, comprised of oxidized massive to vuggy silica, collected 50 metres to the northwest of the Bonanza zone pit, returned a

considerably lower, albeit anomalous gold value of 0.5 g/t Au over 5 metres.

Sample AWK01-075 was collected from massive to locally vuggy silica outcrop at the southwest end of the Ridge zone and returned 1.2 g/t Au and 47.9 g/t Ag over 5 metres.

5.1 HISTORY & PREVIOUS WORK IN RANCH AREA

Early mining activity consisted of a placer operation run by Charles McClair (or McLaren) in the mid 1920's (Western Securities Ltd., 1935). In 1925 he recovered $17,500 worth of gold (with gold at 1920's and 30's prices) which he took with him to Seattle. In 1927 he and a colleague disappeared in the Toodoggone.

McClair's workings were found by Thomas Thomas in 1930, and staking commenced in 1932 on McLair Creek downstream from the Porphyry Pearl showing and east of the Ranch property. Before his death the following year, he had involved a syndicate in Edmonton in the claims, and testing. In 1934 he showed a recovery of $80 in gold from 35 cubic yards of gravel. By 1934 the Two Brothers Valley Gold Mines company was formed to start serious exploration. The company was named after the Two Brothers Valley that is now known as the Toodoggone Valley. The company published a prospectus in 1935 that summarizes this period of history and its results from drilling and sluicing. They used early float planes and a small caterpillar tractor to access and do a great deal of the heavy work.

The publication contained numerous up-beat quotes and testimonials of a promotional nature by contractor J. A. Broley and mine engineer Sam Hancock. Broley estimated a total of 65,000,000 cubic yards of gravel to be present. Various tests by Broley showed a recovery of $1.10 to $2.62 per cubic yard of gravel, and drilling tests done by Hancock allegedly varied from $0.58 to $11.00 per cubic yard. These tests were primarily conducted at the junction of McClair Creek and the Toodoggone River.

The area was mapped by C. S. Lord of the Geological Survey of Canada (GSC) in 1948, and many of the geologic and stratigraphic names were applied at that time. During a hiatus from mining activity in the Toodoggone region over the period from 1935 to 1967, Kennco and Cominco explored the well-known oxide gossans and strong alteration zones in the area and carried out regional geochemical surveys in the quest of porphyry copper deposits.

On the Moose Property, stream silt anomalies in Moosehorn Creek were staked by Sumac in 1971 and geological mapping, geochemistry,

and IP/Resistivity surveying were carried out. Sumac drilled four diamond drill holes on the Porphyry Pearl in 1974 (MM-1, MM-2, MM-3, and MM-6) and intersected anomalous gold and copper values. Hole MM-2 intersected 25 metres of 0.047 oz/t gold and 0.085% copper from 86.0 to 111.5 metres. The deeper sections of the hole associated with the mineralization were described as having intersected a pyritic and base metal anomalous intrusive unit.

In 1978 the Al and Moose Claims were staked by Petra-Gem Exploration Ltd. and optioned to Energex Minerals Ltd. the subsequent year. Energex began prospecting and trenching in 1979 and in 1980 the property was in turn optioned to Texasgulf Canada Ltd and after that to Kidd Creek Mines Ltd. Texasgulf drilled two holes in the Porphyry Pearl and accomplished a comprehensive program of geological mapping, lithogeochemistry and geophysical surveys (IP & EM) over the area covered by the Al, Moose, and JD claims (all immediately east of the Ranch).

From 1982 to 1988 Energex conducted broad geological mapping, lithogeochemistry, diamond drilling, and geophysics on the AL claims – an area now located within the south central portion of the Ranch property. In 1987 a small 6 ton per day pilot mill had been constructed to process ore from the Tesis III for both promotional purposes and perhaps some degree of metallurgical studies. A few gold rings were fabricated and handed out to investors upon visiting the property.

In 1985 Energex drilled eighteen holes on the Moose property. Their primary target at the Moose was a base metal zone while two holes were targeted at the Porphyry Pearl prospect. Energex continued to work on the high-grade gold zones on the Al claims (Ranch), but no additional work was done on the Moose until Golden Rule Resources Ltd. of Calgary optioned the property in 1991. Golden Rule drilled seven holes in the area surrounding the Porphyry Pearl prospect. Golden Rule did not follow up with this program and did not continue the option. The property was then returned to Energex.

While Golden Rule was having its opportunity with the Moose property, Cheni had purchased the Al claims from Energex in 1989 and constructed a 25 km access road in 1990. In 1991 approximately 35,000 tonnes was mined from the BV zone while 3,000 tonnes was gathered from each of the Thesis III and Bonanza zones. The ore was processed at the Cheni mill. Metallurgical problems with the copper bearing ore from the Ghost Pit at the Bonanza Zone had severely interfered with the gold recovery at the Lawyers Mill. About the time Cheni had shut down the Lawyers Mine in 1992, litigation against the firm that designed the under-supplied 500 ton per day diesel powered mill had commenced.

The leading known deposit in the Toodoggone is the Kemess, which is located about 55 Km southwest of AL, and owned by El Condor Resources Ltd. The Kemess North and Kemess South deposits represent large tonnage and very low grade gold and copper mineralization in a porphyry copper-gold system. Published reserves from 1992 for the Kemess North stand at 75.4 million tonnes at a grade of 0.51 g/t gold and 0.21% copper. The Kemess South is estimated to have 185 million tons at a grade of 0.65 g/t gold and 0.23% copper.

In July of 1993 Kilborne Engineering completed a feasibility study of the project which called for a 40,000 tpd operation. Pegasus Gold Inc. undertook a comprehensive due diligence study of the project which confirmed the Kilborne results, but they terminated their interest in acquiring the deposit in May, 1994.

The delineation of the Kemess deposit has resulted in a renewed interest in the Toodoggone District in the exploration for the copper-gold porphyry systems which probably represent the roots for the epithermal precious metal deposits.

The Porphyry Pearl prospects on the Moose claims have been regarded as a potential for this type of mineralization. This, along with the extensive alteration and gold mineralization on the adjacent Al claims, provided the drive for this present compilation and evaluation study.

The surficial geology at AL suggests the likelihood of a blind porphyry copper gold system as well as a potential for the discovery of blind high-grade bonanza precious metal deposits which will be structurally controlled. The Porphyry Pearl offers comparable potential for a buried porphyry system, and/or for structurally controlled mineralization such as was mined at Lawyers.

5.2 2006 WORK PROGRAM

Shallow drilling on the Ranch property in the 1980s defined several zones of high-grade mineralization, with typical intersections of 5 metres to 10 metres of more than 20 g/t gold. Only the near-surface (less than 50 metres) oxide mineralization was tested systematically.

The Company's objectives for 2006 were to drill test previously-reported, near-surface, high-grade mineralization in the Thesis III Zone; demonstrate the likely continuation of this mineralization to depth; and explore for extensions and additions to the previously-tested zones of mineralization by surface mapping and sampling.

5.2A DRILLING

The 2006 drilling program focused on the Thesis III zone, a 175 metres by 100 metres body of mineralization, defined by shallow historical drilling, containing a series of elongate bodies of bonanza-grade mineralization that plunge moderately to the southeast. These bonanza-grade bodies are interpreted as dilated zones developed within a one kilometre-long, northwest–southeast trending structure.

Holes A06-01, A06-02 A06-03 and A06-05 intersected one of the bonanza-grade bodies that comprise the Thesis III zone, confirming the continuity of the high-grade mineralization over a strike and down-plunge distance of approximately 75 metres. Drill holes A06-04 and A06-06 are understood to have drilled below the same body.

Systematic and closely-spaced drilling is required to define the extent of all the bonanza-grade bodies within Thesis III, and determine the overall grade. Similar high-grade mineralization occurs elsewhere within the system, at the Thesis II, Bonanza, and BV zones.

Drill results from the 2006 program are summarized below.

Hole No.	From (metres)	To (metres)	Interval (metres)	Gold (g/t)	Interval (feet)	Gold (oz/ton)
A06-01	24.0	49.0	25.0	8.00	82.0	0.23

5.2B SURFACE SAMPLING

Surface mapping and sampling in the 2006 work program delineated two previously-untested mineralized zones and an additional structure as shown in {Fig.5}. (SEE ALSO APPENDIX C)

BV South Zone: - A zone believed to be a southern extension of the BV approximately 1000 metres to the southeast of the BV Pit. Sampling in old trenches southeast of the past-producing BV pit has extended this altered and mineralized structure by an additional 600 metres. Twenty-two systematic panel chip samples averaged 1.40 g/t gold, with an assay of 68.52 g/t gold on a single sample. This area will be mapped in detail in 2007.

Mickey Structure: -

The Mickey zone is a previously untested zone of epithermal veining composed of numerous outcrops of vuggy silica-iron oxide breccia, located between the Thesis and Bonanza structures at the Ranch project. It was discovered by a succession of prospecting in 2001 along with geological expertise and large-scale sampling in 2006. Surface samples of mostly subcrop and large angular blocks of float averaged 1.36 g/t over 111 samples. The zone includes highest assays of 80.56 g/t Au and 13.82 g/t Au.

Bonanza West Zone: - an outcrop of mineralized andesite, surrounded by glacial till, approximately 500 metres to the northwest of the Bonanza Pit. The outcrop is interpreted as being on strike of the Bonanza structure, indicating that the known mineralization could extend further to the northwest than previously believed. The mineralized outcrop assayed 0.919 g/t Au.

In order to help build a reliable database, surface sampling had taken place in other zones of known mineralization on the Ranch property:

Bingo: - A zone that is very likely the NNW extension of the Thesis II and Thesis III Zones. Many of the old trenches remain open and mineralized bedrock was available for sampling. Four samples were collected here with results ranging from 0.42 g/t Au to 2.39 g/t Au.

Alberts Hump SE: -Lower in elevation than most of the extensive quartz alunite zone to the north, this area area yielded anomalous gold values up to 0.688 g/t Au over six samples.

Bonanza: - As this area had been heavily disturbed, bedrock in mineralized areas was difficult to locate. However with considerable effort, 26 rock chip samples were collected after hand trenching through packed, broken rock through to undisturbed bedrock. Some of the better results returned 10.44 g/t Au, 5.66 g/t Au and 4.05 g/t Au.

Ridge: - The Ridge structure is a silicified zone that extends from an area about 300 metres south of the Ghost Pit (Bonanza Zone) to outcrop significantly at two locations to the northeast; the first outcrop is encountered about 550 metres and the second at about 900 metres on trend, from the Bonanza Zone. Eight samples were collected with values up to 0.74 g/t and 0.96 g/t Au.

Ring: - In the southernmost trench at this location, at an elevation of about 1460 metres, free gold was observed in a loose sample of silica-altered andesite. Subsequent to this find, rock chop samples were collected from this location as well as several other trenches in the area. A high of 0.45 g/t gold was returned. However, the fact that free gold was identified indicates that only large, bulk samples from this area will provide an accurate result. It is believed that free gold had not previously been reported to from this area.

5.2C QUALITY ASSURANCE & QUALITY CONTROL

The 2006 exploration program was conducted under the supervision of Cam Graham, M.Eng., P.Eng., a qualified person under National Instrument 43-101.

The drill core was sawn in half, with one half sent for analysis and the other stored for future reference.

Sampling and assaying procedures were subject to a rigorous QA/QC program, which included insertion of standards and blanks for each batch of samples.

All samples were shipped in sealed packages to Acme Analytical Labs in Vancouver for preparation and analyses.

Mineralized intervals reported are down-hole lengths and may not represent the true width of mineralization.

5.2D SAMPLE PREPARATION & ANALYSIS

Samples were submitted to Acme Analytical Laboratories Ltd. in Vancouver, BC for analysis. Several geochemical analysis's were performed; they included but were not limited to:

Group 1DX- .50gm sample is leached with 3ml 2-2-2 of HCL-HNO3-H2O at 95° C for one hour, diluted to 10ml then analyzed by ICP-ES, an instrument capable of determining the concentrations of elements simultaneously by measuring the intensity of light given off by the samples. This process determines the presence of 36 elements including Mo, Cu, Pb, Zn, Ag, Ni, Co, Mn, Fe, As, U, Au, Th, Sr, Cd, Sb, Bi, V, Ca, P, La, Cr, Mg, Ti, B, Al, Na, K, W, Hg, Sc, Tl, S, Ga, and Se.

Group 3B- Fire Geochem Au- 50gm sample fusion, dore dissolved in aqua- regia, ICP analysis. Upper limits= 10ppm. High grade gold assay recommend for 30gm analysis> 10ppm and 50gm> 5ppm.

Group 6- a precious metals analysis was also performed for Au by fire geochem where a 50gm sample is mixed with flux, lowering the melting point. The mixture is then fused at 1050° C to recover a dore bead. The dore is then dissolved in Aqua-Regia to digest the metals. The precious metals are separated with nitric acid then analyzed by ICP.

5.3 DISCUSSION

The assay results for the first three drill holes at the Thesis III Zone, confirm the presence of bonanza-grade high-sulfidation epithermal mineralization at the Ranch Project that was previously demonstrated by extensive shallow drilling in the 1980s. The 2006 drilling indicates that the Thesis III Zone hosts a mineralized structure of at least 10 metres in true width, with a likely average grade of more than 5 grams per tonne ("g/t") gold (0.14 ounces per ton ("oz/ton")), containing a high-grade core of several metres of more than 40 g/t gold (1.16 oz/ton).

Based on the 2006 results to date, and a compilation of previous drill data from the 1980s, we feel that the Ranch Project, has the potential to develop into a high-grade, multi-million ounce deposit, similar to El Indio, in Chile. We look forward to starting a major drill program at the Ranch Project in 2007, to test the along-strike and down-dip potential of known zones of high-grade mineralization, while exploring for additional high-grade within the four mineralized structures that have been identified to date.

The Company plans to definition drill all five of these zones in 2007.

The planned 2007 drill program will entail approximately 10,000

metres of combined reverse circulation and diamond drilling in approximately 60 holes.

6.0 EXPLORATION POTENTIAL

In the early 1990's, exploration in northern British Columbia had shifted away from the Toodoggone due to the closure of the Cheni mine and new developments near Iskut River, Sulphurets and Eskay Creek. Current interest in the area has occurred because of the recent increase in the price of gold and the success of Northgate's Kemess Mine and activity by other juniors in the vicinity.

Most of the recognized showings were found from 1984-1987. These discoveries were made by prospecting followed up by diamond drilling. These discoveries tended to be on bare ridges or uplands where overburden was slim. The geophysics available at the time was unable to successfully locate mineralization. Exploration in many areas was principally based on backhoe trenching followed up by diamond drilling. Very few new discoveries have been since 1987.

The deposits of the area clearly are associated with silicification and marked by the presence of disseminated sulfides. Also present are broader scale alteration zoning and acid-leach caps which on surface may appear to be barren of gold. Given the strong structural control on mineralization, regional and property level data must be integrated. A large amount of valuable exploration data exists for the Ranch and as a long term goal, Guardsmen and Christopher James are compiling and re-evaluating to prioritize future exploration as time and budgets permit. Past exploration seems to have focused primarily on shallow high grade targets.

The Ranch property still has significant mineral potential even after mining on several zones some of the surface high-grade portions.

Exploration potential remains at Bonanza, Thesis, BV, Ridge, and many other less development mineralized zones. The presence of large barren acid-leach caps requires careful examination since probable mineralization may be concealed beneath them. Mineralization appears to be surrounded by quartz sericite alteration and silicification.

The deposits of the area are related to silicification and marked by the presence of disseminated sulfides, which makes them suitable for detection by modern geophysical surveys. Only recently has parts of the area been subjected to state of the art exploration. In the case of the airborne survey (Hawkins, 1998b) flown by AGC / ANZ, no follow-up has been conducted.

High quality data on high-sulphidation epithermal gold mineralization, similar to that found at the Ranch property, has been gathered mostly in

South America over the last 10 years. As a result, these systems are now better understood than they were in the 1980's and 1990's.

Mineralization at the Bonanza Zone may be a ladder vein system within a structural deformation zone defined by boundary faults and cross cutting structures along significant structural trends. Mineralization hosted within this structural trend, including the Ghost ore shoot, are only one minor segment of this deformation zone. Intersecting structures likely control the location of the other prospective, deep seated plumbing systems. In addition to structural controls, there appears to be high mineral potential in connection with acid-leached dacites forming broad, vuggy silica beds.

7.0 REGIONAL GEOLOGY

The Toodoggone River area encompasses a 1,500 km2 area underlain by strata of the Stikine terrane {Fig 6}. The Stikine terrane is comprised of Paleozoic to Mesozoic island arc assemblages and overlying Mesozoic sedimentary sequences within the Intermontaine Belt of the Canadian Cordillera.

The oldest rocks uncovered within the Toodoggone consist of crystalline limestone of the Devonian Asitka Group, which is unconformably overlain by mafic volcanics of the Upper Takla Group. Takla Group volcanics are in turn overlain by bimodal volcanic and sedimentary strata of the Lower Jurassic Toodoggone Formation (Hazelton Group).

A distinctive lithologic volcanic assemblage of early Jurassic age was first recognized in 1971, and unofficially called the "Toodoggone volcanics". This is a subaerial pyroclastic assemblage of predominantly andesitic composition (Panteleyev, 1983), which unconformably overlies, or is in fault contact with older rocks. Toodoggone volcanic rocks are contained in a 100 x 25 kilometer northwest-trending belt centered on the Toodoggone River. Several key stratigraphic subdivisions of Toodoggone volcanics have been identified. These include a basal, predominantly andesitic flow and minor tuff unit, a middle unit of principally ashfall pyroclastics and flow rocks, and an upper, distinctive "grey dacite" ash flow unit. Radiometric ages signify Toodoggone volcanic rocks were deposited over a 20-million-year span, beginning in the earliest Jurassic.

Toodoggone volcanics and older layered rocks are cut by Omineca granitic rocks of early Jurassic age and by subvolcanic intrusions correlated to Toodoggone volcanism.

The Formation consists of six lithostratigraphic members, comprising subaerial, high potassium, calc-alkaline latite and dacite volcanic strata

emplaced alongside a north-northwest trending, elongate volcano-tectonic depression (Daikow et. al, 1993)

Clastic sedimentary rocks of the Cretaceous - Tertiary Sustut Group overlie older layered rocks near the Stikine River and form the southwestern exposed margin of the Toodoggone volcanic belt. Mineralization within Toodoggone volcanics and/or associated with Toodoggone volcanism is dominated by epithermal precious metal deposits. These include fissure veins, quartz stockworks, breccias, and replacement silicification zones with associated quartz-adularia or acid-sulfate alteration suites. Principal economic minerals consist of native gold and silver, electrum, and acanthite with associated pyrite, chalcopyrite, copper-arsenic sulfosalts, sphalerite, and galena.

The Baker Mine is a fissure vein system developed in late Triassic Takla Group basic volcanic rocks, but mineralized quartz veins are spatially related to dykes believed to be feeders for nearby Toodoggone volcanic rocks. The principal quartz vein, with a 200 meter strike length and a width of 3 meters, had an indicated 90,000 tonnes (to a depth of 40 meters) grading 31 g/t gold and silver. Recovered grades were poorer than anticipated due to initial recovery problems and greater than expected dilution during mining.

The Lawyers deposits, host gold-silver mineralization in banded chalcedony-quartz stockwork veins and breccia zones developed in Toodoggone volcanic rocks. Present reserves in three zones stand at 1,762,000 tonnes grading 6.79 g/t gold and 243 g/t silver.

Numerous additional epithermal gold-silver deposits in the area are hosted by lower and middle units of the Toodoggone volcanic sequence. These include the Shas, Saunders, Moosehorn, Mets, Metsantan, AL, JD and Golden Lion prospects. Most of these are on or adjacent to two regional northwest-striking fault zones; the Baker-Lawyers-AL structure on the west and the McClair-Saunders Fault system on the east (Figure 2).

Soil rock and stream sediment geochemistry have proven to be useful tools in the search for epithermal precious metal deposits in the area. Gold and silver give diagnostic signatures but analyses for copper, lead and zinc are also positive.

Studies of alteration mineral suites have helped to delineate precious metals bearing zones on both the AL and JD properties.

7.1 PROPERTY GEOLOGY

The Ranch claims are underlain by a sequence of subaerial to shallow water volcanic rocks, including tuffs, intrusives, and reworked

volcanoclastic equivalents. The rocks are andesitic, dacitic, latitic, and are invariably porphyritic.

Apart from silicified areas, most outcrop weathers relatively quickly. Lithological contacts are rarely observed. Many units appear to grade into one another and the compositional differences between most units are minimal. Local unconformities are also fairly common between and within units. The gradational nature of some units is characterized by subtle changes in a minor mineral constituent (e.g., quartz, K-feldspar), changing ratios of the dominant mafic phenocryst abundances (e.g., hornblende, biotite), differing degrees of apparent diagenetic hematization, and intercalations of tuffs and sediments. Equally common are fault contacts amid units. Many units have reworked equivalents, where tuffaceous and block material have been moved or washed by local alluvial processes such as debris slides/flows, sheet wash, stream channeling, and other erosive activities present in a dynamic, subaerial volcanic environment.

Sub horizontal stratigraphy and numerous normal and transverse faults complicate the geological understanding. Dyke rocks are compositionally similar to the volcanic units and may represent feeder systems. Felsic intrusions, encountered in several drill holes, are seldom exposed at the surface; these rocks may be genetically linked to the late-stage ore-forming fluids.

Structural interpretation is limited by the poor rock exposure. Where bedrock is exposed, the volcanic units are generally flat lying or dip gently to the west. No folding has been observed. Locally steeper dips (although usually less than 30*) are a probable result of the original paleotopography and/or rotations in a fault plane.

Major fault and fracture patterns control most alteration. The AL claims are near the northwestern end of a linear trend of alteration (and associated mineralization) centers. This northwest trend is reflected in the orientations of the majority lineaments on the property. These northwest lineaments commonly control drainage, and vegetation patterns. A second northeast-southwest trend appears to control alteration zones.

The geometry and chronology of fault movements are poorly understood, and reconstructions are tenuous. Geophysics, trenching and drilling indicate that there are severe structural complexities associated with alteration zones. Block fault dip-slip movement is suggested where alteration is abruptly truncated, and strike-slip movement is common along many linear silicified zones. Slickensides and oriented tectonic breccias are locally present.

7.2 STRUCTURE

The prospect is situated within a Mesozoic volcanic arc assemblage which lies along the eastern margin of the Intermontaine Belt, a northwest-trending belt of Paleozoic to Tertiary sediments, volcanics and intrusions bounded to the east by the Omineca Belt and to the west and southwest by the Sustut and Bowser basins.

Permian Asitka Group crystalline limestones are the oldest rocks exposed in the region. They are commonly in thrust contact with Upper Triassic Takla Group andesite flows and pyroclastic rocks. Takla volcanics have been intruded by the granodiorite to quartz monzonite Black Lake Suite of Early Jurassic age and are in turn unconformably overlain by or faulted against Lower Jurassic calcalkaline volcanics of the Toodoggone Formation, Hazelton Group.

The dominant structures in the area are steeply dipping faults which define a prominent regional northwest structural fabric trending 140 to 170 degrees. In turn, high angle, northeast-striking faults (approximately 060 degrees) appear to truncate and displace northwest-striking faults. Collectively these faults form a boundary for variably rotated and tilted blocks underlain by monoclinal strata.

The Adoogacho and Metsantan members of the Toodoggone Formation underlie the AL property. The Adoogacho Member consists of trachydacite ash-flow tuff with lenses of lapilli tuff, rare marlstone and conglomerate near the base. The Metsantan Member is composed mainly of trachyandesite (latite) flows with lenses of lapilli tuff, and lahar; minor volcanic sandstone and conglomerate Bulletin 86). The Metsantan Member, in part, directly overlies the basal Adoogacho Member and is also in fault contact with it.

7.3 MINERALIZATION & ALTERATION

Alteration at the Ranch property is commonly of the acid-sulfate type, characterized by prevalent argillization and silicification of andesite-dacite host rocks. Significant alteration mineral assemblages include alunite-quartz, hematite-illite-quartz, dictate-quartz, quartz-ban te, and quartz-pyrite, working inwards and downwards in a typical alteration system.

The entire gold mineralization on the Ranch prospect is hosted by silica-sulfate-sulfide bodies flanked by argillic alteration, controlled by moderately to steeply dipping fault zones with northwest to northeast orientations.

The dominant assemblage adjacent to auriferous zones is dickite-quartz (A2); gold is commonly present only in geochemically anomalous amounts in this alteration type. Economic gold grades are almost invariably encountered only in quartz-barite-pyrite and quartz-pyrite alteration phases.

Exploration for gold at the Ranch is essentially a search for alteration phases composed of straight silica, preferably with porosity and sulfate or sulfide minerals. Bodies of such alteration are then tested by channel sampling and diamond drilling to determine gold content. In exploration to date, the presence of clay minerals, and/or the absence of porosity or sulfate and sulfide minerals, radically reduces the likelihood of economically significant gold mineralization in most cases.

Economic gold mineralization ("ore") is hosted by quartz-barite-pyrite-sericite in the BV deposit, by quartz-barite-pyrite-(chalcopyrite, galena, spalerite) in the Thesis III deposit, and by quartz-barite and quartz-pyrite-chalcopyrite-bornite-(barite) in the Bonanza. Mineral assemblages in other zones are essentially alike, with quartz-hematite-pyrite important at the Thesis II and Ridge zones.

7.4 DISCUSSION

Three north trending fault systems, with little evidence of movement, transect a gently, south to southwest dipping sequence of dacitic ash flows and interspersed volcanogenic epiclastic beds of the Adoogacho Member.

The most easterly known structure, the Bonanza fault, strikes north and is steeply to vertically dipping, and appears to extend for over 5 kilometres from Moyez Creek valley in the north to Metsantan Mountain to the south. The Bonanza occurrence lies on this fault and the nearby Ridge occurrence lies on a northeastern splay of the main structure. The Thesis fault crosses the area on a northwest trend and lies to the west of the Bonanza fault. It has been traced for over three kilometres. A third southeast-trending structure, the BV fault, lies 800 metres to the south of the Thesis fault. The BV fault is more than 1600 metres long. They are characterized by strong, often complete argillization and silicification of the hostrocks.

Alteration zones, some of great areal extent (25-75 hectares), occur in large numbers on the property. The alteration zones are apparently structurally controlled, mainly by the Bonanza, Thesis and BV faults. Alteration zones typically contain intensely silicified cores surrounded by wide envelopes of argillic flooding. Subtypes of alteration, including silicification with pyrite, argillization with hematite/goethite, and silicification with hematite/goethite, have also been recognized. Drilling indicates that

alteration intensities around the Bonanza structure are specific to individual volcanic horizons which may be flow tops or unconformable beds with differing composition or textural characteristics. Native gold with minor silver occurs within the silicified cores of many of the zones. This mineralization is almost always accompanied by barite and 2 to 7 per cent copper-rich sulphide.

7.4A BONANZA

The Bonanza developed prospect is located 3.75 kilometres east from the summit of Alberts Hump, south of Abesti Creek, and 4.35 kilometres southwest of Tuff Peak.

The Bonanza structure, which is steeply to vertically dipping, cuts through gently southwest dipping volcanic rocks at approximate right angles to their strike. The structure contains tensional veining and stockwork (30 to 200 centimetres) and transgresses the entire Bonanza area seemingly without any interruption by any faults. It trends northwest and cuts across the north Bonanza area. Branching fault splays striking northwest and northeast from the main Bonanza structure are evidenced by epithermal rock alteration patterns which are typically elongate, parallel to the structures. Crosscutting faults give this structure a sense of right-lateral displacement along strike and create discontinuities.

The Bonanza occurrence is composed of at least three main mineralized zones forming a north-trending lineament of gossans, silicified rocks hosted in the Bonanza structure and extending from the Bonanza occurrence to the Mets occurrence, a distance of over 5 kilometres. Hostrocks are andesitic-dacitic ash-flow tuff and is locally intruded by post-ore porphyritic rhyodacite dikes. These dikes pre-date most of the crossfaulting and are shuffled about along numerous lines of weakness. In some cases the dikes cut through and obliterate all evidence of mineralization except for xenoliths caught up inside the dike walls. The dyke rocks are propylitically altered throughout and generally show evidence of shearing at contacts. The average width of the main silicified orebody is 10 metres.

Surface mineralization along the Bonanza structure occurs within irregular elongate zones separated by less altered to fresh unmineralized rocks. Associated veining is composed of quartz- (pyrite-chalcopyrite-galena-sphalerite), barite-quartz and barite assemblages carrying gold-silver grades over narrow widths. Mineralization in the high grade Verrenass zone consists of barite-hosted native gold, electrum and acanthite deposited in the acid-leached core (alunite) of an intensely altered north-northwest trending structure located at the northern end of

the main Bonanza structure. Fine to very fine grained gold mineralization is hosted primarily in coarse barite crystals (vugs), veins and stockworks.

Late stage tetrahedrite-tennantite occurs sporadically and is locally associated with gold mineralization. Quartz-dickite alteration is dominant adjacent to the mineralization and is enclosed by a quartz-illite-hematite assemblage. Results from the 1984 drill program on the Verrenass zone indicate a rapid vertical change from silicified and leached rocks with abundant barite and anomalous gold at or near the surface to a pyritic system at depth . The apparent feeder structure dips easterly to subvertically. The surface mineralization has less than 15 metres thickness

The originally linear sheet-like Ghost orebody (subsurface Bonanza structure) is comprised of a series of individual mineralized blocks resultant from the net effect of the complicated structural pattern. The Ghost and Verrenass zones merge towards the south.

The Bonanza occurrence has been tested by drilling (greater than 100 drillholes) over 457 metres and trenching over 610 metres strike length. Numerous high grade, near-surface anomalous gold zones were intersected at the convergence of the Bonanza structure with the Ghost system. The Bonanza West zone is parallel to the Bonanza Main structure and is 24.3 metres wide with a 228.6 metres strike length. A diamond-drill hole intersection across 1.98 metres assayed 14.74 grams per tonne gold. A best assay from a diamond-drill hole intersection in the Bonanza South Extension zone analysed 9.94 grams per tonne gold across 1.67 metres.

Geochronological studies of marginal illite-bearing alteration from the Bonanza deposit (Verrenass zone) has resulted in a potassium-argon age determination of 171 +/- 6 Ma and is considered as the minimum age of alteration and mineralization.

Subsequent geochronological studies of sericite alteration, taken from 73.8 metres depth in drillhole 88-33 from the same zone, has resulted in an argon-argon age range of 196.4 +/- 4.7 Ma to 195.9 +/- 5.9. While the plateau age of 207.7 +/- 2.7 Ma is inconsistent with the known age of the hostrocks, the two step ages are considered more reliable than the previous potassium-argon age.

7.4B THESIS II/III

The Thesis II/III occurrence is located 2.60 kilometres east-southeast of the summit of Alberts Hump, south of Abesti Creek, and 800 metres south of the Bonanza occurrence 700 metres due north of the AL BV occurrence.

The Thesis II/III occurrence is hosted by a fault controlled, complex alteration system comprised of at least three distinct "core" zones of

intense silicification separated by and surrounded by haloes of intense argillic alteration developed in hornblende feldspar porphyritic andesite tuff.

The Thesis III alteration system has been explored along 300 metres of strike and is at least 100 metres wide near its centre point. A northwest trending system of faults forming a zone over 100 metres wide in areas of apparent dilation, appears to control both the Thesis III system and the Thesis II system centered 350 metres to the southeast. Other zones to the northwest including the Bingo and BBX zones of the BBX-Bingo occurrence are thought to be genetically related to this fault system.

The central silicified A zone is flanked by a roughly linear B zone to the southwest and a roughly circular to elliptical C zone to the northeast. The A zone consists of 7 to 30 metres of argillic alteration (less than 5 per cent limonite along fractures) flanking an intensely fractured, locally intensely brecciated, (cemented with quartz-barite) intensely silicified zone. The central area is quite massive with little interbedded argillized material; averaging 20 metres true thickness and has been drilled to 50 metres depth. All three zones, at surface, narrow rapidly to linear zones to the northwest. The internal structure is very complex; faulting along north, northeast and southeast trends is evident within the A zone. Slickensides within the core indicate left-lateral movement, often with a gentle south to southwest plunge. The lack of large offsets in the flanking B zone suggest that the A zone was the focus of most post-ore structural failure and the apparent concentration of higher gold values, brecciation and veining also suggests that pre and syn-ore hydrothermal activity was confined to this section. The structure of the poorly exposed C zone is also highly complex. Along strike to the northwest and southeast, the thick central silicified mass appears to split at depth into 2 or 3 silicified bands 5 to 7 metres thick, separated by clay or clay-silica bands of roughly equivalent thickness.

Moderate to high grade native gold mineralization is directly associated with barite and is hosted by intensely silicified, brecciated and microfractured rock with a characteristic porous, vuggy texture; the result of corroded, clay-altered plagioclase phenocrysts. The vugs are commonly partially filled or lined with barite crystals. Some coarse gold, up to 2 millimetres in diameter, occur as dendritic or mossy crystals growing on barite or lying on quartz-barite crystal boundaries. Most of the gold, however, is in the order of 10-100 microns in diameter. Surface mineralogy is dominantly comprised of quartz and barite. Trace amounts of pyrite, hematite or limonite are also present.

Indicated ore reserves (all categories, undiluted) are 121,551 tonnes grading 8.50 grams per tonne gold. A 5.5-tonne pilot mill from the Thesis III zone resulted in 71,694 grams of gold. In 1991 Cheni Gold Mines Inc. mined approximately 60,000 tonnes from the Al deposit and milled it at Lawyers

The Thesis II occurrence lies to the southeast of the Thesis III and is considered to be controlled by the same structure. On surface, the AL Thesis II occurrence consists of a central core of quartz-limonite-hematite breccia which splays to the northwest. The silicified core is flanked by intensely argillized porphyritic andesite. The exposed zone is 150 metres long and has a maximum width of 50 metres. Barite is present but not abundant at surface and in drill core. Higher gold values are associated with hematite and limonite fracture fillings and breccia matrix. The silicified, brecciated core of the occurrence has a vertical to steep southwest dip with a southeast trend. Trace chalcopyrite and galena have been observed. Gold grades and mineralized widths in drill holes steadily increase to the southeast; the southeastern most drill hole intersected 10.1 metres (true width) grading 4.38 grams per tonne gold

7.4C BV

The BV developed prospect is located 2.90 kilometres southeast of the summit of Alberts Hump, south of Abesti Creek, and 2.3 kilometres southwest of the Bonanza occurrence. Smithers is located 300 kilometres to the south. The occurrence lies within the Omineca-Cassiar Mountains in the west-central portion of the Toodoggone gold camp.

The prospect has been exposed by drilling and trenching over some 600 metres along a northwesterly strike. The west limb of the zone trends west-northwest and is hinged to an eastern limb that rends northwest. The zone is up to 15 metres wide and appears to contain several sub-parallel gold-bearing lenses which strike west-northwest and dip to the north. The structure hosting the BV prospect remains open at both ends. The average width of the mineralized surface exposure is roughly 10 metres, along a 170 metre long section of exposed vein structure. Drilling indicates mineralization persists to at least 50 metres depth. On surface the vein structure branches or is faulted into at least two semi-parallel mineralized zones within a repetitious barite-quartz sequence.

The BV occurrence is barite-hosted, but differs from the Thesis III and the Bonanza in that high grade mineralization occurs as narrow, discrete barite-quartz-pyrite veins in a silicified andesite flow, with a more continuous strike length. The BV prospect does not display the lensoidal, advanced argillic alteration, acid-leaching features and porous silicified zones characteristic of an upper level epithermal system, characteristic of other acid-sulphate associated deposits in the area. The mineralization and alteration is more confined and directed by the fault system hosting the occurrence. The veins are commonly brecciated and sheared at depth, and are associated with strong sericitic alteration. The occurrence of minor

galena and chalcopyrite, and less pyrite associated with gold mineralization, the higher than average silver content for the area and the presence of chalcedonic quartz veins suggest deeper epithermal emplacement of the BV mineralization.

7.4D MICKEY

Systematic panel chip samples were taken on all outcrops along a structural corridor with a strike length of 1,500 metres and a width of 50 metres to 150 metres. Potential exists for this newly recognized corridor to extend further south a further 1,000 metres if it is proven that it does include the Thesis II and BV South Zones.

High-grade samples in the Mickey zone include 80.56 grams per tonne (g/t) and 9.7 g/t gold. Of a total of 111 samples taken, 49 samples assayed greater than one gram per tonne gold. The 111 samples averaged 1.36 g/t gold.

The north-trending zone is open on the north, where eight samples averaged 0.95 g/t gold. To the south, strong alteration and gold mineralization are on trend with the Thesis II zone, 150 metres to the south, as well as the BV South zone a further 1000 metres further in the same direction. Free gold in a single sample was noted at the Ring zone however, further sampling yielded results up to 68,520 g/t gold. Conceivably, this gold-bearing structure could have a total strike length of 2.5km. Previous drilling at Thesis II included two holes with near-surface intercepts of 16.1 metres at 3.43 g/t gold, including 3.5 metres of 9.69 g/t gold, and 17.3 metres of 3.86 g/t gold, including 3.6 metres of 13.89 g/t gold.

The Mickey zone is considered to contain a target for high-grade gold mineralization in either a single tabular oreshoot at least 1000 metres long or a series of plunging oreshoots along a structural corridor. Certainly additional potential exists here for the zone to develop into a larger, lower-grade bulk-minable gold deposit.

8.0 CONCLUSIONS & RECOMMENDATIONS

The Mickey Structure is a gold-bearing alteration zone that strikes for at least 850 m, and averages 1.47 g/t Au in 90 surface samples. Along this structure are scattered outcrops and subcrops of quartz-iron oxide crackle breccias, vuggy silica-iron oxide, and minor silica-clay+alunite rocks mostly covered by Quaternary deposits. These rocks are oxidized equivalents of primary gold-bearing quartz-pyrite crackle breccias and vuggy silica-pyrite encountered in

drilling on other high grade deposits in the immediate area (e.g., Thesis HI and Bonanza). The Structure is an excellent target for economic gold mineralization and should be further explored on a high-priority basis. Geochemical signatures (Au-Sb-As-Mo) along with air photo structural interpretation seem to indicate that the zone could extend to the BV South area. If these possible extensions are included, it has a strike of more than 2500 metres. So far within 1300m the zone averages 1.36 g/t Au in 111 samples.

The Alberts Hump area is underlain by Jurassic andesite volcanic rocks and volcanoclastic rocks, intruded by sub volcanic andesite porphyry and later porphyry dikes. Alteration and mineralization occur as silica-iron oxide breccias with subordinate clays, alunite, sericite, barite, and pyrite and is a typical high sulfidation epithermal assemblage. Gold is strongly associated with vuggy silica and quartz crackle breccia, both with strong iron oxide or pyrite and occurs as discrete, high-grade, plunging ore shoots within lower grade alteration envelopes. The dominant structural trend is N45E cut by periodic N40W faults. Ore bodies on the property generally trend N10W-N10E and N40W-50W. The project has excellent potential to host economic gold ore either has high-grade El Indio-type veins or large, lower grade, Yanacocha-style bulk-mineable bodies.

1). Detailed examination and description of select hand samples collected during the 2006 field season followed by petrography and PIMA studies on a selected representative suite of samples. These studies will determine mineralogy and alteration associated with gold mineralization and if vertical or peripheral alteration zoning exists.

2). Lineament analysis of the Mickey, Thesis and BV South structures using in-house black-white and color aerial photos and Aster satellite images. Due to the paucity of outcrop, there is presently little knowledge of structural control. These studies will lend insight for detailed geologic mapping in the 2007 field season.

3). Statistics and correlation coefficients of gold and base metals to determine if other metals can be used as pathfinders to gold mineralization in the altered zone and its potential extensions.

4). Once the above tasks are completed and along with the geologic map and assay results, assimilate the data into a working geologic model of key structures.

5). Further modeling, interpretation and target selection using trench and drill hole data for Thesis, Bonanza, BV and Alberts Hump areas.

6). Perform detailed mapping (1:2500) and sampling of the key structures.

Ranch Property Recommended 2007 Budget

Phase 1

Data Compilation on Ranch Property	40,000
Lithogeochemical Sampling	80,000
Geological Mapping	100,000
Diamond Drilling (7,000 metres)	1,500,000
Project Management & Reporting	25,000
Total	$1,700,000

Upon favorable results from Phase 1:

Phase 2

Data Compilation	20,000
Diamond Drilling (10,000 metres)	2,500,000
Project Management & Reporting	20,000
Total	$2,540,000

Note: All costs are estimates of expenditures and include overhead but do not include GST. Costs include labour, taxes, camp support costs, fuel, surface transportation charges, equipment rental, assaying, field supplies and supervision.

Appendix A

Statement of Qualifications

Statement of Qualifications

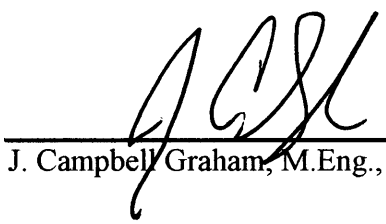
I, J. Campbell Graham do hereby certify that:

1. My permanent address is Suite 606 – 480 Robson St., Vancouver, BC

2. I graduated from the Colorado School of Mines with a B.Sc. in Geophysical Engineering in 1982 and a M.Eng. in Geophysical Engineering in 1985.

3. I am a practicing Member of the Association of Professional Engineers and Geoscientists of British Columbia (Lic. #16488).

4. I am a Qualified Person for the purposes of NI 43-101 with regard to a variety of mineral deposit types, and I have knowledge and experience in the preparation of technical studies and reports.



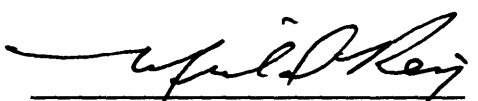
J. Campbell Graham, M.Eng., P.Eng.

STATEMENT OF QUALIFICATIONS

I, Michael Renning of 4048 Dollarton Hwy, North Vancouver, BC, V7G 1A2 do hereby certify that:

1. I have worked in the mining exploration business since 1981 and my knowledge as a prospector has evolved through working with many knowledgeable geologists as well as through much independent reading, research and exploration.
2. Although I have had much exploration experience as a field assistant and independent prospector, I have worked specifically as a prospector for PNC Exploration (Canada) in 1986, Welcome North Mines in 1988, Rio Algom Exploration in 1992 and Christopher James Gold in 2006.
3. I had earned a 25% interest in Guardsmen Resources Inc. for my company, Amber Minerals Ltd., by contributing much research and prospecting time during the period from 1987 to 2003. I own all shares in Amber Minerals Ltd.
4. I also own 100% of a separate company, Future Metals Inc., for the purpose of Rare Earth Element exploration and development in British Columbia.
5. As of February 2007, Christopher James Gold has earned about a 15% interest in Guardsmen Resources and all of its assets.
6. I am presently working as an independent exploration contractor, through my company Amber Minerals Ltd., for Christopher James Gold.
7. Although I am a shareholder of Christopher James Gold, I own less than 10% of the common shares in the company.
8. I consent to and authorize the use of the attached report and my name for use in the public domain.

Signed this 18th day of February 2007 in Vancouver, British Columbia, Canada,



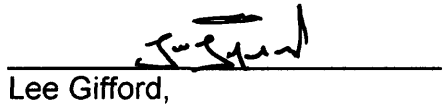
Michael Renning, prospector
bcgold@shaw.ca

STATEMENT OF QUALIFICATIONS

I, Lee Gifford, of 7- 12158- 82nd Avenue, Surrey, BC, do hereby certify that:

1. I have worked in the mining exploration business periodically since 1999.
2. I have experience as a field assistant as well as a geological technician.
3. I have worked solely for Guardsmen Resources Inc. on a variety of Projects in North-Central British Columbia.
4. I am currently under contract by Christopher James Gold Corp for the 2007 season.
5. I do not own or expect to receive any interest in the property described herein.
6. I consent to and authorize the use of the attached report and my name for use in the public domain.

Signed this 18th day of February 2007 in Vancouver, British Columbia, Canada,



Lee Gifford,
lmg212@shaw.ca

STATEMENT OF QUALIFCATIONS

I, Lindsay Graham, of 1108-813 Agnes Street, New Westminster, BC do hereby certify that:

1. I have experience as a Geographic Information Systems Technician since 2004.

2. I am currently a consultant for Christopher James Gold Corp. since May 2006.

3. I have completed 2 years in the Geographic Information Systems Technology Program from Algonquin College, Ottawa, Ontario and attained a certificate in the same program from Mohawk College, Hamilton, Ontario.

4. I do not own or expect to receive any interest in the property described herein.

5. I consent to and authorize the use of the attached report and my name for use in the public domain.

Signed this 19th day of February 2007 in Vancouver, British Columbia, Canada,

Lindsay A. Graham, GIS Consultant
Lindsay@cjgoldcorp.com

D. Surveys

Alberts Hump/Ranch 2006 Cost Statement

Aeroquest Limited

An advance was given to Aeroquest Limited for the possiblity of a survey to be completed on the Ranch Property in 2006.

The advance was wired via the bank; $69,372.00 plus $4,162.32 GST = $73,534.32 total advanced.

The survey was cancelled for 2006 and even though Aeroquest still held the advance, they did subsequently return the funds on May 15, 2007 via wire transfer.

Additional charges may be deducted from the payment amount by the receiving bank and/or its intermediaries ("Receiving Bank"). If this payment cannot be completed for any reasons beyond the control of Royal Bank of Canada ("RBC") you may ask RBC for a refund and RBC shall make best efforts to secure a refund from Receiving Bank and return those amounts to you. If conversion of funds is requested, the rate of exchange will be RBC's rate established at the time the refund is converted. If you need to make an inquiry regarding this payment, or if you ask that RBC attempt to amend or cancel this payment, additional charges will apply (except in cases where an error has been established on the part of RBC or the Receiving Bank).

RBC will not be responsible for any loss or damage suffered or incurred by you except in a case where there has been negligence on the part of RBC, and in any such case RBC will not be liable for any indirect, consequential or exemplary damages (including but not limited to loss of profits), regardless of the cause of action.

Drill Logs

The Ranch DDH A06-01 Geological Drill Log

Lithology	From (m)	To (m)	Description / Comments	Lithology Simplified
OB	0.0	5.8	Overburden, little rec.; likely drilled ±1 m of bedrock before casing	OB
Clay	5.8	15.9	Clay±FeOx±sil, mainly kaolinite, yellow-brown-white; 60% rec	CLAY
pa	15.9	17.4	Plagioclase andesite, moderate alteration to illite-silica, local pyrite <5%	PA
cl	17.4	18.2	Clay±py±sil, yellow-white-black; 75% rec	CLAY
pa alt	18.2	22.9	Plag and, mod altn to il±sil±py in vts	PA
vsil-py-il	22.9	40.2	Sil-py±il, ±bx, generally vuggy, local white qtz-±ser vts; str. frac	SIL
py-sil bx	40.2	41.8	Semi-massive py-sil bx	SIL
sil bx	41.8	43.7	Gray sil bx, minor vugs	SIL
vsil-py-il	43.7	47.0	Sil-py±il; generally vuggy; fines washed out; 75% rec 44.8-47.9 m	SIL
fault?	47.0	47.4	Cave-in, sand and re-ground pebbles, <10% in-situ rock; fault?	FAULT?
vsil-py-il	47.4	57.0	Sil-py±il after plag, generally vuggy, ±white qtz-ser vts; w/ minor	SIL
pa alt	57.0	66.2	Plag and, wk altn to il, py dissem 2-3%; 50% rec 57.0-58.5 m	PA
pa alt	66.2	70.2	Plag-(biot-Kspar?) and; wk altn plag phenos to green ser,	PA
pa alt	70.2	78.6	Plag-Kspar? and, py dissem 3%; mod-str il thru-out	PA

GROUP 1DX - 0.50 GM SAMPLE LEACHED WITH 3 ML 2-2-2 HCL-HNO3-H2O AT 95 DEG. C FOR ONE HOUR, DILUTED TO 10 ML, ANALYSED BY ICP-MS.
(>) CONCENTRATION EXCEEDS UPPER LIMITS. SOME MINERALS MAY BE PARTIALLY ATTACKED. REFRACTORY AND GRAPHITIC SAMPLES CAN LIMIT AU SOLUBILITY.
- SAMPLE TYPE: DRILL CORE R150 Samples beginning 'RE' are Reruns and 'RRE' are Reject Reruns.

GROUP 1DX - 0.50 GM SAMPLE LEACHED WITH 3 ML 2-2-2 HCL-HNO3-H2O AT 95 DEG. C FOR ONE HOUR, DILUTED TO 10 ML, ANALYSED BY ICP-MS.
(>) CONCENTRATION EXCEEDS UPPER LIMITS. SOME MINERALS MAY BE PARTIALLY ATTACKED. REFRACTORY AND GRAPHITIC SAMPLES CAN LIMIT AU SOLUBILITY.
- SAMPLE TYPE: DRILL CORE R150 Samples beginning 'RE' are Reruns and 'RRE' are Reject Reruns.

GROUP 1DX - 0.50 GM SAMPLE LEACHED WITH 3 ML 2-2-2 HCL-HNO3-H2O AT 95 DEG. C FOR ONE HOUR, DILUTED TO 10 ML, ANALYSED BY ICP-MS.
(>) CONCENTRATION EXCEEDS UPPER LIMITS. SOME MINERALS MAY BE PARTIALLY ATTACKED. REFRACTORY AND GRAPHITIC SAMPLES CAN LIMIT AU SOLUBILITY.
- SAMPLE TYPE: DRILL CORE R150 Samples beginning 'RE' are Reruns and 'RRE' are Reject Reruns.

GROUP 1DX - 0.50 GM SAMPLE LEACHED WITH 3 ML 2-2-2 HCL-HNO3-H2O AT 95 DEG. C FOR ONE HOUR, DILUTED TO 10 ML, ANALYSED BY ICP-MS.
(>) CONCENTRATION EXCEEDS UPPER LIMITS. SOME MINERALS MAY BE PARTIALLY ATTACKED. REFRACTORY AND GRAPHITIC SAMPLES CAN LIMIT AU SOLUBILITY.
- SAMPLE TYPE: DRILL CORE R150 Samples beginning 'RE' are Reruns and 'RRE' are Reject Reruns.

GROUP 1DX - 0.50 GM SAMPLE LEACHED WITH 3 ML 2-2-2 HCL-HNO3-H2O AT 95 DEG. C FOR ONE HOUR, DILUTED TO 10 ML, ANALYSED BY ICP-MS.
(>) CONCENTRATION EXCEEDS UPPER LIMITS. SOME MINERALS MAY BE PARTIALLY ATTACKED. REFRACTORY AND GRAPHITIC SAMPLES CAN LIMIT AU SOLUBILITY.
- SAMPLE TYPE: DRILL CORE R150 Samples beginning 'RE' are Reruns and 'RRE' are Reject Reruns.

GROUP 1DX - 0.50 GM SAMPLE LEACHED WITH 3 ML 2-2-2 HCL-HNO3-H2O AT 95 DEG. C FOR ONE HOUR, DILUTED TO 10 ML, ANALYSED BY ICP-MS.
(>) CONCENTRATION EXCEEDS UPPER LIMITS. SOME MINERALS MAY BE PARTIALLY ATTACKED. REFRACTORY AND GRAPHITIC SAMPLES CAN LIMIT AU SOLUBILIT
- SAMPLE TYPE: ROCK R150 Samples beginning 'RE' are Reruns and 'RRE' are Reject Reruns.
