APPENDIX V: MINFILE Reports
APPENDIX VI: Assay Certificates
APPENDIX VII: List of Software Applications

INTRODUCTION

Blind Creek Resources Ltd. of Vancouver, British Columbia mobilized a small field crew to the Atlin area in the late summer of 2006 to conduct assessment work several non-contiguous mineral tenures belonging to the company. On September 15, 2006 work was conducted at the Tagish #3 mineral tenure.

This past season a total area of about 14 hectares was explored adjacent to the Tagish#3 tenure near Graham Arm, and a total of 9 rock samples and 3 soil samples were collected by prospectors Brad Davies and Jeff Merrick. Field assistants were used in the field for safety and logistics reasons, and the entire field crew was managed by Douglas Merrick. Sample locations had their UTM coordinates noted and all reconnaissance samples were shipped to and analysed by Eco Tech Laboratory Ltd of Kamloops, British Columbia. Analytical results include a 28 element ICP and a gold fire assay with atomic absorption finish. The compilation of this report and its data will be reviewed by Blind Creek Resources Ltd. contract geologists in an effort to streamline proposed exploration in the 2007 season.

TENURE NUMBER	CLAIM NAME	AREA (ha)
525452	TAGISH #3	819.43

Table 1: Tenure Details

(note: complete list of Blind Creek Resources Mineral Tenure holdings included in Appendicies)

PHYSIOGRAPHY and ACCESS

The Tagish 3# claim, consisting of 819.43 hectares of land, is located adjacent to the community of Atlin, British Columbia. 100% owned and operated by Blind Creek Resources Ltd., the Tagish #3 is located entirely within the NTS 104M/09 map sheet and is centered at approximately UTM Zone8V 544825E, 6605440N (NAD 83). Combined with the above described claim, at the time of the writing of this report, Blind Creek Resources holds a total of 42,814.58 hectares of non-contiguous mineral tenure in the Atlin area: a complete list of tenures is included in Appendix IV.

The Tagish #3 mineral tenure, as seen in Figure 3 (included at the end of this report), lies within the Tagish Highlands, to the east of the Coast Mountains and is centered approximately 28 kilometres west of Atlin, British Columbia. The 10 celled mineral tenure is located between Rupert Creek and Tagish Lake with its northern boundary intercepting Graham Inlet. Topography of the claim varies from moderate sloping near the shoreline to steep northeast trending slopes further to the south edge of the claim. Access, as stated by project manager Doug Merrick, is most practical by air, either by helicopter or fixed wing aircraft.

Figure 1: Location map of Blind Creek Resources Ltd. mineral property at Atlin, BC

HARD ROCK MINING and MINERAL EXPLORATION HISTORY

The authors of this report are not aware of any historical, recent or active mining activities occurring within the actual confines of the Tagish #3 mineral tenure, although assessment work is reported on adjacent mineral properties and is believed to hold good mineral potential. The nearest reported assessment filings and MINFILE reports occur a relatively short distance to the south east of the Tagish #3 and communications with the field crew of 2006 suggest that the property is located on a trend of mineralization.; hence, the exploration which took place this past season.

The Ministry of Energy, Mines and Petroleum Resources has an extensive inventory of mineral showings and past producers for the area which are summarized in their MINFILE records. One such record exists adjacent to the Tagish #3 a few kilometres to the south east. This record, MINFILE No.104M080 is a low sulphidation, epithermal gold/silver showing and is described as follows:

The Quantity showing is located 30 kilometres west of Atlin, on the eastern portion of the Quantity claim. There are several other showings on the Golden Bee property (104M 076-079).

The claims were staked by Golden Bee Minerals in 1988 to 1989. Golden Bee Minerals conducted a program of sampling, mapping, prospecting and geochemical surveys in 1989 and 1990. Trenches found in 1990 are suspected to be from work done in the 1920s by Consolidated Mining and Smelting Company.

The area, bounded by faults, is underlain by sediments of the Lower Jurassic Laberge Group. These comprise greywacke, argillite, shale and conglomerate intruded by granite near Bee Peak. The Llewellyn fault is 2 kilometres to the west and separates these rocks from the Coast Plutonic Complex. To the east, the Nahlin fault separates the rocks from the Cache Creek Group. The area of the showing contains splays from these major faults. The bedding generally trends north to northwest and dips 10 degrees to vertical.

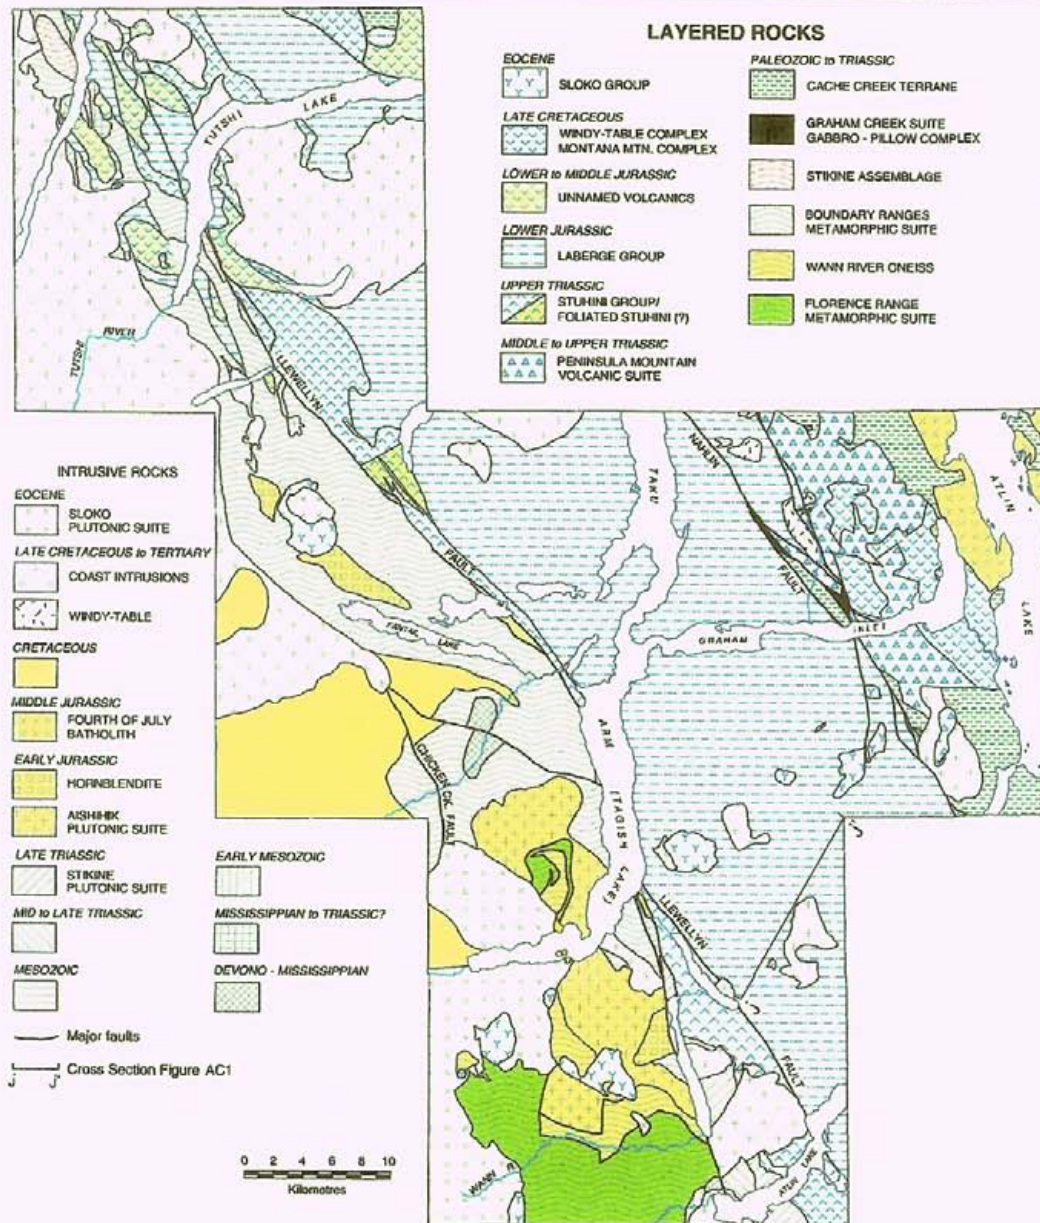

The Quantity showing consists of the Barney zone located 200 metres south-southeast of Fox Bay. The Barney zone is restricted to the west of the splay fault and has a total strike length of 233 metres. The zone is 5 to 25 metres wide. The zone, with some vugs and up to 3 per cent fine sulphides, contains variable carbonate alteration, quartz veining, stockwork and breccia. The southern portion, 60 by 5 to 10 metres, is less altered than the rest of the zone and produced higher metal values. The highest values came from sample GT-04490 which assayed 0.35 grams per tonne gold, 1.0 gram per tonne silver and 0.0165 per cent copper (Assessment Report 21508).

This MINFILE record is included in the appendices of this report.

REGIONAL GEOLOGY

The regional geology, as described by Thompson (1990), states that the area lies within the northwest trending intermontane tectonic province and is bounded by two long deep seated faults. The west is bounded by the sub-vertical Llewellyn Fault system and the coast crystalline complex consisting of palaeozoic metamorphic and plutonic rocks of the NiSling Assemblage. The region around the claim is bounded to the east by the northeast dipping northwest trending Nahlin Fault and the Cache Creek group, cherts, argillites, basalts, andesite, ultramafics, and limestones. The lithology also consists of lower to middle Jurassic Laberge Group argillites, feldspathic wacke, siliciclastics, and conglomerates complicated by splay faults off the Llewellyn and Nahlin Faults and Jurassic to Eocene volcanics.

Figure 2: Regional Geological Setting (from Bulletin 105)

LOCAL GEOLOGY

The geology of Tagish Lake finds its best, most exhaustive treatment in Mihalynuk's Bulletin 105. Mihalynuk has separated the area into four domains, each of which is dominated by northwest-trending structural grain. None of these domains, however, started out with a northwest trend, and the boundaries of most of the domains correspond to the boundaries of terranes, which accreted to the continent at various times through the tectonic history of BC.

Most westerly is Domain I, which encompasses the young intrusive rocks of the Coast belt, and does not represent a distinct terrane. Domain II includes mainly deformed metamorphic rocks, which can be subdivided into a quartz-rich clastic succession of "pericratonic" (near the continent) origin, and a suite of volcanic arc strata which can be traced to the Stikine Terrane. Domain III includes all of the rocks of the "Whitehorse Trough", so called because it originated as deep-ocean basin, though folding and thrusting has shortened the width of this domain considerably. The rocks of the Whitehorse Trough that occurs within the area of this report are called the Laberge Group. The eastern-most domain – Domain IV – contains rocks of the Cache Creek Group, which has already been discussed.

As a part of the structural grain, two crustal-scale faults occur. These faults pass deep enough to serve as conduits for magma intrusions and mineralizing fluids. The Llewellyn Fault forms the boundary between Domains II and III, and marks the eastern-most limits of the deformation and metamorphism that took place in Domain II. The Nahlin Fault forms the boundary between Domains III and IV, and thus it can be seen that the rocks of the Laberge Group (the Whitehorse Trough), are bounded on both sides by these two crucial crustal-scale faults.

PROSPECTOR'S DISCUSSION by Brad Davies

The tiny community of Rupert lies on the south shore of Graham Inlet, near where the inlet diverges from the main body of Tagish at Golden Gate. The entire region was once an ocean basin at the destructive margin of the continent, which has been considerably shortened and folded by tectonic collision (orogeny). Trending north-westerly, this synclinal trough is bounded on the northeast by the Nahlin Fault, and on the southwest by the Llewellyn Fault. These faults are thought to extend downward to the earth's crust, and they have *certainly* served as conduits for hydrothermal and plutonic mineralization.

Rocks within this Whitehorse Trough are known as the Laberge Group, and include siltstones, sandstones, argillite, conglomerates and greywacke. Intrusives and minor limestones are common throughout the region, but are not found near Rupert.

A field crew proceeded from a landing site on the north brow of Golden Mountain to the airstrip near Rupert. The slope down consists of a series of looming outcrops of heavy, black rock which was first referred to as being "volcanic", but was subsequently termed a

“greenstone”. Some confusion remains, but near the bottom the rock changes to a grey, siliceous meta-sediment with traces of mica. For what it’s worth, samples 104313 and 104314 were taken from the black rock, and sample 104315 was taken from the grey, and the assay results appear to be identical. Sample 104409 was taken at the same spot where soil sample 104410 was taken, and this rock sample, too, seems identical to 104313-315. The soil sample, on the other hand, carries no minerals of value. One can speculate that the country rock on Golden Mountain carries anomalous values in gold, and that the gold is not mobile even where the soil is as highly coloured as was sample 104410.

From the bottom of the mountain only overburden and thick, marshy brush were encountered on the way out to the airstrip. Then, at the north end of the strip, a road to the west was followed to where a creek could be heard trickling some 80 meters away. It was here that a major fault was found at a place where the rock crops out along the creek. The fault is some 30 meters wide, and follows black slate on an east-west strike, with a southerly dip. It’s possible that this is a faulted shear zone between the southern argillite and the northern slate, but evidence was not at hand. Samples 104411-414 were taken here, as well as 104316-317.

The slate was traced for almost a kilometre east to where a spectacular waterfall serves as the “water head” for an aqueduct to the community of Rupert. Overburden and heavy brush obscured any trace of the fault in that direction, but there were rumours afloat in Atlin of a drilling crew who are following this same fault to the west.

Gold values at the fault are high, as are the values for arsenic. Apparently—like the Engineer mine—the gold along this fault is carried as the arsenide, which might give some clue as to why soil sample 104410 and a second soil sample (014SRU), though deep crimson in colour, had no gold values.

signed: Brad Davies

FIELD SAMPLING and ANALYTICAL PROCEDURE

All rock and soil samples collected in the field were gathered by prospectors Brad Davies and Jeff Merrick. Each sample was noted to type, position according to a Garmin GPS and general description of the sample taken. Rock samples were mostly representative grab samples of rock outcrops, rare chip sampling was conducted and few rock samples were of float material. These were taken with an appropriate rock hammer and placed then sealed in clearly labeled and tagged clear plastic bags. Soil samples were collected from the B-horizon and carefully placed in brown kraft paper bags appropriate for soil sampling purposes. Each bag was clearly labeled on the outside with a felt tip marker and sealed for shipping.

Each sample was carefully packaged and shipped via Greyhound Canada Transportation Corporation to Eco Tech Laboratory Ltd of Kamloops, British Columbia for geochemical analysis. Eco Tech Laboratory Ltd. completed all of the analysis associated with the

2006 Blind Creek Resources Exploration Program in Atlin. The following data, received from them, addresses the issues of sample preparation and analysis:

- **Analytical Method – gold assay**

Samples are sorted and dried (if necessary). A sub-sample is pulverized in a ring & puck pulverizer to 95% -140 mesh. The sample is rolled to homogenize. Concentrates will be processed in our concentrate sample preparation area.

A 10 to 30g sample, run in triplicate, is fire assayed using appropriate fluxes. Concentrate will be fused in a dedicated furnace to ensure no cross contamination. The resultant dore bead is parted and then digested with aqua regia and then analyzed on an AA instrument.

Appropriate standards (Quality Control Components) accompany the samples on the data sheet.

- **Analytical procedure assessment report - metallic gold assay**

Samples are catalogued and dried. Rock samples are two stage crushed to minus 10 mesh, then split to achieve a 250 gram (approximate) sub-sample. The sample is pulverized to 95% -140 mesh. The sample is weighed, then rolled and homogenized and screened at 140 mesh.

The -140 mesh fraction is homogenized and 2 samples are fire assayed for Au. The +140 mesh material is assayed entirely. The resultant fire assay bead is digested with acid and after parting is analyzed on a Perkin Elmer atomic absorption machine using air-acetylene flame to 0.03 grams/t detection limit.

The entire set of samples is redone if the quality control standard is outside 2 standard deviations or if the blank is greater than 0.015 g/t.

The values are calculated back to the original sample weight providing a net gold value as well as 2-140 values and a single +140 mesh value.

Results are collated by computer and are printed along with accompanying quality control data (repeats and standards). Results are printed on a laser printer and are faxed and or mailed to the client.

- **Analytical procedure assessment report**

- **Sample preparation:** Samples are catalogued and dried. Soils are prepared by sieving through an 80 mesh screen to obtain a minus 80 mesh fraction. Samples unable to produce adequate minus 80 mesh material are screened at a coarser fraction. These samples are flagged with the relevant mesh. Rock samples are 2 stage crushed to minus 10 mesh and a 250 gram sub-sample is pulverized on a ring mill pulverizer to -140 mesh. The sub-sample is rolled, homogenized and bagged in a pre-numbered bag.

- **Geochemical gold analysis:** The sample is weighed to 30 grams and fused along with proper fluxing materials. The bead is digested in aqua regia and analyzed on an atomic absorption instrument. Over-range values for rocks are re-analyzed using gold assay methods. Appropriate reference materials accompany the samples through the process allowing for quality control assessment. Results are entered and printed along with quality control data (repeats and standards). The data is faxed and/or mailed to the client.
- **Multi element ICP analysis:** A 0.5 gram sample is digested with 3ml of a 3:1:2 (HCl:HNO₃:H₂O) which contains beryllium which acts as an internal standard for 90 minutes in a water bath at 95°C. The sample is then diluted to 10ml with water. The sample is analyzed on a Jarrell Ash ICP unit. Results are collated by computer and are printed along with accompanying quality control data (repeats and standards). Results are printed on a laser printer and are faxed and/or mailed to the client.

Note: (1) *** Samples collected from areas next to but not of BCR tenures.

INTERPRETATION AND CONCLUSIONS

Based upon the presented data of this report, the authors must interpret or deduce one or all of a few circumstances:

1. The field crew were following a trend adjacent to the property with intention of further detailed work within the property boundaries but were limited by topography and access.
2. Satellite coverage for the GPS's used in the field was very poor as the samples appear to be nearly consistently taken from a north/south trending line nearly 100 meters to the east of the actual property boundary.

The authors of this report, therefore, conclude that future expeditions should see more advance planning and research to help ensure a successful field season at the Tagish #3 mineral tenure.

RECOMMENDATIONS

Based on the above presented data and basic knowledge of the property the authors of this report recommend the following:

1. Research and compile all available geological, geophysical and geochemical data in an effort to streamline future work programs and define areas with good economic potential *within* the confines of the property.
2. Flag property boundaries at all trails and road intersections if possible.
3. Conduct a preparatory survey of recent orthophotos to help aid in maximizing time spent in the field looking for rock exposures and unique geologic structures.
4. Conduct a well planned and detailed mapping program of the property in an effort to locate anomalous regions and further provide company geologists with future targets to explore.

APPENDIX II
STATEMENT OF QUALIFICATIONS

STATEMENT OF QUALIFICATIONS – Angelique Justason

I, Angelique Justason, of 3972 Goldquartz Drive, Wells, British Columbia certify the following:

- I have studied geology and earth science at Camosun College and the University of Victoria.
- I have studied Civil Engineering Technology and Mining Engineering courses at BCIT of Burnaby, British Columbia.
- I have been employed in the Cariboo Mining District as a geotechnician and mine surveyor for over 7 years.
- I have a total of 4 full seasons of work experience as a field assistant with the BC Geological Survey and the Geological Survey of Canada in various regions throughout British Columbia and the Yukon.
- I have successfully completed and received certificates for the Advanced Prospectors Course (1991) and Petrology for Prospectors Course (1992).
- I have been an avid prospector for over 15 years.
- I currently own and operate a mineral exploration services business, Tenorex GeoServices, which opened in January of 2007 and is based in Wells, British Columbia.
- I was not directly involved in any of the prospecting or exploration activities for Blind Creek Resources Ltd. of the Atlin area until such time it came necessary for the company to file a technical report. At that time, I supervised the compilation and data management of the field samples and technical report.
- I hold no interest in Blind Creek Resources Ltd., any of its sister companies, nor any other properties within the Atlin Mining District.

Signed,

Angelique Justason

APPENDIX III

Prospector's Daily Log

for all non-contiguous Blind Creek Resources Ltd.

2006 field work

August 24, 2006 to October 12, 2006

written by Brad Davies at Atlin, BC

Aug 24

The three of us went through the quarry alongside the highway just north of Atlin. Strike of country rock was 340° . Jeff found sulfides @ Send, and there was folding & alteration just S of that.

Trend: $\sim 20^\circ$ NNE { We went up Otter Ck Rd to Spruce mountain, where the drilling had taken place last fall. Jeff explored a qtz seam S of the last drill hole and found galena. I explored N of the first drill hole and took a reference sample of the mariposite. We looked at a barren qtz seam down the road near Otter Pit.

Aug 25

Jeff's crew went west along the ridge while I explored a glacial cirque on the west side of Spruce Mt. The W. shoulder of Spruce (east rim of cirque) has the same mineralization as is found where we drilled (mariposite). There are many goxans on the S face of the cirque, and much oxidized/ankeritized rock. I found pyrites with qtz on one outcropping, but qtz is hard to find in this cirque.

Aug 26

I returned to the cirque and ran two profiles with the dip needle. Collected 3 rock samples & 3 soil samples.

Aug 27

There is a hump between Otter and Wright Pits (closer to Wright). At N end of the hump there is a Pass or Gap. Bull qtz predominates as float on N side of this Otter-Wright Gap. Faulting? Headed N across hump to the road. It did seem that the rock graded from very siliceous near the Gap to common siltite at the N end of the hump.

Aug 29

Leaving the Gossan - quarry beside Atlin ~~quarry~~^{High} near dump, passed SW end of Como Lk and climbed up to rocky peak. Found galena on fracture planes of siltite where a qtz veinlet ran across the strike of the rock. No other qtz & nothing of value was found, so descended other side and found the blaze line from 2 yrs ago.

Aug 30

Leaving same position as yesterday, explored hump SE. Nothing of value, just siltite, ankeritized and sometimes micaceous.

Aug 31

Climbed Mtn. SE (beside) Como Lk. All granite - probably a batholith. No contact exposed; probably under valleys on either side. Drove around to individual cell just N of Atlin on 4th July Bay Rd, took single sample of ferro-sandstone; no left to rock, but very rusty.

Sept 01

Toured Spruce Ck Rd. Main Spruce Ck Rd leads to eskers & overburden, no bedrock. Recon of Noland's camp. Research & photocopies in PM.

Sept 02

Found Union fault. Recon around SE corner (Wilson Ck, etc). Lots of Limestone. Remember: 0591998 x 6588292
320° ~ 2.5 km.
280° ~ 1 km.

Sept 03

Found contact (N: lime/S: Arg) just past "end of driving" on Burdett CK. Tried to trace it; probably the foot of the Sentinels is a contact (see: Jeff's report near "cinnabar" stain).

Sept 04

Discovered the Dominion CK Rd. Located the E end of Union fault. Much qtz & qtzite, vitreous & carbonatized. Some ox. No pyrites.

Sept 05

Followed Fault E to Diduck's property, then came back to follow branch of fault SE. Peak of obsidian (chert?) just above yesterday's qtzite. Found trace mariposite & phyllitization on E traverse. Still no ore!

Sept 06

Started on someone else's property just SW of Limestone Mtn. and began to trace probable fault. With lime on all sides, found outcrop of altered, silicified rock. Found Mariposite trench on their property and proceeded S down valley. Found Mariposite all the way down, as well as gossan swamp near mouth of valley.

Sept 08

Had been discussing "Black Mtn" as we were working towards it. Jeff's crew found sulfides on NNE foot, so today I began to explore. Found "phyllitized" vertical bed out front on NNW. Then distinctive ribboned, toothpaste calcite on mini-volcano out front on NNW. Mariposite @ foot of talus slope. Boxwork qtz. halfway up. Sulfides in scree. More metals right to NNW side of N. nose (top).

Sept 09

Hit the hill again on ESE. Metals all the way up, and outcrops. Then to N. Nose, then down NNE. Metal and outcrops all over.

Sept 10

Trying to approach volcanics on NE slope just above Eldorado, coming from McKee. Can't get there through willow jungle. Sampled someone else's ground ~~to~~ from Eldorado up along McKee. Many quartz stringers E-W strike, bound in rusty gravel matrix (arg base-rock). Then down to McKee pit, where Jeff found massive sulfides along ck.

Sept 11

Middle Pine bridge @ falls. Following creek ~~above~~ at top of canyon along trail. Canyon walls gossanize & fold lower down. Pictou fault? If so, juncture with Pine fault is at the lower end of the hydraulic pit, where it joins Pine Ck. Probably they followed Pine fault with hydraulicing. Some gullies at top of hill on left bank might be the two faults. Looking back along (Pictou fault?) am always looking @ Imperial minesite.

Sept 13

Take Eldorado trail into alpine. Walk to volcanics area. Lg. red volcanic ridge with quartz seam as spine. All of the qtz seams seem to run perpendicular to faults \therefore the "Black Mtn" proposed fault may continue on this side of McKee. Therefore, there is a juncture with McKee somewhere downstream of McKee dam.
More green obsidian.

Sept 14

Explored most of the rest of the cirque at head of Eldorado trail. All sediments, no mineral or qtz. Much jasper, including a $\frac{1}{4}$ acre hill of it.

Sept 15

Rupert, start at top of mountain. Black stuff grades to grey siliceous as I descend. At N end of airstrip follow road to W for 100m and go down to Ck. Outcrops are fault zone, well mineralized. Traced black "slate" against it (on N) to the E, as far as falls. "Slate" dips S, strikes E-W.

Sept 16

Red Mtn, east across valley from back end of Engineer Mtn. Same stuff as Black Mtn, poorly mineralized. Found intrusive contact (rhyolite) that is mineralized throughout, though lacks heft. No iron stain, looks like concrete. Strike may carry to back end of Engineer Mtn. On N side of intrusive (dike) large outcrop of fault breccia. No (rhyolite) below breccia, seems confined to alpine depression or gully.

Sept 17

SW ~~side~~ corner of (Gleaner) Mtn. Red band across face. Climbed ridge, but rock crumbles and cannot be trusted. Sampled ridge, and found minerals. Red band appears to follow strike, but will take rock bolts & climbing gear to sample it. Probably needs to be sampled. Walked to furthest knob to the W, where volcanic mudstone outcrops.

Sept 18

SW corner Union Mtn. Within sight of Black Mtn, metal splashes are in the volcanics. Out of sight, no metal.

Sept 19

Paralleling "the pass" between Wright Pit & Otter Ck (maybe 150 m S of "pass") Definite alteration zones, seemingly based on series of N-S gullies (jointing?) Maddeningly, the float is enticing, but can't be traced back to anything.

Sept 20

Lousy day in granite on N of (Switzer?) traveling around cirque. To the S on Switzer proper can see a very red ridge.

Sept 21

Training Brad White. Sent him 350m S of "Wright Pass" and went through center to Otter CK. The gullies & alteration don't extend S as far as Brad's walk, but would seem to hold (alteration anyway) to the N.

Sept 22/23 [- I've missed a day in the last 5]

Sampled from property boundary along Blue Canyon Rd. Limestone, chert & "indurated carboniferous sediments." One floatstone of "indurated siliceous sediments" carried pyrites.

Sept 25.

Returned to Como Lake to establish contact with 4th of July Batholith. It probably travels beneath S side of swamp but can be found along hwy. Found alteration zone /qtz nearer town.

Sept 26

Rose Ck near mouth. Probable intrusion has brought mineralization to ~~shale~~ shale along contact. NE strike, dips @ 25° to S. Beds are exposed for 50m along Ck, and again down by main rd.

Sept 27

~~Flown~~ Flown to east side of N Sentinel volcanics. Qtz seam appears on E side of basin. Found textbook intrusion, contact, etc. Sill? Have photo. Traces pyrites in volcanics.

Sept 28

On location @ big find. Chopper basin. Pink (Seldspar?) qtz veins well defined and run every which way in granite. Found rusty vein with trace pyrite while still ~~in~~ at head of chopper basin. Two inches, with black mafic material. 333°/W 75°. Climb into "stockwork" basin, which is scoured clean (relatively). Other members are calling me to "stockwork" vein, but their outcrop is 20m long and disappears into hill to the N and creek to S, with till and glacial lake to S. Parallel veins, 333°/W 80° with 5-inches on strike with gossan on hillside to N, which can be used for definition. Trace vein very easily to S, until it disappears into S lobe of glacier, approx 340m. Rubble where veins disappear heavily oxidized. Alongway stand beneath (relatively) vertical face with evidence of at least 4 parallel veins. Pyrites are heavy along all of the veins, wherever they are found. Min 15%, max 60%. One vein is 2-inch, at least 2 are 4-5 inch, and they are all within a 15m span. Strike is firm @ 333° and dip is around 80°, or almost vertical, dipping W into glacier.

Erosion has occurred at vein surface, adding definition. Wish I'd had time to view the "stockwork" vein, though I'm told that the best mineralization is in the parallel veins. Also I'm told that the granite itself carries, when near the veins and stockwork. Certainly the wall rock does.

Sept 29

Checking out Limestone in SE corner of property, Unload the shit.

Sept 30: Checking lone outcrop of ultramafics, surrounded by limestone. Unload the shit.

Oct 1 Soil Grid @ Como

ORIGIN: 0+00 E/W = 574693 x 6607356

BL: 0+50 W = 574735 x 6607326
1+00 W = 574769 x 6607297
1+50 W = 574807 x 6607263

~~S: 0+50 W~~

S: 0+50 W x 1+25 S = 574640 x 6607236
1+00 W x 1+25 S = 574689 x 6607206
1+50 W x 1+25 S = 574723 x 6607174 (Poor Epe)

N: 0+50 W x 1+25 N = ~~574845 x 6607302~~ 574826 x 6607411
1+00 W x 1+25 N = 574851 x 6607398
1+50 W x 1+25 N = 574890 x 6607352

Oct 2

Checking out limestone on E boundary of Sentinel. Unload the shit.

Oct 3

Using metal detectors up Wright Ck. Damn Garrett squeals when it hits mineralized shale, also serpentinized, quartzose alteration rock in Otter Pit.

Oct 4 - 8

Exploring around mouth of Spruce Ck. Definite fault @ 308° converging with Pine Fault & Pictou Fault in same area, near airstrip.

Also checked site showing towards McKee Ck.

Approx. juncture of 3 faults = 575891 x 6605820

Oct 10

Start @ SW corner Spruce^{Mtn.}, walk S side to Bay. Some evidence volcanics @ Bay.

Oct 11

Searching for drill core. Establish location, steal some hi-grade. Better have someone save this resource, before all the hi-grade gets stolen. Also find road up Pine Ck, passing to N of NW corner Spruce Mtn. Might take a walk.

Oct 12/13

SW ~~SW~~ corner of "lonely" block. Found heavy alteration on hill-side. Seems to be extension of "Spruce" fault.

APPENDIX IV

**Blind Creek Resources Ltd. Mineral Tenure List

SUMMARY

[Summary Help](#) ?

Name	QUANTITY, BARNEY, GB 1, GOLDEN BEE, GM 2-3, TWO FOOT CREEK	Mining Division	Atlin
Status	Showing	BCGS Map	104M059
Latitude	59° 34' 40" N	NTS Map	104M09E
Longitude	134° 14' 03" W	UTM	08 (NAD 83)
Commodities	Gold, Silver, Copper	Northing	6604640
Tectonic Belt	Intermontane	Easting	543259
		Deposit Types	H05 : Epithermal Au-Ag: low sulphidation
		Terrane	Inklin

Capsule Geology The Quantity showing is located 30 kilometres west of Atlin, on the eastern portion of the Quantity claim. There are several other showings on the Golden Bee property (104M 076-079).

The claims were staked by Golden Bee Minerals in 1988 to 1989. Golden Bee Minerals conducted a program of sampling, mapping, prospecting and geochemical surveys in 1989 and 1990. Trenches found in 1990 are suspected to be from work done in the 1920s by Consolidated Mining and Smelting Company.

The area, bounded by faults, is underlain by sediments of the Lower Jurassic Laberge Group. These comprise greywacke, argillite, shale and conglomerate intruded by granite near Bee Peak. The Llewellyn fault is 2 kilometres to the west and separates these rocks from the Coast Plutonic Complex. To the east, the Nahlin fault separates the rocks from the Cache Creek Group. The area of the showing contains splays from these major faults. The bedding generally trends north to northwest and dips 10 degrees to vertical.

The Quantity showing consists of the Barney zone located 200 metres south-southeast of Fox Bay. The Barney zone is restricted to the west of the splay fault and has a total strike length of 233 metres. The zone is 5 to 25 metres wide. The zone, with some vugs and up to 3 per cent fine sulphides, contains variable carbonate alteration, quartz veining, stockwork and breccia. The southern portion, 60 by 5 to 10 metres, is less altered than the rest of the zone and produced higher metal values. The highest values came from sample GT-04490 which assayed 0.35 grams per tonne gold, 1.0 gram per tonne silver and 0.0165 per cent copper (Assessment Report 21508).

APPENDIX VII

List of Software Applications

I, Angelique Justason, of 3972 Goldquartz Drive, Wells, British Columbia certify that the following is, to the best of my knowledge, a complete list of the software programs used in the support of the exploration and development of the Blind Creek Resources Ltd. tenures as well as in the preparation of the related report.

- Adobe Acrobat 6.0
- ArcView 9.2
- ARIS Map Builder
- Garmin MapSource
- Google Earth
- Internet Explorer
- MapInfo Professional 5.5
- MS Excel
- MS Outlook
- MS Word
- OziExplorer version 3.95.4q
- Tatuk GIS
- Windows notepad
- Windows Picture and Fax Viewer

Signed,

Angelique Justason

Aug 23 to Oct 15, 2006

GRAHAM ARM

Introduction

The claim area is in north western B.C., 27.3 km due west of Atlin B.C. Tenure number 525452.

Graham arm juts eastward from Tagish lake. The claim area extends from waters edge ,on the south shore of Graham arm, southward almost to the top of Rupert mountain. It is two cells wide and five cells long. The only practical access is by air. Costs being similar, helicopter was chosen over fixed wing . The advantage being landing on top rather than on the beach.

Property was acquired by Clive Aspinall, local geologist, for Blind Creek. Though there is no history of mining on it, he felt its proximity to other current activities made it a worthwhile site. All the property to the west is staked and diamond drilling is taking place on it.

The Engineer mine is just south of the claim area and this is what drives the search for gold here.

The crew landed on the mountain top and worked there way northward, downhill, through the block. The area is heavily forested and not a lot of bedrock was exposed. Where rock could be found it was inspected and sampled wherever was appropriate.

Twelve samples were taken. Results attached. Field work carried out by Brad Davies and Jeff Merrick certified prospectors.

The results of this work will now be assessed by a geologist for recommendations on proposed work for 2007.

Detailed Cost Statement

Four men	1 ten hour shift	
3 x 10 x \$20.00		\$600.00
1 x 10 x \$30.00		\$300.00
Vehicle Wells/Atlin/Wells		
Atlin/airport/Atlin		\$180.00
Food and lodging		
Atlin Inn and Pinetree cafe		
4 men one day	4@ \$100	\$400.00
Helicopter		\$450.00
	Total cost	\$1930.00

The Tagish/Rupert Zone

The tiny community of Rupert lies on the south shore of Graham Inlet, near where the inlet diverges from the main body of Tagish Lake. The entire region was once an ocean basin at the destructive margin of the continent, which has been considerably shortened and folded by tectonic collision (orogeny). Trending north-westerly, this synclinal trough is bounded on the northeast by the Nahlin Fault, and on the southwest by the Llewellyn Fault. These faults are thought to extend downward to the earth's crust, and they have *certainly* served as conduits for hydrothermal and plutonic mineralization.

Rocks within this "Whitehorse Trough" are known as the Laberge Group, and include siltstones, sandstones, argillite, conglomerates and greywacke. Intrusives and minor limestones are common throughout the region, but are not found near Rupert.

A prospecting survey proceeded from a landing site on the north brow of Golden Mountain to the airstrip near Rupert. The slope down consists of a series of looming outcrops of heavy, black rock which was first referred to as being "volcanic", but was subsequently termed a "greenstone". Some confusion remains, but near the bottom the rock changes to a grey, siliceous meta-sediment with traces of mica. For what it's worth, samples 104313 and 104314 were taken from the black rock, and sample 104313 was taken from the grey, and the assay results appear to be identical. Rock samples 104409 and 104411 were taken at the same spot where soil sample 104410 was taken, and these rock samples, too, have assays that are identical. The soil sample, on the other hand, carries no minerals. One can speculate that the country rock on Golden Mountain carries anomalous values in gold, and that the gold is not mobile even where the soil is as highly coloured as was sample 104410.

From the bottom of the mountain only overburden and thick, marshy brush were encountered on the way out to the airstrip. Then, at the north end of the strip, a road to the west was followed to where a creek could be heard trickling some 50 meters away. It was here that a major fault was found at a place where the rock outcrops along the creek. The fault is some 30 meters wide, and follows black slate on an easterly strike, with a southerly dip. It's possible that this is a faulted shear zone between the southern argillite and the northern slate, but evidence was not at hand. Samples 104413-414 were taken here, as well as 104316-317.

The slate was traced for almost a kilometre east to where a spectacular waterfall serves as the "water head" for an aqueduct to the community of Rupert. Overburden and heavy brush obscured any further trace of the fault in that direction, but there were rumours afloat in Atlin of a drilling crew who are following this same fault to the west.

Gold values at the fault are high, as are the values for arsenic. Apparently—like the Engineer mine—the gold along this fault is carried as the arsenide, which might give some clue as to why the second soil sample (014SRU), though deep crimson in colour, had no gold values, either.

Brad Davis

15. Was GPS used to map work sites? If yes, specify make and model: <i>Garmin 12</i>	16. Work site(s) marking (flagging, cut lines, other): <i>METAL TAGS + FLAGGING AT EACH SAMPLE LOCATION</i>
17. Are photographs of work sites attached? <i>NO</i>	18. Was Notice of work filed? Permit number: <i>HAND ONLY</i>

COST STATEMENT

19. Expense(s):	Total Hours	Hourly Rate	Daily Rate	Total(s) (\$)
Labour cost: (specify type)	30	20.		600 ⁰⁰
<i>3 @ \$20</i>				
<i>1 @ \$30</i>	10	30		300 ⁰⁰
Equipment & Machinery cost: (specify type)				

20. Transportation: (specify type)	Rate(s)	Days / Distance	Total(s) (\$)
<i>4x4 CREW CAB</i>	<i>20%</i>		<i>260⁰⁰</i>
Lodging / Food:	<i>4 @ \$100 PBR DAY/EACH</i>	<i>1 DAY</i>	<i>400⁰⁰</i>
Other: (specify)			
<i>HELICOPTER</i>			<i>780⁰⁰</i>
Total costs:			<i>2340⁰⁰</i>
Amount claimed for assessment:			<i>1858⁹³</i>

Qualifications of report writer. D.W.Merrick

Began field work in April 1966. Trained by B.C. Forest Service to field locate, map, and cruise timber. First put in charge of small field crews 1967. Seventeen years with Forest Service , always field location, mapping ,crew supervision. Vancouver, Courtenay, Powell River, Texada Island, Tatla Lake, Quesnel, Wells.

Prospecting hobby started to become employment, to point where last many years work entirely mining industry.

I have located thousands of claims, usually with a small crew, both placer and hardrock, and field located many boundaries.

I have prospected with ancient prospectors like Bob Mickle and Harold McGowan and Arnie Drinkwater. I have been in the field with many geologists, Dr. Norman Tribe, Dr Richard Hall, Ned Reid, Jean Poutler.

I have hunted claim posts with claims inspector Dennis Lieutard.

Have attended numerous seminars etc sponsored by mines ministry and others over the years. Have attended both Kamloops and Vancouver mining shows. Roundup.

Have received and carried out prospector grant, Mt Tom, Wells area.

Have many times taken samples, both rock and soil, and submitted for assay. Have done this on property held by myself and have done the same work many times for others. Ray Adams. Evan Williams, International Wayside, Gemco Minerals, Alan Tipman.

Have held mining ground for many years. Currently hold interest in several mineral tenures Wells and Princeton areas, as well as 4 placer LPM's Wells area.

I have carried out over 50 claim to lease conversions for myself and others. Lease of Placer Minerals.

Worked at Mosquito creek gold mine mill for over one full year. Worked for Bruce MacGregor placer mining little swift river one whole season. Worked two seasons placer mining for Nelbar Services , Pinus creek, swift river, Burns creek.

My main function on the Atlin job was to ensure efficient use of crew time and to see that all access was explored. We were trying to find something new in a camp many

times explored, but not well reported or mapped. Much of the area is covered with overburden, but by a great deal of walking on ridge tops and other likely areas, bedrock was often found and explored. Wherever there was any sign of mineralization, samples were taken.

I've printed maps of these sample locations at a scale that gives some perspective and some topographic features. They can be reproduced at any other scale if desired.

Doug Merrick
