SUMMARY

The Blackdome Gold Mine is situated in the Chilcotin region of southwestern British Columbia approximately 67 kilometres west northwest of Clinton, B.C. The Blackdome property consists of 40 mineral claims, 11 Crown granted claims and two mining leases and covers an area of approximately 16,695 hectares.

Mining activity dates back over 60 years when placer gold was discovered on Fairless Creek. Soon after, gold and silver bearing quartz veins were discovered on the slopes of Blackdome Mountain. Silver Standard and Empire Valley Gold Mines conducted exploratory work including small-scale underground work in the 1950s. The property lay idle until 1977 when it was acquired by Barrier Reef Resources Ltd. Extensive exploration and development work took place primarily by Blackdome Mines until 1986 when a 200 tonne per day mine was commissioned. The mine operated until 1991 after having produced 7,000,000 grams of gold (225,000 oz) and 17,000,000 grams (547,000 oz) of silver. The mine was briefly reopened from late 1998 to mid 1999 and produced 203,631 grams of gold and 538,000 grams of silver (Gruenwald, 2002).

Gold and silver mineralization occurs in structurally controlled fault and vein systems within Eocene age volcanic rocks. These deposits are classed as epithermal and are believed to have resulted from the upward migration of hydrothermal fluids emanating from a buried intrusive rock source. The main mineralized system, known as the No.1 and 2 veins, has been traced for nearly four kilometres. Less than half of this system has been developed. Significant portions of the No.1 and 2 veins and numerous other undeveloped veins offer additional exploration and development potential. Current “drill inferred” resources stand at 124,120 tonnes averaging 12.8gm/t (0.37 oz/t) gold and 33.7 gm/t (0.98 oz/t) silver (SRK Consulting, 2001).

During October to December 2006, Full Force Drilling and Coast Mountain Geological Ltd conducted the first phase of a drilling programme designed to test targets identified by SRK (2001) and Rennie (2005).

INTRODUCTION

LOCATION AND ACCESS

The Blackdome Mine is situated at an elevation of approximately 1925 metres in the Camelsfoot Range of the Fraser Plateau approximately 67 kilometres west northwest of Clinton, B.C. The mine is located at 51° 19.2' north latitude, 122° 30' west longitude on NTS Maps 92O/7 and 8 (Figure 1). UTM Coordinates are Grid Zone 10U 56857000N; 535400E (NAD 83)

Blackdome is accessible by the Meadow Lake road that heads west from Highway 97 approximately 16 kilometres north of Clinton, B.C. Travel is westerly for 80 km through Canoe Creek to the Gang Ranch Bridge over the Fraser River. Alternatively, the Gang Ranch Bridge may be accessed from from Williams Lake by taking the road south from the Bella Coola highway that goes through Springhouse, Alkali Lake and Dog Creek. William Lake airport is the closest with regularly scheduled flights. Heavy equipment (particularly log trailers) accessing the Blackdome cannot negotiate the turn onto that Gang Ranch Bridge and must cross the Fraser River on the Bella Coola highway before turning south and travelling through Gang Ranch to the start of the Empire Valley road. Travel is then southerly along the Empire Valley road for 18 km to the Blackdome mine road at Brown Lake. The camp and mine site is situated 32 km along this road on a ridge south of the summit of Blackdome Mountain.

HISTORY

Placer gold was discovered nearly 60 years ago in Fairless Creek. This creek flows westerly to Churn Creek from Blackdome Mountain. Prospecting soon after led to the discovery of gold bearing quartz veins on the southwest slopes of Blackdome Mountain.

In the 1950s, surface work and two adits were completed by Empire Valley Gold Mines and Silver Standard Mines Ltd. The property lay dormant until 1977 when Barrier Reef Resources staked the area and completed programs of soil and rock sampling, trenching, drilling and underground development.

In 1978, Blackdome Mining Corporation was formed to continue development. During the next seven years Blackdome and Heath Steele Mines Ltd carried out extensive exploration and underground development work totaling $8,000,000. By 1984, ore reserves of all categories were 222,500 tonnes grading 22.6 gm/t gold (0.61 oz/t) and 106 gm/t silver (3.6 oz/t). The 200-ton per day Blackdome mine commenced production in 1986 with an expenditure of $10,000,000. When mining ceased in 1991 a total of 338,000 tonnes of ore had been milled at an average grade of 21.9 gm/ton (0.64 oz/ton) gold yielding 7,000,000 grams (225,000 oz) of gold and 17,000,000 grams (547,000 oz) of silver.

Figure 1: Map showing the location of the Blackdome Project, British Columbia.

Claimstaker Resources reactivated the mine in November 1998. At the closure in May, 1999 a total of 203,631 grams (6,547 oz) gold and 538,000 grams (17,300 oz) silver were produced from 21,286 tonnes of ore. The inferred mineral resources are estimated at 124,120 tonnes averaging 12.8 gm/t (0.37 oz/t) gold and 33.7 gm/t (0.98 oz/t) silver (SRK Consulting, 2001). Approximately 90% of Blackdome's production came from the No.1 and 2 vein systems. Mining occurred over slightly more than a one kilometre strike length. Extensions of this major vein system and several other veins on the property remain largely undeveloped.

PROPERTY

The Blackdome property consists of 22 mineral claims, 10 Crown granted claims and two mining leases (figure 2) and covers an area of 9,329.6 hectares. The Blackdome property is held 100% by No. 75 Corporate ventures (FMC 133817), which is 100% owned by J-Pacific Gold Inc (FMC 104975). All claims and leases are recorded in the Clinton Mining Division. An additional 18 mineral claims in the southern portion of the property, covering an area of 7,365.61 hectares are owned 100% by J-Pacific Gold Inc.

GEOLOGY

The Blackdome property is situated in a region underlain by rocks of Triassic to Tertiary age. Sedimentary and igneous rocks of the Triassic Pavilion Group occurring along the Fraser River represent the oldest rocks in the region. A large, Triassic age, ultramafic complex (Shulaps Complex) was emplaced along the Yalakom fault; a regional scale structure located some 30 kilometres south of the property. Sediments and volcanics of the Cretaceous Jackass Mountain Group and Spences Bridge/Kingsvale Formations overlie the Triassic assemblages. Some of these rocks occur several kilometres south of Blackdome.

Overlying the Cretaceous rocks are volcanics and minor sediments of Eocene age. These rocks underlie much of Blackdome and are correlated with the Kamloops Group seen in the Ashcroft and Nicola regions. Geochemical studies (Vivian, 1988) have shown these rocks to be derived from a "calc-alkaline" magma in a volcanic arc type tectonic setting. Eocene age granitic intrusions at Poison Mountain some 22 kilometres southwest of Blackdome are host to gold bearing porphyry copper-molybdenum deposit. It is speculated that this or related intrusions could reflect the source magmas of the volcanic rocks seen at Blackdome. There is some documented evidence of young granitic rocks several kilometres south of the mine near Lone Cabin Creek. The youngest rocks present are Oligocene to Miocene basalts of the Chilcotin Group. These are exposed on the uppermost slopes of Blackdome Mountain and Red Mountain to the south.

The stratigraphy of volcanic rocks on the property is well known and divided into five units. Within these units individual members are also identified. Some areas are underlain by thick homogeneous units, while other areas (such as on the north side of Blackdome peak) have diverse members that provide substantial geological record of the volcanics. The following stratigraphic description is taken almost verbatim from Rennie (2004). Units are described from oldest to youngest.

Fairless Volcanics – Exposed northwest of the mine, along Fairless Creek. The unit comprises grey to grey-green fine-grained (aphanitic) andesite flows, medium to dark grey basalt flows, rhyolite ash with minor tuffaceous sandstone and siltstone, rhyolite crystal-lithic tuff and lapilli tuff.

Lower Andesite – Largely consists of rhyolitic and basalt members with andesite flows. Lowermost component is the Watson Member, comprising dacite to rhyodacite tuff, lapilli tuff, and flows. Overlying the Watson Member is the 1870 Member, which consists of interlayered medium grey amygdaloidal to dark grey aphanitic basalt flows, medium grey sparsely porphyritic andesite flows, white massive and flow-banded rhyolite, and white to grey-green lapilli tuff with rhyolite and andesitic clasts.

Rhyolite – From top to bottom: buff to grey-green rhyodacite to dacite flows with minor lapilli tuff, white to grey-green lapilli tuff with rhyolite and andesite clasts, white to grey-green flow-layered and locally spherulitic rhyolite, lapilli tuff comprising rhyolite and dacite clasts, and undifferentiated lapilli tuffs and flows. There is a wide range of breccia textures, clast size, and relative proportion of lapilli in the volcanic sequence. The rhyolite flows are observed underground to be auto-brecciated in places. Individual components of the volcanic stratigraphy are sometimes complexly interlayered, indicative of a chaotic depositional environment typical of a rhyolitic volcanic centre (or centres).

Fossilized graphitic remains of vegetation have also been reported in some localities within the tuffaceous members.

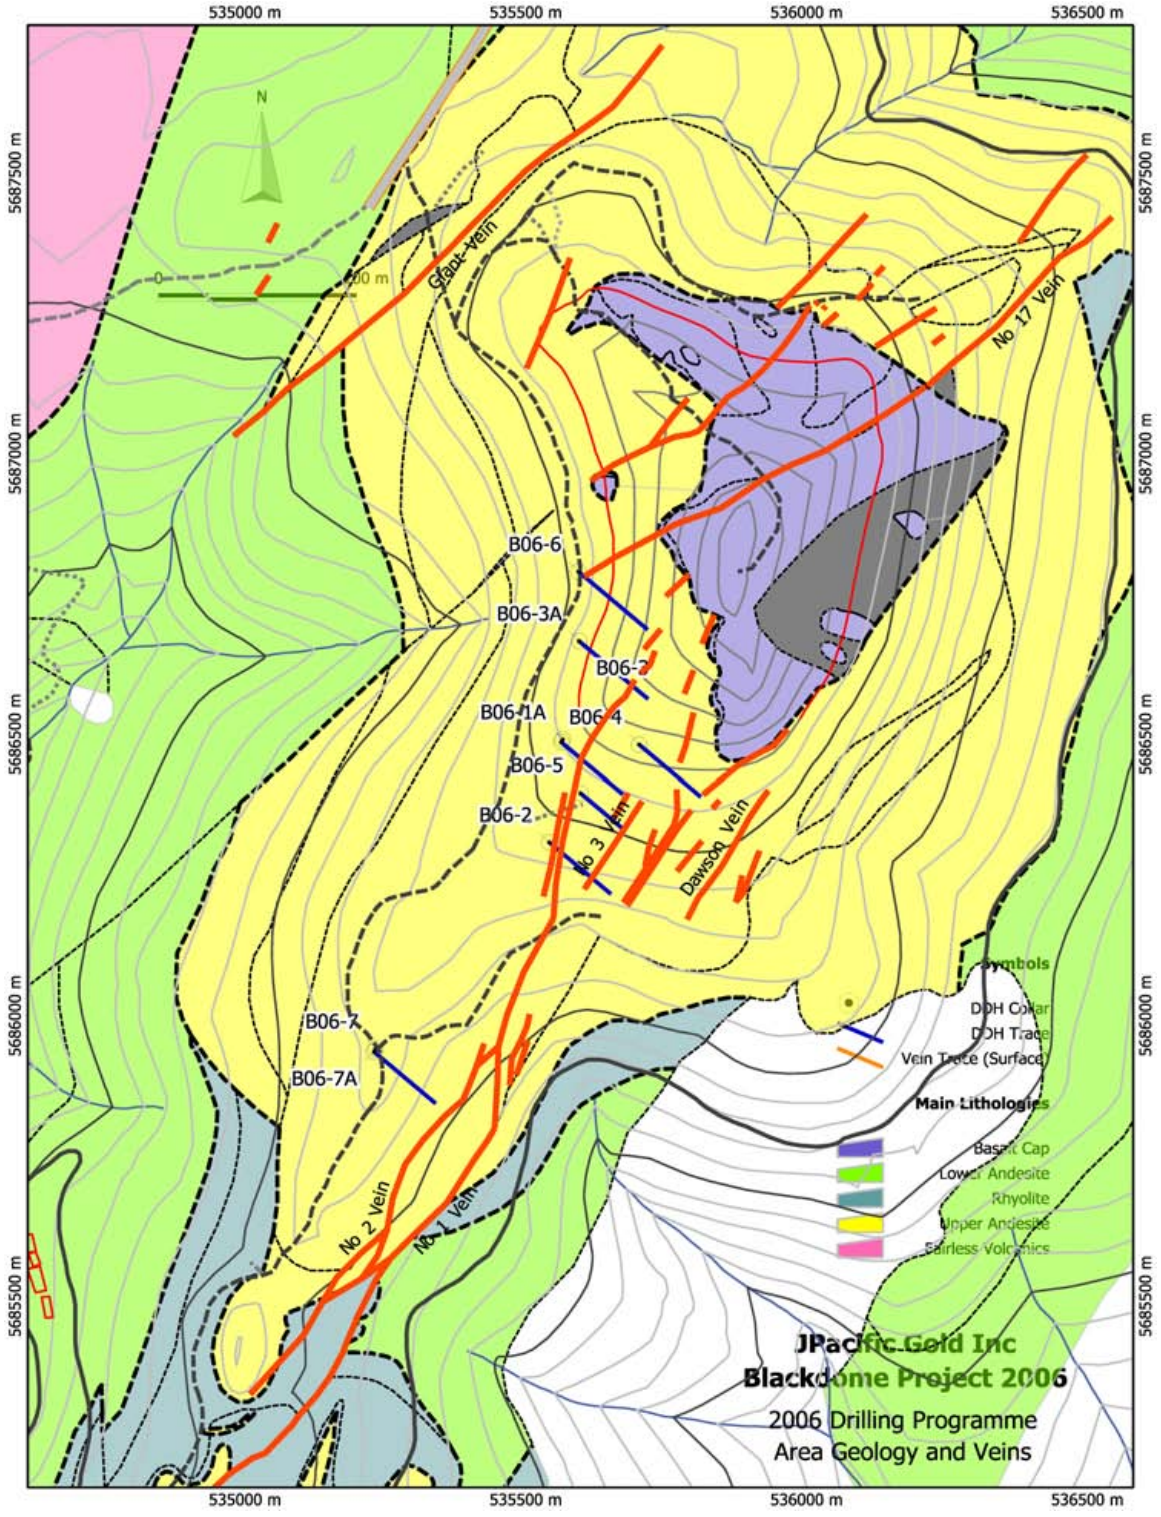

Figure 5: Property Geology

Upper Andesite – Comprises three members: the lowermost Lexington Member, which is a package of medium grey-green dacite flows; the Noranda Member, which consists of flow-layered dacite flows overlying a basal green and maroon dacitic tephra; and the uppermost Redbird Member, which is a basal lapilli tuff and volcanic breccia overlain by porphyritic dacite flows with hornblende granodiorite inclusions.

Basalt - Near the top of Blackdome Mtn., at the uppermost contact of the Upper Andesite, is a rusty weathered erosional disconformity marking a 25 million year hiatus in volcanic activity. Above this contact lies the Miocene basalt, which consists of medium to dark grey aphanitic basalt, with red oxidized and grey unoxidized basaltic tephra. The Eocene erosion surface is strongly weathered to a reddish colour. At the contact between the basalt and Upper Andesite, it is possible to pry chunks of basalt off of the regolith and find pebbles and cobbles embedded in the basaltic lava. The Miocene flows are post-ore and obscure traces of the veins. However, fracturing associated with the faults that host the veins have been observed to progress upwards into the basalt (Read, 1989, and Lee and Michaud, 2004), which indicates that movement along these faults continued into the Miocene. Some veins, notably the Redbird Vein, are hosted in structures that contain feeder dykes presumably for the basalt. Since only a few of the structures host feeders it would seem likely that only these were still active during the Miocene.

In the interior of British Columbia widespread, but sparse prospects and deposits may be

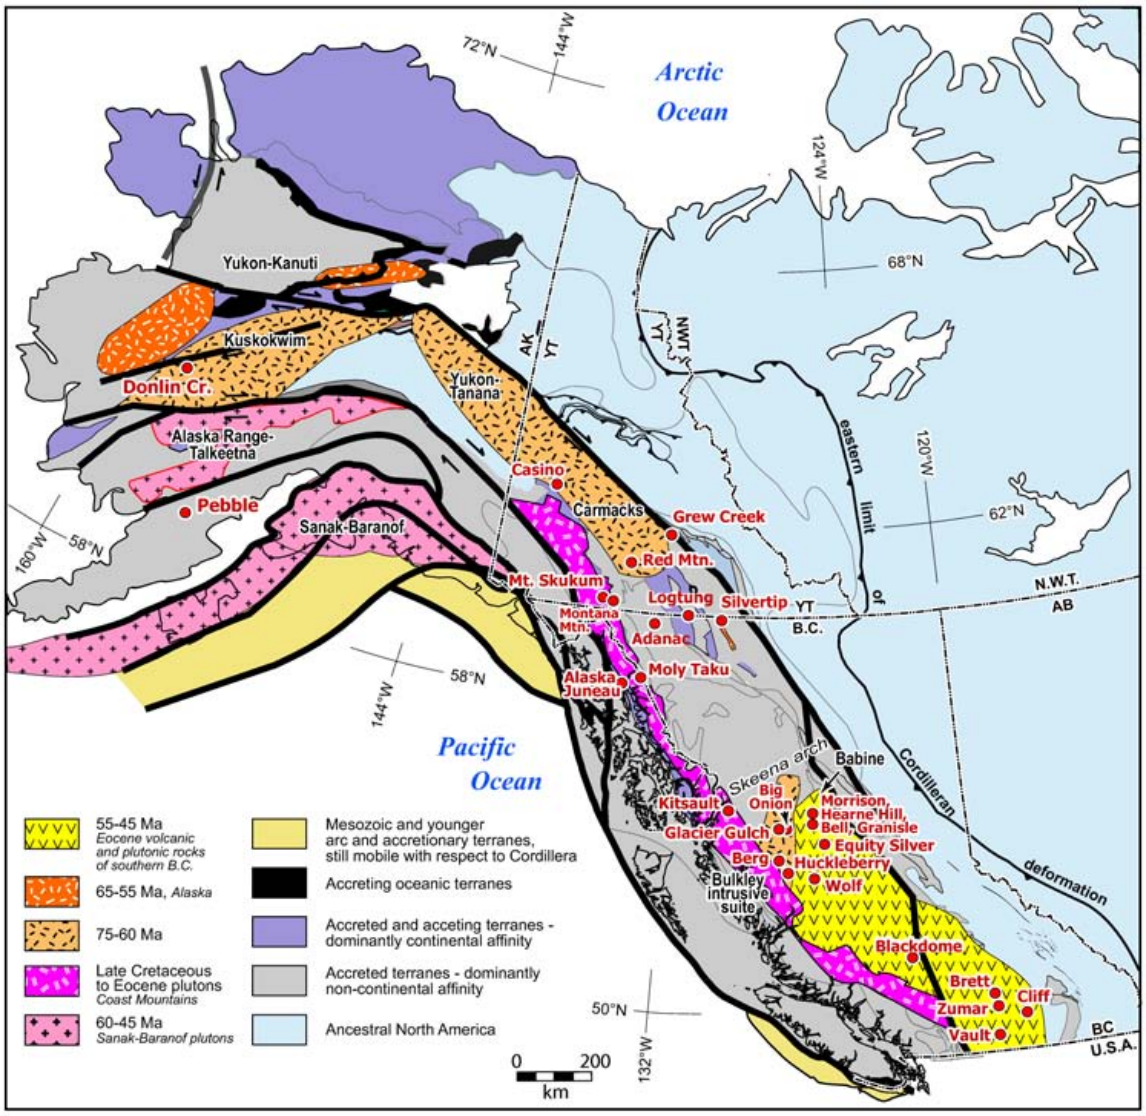

Figure 6: Late-Cretaceous to Eocene magmatism, volcanism and associated deposits/prospects in the cordillera of BC, Yukon and Alaksa.

found that formed in similar Eocene or slightly earlier environments. If the range is expanded to include late Cretaceous to Eocene then a series magmatic and volcanic belts running through cordillera in British Columbia, Yukon and Alaska can be seen which host epithermal and mesothermal vein systems in addition to intrusion associated gold occurrences.

A number of regional scale geologic structures are present. Major structures include the Fraser Fault, a north-northwest striking, right lateral, strike-slip fault. The Yalakom Fault and Hungry Valley Fault are subsidiary structures to the Fraser Fault and are also primarily dextral, but with some dip-slip movement. The latter fault occurs 5 km south of Blackdome and has displaced Lower Cretaceous sediments northward onto Upper Cretaceous and Tertiary rocks. The Yalakom Fault is thought to have controlled emplacement of the Shuswap Ultramafic complex. North to northeast trending extensional structures that were generated by the regional northwest trending faults are the host for gold mineralization at Blackdome.

ECONOMIC GEOLOGY

Blackdome is classified as a low-sulphidation, epithermal, Au-Ag type deposit. Gold and silver mineralization occurs in quartz veins and siliceous breccias which are believed formed from the upward movement of hot hydrothermal fluids in mid Eocene to early Oligocene time. Precious metal minerals include native gold, electrum, silver and several silver sulphides and sulphosalts. Accessory minerals include pyrite, chalcopyrite, galena and sphalerite. These minerals occur as fine to medium-grained disseminations and fracture fillings that generally represent ≤1% of the vein material. Visible gold is not unusual and gold values have significant nugget affects as evidenced by the >0.5 mm grains found in gravity concentrates during mining.

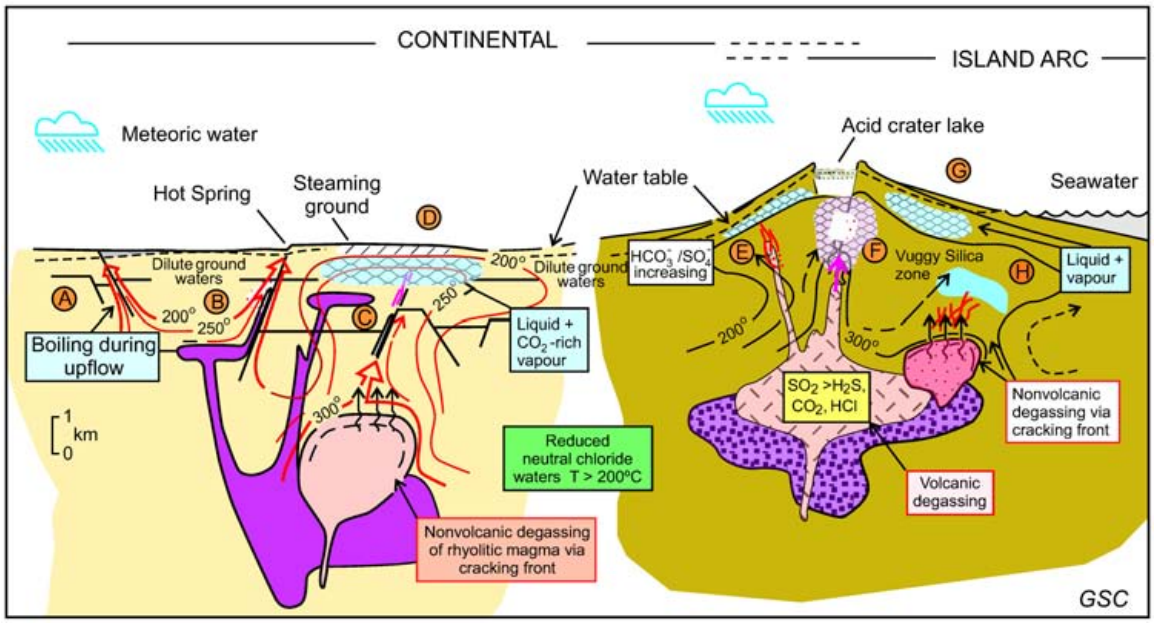

Figure 7: Diagram from Taylor (2007) showing the position of various mineral deposits in the epithermal model. Low-sulphidation system include A, B, C, and E. Blackdome is modelled in the setting of C in the diagram.

Veins are structurally controlled and occupy faults and extensional structures. Vein/fault systems generally strike north-northeast and dip 40-70° NW. The No. 1 and 2 veins are the major mineralized structures and have been traced for almost four kilometres. The vein/faults range from 0.5 to 3.0 metres wide and are comprised of variable amounts of clay gouge, solid quartz and gouge-vein mixtures. Work by Lee and Michaud (2001) identified two sets of structurally distinct veins at Blackdome. One set, includes the Redbird, Giant, and No 17 Veins and are secondary structures of the Faser fault system with strike slip movement. Most of these have received little development work. The other set, which includes the No. 1 and No 2 Veins may have more dip-slip movement and are subordinate to the previous set. This set of veins has received the most attention and has produced the most ore. The ore zones are elongate, moderate to steeply plunging *"bonanza shoots"* associated with quartz rich sections of the fault zones. Very little gold and silver has been found in vein wall rock. Ore shoots are 30 to 50 metres long, 60 to 100 metres high and 0.5 to 3 metres wide. The majority of known stopes are located between the 1870 and 1920 metre elevations. Such depositional control characteristics are not uncommon in epithermal deposits. However, the range of levels can vary along strike and within other mineralized zones.

MINING AND MILLING

Mining utilized cut and fill methods with the fill being comprised of waste rock until 1988. After this time, mill tailings mixed with cement were pumped into worked-out sections by the use of a backfill plant. Mining took place at 50 metre levels. Two of the major access points are the 1870 and 1920 metre levels. Trackless haulage equipment was used throughout the mine, with ore being hauled from the portals to the mill by dump trunks.

Blackdome ore has a relatively simple metallurgy with over 60% free gold. Milling consisted of a gravity circuit for the free gold and a flotation circuit to recover precious metal bearing sulphides. Gravity concentrates were refined into doré bars and the flotation concentrate was shipped to Japan for smelting. Gold recovery was reportedly over 90% during the life of the mine.

The mineralogically simple and benign nature of the ore resulted in tailings that posed little environmental impact. Tailings were discharged into a pond ~80 metres below the mill and were impounded by a rock and clay fill dam. Tailings water was monitored for heavy metal content and suspended solids and then passed through a settling pond.

PHASE I DIAMOND DRILLING PROGRAM

The 2006 drilling programme was designed to focus on the projected northern strike extension of the previously producing No 1 and No 2 veins to where the basalt cap covering the peak of Blackdome masks their surface expression. This northern extension has only been partially drill tested and the 2006 programme stepped out from 25 to 125 metres from previous work. A total 10 holes (2014.9 metres) were drilled. Three holes (B06-01, 03 and 07) were abandoned due to bad ground with a second attempt being

made at the same dip and azimuth immediately adjacent. Only one of the three second attempts failed to complete all targets.

Hole #	UTM E	UTM N	Elev	Length	Az	Dip
B06-01	535,566	5,686,491	2118	70.7	132	55
B06-01A	535,566	5,686,491	2117	174.7	132	50
B06-02	535,535	5,686,331	2090	282.3	125	55
B06-03	535,601	5,686,653	2133	84.7	125	45
B06-03A	535,601	5,686,651	2133	325.7	125	45
B06-04	535,702	5,686,482	2145	172.5	115	50
B06-05	535,617	5,686,420	2112	247.8	100	68
B06-06	535,594	5,686,790	2106	252.1	100	50
B06-07	535,213	5,685,927	2040	102.7	122	61
B06-7A	535,212	5,685,927	2040	301.7	122	61

Further northern extension, below the basalt cap on Blackdome peak, was deferred to a later phase where the relationship between the No 1 and 2 veins and the No 17 vein can be tested. The surface trace of the No 17 vein is known on the northeast side of the basalt cap. The projections of the three veins intersects below the basalt cover and as with other structural intersections, is a prospective target.

Drilling during the 2006 season began quite late in the season. Difficulties in drilling due to poor ground conditions and weather resulted in significantly lower productivity than had been predicted. The second target of the programme was the depth intersection of the No 1 and No 2 veins. Due to the difference in dip between the two veins and their anastomosing shape, a keel shaped zone of intersection was predicted. Unfortunately, only one hole was attempted on this target before weather forced the suspension of the programme until the spring. This hole, B06-07A was lost shortly before it reached target depth. Casing was left in the hole to enable re-entry and completion during the 2007 season.

Core Handling and Analysis

Core was brought from the drill to the mill site where a logging and sampling facility had been constructed in the existing buildings and winterized to the extent possible. Core was initially cleaned and inspected for misplaced or reversed core, block positions and block labelling. Block labels were then converted to metric. Core was not photographed until sample intervals had been marked. Two types of drill logs were recorded into laptop computers: 1) A descriptive log which described lithological, alteration and mineralization features was made using a word processor, 2) An attribute log which records quantitative and categorical data by sample interval or where no samples were taken by block interval was recorded into a spreadsheet. Intervals were also broken at lithological boundaries. Selected core photography was embedded in the descriptive log. The attribute log is designed facilitate data loading into GIS, database or statistical software. Both sets of drill logs are provide in appendices.

Samples were sawed in half and half the sample was returned to the core box. The other half of the sample was placed in a plastic sample bag with one part of the three part sample tag. The bag was then sealed and delivered to the analytical laboratory by Coast Mountain Geological or J-Pacific personnel. Every tenth sample was taken from one of

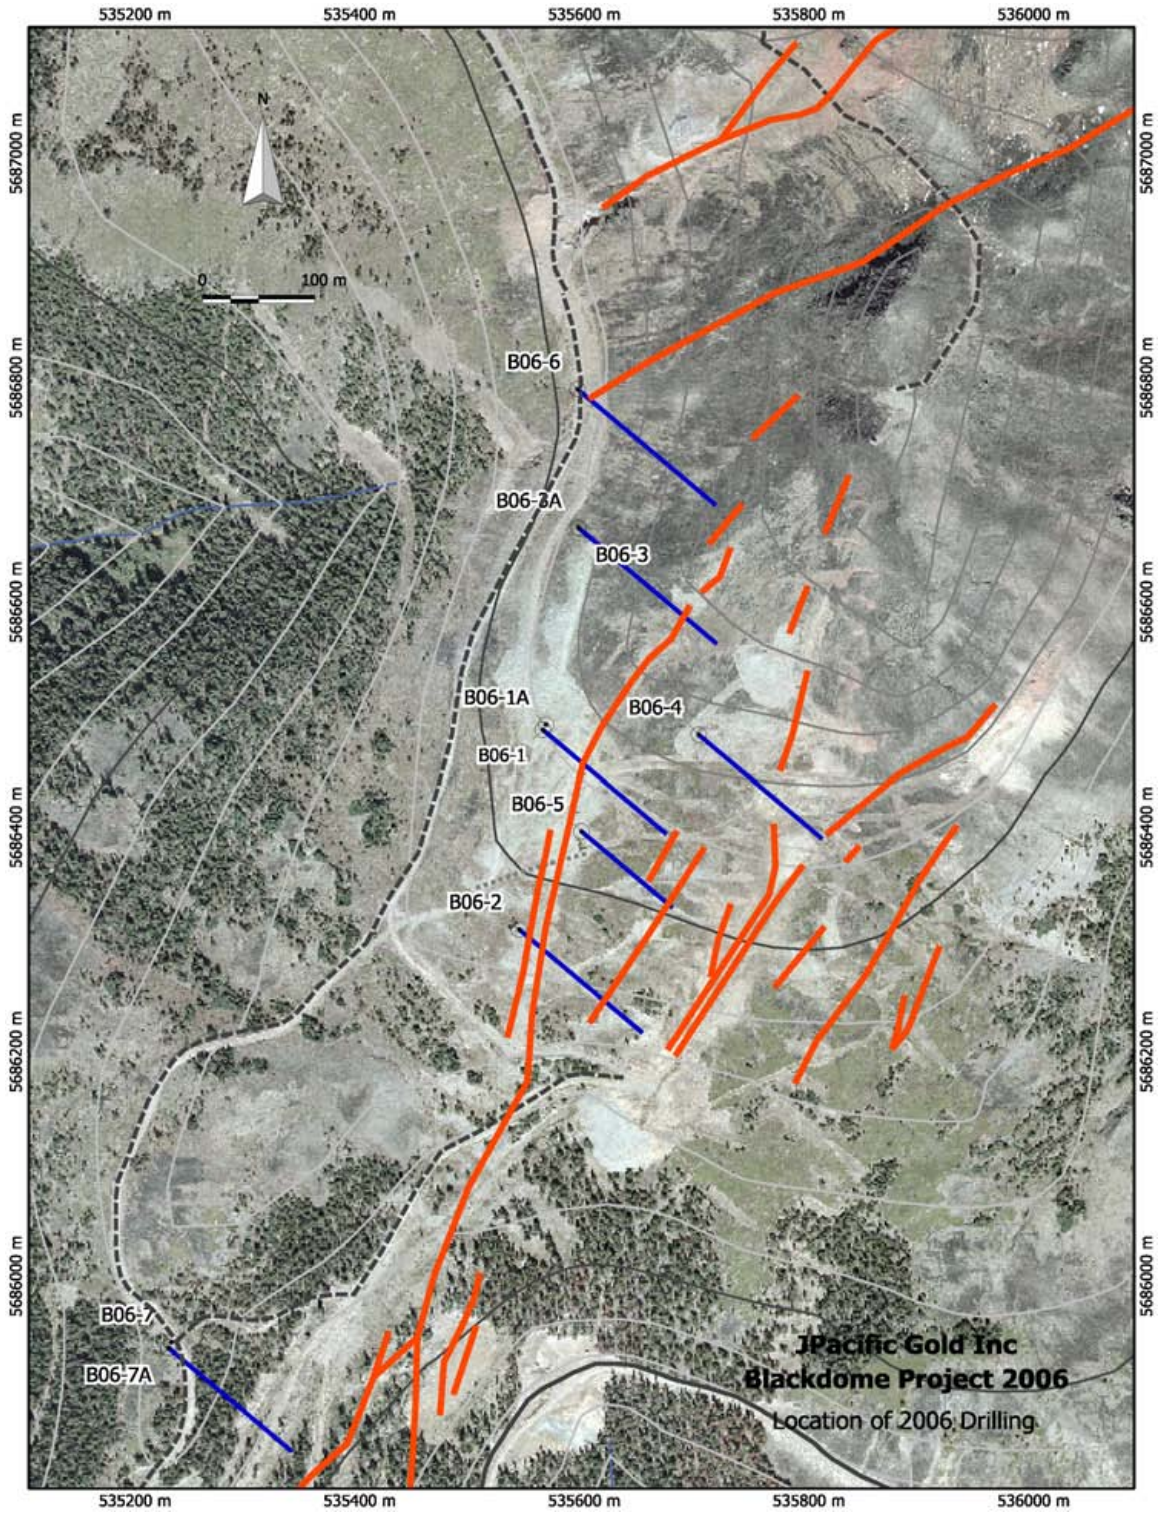

Figure 8: Drill Traces on Airphoto Base

three certified standards purchased by Coast Mountain Geological. Standards were

provided in the form of pulps.

A total of 185 samples were delivered to Eco-tech Laboratories of Kamloops, British Columbia who provided analytical services during the project. Of these samples, 16 were standards and two were field-split replicates. Fire assay for Au (using 30g samples) and 28 element ICP-AE was performed on all samles.

Drilling Results

Drilling of the No 1 Vein in the vicinity of the 1960 North mine area, where a mineral resource has previously been defined, intersected the No 1 Vein with two holes (B06-02 and B06-05). These intersections were spaced approximately 150m apart along strike at the 1870m level – 90m down dip of of the mineral resource. Hole B06-02 returned 5.3 g/t Au and 1.8 g/t Ag over 0.60m. Hole B06-05 returned 28.9 g/t Au and 516.0 g/t Ag over 0.30m. Two other holes intersected the No 1 Vein approximately 150m along strike to the north of the mineral resource. Both of these returned only anomalous gold and silver values. When step-out drilling is being interpreted, it should be noted that historically, ore shoots at Blackdome are typically 30 to 60m wide (along strike) and 50 to 100m up and down dip.

Two holes drilled to intersect the northern strike extension of the No 2 Vein structure intersected typical quartz veining at 25m and 175m along strike, north of historical drilling. Hole B06-03A (25m along strike) returned 14.2 g/t Au and 67.1 g/t Ag over 1.90m. B06-06 (175m along strike) returned anomalous assays.

The following table summarizes the more significant results of the 2006 drilling.

Drill Hole	Sample Interval* (metres)				Assay Results	
	Vein	From	To	Width	Au (g/t)	Ag (g/t)
B06-01A	No 2 Vein	48.95	49.80	0.85	2.2	14.7
B06-02	No 1 Vein	237.90	238.50	0.60	5.3	1.8
B06-03A	No 2 Vein	42.40	43.85	1.90	14.2	67.1
B06-05	No 1 Vein	239.90	240.20	0.30	28.9	516.0
* intervals reported above are core lengths; true widths will be shorter.						

CONCLUSIONS AND RECOMMENDATIONS

While the intersected extension of the No 1 and No 2 Veins is similar in mineralization content to the previously mined ore at Blackdome Gold Mine, its presence does not necessarily indicate that additional mineral resources will be delineated.

Only one of the targets identified in previous work has been drill tested. Two additional targets were identified for the next phase of drilling. These are 1) the depth intersection

of No 1 and No 2 Veins, and 2) under the basalt cap where No 17 should join or intersect No 1 and No 2 Veins. None of the results in the first phase discourage moving ahead with the program planned for the second phase. Further recommendations would be premature, other than to note important logistical lessons learned during phase one. Winter drilling at Blackdome was found to be both difficult and costly. Until such time as a permanent, all weather camp can be established at Blackdome, winter drilling should be avoided.

Reviewing gold values in drill core has raised questions about what threshold(s) to use when deciding how significant intersections are in targeting and identifying proximity to ore zones. During mine life thresholds between 1 and 2 g/t Au were often contoured as the outer threshold surrounding areas of interest. These levels may be too high and the thresholds may vary between veins sets. In particular, work by Lee and Michaud (2001) suggests the veins associated with No 1 and No 2, and those associated with the Giant, Redbird and No 17 Veins may have distinct characteristics including different gold thresholds. As more data becomes available from phase 2 a review of gold thresholds by vein set is warranted.

Compilation continues to be an important area for off-season work. While there has been substantial progress in this area during work by Lee and Michaud (2001) and later by Rennie (2004), the majority of the data compiled has been from the mine. Exploration data collected before and during the mine life that is not already part of the compilation needs to be reviewed and added.

APPENDIX A – STATEMENT OF EXPENDITURES

STATEMENT OF EXPENDITURE
Blackdome Gold Mine, 2006
Prepared by J-Pacific Gold Inc. Management

Consulting Fees / Labour

Coast Mountain Geological		
R Parish, P. Geo ($700 per day)	$39,200.00	
56 days (Oct 25 06 - Feb 25 07)		
J Harrop P. Geo ($700 per day)	$5,425.00	
7.75 days (Oct 25 06 - Feb 25 07)		
A Pollmer P. Geo ($700 per day)	$9,450.00	
13.5 days (Oct 26 06 - Dec 10 06)		
W Fitzgerald, Tech ($425 per day)	$1,275.00	
3 days (Oct 26 06 - Nov 26 06)		
Expenditures		
Administration	$741.79	
Truck rental	$5,525.00	
Communications	$1,265.89	
Saw and other equipment rental	$1,512.50	
Other (meals, travel, camp supplies, etc)	$4,554.42	$68,949.60
Blackdome Gold Mine (Oct 25 06 - Feb 28 07)		
Mike Michaud, P Geo ($10,000 per month)		
Allocation 67% salary (Oct 06 - Dec 06)	$20,510.50	
Allocation 25% salary (Jan 07 - Feb 07)	$2,683.14	
Larry Camille (539 hrs @ $15.68 per hr Oct 06 - Dec 06)	$11,932.49	
Labour / First Aid		
Eric Archie (380 hrs @ $19.90 per hr Oct 06 - Dec 06)	$8,148.21	
Labour / Cat Operator		
Dwayne Sergent (208 hrs @ $15.00 per hr Oct 06 - Dec 06)	$3,303.92	
Labour		
Floyd Haller (63 hrs @ $15.75 per hr Oct 06 - Dec 06)	$3,560.76	
Labour / Cat Operator		
Clara Camille (643.25 hrs @ $15.00 per hr Oct 06 - Dec 06)	$9,829.03	
Cook / Cleaning		
Rose Wilson (155 hrs @ $15.00 per hr Oct 06 - Dec 06)	$2,454.06	

Cook / Cleaning		
Dave Hodson (588 hrs @ $20.00 per hr Oct 06 - Dec 06)	$12,021.93	
Labour / Mgr		
Larry Emile (10 hrs @ $15.00 per hr Oct 06 - Dec 06)	$152.81	
Labour		$74,596.85
Drilling		
Full Force Drilling (2,014 metres)	$347,250.50	
Mob crew	$3,000.00	
Debmob crew	$3,000.00	
Mob drill	$3,750.00	
Debmob drill	$3,863.70	$360,864.20
Analytical Costs		
EcoTech		
185 36 element ICP		
185 fire assays for gold		$6,591.60
Road clearing, sanding and maintenance		
Access roads - GNS Contracting	$3,332.61	
Illidge Contracting and Blasting	$9,473.50	
Canoe Creek	$2,406.90	
Warren Koster	$5,720.00	$20,933.01
Camp (food and misc camp items)		
Provisions	$8,511.68	
RV rental	$6,418.37	
Radios	$3,407.42	
Repeater upgrade and batteries	$7,542.64	$25,880.11
Propane and Diesel		
Del's Propane	$12,357.05	
Finning	$48,244.44	$60,601.49
Other		
CAT rental	$31,000.00	
Build 2 core shacks (10,000 metres storage)	$24,380.00	
Communications	$842.56	
Vehicle gas, mileage and oil	$3,299.92	
Field supplies	$561.34	
Other	$299.60	$60,383.42
		$678,800.28

APPENDIX C –DESCRIPTIVE DRILL LOGS

Blackdome Project 2006

Drill Hole Name: **B06-01**

Area: **No 1 and No 2 Vein North**

Drill Log

UTM Easting	535566	Drill Contractor	Full Force Drilling	Pad Number	P06-3
UTM Northing	5686491	Mine Grid E	4652	Start Date	28 Oct, 2006
Elevation (m)	2118	Mine Grid N	13520	Finish Date	31 Oct,2006
UTM Zone	10 U	Logged By	R. Parish	Reclaim Date	
Datum	Nad 83 Canada	Core Type/Size	NQ2	Log Date	12 Dec, 2006

Length (m)	70.7
.Azimuth	130
Dip	-55

Target	Test the #2 vein above the 2050 level. Test the #1 vein below the 1960 level.
Stopped for:	Lost hole in working at 70.7m 12 feet of open space.
Result	

Note: Since hole B06-01A is a twin of this hole, just the interval around the #2 Vein intercept was logged and sampled.

44.6	**60.6**	**and**	**Andesite**

Fine to medium grained, porphyritic andesite. Weak to moderate propylitic alteration consisting of chlorite+/-calcite+/- epidote replacement of groundmass and phenocrysts. The # 2 Vein in this hole appears to be manifest as zones of brecciation with white quartz veins forming the matrix, rather than as a discrete, through going quartz vein. White, vuggy quartz veins are scattered throughout the interval. Highest concentrations are noted below.

46.7	47.3	White cockscomb quartz vein running down edge of core. 3 cm thick . Sample 3634.
48.2	48.3	10 cm wide breccia vein consisting of silicified andesite clasts in a matrix of white cockscomb quartz veins. Upper and lower contacts at 45 to CA. Several smaller qtz veins in the footwall and hanging walls. Sample 3635.

52.5	53.1	Main portion of the #2 vein? Crackle breccia with white quartz vein matrix. Veins have open spaces where angle wing calcite was leached from the quartz, and later dusted with drusy quartz. Footwall portion is a 15 cm white cockscomb quartz vein with trace oxidized pyrite and limonitic surface stain. Lower contact of this vein is 35 to CA. Sample 3637

56.5	57.1	Brecciated andesite with white vuggy quartz veins as matrix. Samples 3639 and 3641
38.5	38.8	Gray-green clay seam at 10 to CA.

Blackdome Project 2006

Drill Hole : **B06-1A**

Area: **#1 Vein North**

Drill Log

Easting	535566	Drill Contractor	Full Force Diamond Drilling	Pad Number	P06-3
Northing	5686491	Mine Grid W	4655	Start Date	31 Oct, 06
Elevation (m)	2118	Mine Grid N	13510	Finish Date	4 Nov, 06
UTM Zone	10	Logged By	R. Parish	Reclaim Date	
Datum	NAD 83 Canada	Core Type/Size	NQ2	Log Date	7 Nov, 06

Length	174.65m
.Azimuth	132
Dip	-50

Target: Test the #2 vein above the 2050 level. Test the #1 vein below the 1960 level

Stopped for: Abandoned hole in broken andesite rubble with clay, seams after wearing out two bits and a shell trying to drill the last 6m of the hole. Hole would not advance.

Result: Intersected #2 vein zone from 49.15 to 52.2m.

DRAFT

0	**3.05**	**ovbd**	**Casing**
			No core recovered.
3.05	**174.65**	**and**	**Andesite Flows**

Tan to greenish-grey to grey, volcanic flows of intermediate composition. Flows tend to be massive and generally without flow features. They contain occasional rounded xenoliths of porphyritic andesite and local, clast supported breccias which may be intra-flow breccias.. The flows have a medium to coarse-grained, porphyritic texture. Phenocrysts consist of up to 30% tabular to lath-shaped plagioclase. These are subhedral to euhedral and up to 5mm long. The plagioclase is often altered to calcite, sericite and possible chlorite. Hornblende occurs as subhedral to euhedral, tabular to prismatic phenocrysts to 1 mm. They occur as isolated crystals and as clots with plagioclase up 1 cm across. The hornblende is usually altered to a fairly soft, massive mineral, possibly chlorite. Hornblende is usually less than 5% of the rock. Groundmass is fine-grained to aphanitic. Most of the core is propylitized to some degree, ranging from weak to very strong. Bleaching occurs as envelopes adjacent to structures, and to zones of quartz veining. Argillization occurs as a broad halo, along with bleaching, adjacent to structures and quartz veining. Silicification of wall rocks is generally confined to areas immediately adjacent to quartz veins, or rarely, as passive flooding of groundmass.

3.05	26.50	Intermittent strong oxidation where feldspar phenocrysts are altered to clay and possible sericite, hornblende completely altered to chlorite? Bleaching of groundmass. Strong feox on some fractures, presumably after pyrite. Moderate black MnO2 on fractures. Less oxidized portions are

					green from propylitization.
9.9	16.2				Local, patchy areas of bluish grey, cryptocrystalline silica forming matrix in brecciated andesite. Mostly crackle breccia. Andesite clasts are oxidized and somewhat argillized.
			16.95		2 cm fault at 25 to CA. Gouge consisting of orange tan clay and rock fragments.
23.6	26.4	Bx			Zone of brecciation consisting of rounded to sub angular andesite clasts in porphyritic andesite matrix. Possible autobreccia representing flow surface. Moderately oxidized and locally bleached. Matrix is partially hardened by grey silica around 25m.
			28.0	29.0	Fracture set at 5 to CA, strong feox and Mn02 on surfaces
26.5	48.05				Moderately propylitized to locally oxidized andesite. Soft to moderately hard. Feldspars mostly altered to calcite and sericite? or clay. Hornblende altered to greenish black chlorite. Common calcite + chlorite veinlets.
			32.4		5mm wide fracture or fault with orange-tan clay gouge 35 to CA
			41.45		2 cm wide silicified and qtz veined shear at 30 to CA. Brecciated with white qtz vein clasts and silicified andesite clasts. Shear zone is silicified and the walls are progressively silicified for 10 cm approaching the shear. Trace pyrite.
			44.81	49.15	Beginning of veining associated with #2 vein structure. Propylitization gradually decreases and oxidation increases approaching main structure at 49.15m Interval consists of numerous sub-parallel, white, toothy qtz veins and veinlets at 25 to 40 to CA. Intervening andesite is often strongly silica flooded. Minor local brecciation with quartz veining as the matrix.

			49.15	49.80	Zone of intense shearing and brecciation. Seems to be oriented at appx. 40 to CA. Matrix supported breccia with angular andesite clasts in matrix of grey, fine grained qtz, greenish -tan chalcedonic qtz, and white cockscomb qtz, which appears to be later. Some of the matrix appears to be silicified milled rock flour. White adularia? occurs as breccia clasts inter grown with colour quartz scattered through matrix. Trace grey-black sulfide- possible silver mineral. 1% oxidized

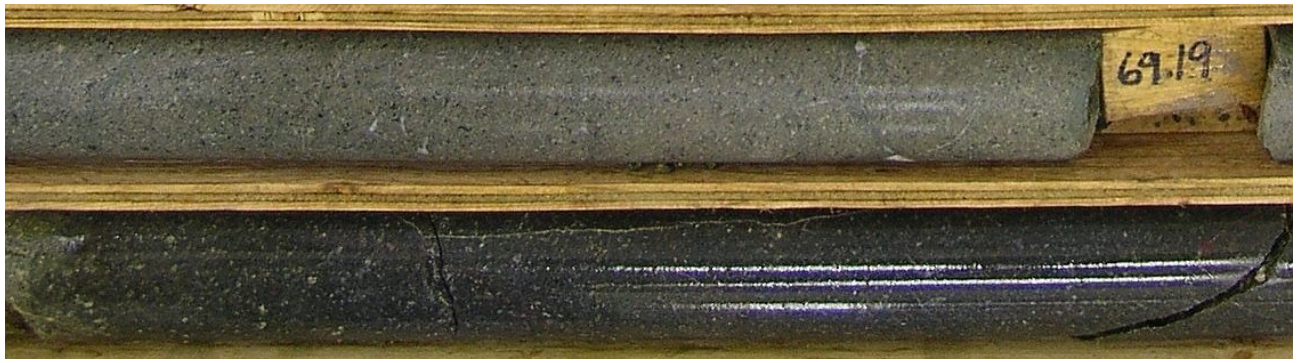
disseminated pyrite. Minor white clay, Illite?, and yellow jarosite? in vugs and on fractures.

51.0 52.2 Matrix supported breccia with white cockscomb quartz veins forming matrix. Orange-red clay in medial cavities. Appears to be single phase breccia without multiple episodes of hydro fracturing.

From	To	Width	ID	Au g/t	Ag g/t	Au/Ag
44.81	45.25	0.44	3503	0.45	4.7	0.10
45.25	46.35	1.10	3504	0.27	0.6	0.46
46.35	47.95	1.60	3505	0.24	1.5	0.16
47.95	48.95	1.00	3506	0.78	1.7	0.46
48.95	49.80	0.85	3507	2.23	14.7	0.15
49.80	51.05	1.25	3508	0.18	6.7	0.03
51.05	52.25	1.20	3509	0.69	15.3	0.04
52.25	53.25	1.00	3511	0.28	3.9	0.07

56.67 57.40 Weakly brecciated, with minor bluish grey silica matrix and numerous white toothy quartz veins to 5mm at 20 to 40 to CA. Strong yellow-tan clay associated with white qtz veins. Moderate silica flooding adjacent to qtz veins.

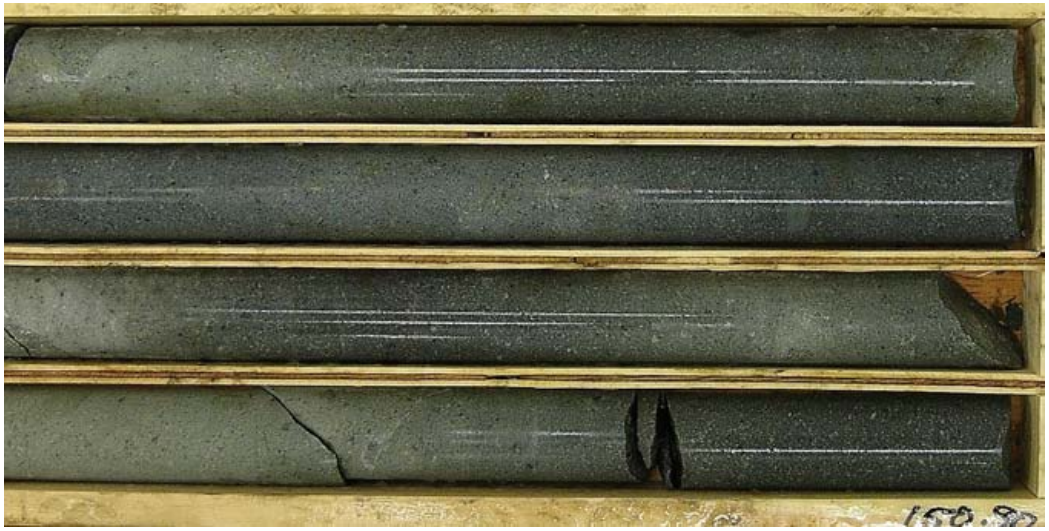
58.6 59 Several clay and rock fragment filled faults at 25 to 35 to CA.



60.0 104.50 Porphyritic andesite flows as above, however propylitization is more persistent. Green to greenish grey groundmass, locally strong replacement of feldspar by calcite and possible sericite or clay. Hornblende often altered to chlorite. Epidote and chlorite abundant as alteration of groundmass and as matrix of autobreccias. Blood red mineral locally common in groundmass and in veins, often with chlorite and calcite. Looks like cinnabar, but is probably hematite.

69.85 70.05Soft, strongly argillized shear zone at 45 to CA

81.38		4 cm grey clay seam/ fault gouge. Indeterminate orientation.
83.8	85.0	Breccia. Clasts are 10s of cm wide and are separated by matrix of grey-green, silicified rock flour or chalcedonic quartz vein.? and minor white calcite. Not much clast rotation. Appears to be a large scale crackle breccia.
87.0	88.2	Numerous calcite +/-chlorite filled tension veins at 15 and 40 to CA.
96.25	96.35	Chloritized shear at 40 to CA.
102.7	108.5	Several greyish-green chalcedonic qtz veins or silicified shears. Often contain spots and blebs of blood red hematite within the veins and as envelopes around veins.



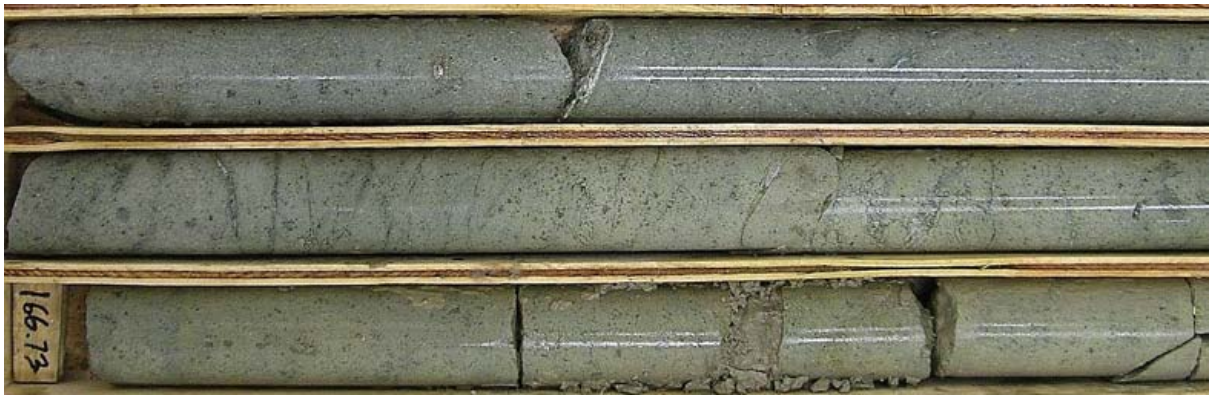
108.8	Clay lined fault at 35 to CA

104.50 159.80

Monotonous package of andesite flows? as described above. Like previous intervals,these rocks are quite massive, and except for a very weak alignment of phenocrysts, show no flow textures. Discernible flow margins are very rare. They may be part of a hypabyssal intrusive instead of extrusive flows. Xenoliths of porphyritic andesite and finer-grained mafic phases are more common in this interval, and occur every 1 to 2 meters.

111.3	111.6	Bleached zone with greenish chalcedonic veins or silicified breccia matrix with red hematite blebs.
115.8	125.0	Marked increase in red hematite veinlets, and hematite as envelopes adj to veinlets.
	126.10	5mm fault with clay and milled rock fragments, 40 to CA.

136.25	139.50	Zone of strong passive silica flooding of groundmass ,and less so of phenocrysts.
142.0	142.7	Zone of bleaching centred on tan clay-lined fault at 142.30. 50 degrees to CA.
148.65	148.95	Bleached zone centred on 1 cm wide breccia at 50 to CA with calcite, chlorite, epidote and red hematite matrix.
150.3	150.8	Bleached zone as above., but centred on hairline fracture, no breccia.



159.8 174.65

Fairly abrupt increase in propylitization of andesite beginning at 159.8m. Rock is green, fairly soft, and feldspar phenocrysts are largely altered to calcite and clay. Mafic minerals are altered to chlorite and epidote. Groundmass is altered somewhat to chlorite and epidote. Fragmental texture is more common, and these rocks may represent a series of thinner flows with autobrecciated tops and bottoms. Breccia matrix is largely replaced by epidote, chlorite, and calcite. Numerous, greenish clay seams occur throughout the interval. Below 170m the rock is quite broken and clay seams are much more common. The hole was abandoned after spending two shifts, and wearing out two bits and a shell trying to get through the last 6 m of this interval.

166.25	167.0	Several green clay seams up to 5 cm wide at 75 to 90 to CA.
169.6	170.0	Several joints at 30 to CA
170.3	170.5	20 cm wide green clay seam
171.0	172.1	Rubbly core with breaks at all angles to CA, abundant clay.
173.0	174.65	Broken core with abundant clay seams. Fractures tend to be from 5 to 20 to CA forming wedge shaped pieces

174.65 EOH

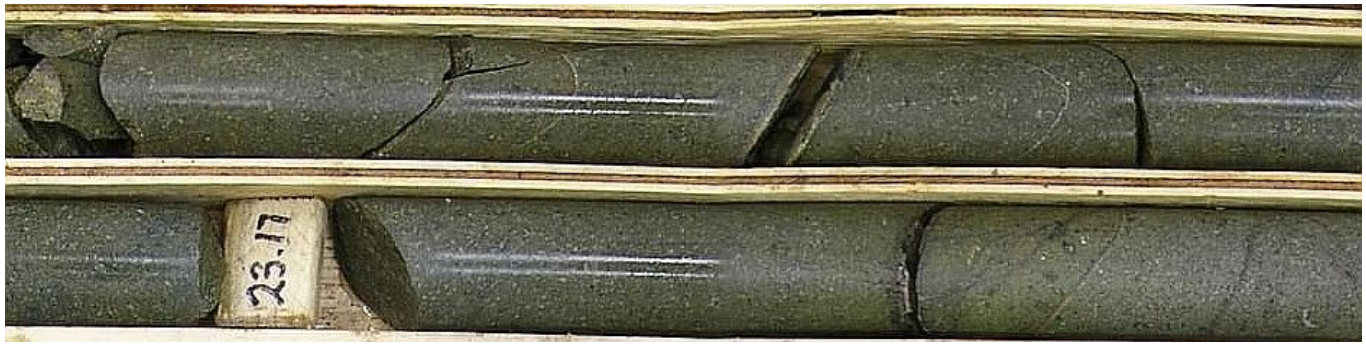
Target	Intersect #1 vein below 1960 level. Determine geometry of splay off of the #1 vein below the the north end of the 1960 level workings.
Stopped for:	Reached target depth
Result	

Selected sample results are included. See attribute table or assay sheets for complete results.

0	**2.1 m**		**Casing** No Core.
2.0	**160.33**	**And**	**Andesite Flows**



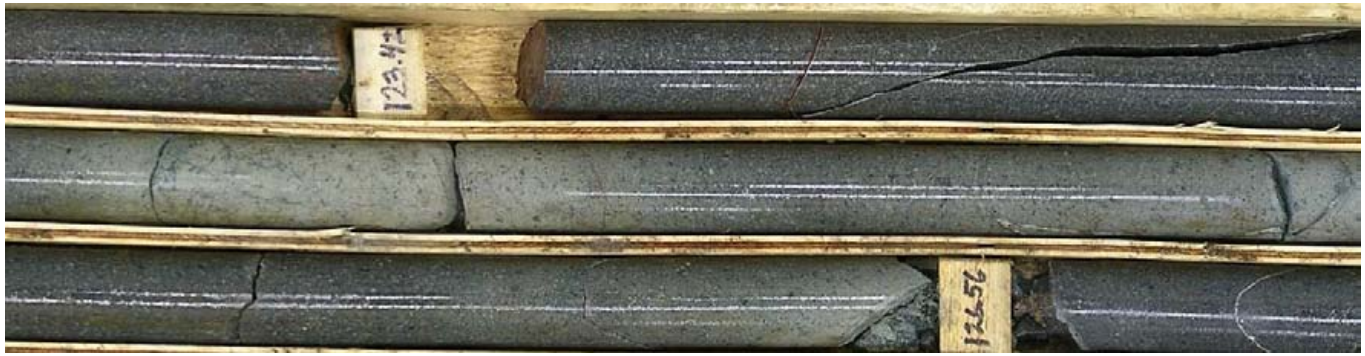
Green to greenish-grey to purple grey flows of intermediate composition, Medium-grained, porphyritic texture. Typical rock consists of 30% tabular to lath shaped plagioclase phenocrysts up to 3mm and 5% anhedral to euhedral hornblende prisms to 4 mm. Hornblende occurs as single crystals and as clots with plagioclase. The groundmass is fine grained. The flows are quite homogeneous, and usually are without flow textures. Individual flows are hard to discern, but where they can be identified they are often separated by breccia zones consisting of rounded to sub-angular andesite clasts in finer grained andesite lava, or sediments. Propylitization is common throughout the hole, though it appears to be localized around structures which may have acted as fluid conduits. In propylitized rocks, groundmass is light to dark green, and often calcareous, feldspars are altered to calcite+/- clay, hornblende is altered to chlorite +/- epidote, and calcite+/-chlorite+/-epidote occurs in veins and breccia matrix. Bleaching, argillization, and silicification occur closer to mineralizing structures.

2.0	10.25		Andesite flows have a decided purplish hue due to weak hematite? in the groundmass, often rimming feldspar phenocrysts.
		7.5	8.0 Zone of strong oxidation and argillization emanating from several 1 mm sized fractures.
10.25	32.31		Core is moderately to strongly propylitized, except where bleached and oxidized adjacent to quartz

veins. Numerous chlorite and calcite veins and fracture surfaces throughout interval.

16.7	19.30	Numerous white quartz+/-calcite veins up to 5mm, spaced every 30 cm. Most veins are roughly 45 to CA.
19.5	20.20	Swarm of toothy white qtz veins and breccia matrix in oxidized, bleached, and locally silicified andesite. Breccia and veins are oriented at roughly 45 to CA.
20.7		1 cm wide fault at 30 to CA. Clay and rock fragment gouge.
24.2	29.26	Core is quite broken with chlorite and feox lined fractures. Main fracture set at 55 to CA, others at 25 and 5 to CA.
29.3	38.4	Numerous white quartz veins to 5mm spaced 10 to 30 cm apart. Veins at all angles, but dominant set at 40 to 50 to CA. Wall rocks somewhat oxidized, and rarely silicified adjacent to veins. This interval includes sample 3514, which contains several larger white toothy quartz veins , and a small orange red clay gouge zone.

39.5	57.0	Light greenish propylitized andesite flows, without the veining and oxidation of the previous interval. Core is fairly soft, broken and rubbly to 44.5m. Interval contains increased, small, clast supported breccia zone consisting of sub angular to rounded andesite clasts in fine grained lava? matrix. Could indicate numerous small flows.
50.9	53.5	Zone of broken, rubbly core, locally strong chloritization and argillization. Fractures at all angles to CA but 50 to 60 to CA most common.
62.8	160.35	Grey to green grey andesite flows, generally less propylitized and chloritized than previous interval. Locally, contains up to 2% red hematite replacement of mafic phenocrysts and veinlets. Includes chloritized intervals as noted below. These probably represent alteration along fractures and fault zones.



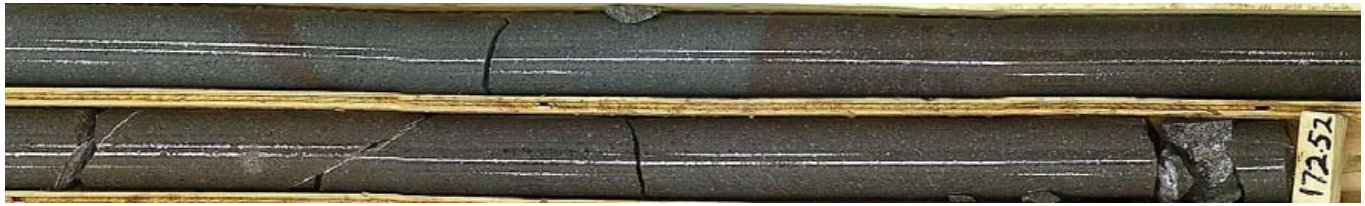
75.5		Several chlorite lined joints of faults at 5, 20, and 40 to CA.
78.2	81.0	Fault zone. Strongly chloritized and argillized rubble zone. Evidence of shearing on some surfaces.
83.4	83.5	Fault. Unhealed clast supported breccia, strongly chloritized and argillized, upper contact at 40 to CA.
90.0	92.4	Chloritized, argillized, and somewhat bleached zone. Increased fracturing and veins or small faults lined with chlorite, calcite, and clay. Faults oriented from 40 to 5 to CA. Strongly chloritized and argillized rubble zones at 91.3 and 92.0m.
96.0	98.75	Numerous faults or veins to 3mm lined with chlorite, calcite and clay. Most common orientation at 40 to CA.
101.7	102.8	Chloritized and bleached fault zone with chlorite, calcite, and clay lined fractures at 70 to CA.
108.7	113.2	Numerous chlorite, calcite and clay veins at 15 to 25 to CA.
111.0	111.1	Several blood red, hematite + Qtz veins, 5mm wide, at 5 to 10 to CA.
113.5	114.4	Chloritized broken zone with numerous chlorite, calcite, and clay veins and fractures. at all angles to CA. Ends in 3 cm grey clay seam at 50 to CA.
116.85	116.95	Green clay and rock fragment filled fault at 60 to CA.
128.3	134.3	Zone of strongly fractured and chloritized andesite with abundant faulting and chlorite,calcite and clay veins. Dominant fault and vein orientations are 35 to 45 to CA and 5 to 20 to CA.
132.2		Fault with 6mm wide gouge consisting of chlorite, calcite, clay, and rock fragments. Fault at 35 to CA, slickensides at 50 to CA
140.7	143.8	Strong fracture/vein set at 5 to 10 to CA. Filled with calcite, epidote, and clay veins. Vein material is quite soft, and the core readily cleaves along these veins.
146.9	149.7	Broken, rubbly core with all surfaces coated with soft, powdery calcite-chlorite.
153.3	154.0	Chloritized, but still competent core with numerous calcite, chlorite and epidote veins at 50 and 5 to CA.

156.88	157.4	Clast to locally matrix supported breccia with angular andesite clasts in fine grained lava or silty matrix. Breccia has been brecciated and re cemented with white, open space quartz vein. Clasts and matrix are silicified.

160.33 162.4 vcbx Volcaniclastic Breccia

Heterolithic, clast-supported breccia consisting of angular clasts of andesite, siltstone, possible flow banded rhyolite or dacite, and rare pieces of breccia, in a silt to sand matrix. Clasts are green, red and black and matrix is grey to green. Breccia is poorly sorted and clasts range from sand sized grains to 5 cm cobbles. Abrupt lower contact with andesite flow at 60 to CA. Matrix is silica and red hematite flooded at 160.37 to 160.4m.

162.4 190.81 And Andesite Flows



Grey to maroon, medium grained andesite flows as above. Somewhat finer-grained than previous flows. Andesite and siltstone xenoliths are common . Weak propylitic alteration. Flows are often purple-maroon from hematite staining or replacement of groundmass. Core is often quite hard in these areas, possibly from passive introduction of silica. These could also be unaltered, fresh andesite, however hematite looks introduced.

174.4	1 cm qtz+calcite+epidote vein at 45 to CA. Wall rock is bleached for 10 cm either side of vein and silicified adjacent to vein.

174.5	174.57		Volcaniclastic breccia as described above, but with clasts to 15 cm , and matrix and clasts are largely hematized
		175.5	189.0	Core is dark maroon-purple from Hematite. Increases veins and veinlets of dark red hematite +silica.
		190.81	191.0	20 cm silicified breccia with breccia clasts and veins of white quartz. Oxidized, and with trace black silver sulfide?

191.0 **207.7** **bx** **Breccia**

Green to purple-maroon, monolithic, clast supported breccia consisting of angular clasts of vesicular volcanic rock, which has a rhyolite or dacite appearance. Breccia is poorly sorted with clasts ranging from sand to large cobble size. Clasts often have ragged, embayed margins and often show flow banding and stretched vesicles. These could be pumice clasts. Matrix can be either vesicular lava or fine grained sediment. Matrix and clasts are propylitized, and often contain very fine-grained euhedral, disseminated pyrite. Vesicles are filled with calcite, epidote, and occasionally red hematite. Matrix locally replaced by dark grey silica. Thin, banded dacite flows scattered throughout interval. This unit could be an explosive or lapilli tuff breccia.

190.8	193.0		Very fine grained, grey, felsic? flow within the breccia described above.. At first appears to be a laminated siltstone or mudstone, but has sparse, bedded amygdules, and grades into vesicular flow at 193m. Internal flow banding at 45 to CA.
		203.0	208.0	Increase in silicification of breccia matrix. Clasts typically not silicified. Silica up to 25% of rock.

207.7 257.5 dac Dacite Flows

Green to reddish-brown to dark grey felsic flows. Appear to be dacite. Aphanitic to porphyritic texture, with prominent flow banding defined by layering or alignment of stretched vesicles. Phenocrysts consist of up to 15 % subhedral to euhedral feldspar to 3mm, and up to 2% euhedral quartz phenocrysts to 2mm. Very little hornblende or other mafics are seen. Intercalated clast-supported, lapilli tuff? breccias may represent explosive eruptive events, or possibly autobrecciated flow margins. The dark grey to red brown flows tend to be very hard, possibly silicified, and may have red hematite+silica veining and patches. Feldspar phenocrysts and vesicles within these flows are altered to green chlorite Other flows are weakly to moderately propylitized. The lapilli tuff breccias are usually green to red brown and show devitrification textures. Vesicles are filled with clay and possibly chlorite.

211.8 215.0 Prominent fracture/veinlet set at 0 to 5 to CA. Fractures lined with green chlorite, calcite, manganese, and feox.

214.4 220.8 Strong silicification of dacite flows. Appears to be passive flooding without brecciation. Local white to grey quartz veinlets and small veins.

218.8 219.25 Numerous grey quartz veins to 5 mm, and one quartz vein matrix breccia vein with trace fine-grained black silver ? sulfide mineral Veins and breccia vein at 25 to 35 to CA.

From	To	Width	ID	Au g/t	Ag g/t	Au/Ag
218.75	219.55	0.80	3531	1.66	0.7	2.37
219.55	220.85	1.30	3532	0.19	0.7	0.27
220.85	221.40	0.55	3522	0.15	0.5	0.30
221.40	222.50	1.10	3523	0.38	0.9	0.42

221.4 222.0 Breccia. Crushed clast supported breccia, partially silicified, clasts consist of silicified dacite and lesser quartz vein. Strong limonite, and argillization, 30 % of interval is silicified. Trace black

needle like silver? sulfide mineral. Dacite below the breccia is strongly fractured and limonitic to 223.73.

226.8 227.75 Sheared, clay altered, matrix supported breccia. Small, milled clasts of dacite and quartz vein in orange-tan to white clay matrix. Clasts appear milled. Main shears at 45 to CA.

230.4 231.7 bx Matrix to clast -supported breccia consisting of green propylitized dacite clasts in red-purple hematized? matrix. Clasts are somewhat rounded and moderately well sorted. Upper contact is is a limonitic fracture or fault at 30 to CA. Lower contact is gradational with green, propylitized dacite flow

231.7 257.0 dac Green to light blue-green dacite flows, with a few interbedded breccias. Flows are porphyritic with aphanitic groundmass, to aphanitic with faint flow layering and stretched vesicles. The breccias, except for the one noted below, tend to be less than 50 cm and consist of dacite similar in texture to the surrounding flows. These are probably auto breccias representing flow margins.

235.4 237.85 bx Breccia similar to above, but clasts smaller, from 3 mm to 1 cm, and are more rounded. Matrix of purple grey hematite. Below 235.9 the matrix is black and silica flooded, and the clasts are light grey and silicified. Upper contact with the dacite is sharp and planar at 15 to CA. The lower contact is a limonitic fault at 15 degrees.

237.85 238.45 Clast supported breccia. Breccia with milled and crushed clasts of quartz vein, silicified dacite, and breccia in sheared matrix of clay and limonite. Trace black silver sulfide mineral in quartz clasts.

From	To	Width	ID	Au g/t	Ag g/t	Au/Ag
237.85	238.45	0.6	3528	5.34	1.8	2.97
238.45	239.45	1	3529	0.62	0.8	0.78

242.8 243.0 20 cm wide fault zone with limonite and clay gouge, trace quartz veining. Fault surfaces at 50 to CA with dip slip slickensides.

245.05 1 cm wide gray quartz vein. Cockscomb texture, with calcite and adularia? in medial cavity. Trace black sulfide mineral, possible silver mineral. Weak bleaching of walls. Vein at 20 to CA.

247.4		1 cm wide limonitic fault at 30 to CA. Slickensides at 20 to CA.

257.5 **282.25** **bx** **Breccia**

Poorly sorted, chaotic, clast supported breccia. Clasts are green to red-brown to ochre and range from sand sized grains to1 m boulders. Most clasts are angular to embayed pieces of vesicular dacite that show stretched vesicles and devitrification textures. Other clasts are porphyritic-aphanitic dacite with feldspar and minor quartz phenocrysts. These often have prominent flow banding. Clasts and matrix are generally propylitized or oxidized. Vesicles are filled with chlorite + clay?. Several, one to two metre thick banded dacite flows occur throughout the interval, however these are probably large breccia clasts since layering orientations are at all angles to core axis and upper and lower contacts with the breccia is sharp and show no invasion of the breccia.

256.6	258.0	Hanging wall to breccia sampled in 3536. Weakly argillized breccia with local, patchy silicification of matrix.
258.0	258.75	Silicified, quartz veined breccia that was oriented at 40 to CA. Breccia was subsequently faulted and sheared and is now a rubble zone with strong limonitic, earthy matrix.

From	To	Width	ID	Au g/t	Ag g/t	Au/Ag
258.00	258.75	0.75	3536	0.93	2.0	0.47
258.75	260.20	1.45	3537	0.34	0.7	0.48

264.0	264.2	Tan clay seams to 3 cm filling fractures at 80 to 90 to CA. Strong oxidation and argillization and trace qtz veinlets.
279.2	279.2	Numerous shears at 45 to CA with strong yellow to tan feox and white clay gouge. Tr qtz veining.

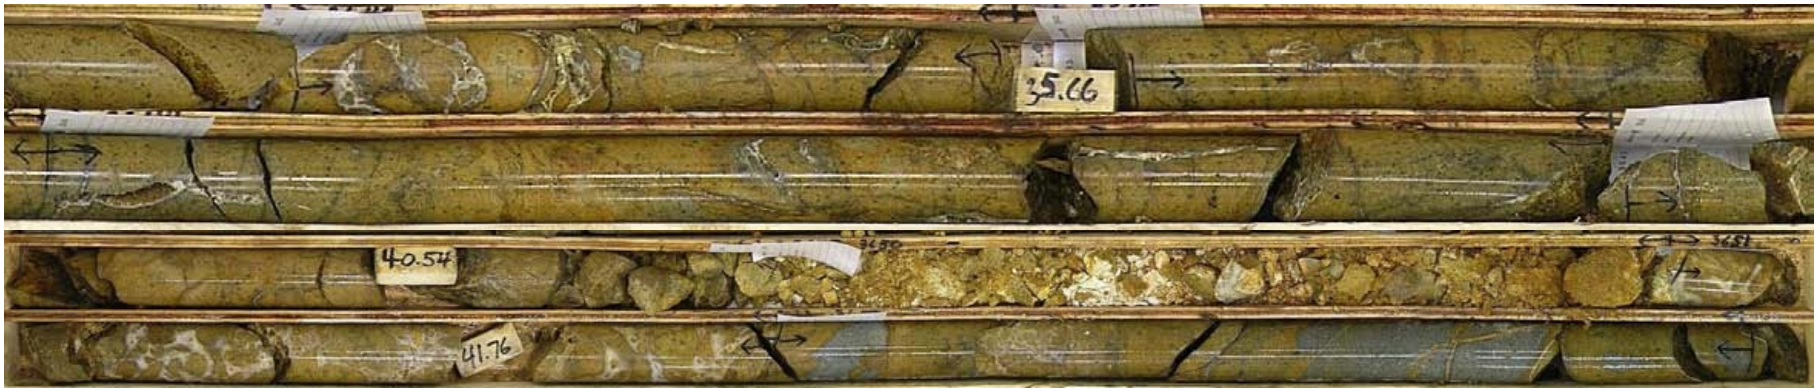
Dip	-45

Target	The north extension of the # 1 and #2 veins under the Blackdome basalt cap.
Stopped for:	Lost hole when caving rock apparently trapped bit.
Result	Intersected # 2 Vein

Note: Since hole B06-03A is a twin of this hole, only the interval around the #2 Vein intercept was logged and sampled.

32.4	**48.3**	**and**	**Andesite**

Green to brown porphyritic andesite. Weakly to moderately propylitized except where oxidized adjacent to quartz veining. Weak to moderate quartz veining peripheral to a stronger core of veining from 40.75 to 41.95m. This interval is thought to be the # 2 Vein structure.



35.25	40.75	Oxidized andesite with scattered white quartz veins and veinlets at all angles to CA. Veins are typically anastomosing, and often have open space lined with euhedral quartz crystals. Veins also occur as irregular breccia veins with the quartz forming the matrix to oxidized andesite clasts. These can occur as crackle breccias, or clasts can show rotation. Samples 3642 to 3648.
40.75	41.35	Intensely argillized and faulted andesite. Core is rubble in box. Abundant clasts of gray and white quartz vein fragments, silicified andesite, and strongly argillized andesite in orange-tan limonitic gouge. Abundant white clay as seams and as alteration of andesite. Clasts have a milled appearance, as if they have been rounded by fault motion. Sample 3649
41.35	41.95	Breccia consisting of oxidized andesite clasts in a matrix of white vuggy quartz veins. Matrix supported breccia with some clast rotation . Quartz makes up 30% of sample. Upper contact is obscured by faulting, lower contact is sharp at 60 to CA. Sample 3651.

41.95 48.3 Propylitized andesite. Footwall to #2 vein is oxidized and has minor quartz veining from 41.95 to 42.8m. Sample 3642

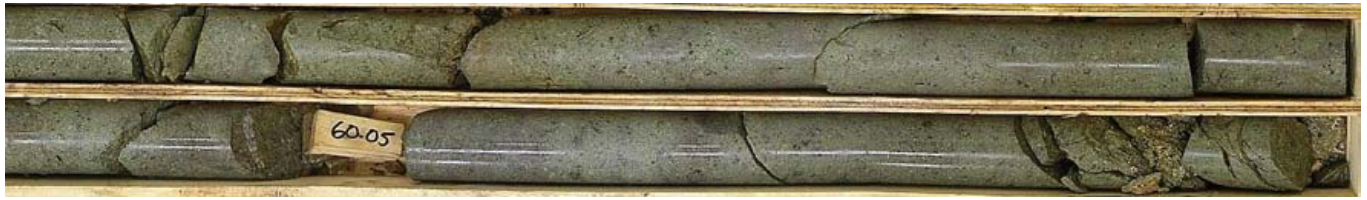
Stopped for:	Reached target.
Result	

0	**1.8 m**	**ovbd**	**Casing** No core.
1.8	**263.2**	**and**	**Andesite Porphyry**



Grey to greenish grey, porphyritic rock of intermediate composition. Phenocrysts consist of feldspar, hornblende, and possibly pyroxene. Feldspar phenocrysts are subhedral to euhedral, up to 4 mm, equant to lath shaped and comprise up to 40% of rock. Most of the feldspar appears to be plagioclase. Hornblende phenocrysts occur as anhedral to euhredral crystals to 3 mm and comprise up to 5% of the rock. They occur as single crystals or as clots with feldspar. Groundmass is typically fine grained, though can be aphanitic. Core is often propylitized, consisting of weak to locally strong pervasive greenish alteration of groundmass to chlorite+/-calcite+/- epidote. Feldspar phenocrysts are altered to chlorite +/- clay +/- calcite. Hornblende crystals are altered to chlorite? Propylitization is often overprinted by bleaching, and rarely silica flooding adjacent to fractures, faults, and quartz veins. This unit appears to be either an intrusive body, or just a few massive flows, without flow banding or alignment of phenocrysts. Rock for several metres approaching the lower contact with the volcanic breccia is finer grained, appears to be chilled, and is somewhat silicified. The lower contact with the volcanic breccia is sharp.

11.5	12.0	Zone of light bleaching and silica flooding adjacent to clay seams up to 5 mm thick. Dominant set at 60 to CA. Several small qtz veinlets.
15.3	15.7	4 mm grey qtz veinlet at 75 to CA, Bleached clay lined 3 mm fault at 10 to CA cuts qtz vein.
17.37	23.5	Rock is somewhat bleached and locally silicified. Silicification is passive, with very few qtz veinlets.
25.9	26.2	Rubble zone, possible fault. No sign of shearing, but all pieces are coated with limonitic and chloritic clay. Hanging wall fracture at 60 to CA.

34.5	35.1	Andesite is oxidized and locally silica flooded adjacent to qtz veinlets. Dominant fracture set and veinlet orientation at 50 to CA.

38.7	42.4	Andesite has a mottled orange-tan and grey appearance. The grey patches are unoxidized, often silica flooded and contain up to 2% fresh brassy euhedral pyrite cubes to 1 mm. The oxidized portions are often silicified and contain limonitic casts after pyrite. Locally abundant, irregular white quartz veinlets are found throughout interval, but are more common in oxidized core. Veinlets are abundant enough to form matrix of crackle breccias. This interval forms the hanging wall to the #2 vein.
42.4	43.85	Main portion of the #2 vein. Consists of two areas of quartz veining separated by 40 cm of weakly veined andesite. The upper vein is at 30 to CA and consists of multiple silica pulses. The earlier phase is fine grained, greyish white quartz containing silicified andesite clasts . 8 small gold grains and trace amounts of black silver sulfide? mineral, and trace bornite was seen in this vein type. White, coarse grained cockscomb quartz veins seem to cut the greyish quartz. No gold was noted in this vein type. The lower vein has a sharp upper contact at 50 to CA, though it appears to be more breccia matrix than a discrete vein. This vein also contains a few gold grains in greyish white fine-grained quartz.
43.85	45.7	Foot wall to # 2 vein. Sparse quartz veins to 5 mm at 20 to 45 to CA. White, cockscomb veins.

From	To	Width	ID	Au g/t	Ag g/t	Au/Ag
38.71	40.05	1.34	3539	0.42	1.6	0.26
40.05	41.40	1.35	3541,3542	0.46	1.7	0.27
41.40	42.40	1.00	3543	0.66	2.2	0.30
42.40	43.00	0.60	3544	0.16	2.3	0.07
43.00	43.85	0.85	3545	17.60	58.2	0.30
43.85	44.90	1.05	3546	11.50	74.3	0.15

51.0	53.6	Andesite is oxidized and somewhat silicified. Numerous quartz veins to 3 mm at 35 to 45 to CA.
60	65.7	Marked increase in propylitic? alteration. Ground mass is green, and feldspar phenocrysts are largely replaced by epidote. There is almost no calcite as alteration product. Chlorite is limited to alteration of hornblende and on fractures.
69.0	87.5	Andesite is markedly harder, and appears to have been leached and then silica flooded. Silicification appears to be passive, without brecciation. In some intervals, rock textures are some what muted by the silica flooding. Fine, micro quartz veinlets, and small veins are fairly common.
75.20	76.0	Sample # 3547. red brown andesite with abundant micro-quartz veinlets and veins. Andesite is densely silica flooded. Appearers to have been leached prior to silica flooding.
81.3	82.6	Strong epidote replacement of feldspar phenocrysts and groundmass. Particularly strong adjacent to vugs lined with colorless to grey toothy quartz veins.
89.0	89.8	Strong fracture zone. Broken andesite with clay and chlorite lined fractures. Dominant fracture orientations at 20 and 45 to CA. Sticky orange-tan and white clay gouge at 89.8m.

90.2	92.2	Small quartz veined structure consisting of silicified and oxidized andesite cut by grey quartz veins to 5 mm., mostly at 40 to CA. These veins are cut by white cockscomb quartz veins. A 10 cm wide white quartz vein at 91.9m has sharp contacts at 40 to CA. Samples 3548 and 3549.

From	To	Width	ID	Au g/t	Ag g/t	Au/Ag
90.3	91.4	1.1	3548	0.99	25.7	0.04
91.4	92	0.6	3549	1	10.7	0.09

92.60	102.9	Green andesite with mod to strong epidote replacement of feldspars, and locally of the groundmass. Chlorite alteration of hornblende. Chlorite on fractures. No calcite in groundmass or as alteration of phenocrysts. Propylitic alteration or possible metasomatic alteration.
99.85	100.95	Sample 3551. Several red hematite + silica vein groups, 10 cm and 20 cm wide at 45 to CA. Cut by later qtz and qtz calcite veins.

		94.7	1 cm wide, chloritic fault gouge at 25 to CA. No slickensides.
		109.2 112.0	Small mm size qtz veins at 45 to CA, several coarse grained calcite veins at same orientation. Andesite is fresh, unaltered in this interval.
		113.8 117.5	Propylitized and argillized andesite with minor brecciation, possible flow margin. Clay gouge at 114.25 to 114.35m.
		117.5 136.5	Very weak to weak propylitization, local weak argillization. Minor red hematite as veins and rare replacement of matrix.
		123.0 123.2	Zone of white vuggy qtz veins at 45 to 90 to CA. Contains white clay in medial cavity. Minor silica flooding as envelopes.
		136.5 144.8	Low to moderate propylitic alteration and moderate argillic alteration. Weak oxidation on fractures and pervasive in groundmass. 136.3, 3 cm clay seam at 90 to CA.
!40.0	144.8		Strong increase in calcite + clay fracture filling at 15 to 25 and at 70 to 90 to CA.
		142.0 142.12	12 cm wide bleached envelope with clay and limonite filling at 60 to CA.
		142.55 142.65	10 cm clay seam.
		144.8 145.4	Sample 3552. Moderate propylitic alteration . grey low angle qtz veins to 5 mm, cut by 3 cm white vuggy qtz vein.
		145.4 147.0	Moderate propylitization and argillization at footwall of vein sampled in 3552. Highly fractured with numerous calcite veins and limonite stain.
		153.0 153.8	Small limonite filled fractures @ a high angle to core. 10cm clay seam @153.6; hosted within a moderate propylitization
		153.8 164.2	Low to moderate propylitic alteration and low argillic alteration. Several small calcite filled fractures.
		158.1 160.63	Fractured core and numerous small fractures ranging from 20 to 45 degrees to axis; some limonite filled; some clay filled; some minor qtz-calc filled.
		167.9 168.9	Sample 3553. Moderate limonite filled fractures; more pervasive banded limonite alteration. Low silica; moderate clay associated clay alteration.
		172.2 182.7	Decrease in alteration to low propylitic alteration and low argillic. Core fairly massive with minimal fractures and minor quartz and calcite filled veinlets.
182.7	185.0		Broken core, leading to possible small fault zone. Increased alteration to moderate argillic and clay.
183.50	183.58		Sample 3554. Banded alteration ranging from Fe stained moderate argillite-clay to lenses of high quartz with disseminated pyrite, minor grey quartz veins (2).
		188.3 193.3	Increased propylitization and argillization, numerous calcite veins at low angle 70 to 80 degrees, ranging 2mm to 1cm.
		191.5 191.7	Two quartz veins, vuggy 70 to core axis; 3cm and 1 cm.

193.3	203.05	Decreased alteration to weak propylitization, massive core.
203.05	204.9	Low to moderate argillic and clay alteration.
204.9	209.8	Low to moderate propylitic alteration; quartz-calcite veins 206.75; 207; 207.06; 208.at 45 to 70 degrees to core axis.
210.0	210.7	Increased argillic and clay alteration; small silicified zone @ 210.1 followed by clay gouge @ 210.55.

210.7	216.4	Low to moderate propylitic and argillic alteration;
216.4	216.8	Sample 3555. 2cm wide quartz (grey) vein within a limonite stained envelop 50 degree to core axis.

From	To	Width	ID	Au g/t	Ag g/t	Au/Ag
216.4	216.8	0.4	3555	1.65	1.7	0.97

220.25	220.45	Small 10 cm silicified zone within 20cm wide limonite stained envelope originating from the disseminated pyrite present.
220.45	224.8	Low to moderate propylitic alteration;
224.8	225.35	Silicified zone within 26cm wide limonite stained envelope; minor pyrite.
225.3	230.7	Low to moderate propylitic alteration; minor epidote on fractures.
227.7	229.8	Quartz-calcite veins 1cm to mm at 30 to 70 to CA.
230.7	238.4	Low to moderate propylitic alteration; occasional xenolith with mafic phenocrysts & sericite alteration.
230.7	238.4	Broken and more densely fractured core.

234.8	235.1	5cm clay gouge zone; limonite stained; 1cm qtz vein; both @ 70 degree to core.
238.4	250.8	Propylitic alteration fluctuating from low to moderate; minor epidote along fractures; minor limonite staining generally associated with one or more quartz veins.
241.9	242.1	3small quartz veins @45 degree to core; within argillic/limonite envelope.
242.8	245.0	Broken and more highly fractured core.
249.2	251.6	Broken and more highly fractured core.
261.2	263.2	Contact with volcanic breccia. Phenocrysts are finer grained and groundmass is aphanitic. Appears to be a chilled margin. Core is somewhat silicified. Abrupt transition to breccia at appx. 90 to CA.

263.20 287.4 bx Volcanic Breccia

Volcanic breccia consisting of poorly sorted, angular to rounded clasts in a fine-grained matrix. Several different clast types ranging from fine-grained volcanic rock to flow banded dacite? to vesicular pumice fragments. Pumice clasts often have ragged, embayed margins and stretched vesicles. Clasts range from 2mm to 10 cm. Matrix is fine grained, grey to green to brown and could be fine-grained lava or sediment. Alteration consists of pervasive weak to moderate propylitization which appears to have been largely overprinted by variably moderate to very strong argillization. Clasts are always more argillized than the matrix, and are often completely altered to clay. Much of the breccia is grey, leached appearing with upwards of 6% disseminated, euhedral, brassy pyrite in the matrix and clasts. Silicification is very rare, and limited to selvages around quartz veins. The upper contact is abrupt and close to right angles to the core, whereas the lower contact appears gradational with no distinguishable contact with the underlying dacite.

263.0	264.86	Dark brown lava matrix with light brown sub angular to rounded fragments. Pervasive limonite stain and moderate argillic alteration. Some clasts have a moderately high clay replacement and are eroded, creating a vuggy texture.

264.55	264.84	Dark brown mud gouge zone, which has a homogeneous silt/clay consistency.
265.5	285.2	Moderate to strong argillic alteration of the volcanic breccia. Rock is grey to rarely greenish grey. Clasts are often completely altered to clay or rarely clay and chlorite. Matrix is less altered, but still quite soft. Matrix and clasts contain up to 6 % disseminated euhedral pyrite. grey clay gouge is common. Fractures are lined with clay, with lesser chlorite and rarely limonite. It appears that the argillic alteration is an overprint on the propylitic alteration.
266.2	268.3	Several white cockscomb qtz veins with strong limonite filling medial cavities and as selvages. Veins to 2 cm, and at 10 to 25 to CA. Samples 3556 and 3557.
269.5	270.15	Maroon brown clay gouge, possible fault.
284.3	285.0	White cockscomb quartz veins forming breccia matrix. Veins up to 1 cm wide. Strong limonite on fractures. Sample 3561.
286.0	287.5	Matrix of volcanic breccia is silicified. Clasts are argillized and oxidized. Sample 3563.

287.4 313.5 dac Dacite? Porphyry Flows

Grey to greenish to tan porphyritic flows and inter flow breccias. Phenocrysts of euhedral to subhedral feldspar which comprises up to 30 % of the rock. These phenocrysts tend to be more equant than in the andesite porphyry and appear to be mostly potassium feldspar rather than plagioclase. Very little to no hornblende is seen. Rounded to stretched vesicles are locally abundant, and, along with the alignment of feldspar phenocrysts, often give a distinct flow texture. Breccias of rounded to sub angular dacite clasts in lava? matrix are common and may represent flow margins. Alteration consists of weak propylitization to weak to moderate argillization and bleaching. These rocks appear to be more felsic than the andesite.

292.5	296.25	Several white cockscomb quartz veinlets and veins with calcite filling medial cavities where rock

		is unoxidized. Often with strong limonite selvages. Veins typically at 30 to 50 to CA.
300.8	301.7	Numerous white cockscomb quartz veinlets to 5 mm at 30 to 50 to CA. Interval is oxidized and contains locally strong limonite selvages and fracture coatings. Sample 3566.
301.7	308.8	Weakly propylitized dacite flows with sporadic white to grey qtz veins. White veins tend to be cockscomb texture, and often have strong limonite selvages. Very little bleaching or alteration of walls.
309.2	309.97	Blood red hematite + silica veins and breccia matrix. Appears to be earlier than white and grey qtz veins. Sample 3571.
311.0	311.5	Two qtz breccia veins to 5 cm with qray qtz bx matrix. Veins at 30 and 40 to CA. Samples 3572 and 3573.
312.6	313.5	Main Quartz vein. Breccia zone consisting of tan oxidized dacite clasts in grey and white qtz vein matrix. Multiple episodes of brecciation from quartz healed breccia clasts. Abundant cockscomb quartz vein and vein clasts. Core is quite broken. Recovery is approximately 50% for the interval. Sample 3574.

313.5 321.0 vbx Volcanic Breccia

Poorly sorted, clast supported heterolithic breccia. Angular dacite clasts from sand size to 10 cm. Clasts are fine grained flow banded dacite, vesicular dacite, and dacite porphyry. In other places, clasts are dominantly flow banded dacite with seemingly little rotation. Matrix is a fine grained silt or possibly lava. Contains some flow banded dacite flows.

313.5	316.1	Intensely argillized and strongly oxidized footwall to quartz vein. A few grey quartz vein fragments. Samples 3575 and 3576.

321.0 325.71 dac Flow Banded Dacite?

		Grey, fine-grained felsic volcanic. Strong flow layering defined by red-brown bands at 30 to 40 to CA. Sparse euhedral feldspar? phenocrysts scattered throughout. Contains minor breccia interbeds consisting of flow banded dacite clasts. Gradational contact with overlying volcanic breccia.

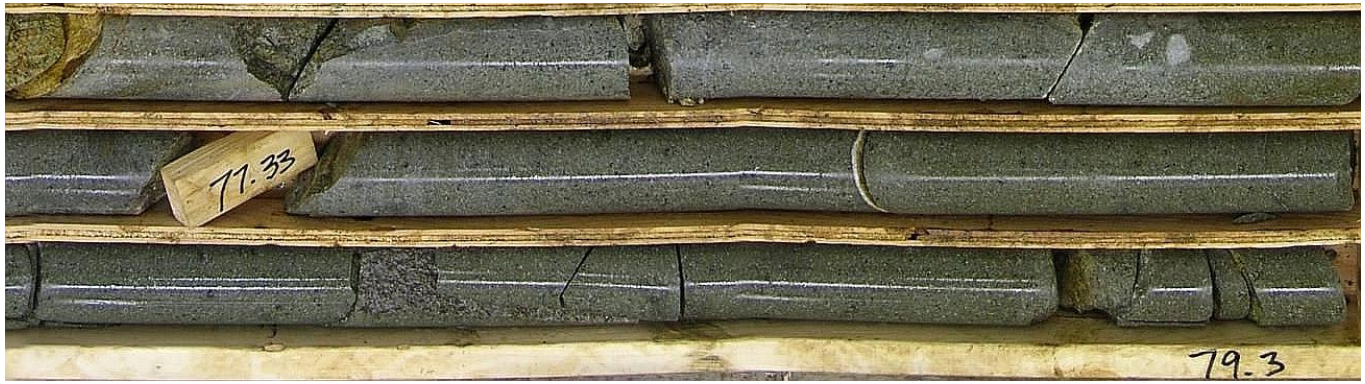
Stopped for:	Hole may have unintentionally been stopped in the east splay of the #1 vein.
Result	

0	**3.2 m**		**Casing** No Core.
3.2	**157.7**	**And**	**Andesite Flows**



Medium to fine grained, porphyritic texture with euhedral hornblende and plagioclase phenocrysts set within a fine-grained groundmass. Apart from alteration variations, the andesite flows are quite homogeneous. The propylitized intervals range from green to greenish-grey colour and tend to enhance the porphyritic texture. The flow structures are rare and individual flows are difficult to identify. Breccia zones displaying sub-angular andesite clasts set in finer grained andesite lava are rare. These occur across either short <30cm intervals or >1.0m. Propylitization is the most common alteration throughout the hole. In order of abundance argillic, limonite staining, bleaching and silicification are the secondary forms of alteration most common to the core. Quartz veins and limonite stained fractures occur randomly throughout the Andesite flow, with the exception of the brecciated zones..

3.2	9.20		Andesite porphyry, slightly propylitized, minor flow banding with aligned feldspar phenocrysts.
	6.0	7.31	Oxidized mud seam and weathered core.
	7.31	8.94	Low propylitic alteration
9.20	20.8		Buff brown and olive green andesite porphyry, more intensely fractured with prevailing argillic and clay alteration. Feldspar phenos largely clay altered and fracture have a limonite with minor

manganese coating. Some sections moderately bleached. Low angle fractures of 45 to 80 degrees have limonite as fracture filling. The higher angle fracture > 45 degrees have lesser amounts of Fe.

17.4	18.4		25 cm silicified breccia with sharp, limonitic fault contact at 10 to CA. 10 cm white vuggy qtz vein, 80 to CA, at 18.4 m. Strong limonite associated with breccia. Sample 3578.
18.4	22.50		Numerous limonite filled fractures, mainly <= 45 degrees to core axis.

22.8	53.5	A fairly consistent and uniform low to moderate propylitic alteration resulting in a competent core. Within this alteration type limonite appears much less prevalent, whereas a quartz-calcite and chlorite assemblage is hosted in veins ranging from mm to 1.5 cm. From 43.7m onward the core is slightly more silicified and many fractures have a clay residue.

31.5	32.3		Larger quartz-calc veins approximately 1.5cm wide occur at 31.5 @ 50 deg; 32.1 @ 82 deg; and 32.3 @ 65 deg.
	40.6	53.5	Fracture density increases and limonite staining increases marginally.
53.6	54.5		Strong increase in argillic alteration and bleaching seeming to emanate from numerous fracture and clay gouges at 40 to CA.
55.8	57.0		Core is strongly fractured with numerous gouge zones and limonite lined fractures. Dominant fault set at 20 to CA with limonitic clay gouge . Several high angle “veins” consisting of silica +red hematite flooded , vein like structures with sharp walls. Surrounding andesite is bleached and argillized.
56.8	63.3		Sporadic white cockscomb qtz veins to 1 cm. Veins typically from 50 to 70 to CA. Very little alteration of walls. 3 cm banded grey and white qtz vein at 63.3m. Str limonite selvage and bleached , somewhat argillized walls.

63.6	83.5	Fairly uniform interval of weakly to moderately propylitized andesite. Weak flow alignment of phenocrysts. Lacking breccias, possibly massive flow or intrusive body. Weak alteration of phenocrysts to calcite and chlorite. Weak red hematite replacement of groundmass and some phenocrysts., and rarely as discrete veinlets. Fractured surfaces lined with chlorite, calcite, clay and occasionally limonite. More broken zones are usually more bleached and argillized. Quartz veining is largely absent from this interval, but where it occurs veins contain abundant intergrown calcite.

69.4	69.6		Fault zone consisting of brecciated andesite with numerous chloritic and limonitic gouge seams at 20 and 80 to CA.
73.0	75.6		Core is quite broken with chlorite+clay+/- limonite fracture coatings. 2 cm thick sheared white clay seam at 60 to CA @ 73.0. Crushed, friable brecciated andesite, strongly chloritic, @75.5m.
79.9			7 cm white cockscomb qtz vein at 35 to CA. No alteration of wall rock.
81.0	84.0		Broken core with thin limonite and manganese fracture coatings.

		84.13	84.4	Broken zone containing white qtz pieces and red-orange clay gouge seams and fracture coating. Wall rocks are bleached and argillized. Vein was probably 1 to 2 cm thick.
83.5	93.8			Moderate propylitization and weak to locally moderate oxidation of andesite flows, possibly associated with increase in quartz veining approaching main qtz vein at 99.2m.
		85.7	86.1	Numerous fractures at 50 to CA lined with red-orange hematitic clay gouge.
		88.1	88.9	Several parallel fractures or faults at 35 to CA lined with red-orange hematitic clay and rubble gouge. Below these are numerous white cockscomb quartz veins ,at 35 to 45 to CA, scattered over the interval. These veins are up to 2 cm thick and sometimes contain andesite clasts. Sample 3579.
		91.4	92.5	Sporadic white and grey vuggy quartz veinlets at 70 to CA Weak wall rock bleaching and oxidation. Sample 3581

		92.5	93.25	Numerous white and grey quartz veins up to 1cm at appx. 50 to CA. Strong red-orange clay gouge associated with some veins. Moderate wall rock bleaching and oxidation. Sample 3582.

From	To	Width	ID	Au g/t	Ag g/t
92.80	93.25	0.45	3582	1.66	2.9

		96.6	98.9	Sporadic white to grey vuggy qtz veins to 5mm. Most at 45 to CA. Very little wall alteration. Possible hanging wall veins associated with vein at 99.3. Sample 3583

		98.9	99.6	45 cm wide, complex quartz breccia vein consisting of multiple pulses of brecciation , quartz veining and silicification. Both grey and white cockscomb veins are brecciated and silica healed. Trace white adularia? in grey qtz matrix. upper and lower contacts at 50 top CA. Possible #1

			Vein. Sample 3584.
		99.6 100.75	Footwall to main vein. Numerous small qtz veins , mostly at 50 to CA and a 10 cm silicified breccia, at 70 to CA. Sample 3585
		100.75 107.0	Footwall to main vein. Numerous scattered quartz veins, mostly less than 5 mm and at appx 50 to CA. Core is variably oxidized and occasionally argillized for several 10's of cm adjacent to qtz veins.
		107.0 108.0	Hydrothermal breccia. Angular, oxidized andesite clasts in a matrix of white vuggy quartz. Grades with depth into a matrix of grey cryptocrystalline quartz. Smaller clasts are silicified, while larger clasts are argillized. Sample 3587.
108.0	119.0		Fairly consistent moderate propylitization. Oxidation tends to be weak and is pervasive without being restricted to fractures and quartz veins. Several greenish clay and chlorite gouge filled fractures.
119.0	144.4		Change in alteration style. Andesite is grey, locally pyritic and appears to be fresh except where it is oxidized. Propylitization is much less in this interval. Oxidation occurs as fronts emanating from fractures and veins at the expense of disseminated pyrite. These oxidation selvages are usually less than 4 cm, but can extend up to 1 metre with increased fracture or vein density.
		127.55 127.6	8mm vuggy white qtz vein at 55 to CA. Hanging wall is sheared and brecciated andesite with qtz vein fragments and fresh disseminated pyrite. Entire breccia zone is silicified. No limonite selvage associated with silicified zone.
		128.5 128.7	1 cm grey vuggy qtz vein at 55 to CA. Hanging wall is silicified and brecciated for 1 cm above the qtz vein. Breccia and qtz vein have str limonite selvages.
		130.3 132.9	Numerous limonitic fractures with or without quartz veinlets. Most at 45 to 55 to CA.
		140.2 142.1	Several white vuggy qtz veins to 1 cm and several limonitic shears. All at 45 to 50 to CA.
		142.45 142.95	Zone of quartz veinlets and two 6 cm quartz veins all at 50 to CA. Wider veins are white to grey cockscomb veins with a few breccia clasts of silicified andesite. Trace fresh pyrite and oxidized pyrite cubes in walls with pervasive limonite selvages. Footwall is a partially silicified volcanic breccia that extends to 143.5m. Sample 3589.
143.0	155.0		Weak to moderately propylitized andesite. Local pervasive silica flooding adjacent to quartz veins. Core is essentially rubble below 150.0m
		146.7 148.55	Abundant white and grey, vuggy quartz veins and veinlets at all angles to CA, though the most common orientation is 45 to CA. Andesite is strongly oxidized to 147.4m. Below that, rock is propylitized and has strong silica flooding adjacent to fine quartz veinlets. Samples 3591 and 3592.
		149.4 149.9	Strongly oxidized andesite with a 5 cm, silicified, qtz veined shear at 55 to CA. Footwall to shear

is crackle brecciated andesite with limonite vein matrix and irregular, grey chalcedonic qtz veins. Sample 3595

149.9	150.1	Fault. Upper contact at 50 to CA,lower contact at35 with slicks at 20 to CA. Orange tan gouge consisting of limonite, clay and rounded rock fragments. Included in sample 3595.
149.9	155.2	Crushed zone, possible fault. Rock is broken to rubble with numerous chloritic zones. Most pieces have limonite surface coating. No slickensides seen.

157.7 172.52 vbx Volcanic Breccia

Poorly sorted, heterolithic breccia. Irregular shaped clasts of vesicular volcanic- possibly dacite, and fine grained porphyritic andesite? Clasts range from sand size grains to 8 cm cobbles. Matrix is green to maroon, fine grained, and is often laminated and somewhat contorted. Matrix could be fine grained sediment, in which case, this could be a volcaniclastic breccia. The upper part of this unit is strongly argillized and faulted. Numerous tectonic breccias overprint the primary breccia textures. Below 162m the interval is weakly to moderately propylitic, with local chloritic shears.

155.5	159.7	Large fault zone. Strongly argillized core with many zones of crushed and milled fragments bounded by clay gouge with slickensides. Dominant shear orientation at 20 to 30 to CA. Horses of less sheared and argillized volcanic breccia.
156.9	157.6	Brown to dark brown-black friable rock that has been strongly sheared and brecciated. Trace qtz veinlets. Sample 3596.
157.6	158.4	Sheared, brecciated fault zone. Strongly argillized with limonitic seams. Sample 3597.
163.0	171.8	Gradational transition to propylitic alteration. Weak to moderate chloritization of clasts and groundmass. Very weak calcite replacement, mostly of vesicles in dacite clasts. Trace

			disseminated pyrite.
		165.4	166.3	Chloritized fault zone. Broken, chloritic rubble and several chloritic shears at 10 to 20 to CA.
		178.1	172.47	Fault . Strongly sheared and brecciated zone increasing in intensity toward contact with quartz vein. Argillized and chloritic gouge with milled clasts of volcanics and minor white quartz vein. Contact with quartz vein at 80 to CA. Slicks at 80 to CA. Sample 3598.
		172.47	172.52	Possible eastern splay of # 1 Vein. White cockscomb quartz vein with limonitic fractures and trace pyrite. 8 mm wide silicified, limonitic breccia at upper fault contact. Sample 3599.

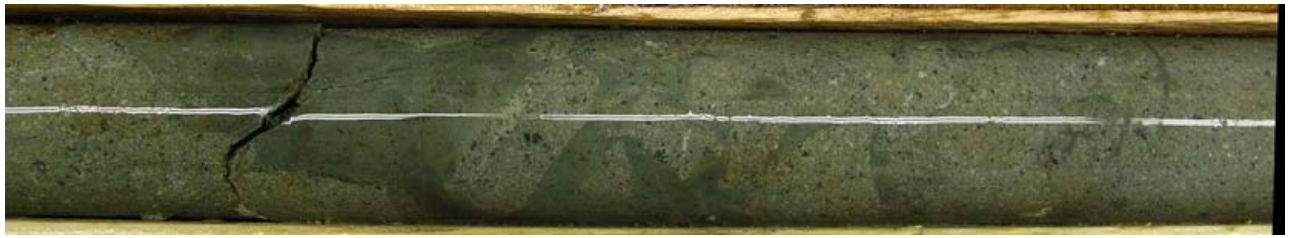
Result	

0	**4.0 m**		**Casing** No core.
4.0	**154.5**	**and**	**Andesite**

Grey to greenish grey, porphyritic rock of intermediate composition. Phenocrysts consist of feldspar, hornblende, and possibly pyroxene. Feldspar phenocrysts are subhedral to euhedral, up to 4 mm, equant to lath shaped and comprise up to 40% of rock. Most of the feldspar appears to be plagioclase. Hornblende phenocrysts occur as anhedral to euhredral crystals to 3 mm and comprise up to 5% of the rock. They occur as single crystals or as clots with feldspar. Groundmass is typically fine grained, though can be aphanitic. Core is often propylitized, consisting of weak to moderate pervasive greenish alteration of groundmass to chlorite+/-calcite+/- epidote. Feldspar phenocrysts are altered to chlorite +/- clay +/- calcite. Hornblende crystals are altered to chlorite? Propylitization is often overprinted by bleaching, and rarely silica flooding adjacent to fractures, faults, and quartz veins. This unit appears to be massive, without flow banding or alignment of phenocrysts. Xenoliths of coarser or finer grained andesite are common throughout the unit. Intra flow breccia are quite common in this unit to a depth of 44.5m. They consist of angular andesite clasts in a green to grey green, fine grained siltstone? or lava matrix. The matrix is occasionally laminated, and often is at least partially silicified.

4.4	4.8	Green grey clay. Possible fault gouge.
7.9	8.2	Fault at 20 to CA. Limonitic clay gouge 3mm thick. Surrounding andesite is strongly argillized, chloritized and brecciated.
6.0	9.8	grey silicified breccia matrix. Andesite clasts are weakly argillized and propylitized. Sample 3601
9.7	10.6	Limonite, clay and chlorite lined fractures at 10 to 20 to CA. Possible fault zone.



13.4	21.8		Possible inter-flow breccia. Large angular andesite clasts in fine grained green siltstone? matrix. Matrix partly silicified and contain red brown oxidized pyrite cubes. Appx 10% matrix.
		29.75	29.8	Fault gouge. Brown clay. Argillized and chloritic footwall.
38.0	43.1		Possible inter-flow breccia. Increase in green fine grained matrix. Clasts are quite large and are without chilled margins or any alignment of phenocrysts.
		44.3	72..2	Weak to only locally moderate propylitic alteration. Sparse scattered calcite veinlets. Lack of brecciation and fine grained breccia matrix. Minor scattered xenoliths of coarser and finer grained andesite.
		46.6	47.2	Several calcite, chlorite and limonite lined joints at 10 to CA. Increased pervasive bleaching and propylitic alteration peripheral to joints.
		57.7		5 mm clay lined fracture at 20 to CA.
		70.0	74.0	Several calcite and chlorite lined fractures at 20 to CA.
		72.4	98.1	Monotonous porphyritic andesite as above, but with moderate propylitization and increase in bleaching and clay seams.
		87.48	88.0	Several joints at 20 to CA. Surrounding rock is chloritized and broken.
		88.7	92.0	Numerous chlorite and calcite lined fractures at mostly 20 and 45 to CA.
		90.5	90.65	grey clay seam. Upper and lower contacts at 90 to CA.
		93.0	99.2	Increase in calcite veins to 5mm. These appear to be mostly tension veins and minor breccia matrix.
		96.8	96.95	Fault gouge consisting of grey clay and milled andesite and calcite vein clasts. Upper and lower contacts at 30 to CA.
		101.0	102.3	Area of increased propylitization centered on greenish clay and chlorite seam at 102.0m. Minor reddish hematite replacing phenocrysts and groundmass.
		108.6	110.3	Numerous chlorite, clay and calcite veins and lined fractures. Most at 55 to 70 to CA. Surrounding core is propylitized and somewhat argillized.
		112.4	112.5	10 cm fault filled with clay, calcite, chlorite and milled andesite clast gouge. Upper and lower

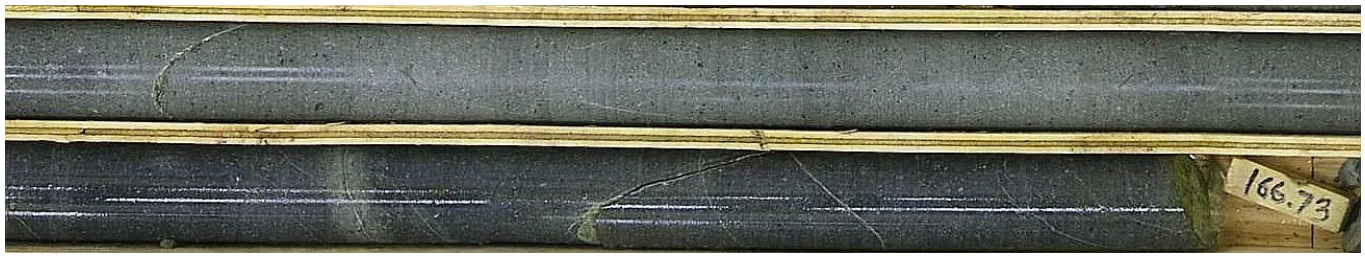
		contacts at 50 to CA.
114.4	114.5	Chloritic shear with calcite + chlorite veins. 25 to CA.
124.0	126.7	Increased propylitic alteration of andesite. Trace disseminated, very fine-grained pyrite, and increased epidote replacement of groundmass and phenocrysts.
124.2	124.25	White, coarse-grained calcite vein with epidote selvages and inclusions. Minor red hematite + silica veins and blebs.
136.5	143.5	Increased propylitic alteration. Stronger alteration of phenocrysts and groundmass to chlorite, epidote and calcite. Common calcite veins and veinlets. Increased red hematite in groundmass and as micro veinlets. Trace disseminated fine grained pyrite.
143.5	151.0	Weakly propylitized andesite.
149.5	149.8	2 cm calcite + quartz vein . Footwall is brecciated and silicified for 5 cm. Several calcite + quartz veins to 5 mm in hanging wall to large vein. Veins and fracturing at 35 to CA. Sample 3602

154.5 161.1 vcbx Volcaniclastic Breccia

Matrix supported, heterolithic breccia. Large, angular andesite clasts and smaller, angular to rounded clasts of andesite, aphanitic volcanic, breccia and possible siltstone. Matrix is poorly sorted, and consists of silt to large sand sized grains with no apparent bedding or lamination. Several small andesite flows within the breccia. Upper contact is sharp at 50 to CA. Faint sense of bedding in breccia at 45 to CA.

160.1 **186.4** **and** **Andesite**

Typical porphyritic andesite as described above. Propylitic alteration varies from very weak to



moderately strong. Strongest propylitic alteration characterized by epidote replacement of phenocrysts and groundmass, and by increased calcite veins and veinlets. Andesite becomes gradually finer-grained and less propylitized approaching lower contact.

169.0	177.0	Moderate propylitic alteration. Scattered calcite veins, most at 45 to CA. Trace disseminated pyrite and minor red hematite replacement of phenocrysts and as spider web veinlets in groundmass.
178.7	180.3	4 mm calcite + chlorite vein at 178.7m. 20 to CA. Footwall is chloritized and broken to 180.3m.
180.7	186.4	Andesite is finer grained and less propylitized. Below 183.4 the rock is harder, possibly from pervasive silica flooding, and primary textures are somewhat muted. Abundant calcite+ qtz veinlets at 25 to 40 to CA. Contact with underlying volcaniclastic breccia is indistinct, possibly obscured by silica flooding.

186.4 **193.7** **vcbx** **Volcaniclastic Breccia**

Heterolithic, clast to matrix supported breccia . Upper part finer grained, lower part coarser grained as described below.

186.4 189.2 Much of interval is a coarse, poorly sorted volcaniclastic sandstone with grains up to 3 mm and

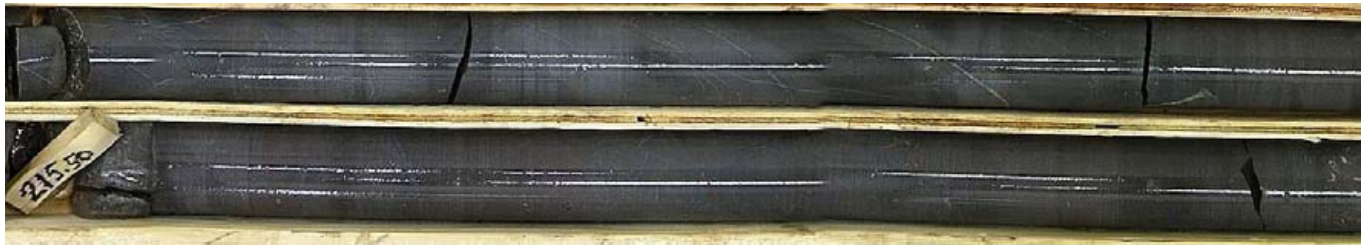
scattered clasts of mixed volcanic rock. Bands of heterolithic conglomerate or breccia with mixed volcanic clasts to 3 cm. Faint bedding at 50 to CA Unit is weakly propylitized.

186.4	187.1	Several grey, vuggy quartz+calcite veins at 40 to 50 to CA, up to 5mm thick, and numerous grey, fine spider web quartz veinlets. Sample 3603.

189.2 193.7

Coarse, heterolithic, poorly sorted, breccia. Angular clasts of dacite, vesicular dacite? to 5 cm, and smaller sandstone? clasts. Sand to silt matrix, and interbeds of volcaniclastic sandstone.

189.2	189.7	30 cm zone of hydrothermal breccia with white, vuggy quartz vein matrix and cross cutting quartz veins. Silicified clasts of dacite. Footwall to breccia is silicified. Sample 3604.
189.7	190.3	Zone of densely silicified breccia. Much of the matrix has a white to grey, sugary texture. Abundant fine, grey quartz veinlets and some vuggy quartz veins. Sample 3605
191.3	192.6	Variably silicified and oxidized breccia. Silicification as patchy flooding of the matrix and scattered grey vuggy quartz veins and veinlets.
192.6	193.7	Stronger oxidation and patchy silicification of breccia. 6cm limonitic tectonic breccia at 20 to CA with milled, silicified volcanic and quartz vein clasts. Sample 3608.



193.7 218.0 bas Basalt

Aphanitic, weakly porphyritic, black to grey to greenish grey volcanic rock. Possible dike. Sparse, to locally abundant euhedral feldspar phenocrysts, usually replaced by calcite and chlorite. Less altered rock contains sparse feldspar, hornblende and and possible olivine phenocrysts Locally abundant stretched vesicles? near top of unit which may represent flow margins. These are filled with calcite and chlorite. Flow banding is very rare. Weak to moderate propylitic alteration, often associated with broken and sheared zones. Upper contact with breccia appears to be sharp at 30 to CA.

196.0		1cm vuggy grey quartz vein at 30 to CA, with 1 cm wide, brecciated and silicified hanging wall.
199.3		4 cm clay+chlorite gouge. Orientation uncertain. Strongly bleached and argillized walls.
201.6	203.5	Broken core. Chloritized breccias and shears, generally at 5 to 20 to CA.

203.6		2 cm grey vuggy quartz breccia vein at 30 to CA. Clasts and walls are strongly replaced by epidote and chlorite. Trace disseminated pyrite.
204.0	217.2	Basalt is mostly black to dark grey-green. Numerous scattered calcite and chlorite veinlets. Local areas of weak propylitic alteration. Interval is very weakly porphyritic and free of vesicles.
217.2	218.0	Basalt becomes brecciated and vesicular approaching the lower contact . Increase in propylitic alteration and calcite veining.

218.0 225.0 vcbx Volcanic Breccia

Monolithic, clast supported breccia consisting of flow banded and vesicular dacite clasts in a matrix of coarse sand to silt. Breccia is poorly sorted with angular to sub angular clasts ranging from 10 cm to sand size. Entire interval is propylitized and has trace disseminated pyrite sparse calcite veinlets. Inter bedded dacite flows common near base of unit as the breccia grades into massive dacite flows.

218.2		1 cm vuggy grey qtz vein that blows out to 3 cm wide with 2 cm open medial cavity ,and inclusions of silicified dacite. Vein at 45 to CA.
221.55	223.0	Zone of broken core. All surfaces with strong clay and chlorite coating. Possible fault.

225.0 234.2 dac Dacite Flows

Grey to green, porphyritic volcanic with distinct flow banding defined by alternating light - dark layers and by slight alignment of phenocrysts and rounded, vesicle-like blebs. Phenocrysts are mostly feldspar that has been altered to epidote? and chlorite? Flow banding is quite consistent a 50 to CA. Upper contact is gradational with dacite breccia. Lower contact with breccia is sharp at 45 to CA.

234.2	**240.9**	**bx**	**Breccia**

Chaotic zone of brecciation that appears to be a fault zone that was later overprinted by hydrothermal brecciation, silicification and quartz veining. Clasts consist of angular to sub rounded, multi-coloured dacite, and possibly basalt and siltstone. Many of the clasts have a milled appearance. The clasts are set in a fine grained matrix. This breccia was subjected to strong hydrofracturing and was healed by quartz veining, as well as silica flooding. Quartz veins consist of grey veinlets that form crackle breccia matrix and later white cockscomb quartz. A later, unhealed fault breccia cuts the main zone of quartz veining, and consists of clasts of quartz veined and silicified breccia and quartz vein in a limonitic clay gouge.

234.7	235.7	Brecciated and silicified breccia with abundant grey and white quartz veins and quartz vein crackle breccia matrix. Rock had up to 2 % disseminated pyrite that is now largely oxidized. Samples 3611 and 3612.
236.8	237.4	Brecciated and silicified breccia. Abundant grey quartz veinlets forming breccia matrix. 10 % vuggy grey and white quartz veins with strong limonite. Sample 3614.
237.4	238.2	Unhealed fault/shear zone consisting of clasts of silicified breccia, , quartz vein, and silicified volcanic in a limonite and clay gouge. Sample 3615

239.9	240.2	White and grey vuggy quartz veins cutting silicified and leached breccia. Trace disseminated

pyrite and possible black silver mineral in quartz vein. Veins at 45 to CA. Sample 3619

From	To	Width	ID	Au g/t	Ag g/t

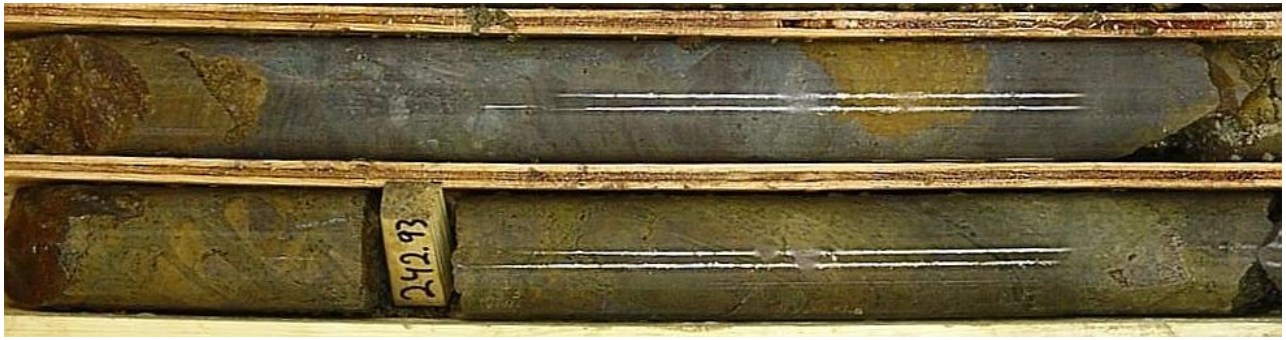
240.2	240.9	0.7	3618	0.28	9.7

240.9 247.8 dac Dacite

Maroon to grey green, weakly porphyritic flows. Prominent flow banding at 60 to 70 to CA. Brecciation common near the top of the interval.



240.9	243.8		Brecciation decreases through this interval. Mostly clast supported, monolithic breccias with dacite clasts in a fine grained sediment, or possible lava matrix. Locally contains fine-grained disseminated pyrite, and may be partially silicified.

6.4	**61.2**	**and**	**Andesite**

grey to greenish grey, to maroon porphyritic rock of intermediate composition. Phenocrysts consist of feldspar, hornblende, and possibly pyroxene. Feldspar phenocrysts are subhedral to euhedral, up to 3mm, equant to lath shaped and comprise up to 30% of rock. Most of the feldspar appears to be plagioclase. Hornblende phenocrysts occur as anhedral to euhredral crystals to 2 mm and comprise up to 5% of the rock. They occur as single crystals or, more commonly, as clots with feldspar. Groundmass is typically fine grained, though can be aphanitic. Core is often propylitized, consisting of weak to moderate pervasive greenish alteration of groundmass to chlorite+/-calcite+/- epidote. Feldspar phenocrysts are altered to chlorite +/- clay +/- calcite. Hornblende crystals are altered to chlorite? Propylitization is often overprinted by bleaching, and rarely silica flooding adjacent to fractures, faults, and quartz veins. This unit appears to be massive, without flow banding or alignment of phenocrysts. Xenoliths of coarser or finer grained andesite are common throughout the unit. Intra flow breccia are rare in this unit. They consist of angular andesite clasts in a green to grey green, fine grained matrix.

10.0	11.3	FZ	Core is broken and argillized. Abundant fractures filled with brown and grey clay at mostly at 10 to 30 to CA.
15.2			White, 3mm qtz vein at 45 to CA.
15.4	15.45		Orange-tan clay gouge with white qtz fragments . 40 to CA.
19.0	20.5		Zone of white quartz veins at 20 to 40 to CA. Often with white clay selvages. Andesite walls partially silicified and oxidized. Sample 3621
22.8	23.9		Partially silicified and weakly pyritic andesite. Numerous white quartz veins centered on breccia zone at 23.1m. Breccia is 20 cm wide at 40 to CA. with matrix formed by white vuggy quartz veins. Samples 3622 and 3623. # 2 Vein structure?

23.9 53.0 Andesite is maroon to purple coloured. it appears to be fairly fresh and unaltered except in areas where propylitized, as noted below.

26.2	29.9	Green, moderately propylitized and weakly argillized andesite. Propylitization seems to emanate from broken brecciated zones with increases chlorite and clay alteration.
38.0	44.0	Green, propylitized andesite. Alteration is gradational above and below with the fresh andesite.
39.5	40.2	Brecciated, argillized and chloritized fault zone at 10 to CA.
42.4	61.2	Weak to moderate propylitic alteration.

61.2 85.2 dac Dacite? Flows and Breccias

Flow banded, aphanitic extrusive rock. Very rare phenocrysts of feldspar. Unaltered rock is maroon to grey, but much of the rock is green from strong pervasive propylitization. Volcanic breccias are common, particularly at the top and bottom of the unit. These consist of dacite clasts and vesicular basalt or dacite clasts in a swirly, contorted fine grained matrix. The breccias can be either clast or matrix supported. Much of the unit, and especially the breccias, are green from strong propylitization and argillization. Most of the flow and breccia textures are obscured by this alteration. It is possible that this unit is a basalt with associated agglomerates, but the flow banding and purple colour of the less altered flows point to dacite. The contact with the lower basalt agglomerate at 85.2m appears to be gradational, but is largely obscured by strong alteration.

61.2	67.1	Chaotic, heterolithic breccia consisting of angular to sub rounded dacite, andesite and vesicular dacite or basalt clasts in a sand or silt size matrix. Upper part of breccia contains only sub rounded andesite clasts in fine grained red hematized matrix. Lower down, the clasts are mixed and include interbedded flow banded dacite flows. Most of the unit is either strongly propylitized or hematized.
67.1	85.2	Flow banded dacite with minor interbedded breccias as above. Upper part of unit is weakly propylitized, which enhances the flow banding. From 75.3 to 81.0m the flows are maroon to purple and are mostly unaltered. Abundant calcite veinlets at all angles to CA. Below 81.0m the flows are strongly propylitized and argillized.

85.2 185.9 vbx Volcanic Breccia

Poorly sorted, clast to matrix supported breccia. Angular to sub-rounded clasts of vesicular basalt?, and basalt, dacite and possible andesite. Matrix appears to be fine grained sediment. Most of the interval is either brick red or green from intense hematization and propylitization. The entire interval is moderately to very strongly argillized. Clasts are often more argillized than the matrix. Vesicles in the basalt or dacite are filled with calcite, or rarely dusted with fine euhedral quartz needles. The core is usually quite soft, and can often be cut by a knife. Breccia textures are strongly obscured by the intense alteration.

85.2	89.5	Core is green from intense propylitic alteration and is strongly argillized.
88.5		1 cm green clay seam at 20 to CA.
89.5	104.0	Brick red, strongly hematized and argillized. Some of the clasts are green , propylitized basalt. Many of the basalt clasts have vesicles filled with calcite. Trace amounts of fine, disseminated pyrite in the matrix and clasts.
98.0	99.0	Red clay seam to 5mm wide filling irregular fracture at 5 to CA
104.1		2cm wide white quartz vein and silicified breccia at 30 to CA. Strong argillization adjacent to vein.
104.1	129.65	Mixed hematitic and propylitic breccia. Core is quite soft from intense clay alteration. Locally up to 2 % oxidized disseminated pyrite cubes to 1 mm.
121.2	121.7	Strongly oxidized and leached rock. 2% oxidized disseminated pyrite.
128.1	128.3	Silica flooded vesicular clast and matrix Subsequent intense argillization leaving core friable with silicified areas. Fine euhedral quartz needles filling vesicles.
129.65	131.5	Oxidized and leached volcanic breccia. 1% disseminated pyrite. Minor patchy silica flooding. Some vesicular clasts with empty vesicles dusted with euhedral quartz needles. Samples 3624 and 3625.
141.0	142.6	Oxidized and leached breccia as above. Disseminated, oxidized pyrite cubes to 3 mm. Minor silica flooding of vesicles. Sample 3626

143.3 147.0

One of the few places in the interval where primary breccia textures are not obscured by argillization and propylitization. This unit appears similar to the volcanic breccia found under the andesite in previous holes. Interval consists of chaotic, clast supported, poorly sorted breccia with porphyritic dacite, and lesser vesicular dacite or basalt clasts. These clasts are in a red, fine-grained sediment or lava matrix. Within this breccia are beds of finer grained, more heterolithic, better

sorted breccias that may be of volcaniclastic origin. Clasts are various multi-coloured volcanics, and possible siltstone.

147.0	154.7	Increase in propylitic, argillic and hematite alteration which again obscures primary textures. Seems to be the same unit as above.

158.0	170.0	Monolithic breccia consisting of porphyritic dacite clasts in a swirly, flow-banded porphyritic dacite matrix. Small intervals of flow banded, non brecciated dacite occur interbedded with the breccias. Argillization and propylitic alteration much decreased in this interval and breccia textures are more apparent. Sparse calcite and quartz veinlets throughout the interval.
170.0	172.9	Clast supported, well sorted breccia consisting of platey dacite clasts with finer-grained, possibly chilled margins. The clasts have rounded margins, and are aligned at 55 to CA. Matrix is a dark green, propylitized sediment or lava. The clasts appear imbricated as if they were deposited in flowing water.

172.9	185.9		Heterolithic, clast supported, poorly sorted breccia. Angular to rounded clasts of dacite, andesite, and fine-grained siltstone up to 10 cm. Matrix appears to be a fine-grained sediment, but locally may be fine grained lava. Clasts and matrix are not aligned or flow banded, except near the lower contact with the andesite where there is faint, contorted layering of the matrix and vague alignment of clasts at 60 to CA.
		175.5	175.9	Strongly argillized zone. Possible shearing at 80 to CA.
		184.9	185.8	Partially silicified primary breccia at contact with andesite. Somewhat contorted, strongly oxidized matrix. Unoxidized portions of breccia with 1% very fine grained disseminated pyrite. Several white vuggy quartz veinlets at 60 to 80 to CA. Sample 3627.

185.9	**255.1**	**and**	**Andesite**

grey to green, fine grained porphyritic rock. Up to 40 % euhedral to subhedral feldspar phenocrysts to 3 mm. Most feldspar appears to be plagioclase. Up to 5 % lath shaped hornblende phenocrysts to 4 mm which occur singly, or in sub cm sized clots with plagioclase crystals. Blood red hematite occurs as veinlets and replacement of the matrix, and rarely, replacing or rimming phenocrysts. Rounded andesite xenoliths up to 5 cm are common throughout the interval. Propylitic alteration is common throughout the interval, and is usually associated with areas of increased fracture density and shearing or brecciation. Upper contact with the breccia unit is gradational over 40 cm with andesite clasts in the breccia.

189.3	189.9	Several chlorite+calcite veins or lined faults at 20 to 30 to CA. Surrounding core is propylitized for a meter on either side.
196.9	204.6	Moderate propylitic alteration with numerous joints and chlorite+calcite veins or lined fractures at 15 and 45 to CA. Increased calcite veinlets and tension veins.
196.9	172.3	Chlorite calcite lined fractures at 20 and 45 to CA
198.5	198.9	Zone of fracturing and chlorite+calcite veins at 40 and 10 to CA.
202.7	202.8	Crushed, argillized fault zone at 45 to CA.
204.6	230.5	grey, fresh andesite, with weak propylitic alteration and bleaching confined to rare, scattered calcite + chlorite veins. Otherwise unaltered.
230.5	238.7	Weak to moderate propylitic alteration, possibly associated with quartz veining at 239m. Scattered calcite veinlets at 60 to 80 to CA.
238.7	239.7	Possible #2 vein. Breccia vein zone consisting of andesite clasts in matrix of white cockscomb quartz veins. Breccia clasts are generally silicified and quartz veined. Core of zone is broken rubble quartz breccia, but recovery was good. Minor red-tan clay gouge in center of breccia. Some of the vein is a mocha colored, chalcedonic silica with silicified andesite clasts. Upper and lower contacts are defined by white vuggy quartz veins at 35 and 40 to CA. Samples 3629 and 3631.
239.7	255.15	Moderate propylitic alteration to end of hole.

246.2 247.6 Heterolithic breccia consisting of rounded to sub angular clasts of dacite, andesite and possible siltstone. clasts are green, grey and brick red. Matrix is coarse sand of same material. Patchy silicification of matrix and trace oxidized disseminated pyrite. Upper and lower contacts are indistinct, but appear to be gradational with andesite.

246.6	246.8	Zone of veining consisting of breccia clasts in matrix of white vuggy quartz veins. Breccia veins

			and surrounding veinlets at 35 to 50 to CA. Sample 3633.
	250.5	250.7	Green clay+chlorite gouge with crushed rock fragments. Upper and lower fault surfaces at 50 to CA.
	260.0		1.5 cm white quartz vein at 50 to CA.
	254.1	255.12	Finer grained andesite with limonite on fractures.

End of Hole

Blackdome Project 2006

Drill Hole Name: **B06-07A**

Area: **Intersection of No 1 and No2 veins at depth**

Drill Log

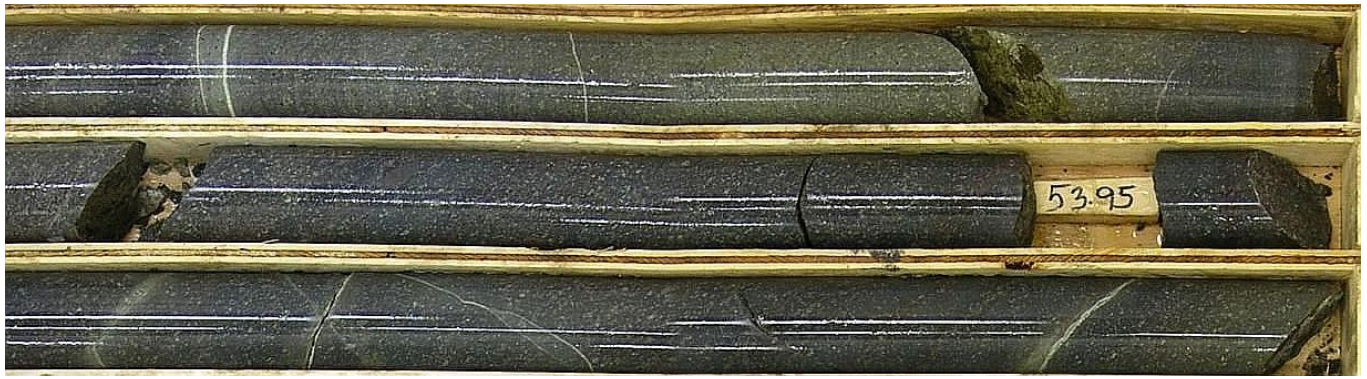
Target	Intersection of the #1 and #2 veins below the level of the mine workings.
Stopped for:	Drill bit broke off in a fault. Unable to continue.
Result	

0	**3.05m**		**Casing** No core.
3.05	**97.8**	**and**	**Andesite**



Grey to greenish grey, porphyritic rock of intermediate composition. Phenocrysts consist of feldspar, hornblende, and possibly pyroxene. Feldspar phenocrysts are subhedral to euhedral, up to 4 mm, equant to lath shaped and comprise up to 40% of rock. Most of the feldspar appears to be plagioclase. Hornblende phenocrysts occur as anhedral to euhredral crystals to 3 mm and comprise up to 10% of the rock. They occur as single crystals or as clots with feldspar. Groundmass is typically fine grained, though can be aphanitic. Weak to fairly prominent flow banding as defined by darker bands in the groundmass and weak alignment of phenocrysts. Core is often propylitized, consisting of weak to moderate pervasive greenish alteration of groundmass to chlorite+/-calcite+/- epidote. Feldspar phenocrysts are altered to chlorite +/- clay +/- calcite. Hornblende crystals are altered to chlorite? Xenoliths of coarser or finer grained andesite are fairly common throughout the unit.

7.5	8.7	Several fractures at 25 to CA. 3 mm grey clay gouge.
9.7	9.9	Several clay lined fractures at 45 to CA with increased propylitic alteration of surrounding andesite.
15.2	16.1	fractured and locally brecciated core with strong chloritic clay gouge.
17.0	26.65	Increased propylitic alteration. Minor calcite veinlets and gash vein fillings in matrix. Trace

			oxidized, disseminated pyrite cubes. Weak local limonite on fractures. Subtle to weak flow banding at 50 to core axis, as defined by darker bands in groundmass and slight alignment of phenocrysts.
		26.65	27.05	Strongly oxidized and argillized, flow banded andesite. Strong vuggy, leached texture with later patchy silicification. In places looks like a quartz vein, but is probably white silicified andesite. Up to 2% oxidized disseminated pyrite cubes. Flow banding at 70 to CA. Sample 3653.
		27.05	27.55	Pyritic grey andesite that has mostly been oxidized to tan -orange adjacent to numerous white quartz veins and veinlets. Most veins at 50 to CA. Sample 3654
		27.55	34.95	Propylitized andesite. Weak flow banding , usually at 50 to CA. A few white or grey vuggy quartz veins.
		32.0	33.5	Core is strongly fractured into wedge shaped pieces. Fractures oriented at 10 to CA.
		34.95	35.7	Propylitized andesite with several white to grey vuggy quartz veins to 8mm. Veins at 50 to 60 to CA. Sample 33655.
		35.7	50.0	Propylitized andesite. Weak flow banding , mostly at 50 to CA. Scattered white to grey vuggy quartz veins.
46.5	66.0			Dark flow bands in groundmass much more prominent. Phenocrysts are smaller and less abundant. Groundmass is finer grained to aphanitic. Flow bands at 50 to CA. Taking on appearance of flow banded dacite in previous holes, but hornblende still present as single phenocrysts and as clots with feldspar phenocrysts. Flows are dark grey to black except where bleached or propylitized adjacent to quartz veins and clay seams. Rock is very hard, and often appears to be silicified. numerous scattered quartz+/-calcite+/-epidote veinlets typically less than 3 mm. Most veins at 70 to 90 to CA
		50.7	50.9	Several faults at 45 to CA with 5 mm tan clay gouge.
		60.7		Prominent red-brown flow banding at 45 to CA.
		64.2	66.0	Strong joint/vein set at 0 to 5 to CA. Joints lined with quartz/calcite/chlorite.
		67.8		1 cm vuggy grey quartz vein with strong epidote replaced walls. Vein at 70 to CA.
		68.6	69.1	Zone of strong epidote? alteration with numerous grey quartz veins . Moderate pervasive oxidation after disseminated pyrite. Some clast supported brecciation. Sample 3656
80.0	97.8			Dark grey to greenish grey andesite porphyry. Aphanitic groundmass. Feldspar phenocrysts rarely exceed 2 mm. Massive, without flow banding or alignment of phenocrysts except where noted. Scattered quartz +/-calcite veinlets. Weak propylitic alteration and bleaching surrounding some quartz veins. Lower contact with rhyolite breccia is sharp, but fairly irregular at 45 to CA.
		87.9		2 cm calcite vein in white clay gouge. Vein at 45 to CA. Strong bleaching adjacent to vein.
		91.6	92.1	2 cm white quartz and calcite vein and 1 cm quartz vein at 30 and 20 to CA. Strong epidote selvages inclusions in veins. Sample 3657

93.7	96.0	Faint flow banding .
97.4	97.8	Andesite at contact is finer grained, possibly chilled. Contains 1% very fine grained disseminated pyrite where rock is unoxidized. Several 3 mm grey quartz veins.

97.8 144.4 rhy Rhyolite Flows or Ignimbrites

Chaotic assemblage of rhyolite flows, breccias and possible ignimbrites. Rock is grey where fresh, but is usually tan from oxidation of disseminated pyrite, or light green from weak propylitization. Zones of strong argillic alteration occur. Phenocrysts consist of rounded to sub- rounded feldspar to 4 mm, which make up upwards of 20 % of the rock, and rounded quartz eyes to 3mm which comprise up to 5 % of the rock. The flows have a fragmental appearance consisting of angular to sub angular, well sorted clasts of darker coloured rhyolite to 1 cm, in a lighter coloured rhyolite matrix. In places this appears to be a clastic texture, but in others it seems to be a devitrification texture, since relict flow banding is occasionally seen to cross several clasts with out rotation. Where the primary rock was a breccia, adjacent clasts are the same colour and texture, surrounded by a lighter coloured, possibly devitrified matrix. Orbicular texture is common from 98 to 102.7m, consisting of spherical, concentrically banded silica growths. Flow banding is also common throughout the interval, but bands are usually affected by the devitrification texture. True clastic breccias occur, but are rare.

98.0	101.0	Dense silicification, strongest near contact with andesite, patchy below 100.0m. Abundant spherical orbicules to 3 cm.
103.6	104.2	Rhyolite flow with numerous grey quartz veinlets and one 3 cm vuggy quartz vein with strong manganese? stain. Veins mostly from 45 to 80 to CA. Sample 3658.
106.7	107.6	Numerous white to grey quartz veinlets at all angles to CA. Sample 3659
111.6	111.7	1 cm quartz vein at 45 to CA surrounded by brown clay gouge and bleached rhyolite walls.
112.0	112.3	1mm limonitic fracture, with dense silicification extending outwards for 2 cm. Sharp and abrupt

		outer edge to silicification. Fracture at 10 to CA.
112.5	113.2	Strong sheared, breccia zone with main fractures at 10 to 20 to CA. Very strong tan clay gouge and clay coatings on clasts.
115.1	115.8	Strongly argillized fracture/fault zone. Most fractures at 20 to CA.
122.3	126.8	Fault zone. Strong argillization associated with abundant shear surfaces at low angles to CA. Slickensides on fault surfaces at 70 to 80 to CA.

144.4 159.6 vcbx Volcaniclastic Breccia and Lapilli Tuff

Chaotic package of breccia, volcanic sandstone and lapilli tuff. Breccias can be fairly well sorted, clast supported and consist of mostly rhyolite clasts in a sand matrix. There are occasional clasts of other lithologies, including sediments. Other breccias are heterolithic, poorly sorted, matrix supported with a coarse sand matrix. Volcanic, possibly tuffaceous sandstones are common throughout the unit interbedded with the breccias. These tend to form normally graded beds of lithic sandstone up to 20 cm thick, with scattered, large volcanic or sedimentary clasts. These could be lapilli tuff beds. Bedding within the sandstone and tuff layers is typically 45 to CA. The unit is grey and contains sparse disseminated pyrite. The breccia matrix and some of the sandstone has a greenish tint from possible weak propylitic alteration. Upper contact is sharp and planar with overlying rhyolite flows at 45 to CA. Lower contact is sharp with flow banded rhyolite flows at 35 to CA.

154.1	154.3	20 cm thick clay gouge at 45 to CA. Parallel to layering in rhyolite. Tan gouge w/ ground rock fragments. White quartz vein to 1 cm. Fault gouge, or alteration related to quartz vein.

159.6 224.2 dac Dacite? Flows

Flow banded dacite flows (possible rhyolite?) and breccias. Tan to greenish tan flow banded dacite with feldspar phenocrysts and sparse quartz eye. Darker flows bands often have a pseudo-clastic texture from devitrification. Thin breccias occur throughout the interval and consist of dacite clasts in a fine-grained, possible lava matrix. Flow banding is variable throughout the unit from low angle to perpendicular to CA. Most common orientation is 65 to CA.

162.8	163.2	Shearing and faulting, mostly at low angles to CA. Tan clay and rock fragment gouge.
165.4	166.1	8 mm grey quartz vein running down length of core. Numerous small quartz veinlets at all orientations. Patches of grey, unoxidized , pyritic dacite. Sample 3662.
166.1	166.73	Vein structure. Upper contact at 40 to CA. Lower contact obscured in rubble. Vein is at least 25 cm wide, but most of interval is broken core, and recovery is only 50%. Structure consists of brecciated, limonitic rhyolite with white quartz matrix and cross cutting white and grey quartz veins. Breccia clasts of dacite, quartz vein and breccia. Complete silica flooding. Disseminated oxidized pyrite. Sample 3663
166.73	167.6	Upper 40 cm of the interval is rubble of dacite with some quartz veining and silicification as in the previous sample. Rest of the sample is dacite with minor crackle breccia zones and quartz vein matrix and several white quartz veins to 1 cm. Sample 3664

170.3	172.0			Tuffaceous sediments. Volcanic sandstones and fine grained tuff beds. Bedding at 45 to CA. Fine grained disseminated pyrite, mostly oxidized.
		171.3	171.4	1cm white vuggy quartz vein at 20 to CA. Silica flooding of the dacite walls.
		172.8	178.6	Greenish tan propylitized dacite flows.
		178.6	180.5	grey, fresh , pyritic dacite. Over half of interval is oxidized adjacent to fractures and quartz veins and veinlets.
		180.2	180.4	Limonitic fracture or fault at 5 to CA with slickensides at 70 to CA.
181.2	224.2			Green-grey porphyritic dacite or possible rhyolite flows. Feldspar phenocrysts locally altered to chlorite+epidote? Flow banded. Occasional flow breccias with porphyritic dacite or rhyolite clasts in matrix of the same.
		188.3	189.4	Breccia with dacite clasts in fine silt or tuff matrix.
		190.2	194.6	Broken core. Numerous fractures at all angles to CA. Weak iron oxide and clay coatings on fractures. A few white clay seams to 5mm.
		197.0	197.4	40 cm wide fault zone at 45 to CA. Numerous Fault gouges consisting of white to tan clay and milled, crushed dacite fragments and a few quartz vein clasts. Footwall is fractured and has strong limonite stain on fracture surfaces.
		202.2	203.8	Breccia consisting of mostly rounded dacite clasts in dacite or possible sediment matrix. 2% disseminated pyrite cubes.
		204.7	205.3	Broken core. Abundant fractures at all angles to core, but dominant set at 5 to CA. Clay lined fractures.
		206.35	208.8	grey dacite with up to 2% disseminated fresh pyrite cubes. Strong oxidation along fractures. Several sub cm white quartz veins.
		208.8	210.7	Core is very broken. Strong chlorite +/-epidote alteration associated with faulting and quartz veining. Many surfaces are sheared and have clay + chlorite fracture coatings. Quartz veins at 35 to CA.
		223.12	223.8	Broken , limonite stained fractures. Numerous white vuggy quartz veins at 40 to CA.

224.2	**232.2**	**vcbx**	**Volcaniclastic Breccia**

Heterolithic, poorly sorted breccia. Angular clasts of many rock types from small gravel to 30 cm blocks. Matrix is coarse sand to fine gravel sized grains. Larger clasts are suspended in this matrix and thus appear to be matrix supported. Clasts and matrix comprised of multi-coloured dacite, andesite, siltstone, vesicular basalt? and devitrified volcanic glass. The breccia is massive, without indication of bedding. Some clasts, and to a lesser extent, the matrix have fine grained disseminated pyrite. Upper contact with the Dacite is sharp at 70 to CA. Breccia becomes gradually finer approaching lower contact.

227.1	227.3	Abundant fractures at low angles to CA.

232.2 239.2 dac Dacite

Porphyritic dacite flows. Greenish except where tan from oxidation of disseminated pyrite. Up to 10% feldspar phenocrysts. No flow banding. Gradational upper and lower contacts with breccia units.

233.9	234.4	Zone of quartz veining. Veins from 40 to 55 to CA. Main vein is 20 cm wide breccia vein with silicified dacite and quartz vein clasts in a matrix of grey quartz veins and later white cockscomb quartz vein. Trace disseminated pyrite. Upper and lower contacts are sharp at 45 to CA. Sample 3665
234.9	235.7	White and grey quartz veined dacite. Main orientation at 40 to CA. 2cm wide open space fill white quartz vein with euhedral toothy quartz filled cavity. 40 to CA. 5cm wide breccia with white cockscomb quartz vein matrix at 40 to CA. Trace disseminated pyrite. Numerous smaller white quartz veins in interval. Sample 3667
235.7	236.1	Core is strongly broken along fractures at 5 to 10 to CA.

239.2 234.8 vcbx Volcaniclastic Breccia

Heterolithic, poorly sorted breccia with some small dacite flows. Could be volcanic breccia, but many different clast types point to sedimentary origin. Gradational upper and lower contacts.

240.5	240.9	Primary breccia that seems to have been hydrothermally brecciated and silica healed. White quartz and silica flooded matrix. Several white quartz veins at 45 to CA with clasts of primary breccia. Trace disseminated pyrite. Sample 3668.
241.9	242.6	Fault zone. Strongly argillized and sheared dacite and primary breccia. Dominant shear direction at 45 to CA.

234.8 259.3 dac Dacite

Grey to greenish porphyritic dacite? Feldspar phenocrysts are smaller than in other dacites. Weak propylitic alteration. Unit includes several flow breccias consisting of dacite clasts in lava or possibly

sediment matrix. Matrix is often hematized. Distinct flow banding in dacite below 265.0m.

243.7	248.2		Zone of broken core. Breaks at all angles to CA, but 20 to 35 to CA most common.

254.0	257.5	Flow breccia. Angular dacite clasts in purple hematized matrix. Mostly clast supported.
259.6	263.5	Fine, dacite-clast conglomerate which grades into pyritic interbedded sediments or possibly flow banded dacite. This unit grades into coarse breccia consisting of angular, flow banded dacite clasts in hematized lava or sediment matrix. Flow banding has a distinctive green and white striped look, possibly from partial devitrification. This breccia grades into flow banded, green and white dacite with bands at 20 to CA. This transitions into more typical, finely flow banded, porphyritic grey dacite. Flow banding gradually shallows to 45 to CA.
265.3	301.76	Grey to green grey flow banded dacite. Sparse, fine-grained feldspar phenocrysts. Fine grained disseminated pyrite. Flow banding varies from 45 to 75 to CA.

277.8	280.7		Numerous limonite lined fractures at 0 to 10 to CA. Coarse brassy pyrite cubes deposited along these fractures. Several white clay lined joints at 45 to CA. Interval is slightly bleached.
290.0	292.0		Broken, fractured core. Weak clay on fractures, no obvious shearing. Red hematite on fractures.
290.6	298.3		Dacite is light grey and has a somewhat bleached appearance and a slightly sintery feel. Up to 2% disseminated and veinlet pyrite. Pyrite is coarse grained , euhedral and brassy. Reddish hematite occurs as thin coating on many fractures. Dacite has patchy silicification with locally abundant grey micro quartz veinlets.
295.0	301.76	FZ	Fault zone. Core is hard, abrasive broken rubble to 298.4m. Below 298.4m core is strongly argillized, brecciated and sheared. Much of interval is tectonic breccia with milled, crushed rock fragments in sheared clay matrix.

CODING DESCRIPTION (Continued)

Quartz veining

% qtz vn	% Quartz veining and quartz veining as Breccia matrix
% adularia	% Adularia in quartz veins and breccia

Breccia Intensity:

1	Crackle breccia, interconnecting network of fine veinlets, no rotation.
2	Clasts>>veins/matrix, no rotation, single phase (no breccia clasts, single vein type) Includes autobrecciation.
3	Clasts>veins/matrix, may have more than one vein type, no veins >2mm, no rotation, easy to moderate to reconstruct.
4	Clasts>veins/matrix, some veins >2mm, may have some rotation (locally clast supported), may be multiphase, moderate to difficult to reconstruct.
5	Clasts <= veins/matrix, multiphase, multi vein style, may have rotation at least locally, many veins >2mm, hard to impossible to reconstruct.

APPENDIX E – – CERTIFICATE OF QUALIFICATIONS

I, John Harrop, residing at 1 – 2978 Walton Ave, Coquitlam, British Columbia do hereby certify that:

1. I am a Geologist with J-Pacific Gold Inc. with an office at Suite 802, 1166 Alberni Street, Vancouver,
British Columbia, Canada and Coast Mountain Geological Ltd with and office at Suite 620, 650 West Georgia Street, Vancouver, British Columbia.

2. I graduated of the University of British Columbia with a BSc. in Geological Sciences in 1983, and have practised my profession continuously since then;

3. I am a Professional Geoscientist registered with the Association of Professional Engineers and Geoscientists of the province of British Columbia.

4. I am not aware of any material fact or material change with respect to the subject matter of the technical report, which is not reflected in the technical report, the omission to disclose which makes the technical report misleading.

5. I, as the qualified person, am not independent of the issuer as defined in Section 1.5 of National Instrument 43-101. I am an employee of J-Pacific Gold Inc. and Coast Mountain Geological Ltd

6. I have had any prior involvement with the property that is subject to the technical report.

8. I visited the Blackdome Project at numerous times between 2004 and 2007.

9. I was the author of the report.

John Harrop, PGeo
Vancouver, British Columbia
8 October, 2007
