Rock, Silt and Soil Geochemistry on the MO Property

Introduction

The MO Property was examined by the author on June 28 and Sept 6-7, 2007. The purpose of the visit was to assess the potential of a large molybdenum soil and stream sediment anomaly and to attempt to locate outcrop or subcrop of a molybdenum porphyry system. An initial traverse in June was made to locate outcrop, examine float boulders, and resample two RGS stream sediment anomalies. A second day was spent on the property looking in detail at local float boulder fields and digging soil pits in order to assess the possible relationship between the local soil profile and anomalous Mo values reported by previous workers. All work including report writing was completed at a cost of \$12,478.97.

Location and Access

The MO Property is located 28 kilometres southeast of Dease Lake and 17 kilometres east of Highway 37 in northwestern B.C. The property is located in NTS 104I/05, latitude 58°19'N, longitude 129°34'W. Access to the property is by helicopter from Dease Lake although a 4WD road is accessible from Highway 37 up Zuback and Cariboo Creeks into the Turnagain River drainage, and passes within 5 kilometres of the property. A rough all-terrain vehicle track heads off the Zuback road to the southeast and extends to an old cabin in the southwestern corner of the MO property.

Physiography, Climate and Vegetation

The MO property occupies a glacial till plain cut by Snowdrift Creek on the north flank of the Three Sisters Range in the Cassiar Mountains. Elevations range from 1400 to 1600 meters, and topography is subdued. There are few trees on the property, and the area is covered by sometimes thick buckbrush, willow and alder. Climate is typical of interior areas in northern B.C., with long, sometimes severe winters, and short summers.

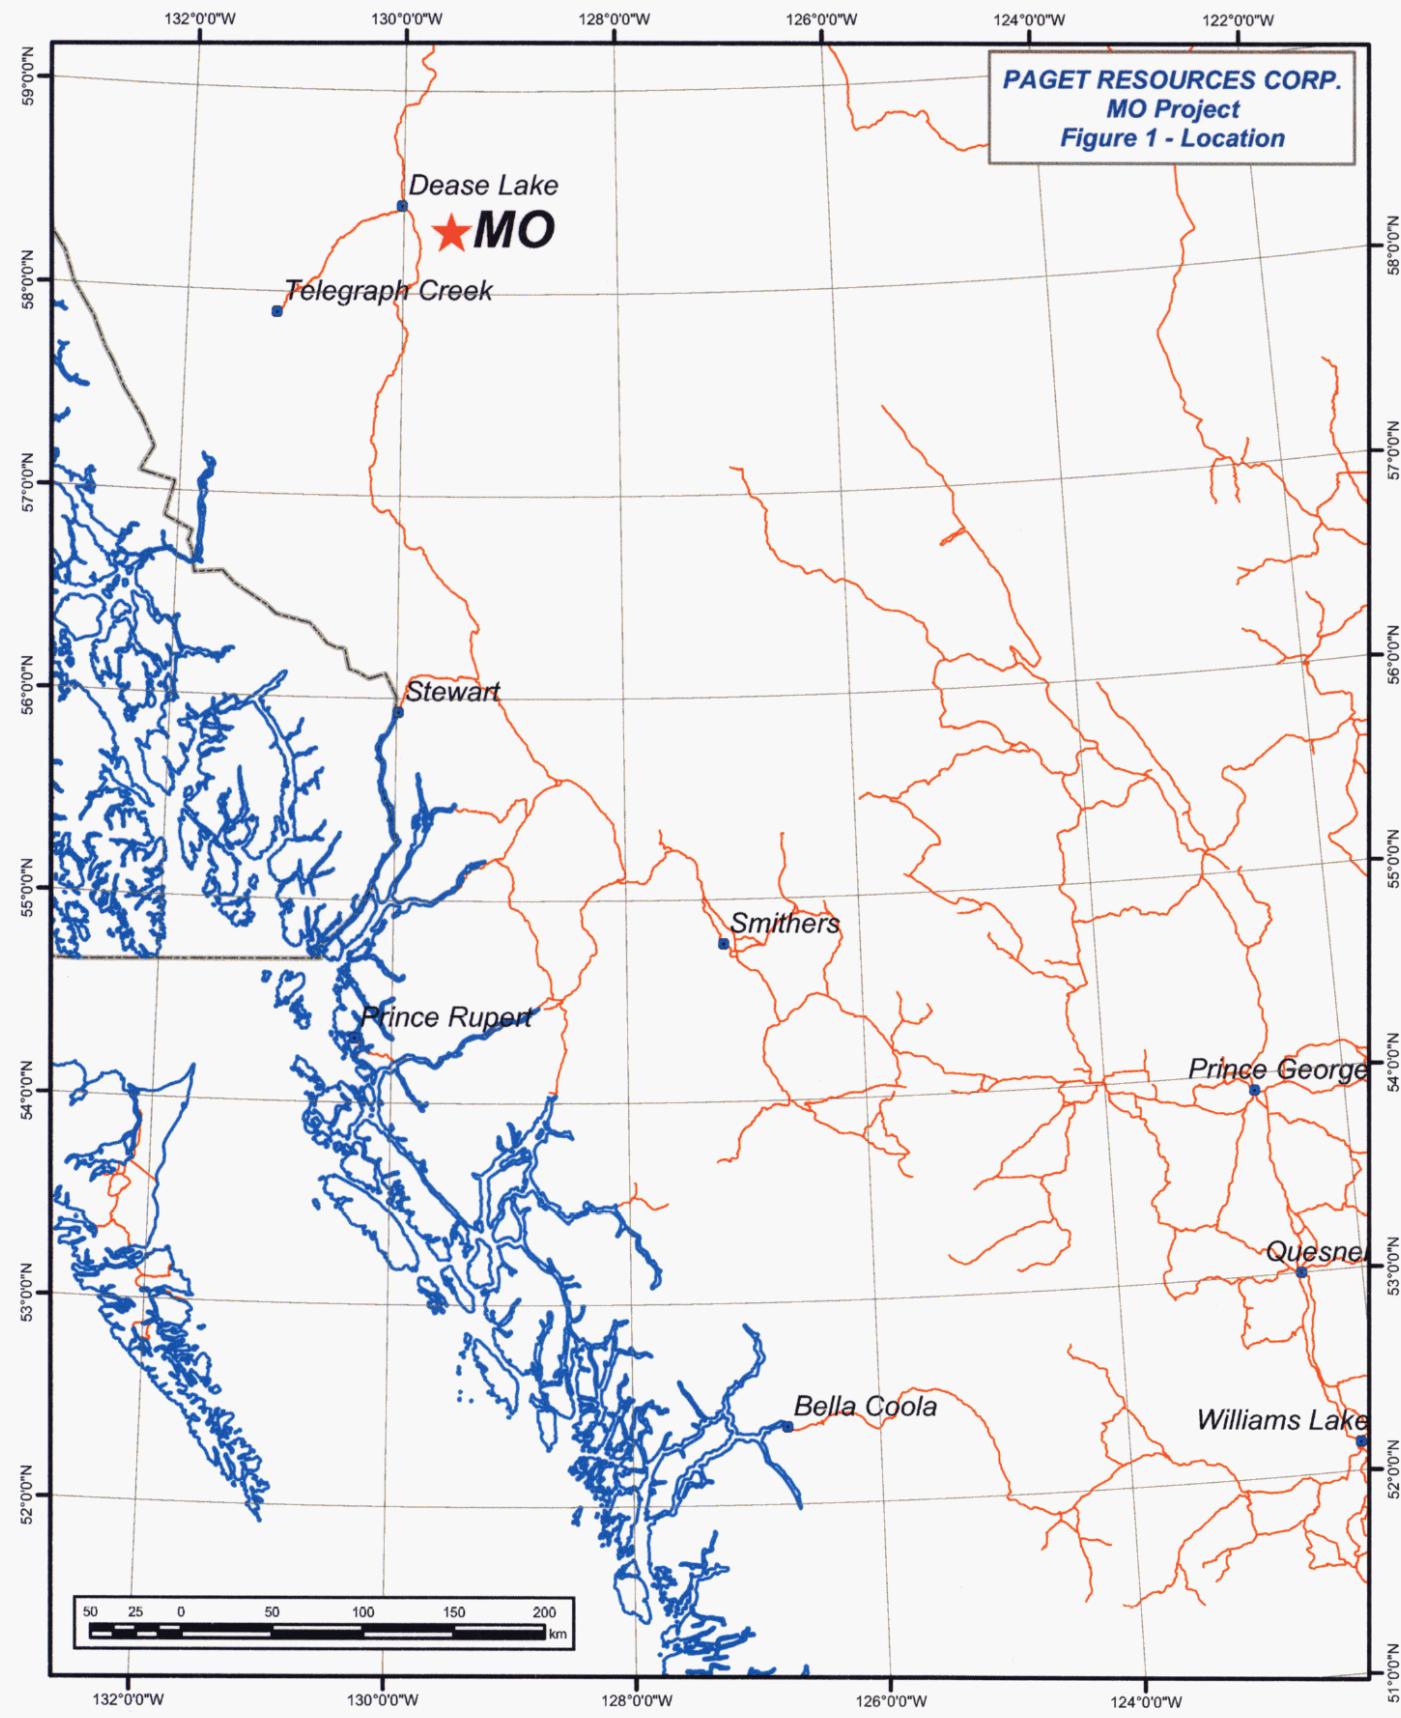

Claims and Ownership

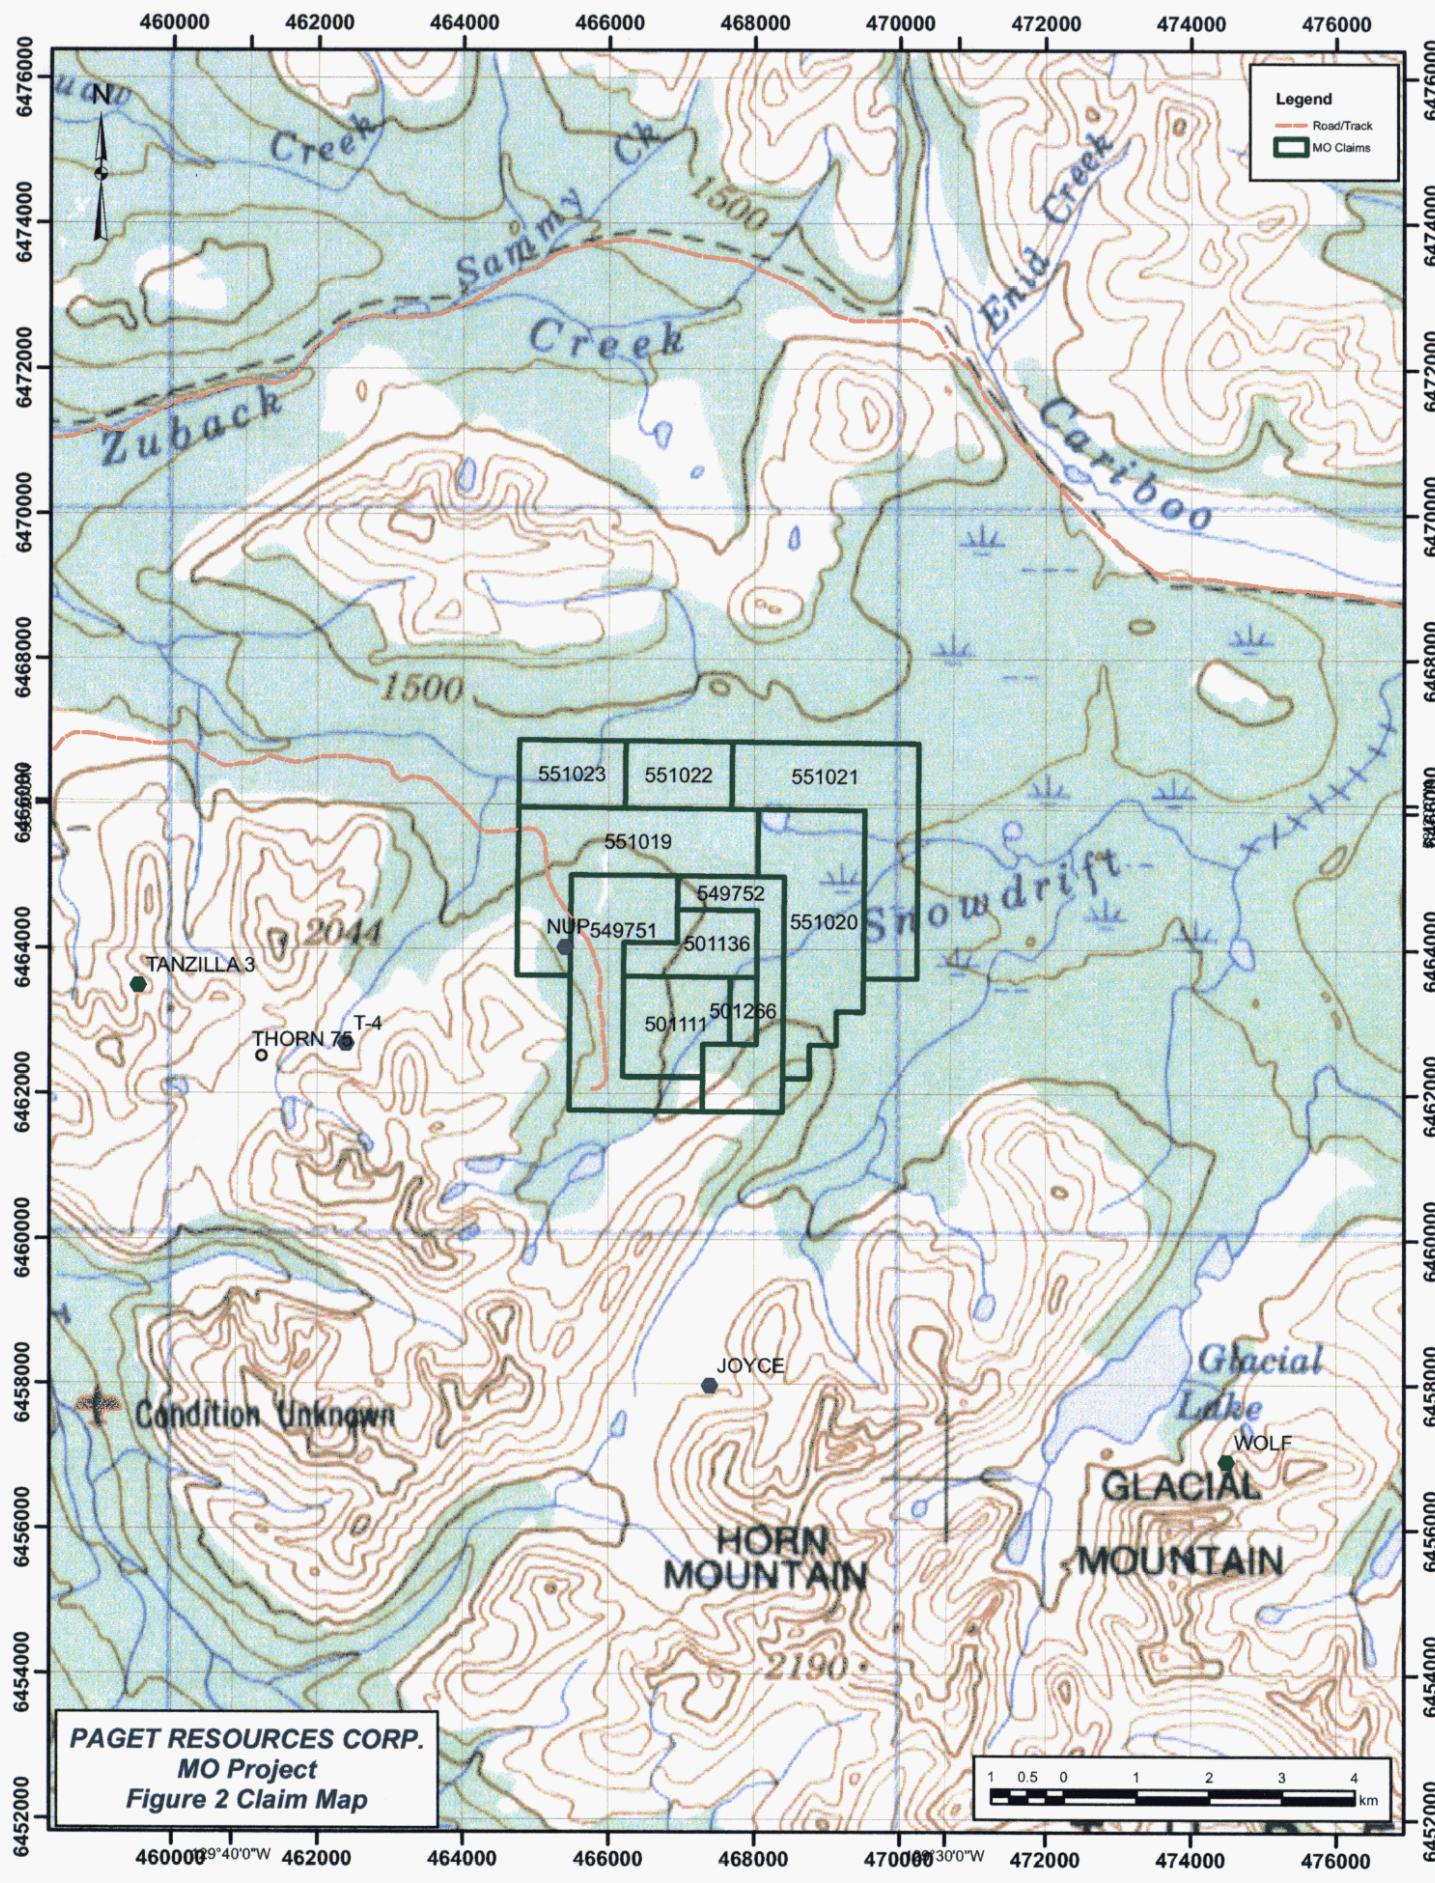

The MO Property consists of ten contiguous claims which total 2431 hectares, as indicated on Figure 2. They are owned 100% by Brian Kent Bowen (BCE ID number 102947) of 12470-99A Avenue, Surrey, B.C., and are subject to a property purchase

agreement between Bowen and Paget Resources Corp. The claims are currently valid until March 15, 2009.

Exploration History

Exploration in the area of the MO Property took place in the 1970's and 1980's as documented in six assessment reports available on the B.C. Ministry of Mines ARIS website (<http://www.em.gov.bc.ca/cf/ariss/>). Work completed and documented in these reports is summarized in Table 2.

Table 2: Historical exploration work in the MO Property area.

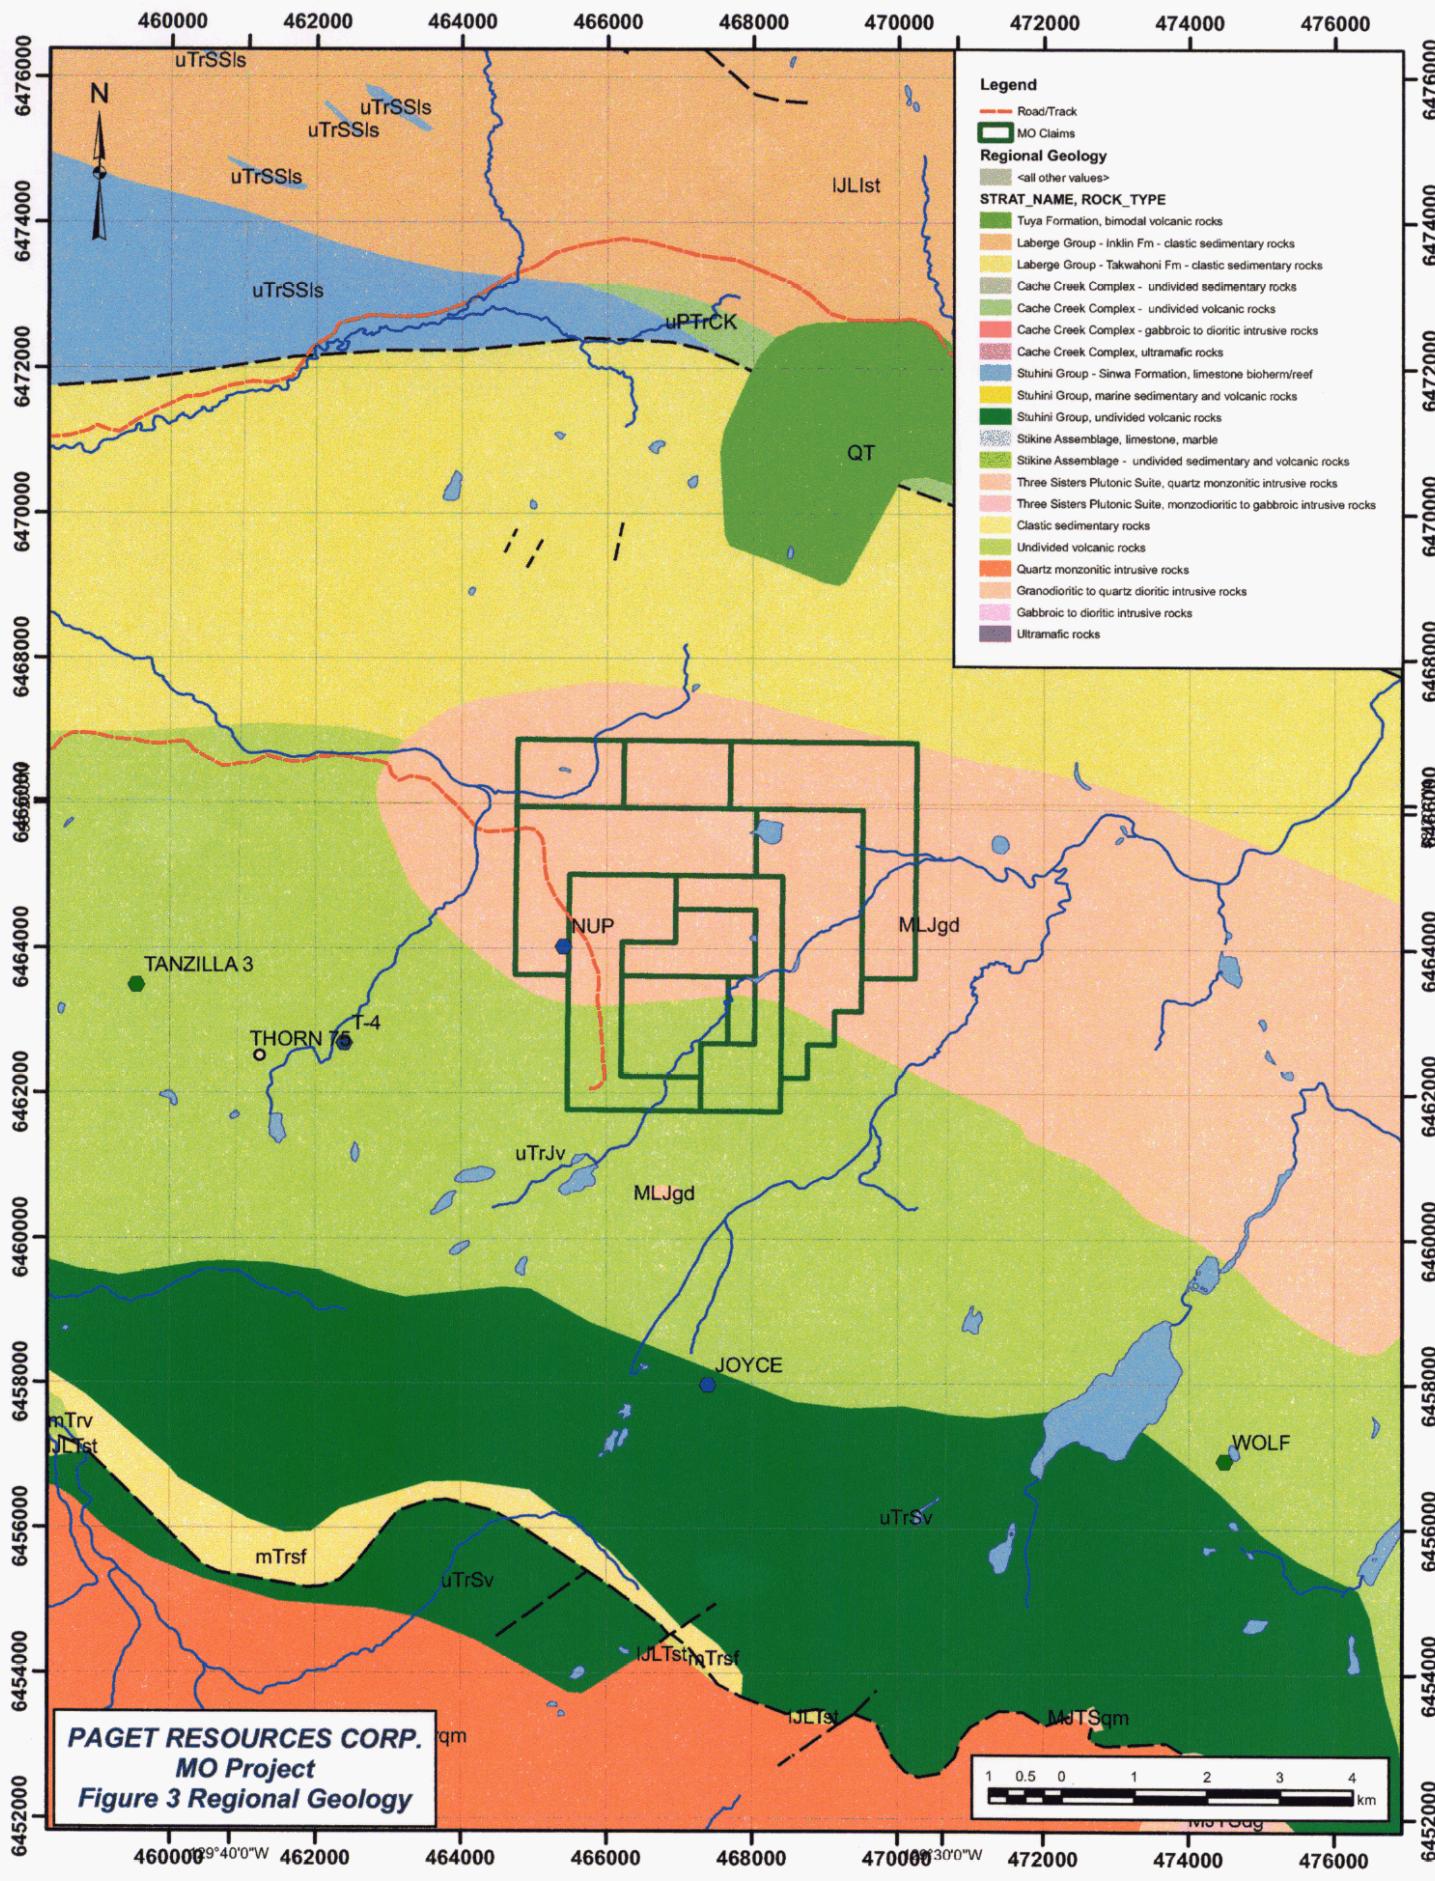

Report #	Year Work Done	Company	Work Done
4644	1973	Kennco	IP
4645	1973	Kennco	Soil sampling
4659	1973	Kennco	Airborne magnetics
4660	1973	Kennco	Ground magnetics
10356	1982	Serrana Res / Noranda	Soil sampling
10923	1982	Serrana Res / Noranda	Soil sampling

Initial exploration of the property in the early 1970's by Kennco included property-wide soil sampling, IP, and airborne and ground magnetic surveys. Between 1975 and 1976 Utah Mines carried out advanced exploration including drilling several diamond drill holes, two of which were located within the western boundary of the property (B.K. Bowen, pers. comm., 2007). Between 1977 and 1980 Noranda Mines and Canadian Superior Oil held the property. No assessment work was filed during the period 1975-1980.

In 1981 Serrana Resources began a second wave of exploration by staking the Drift claims, and in 1982 carried out a soil sampling survey in 1982.

Regional Geological Setting

The MO Property is located in northern Stikine Terrane, which comprises mid-Paleozoic to Middle Jurassic arc volcanic and intrusive rocks. The property is situated within the east to northeast trending Stikine Arch, a positive tectonic element that separates Jurassic sedimentary basins, with the Whitehorse Trough to the north, and the Bowser Basin to the south. The property is underlain by undifferentiated Upper Triassic to Lower Jurassic volcanic rocks which are overlain to the north by Lower Jurassic Takwahoni Formation clastic sedimentary rocks (Figure 3). The Triassic-Jurassic sequence is intruded by Middle to late Jurassic granodiorite of the Snowdrift Creek pluton, which underlies most of the property. The MO property is about 5 kilometres south of the King Salmon Fault, which marks the collisional suture zone between Stikine Terrane and the Cache Creek oceanic terrane.

Property Geology

As most of the MO property is covered by a mantle of glacial drift, very little can be said with confidence about the property geology. In the western part of the property, there are several areas of outcrop and felsenmeer which consist of biotite-hornblende granodiorite. Toward the western property boundary the granodiorite is weakly sericite altered with biotites replaced by sericite and intact unaltered hornblende. The sericite altered intrusive is characterized by buff-yellow weathering colours, a few clear quartz veins and very minor pyrite and trace specular hematite (after magnetite?). One large area of nearly fresh to weakly sericitized granodiorite contains numerous 1mm-1cm clear to yellowish quartz veinlets and local fracture controlled pyrite. Rare quartz stringers contain minor amounts of fine-grained molybdenite.

In the eastern part of the property near Snowdrift Creek, a few boulder fields consist largely of angular to subrounded boulders of quartz phryic biotite granite. This is a much more felsic and evolved intrusive phase than the granodiorite, with abundant clear to smoky quartz. Much of the float in this area consists of a more dioritic intrusive phase. Numerous volcanic boulders are also present.

Mineralization and Alteration

Molybdenite and chalcopyrite are present in outcrop and float in a few widely separated areas. In the western part of the property, outcropping biotite-hornblende granodiorite contains rare molybdenite bearing quartz veinlets. In the eastern part of the property, a fairly homogeneous boulder field (subcrop?) consisting dominantly of angular quartz-phryic biotite granite boulders contains widespread disseminated chalcopyrite and quartz stringers with K-feldspar envelopes with weak molybdenite along the margins. About 320 metres north of this location a 50 metre wide boulder field contains significant molybdenite in quartz stringers in both biotite altered quartz diorite?/granodiorite and intensely biotized volcanics.

Work Completed 2007

The MO Property was examined by the author on June 7 and September 7, 2007. The purpose of the visit was to assess the potential of a large molybdenum soil and stream sediment anomaly and to attempt to locate outcrop or subcrop of a molybdenum porphyry system. An initial traverse in June was made to locate outcrop, examine float boulders, and resample two RGS stream sediment anomalies. A second day was spent on the property looking in detail at local float boulder fields and digging soil pits in order to assess the possible relationship between the local soil profile and anomalous Mo values reported by previous workers.

Rock Geochemistry

Rock samples were collected from variably altered and/or mineralized boulders and outcrop. Data from these selected grab samples can be used to assess the tenor of specific styles and intensities of mineralization with little or no implication about the overall economic potential of the occurrence. Samples were collected in plastic sample bags and sealed with plastic zip ties. Sample locations were recorded by GPS. Sample locations are marked with flagging tape and embossed aluminum tags. Samples were bundled in security sealed rice bags and trucked to Paget's Burrage air strip storage facility, south of Iskut B.C., from where they were palletized and shipped by Bandstra to International Plasma Labs of Richmond B.C.

At the laboratory, the samples were dried, crushed and a 250 gram split pulverized to 90% passing -150 mesh using standard rock preparation procedures. The pulps were then analyzed for Au using a 30 gram fire assay with AA finish and for 30 elements by ICP-AES following a multi-acid digestion. Quality control at the laboratory is maintained by submitting blanks, standards and re-assaying duplicate samples from each analytical batch.

Rock sample descriptions and analytical results are in Appendix C. Sample locations are plotted on Figure 4.

Two samples were taken from granodiorite outcrops in the western part of the property. Sample 148077, a grab sample of granodiorite cut by quartz veins with minor molybdenum mineralization returned a value of 381 ppm Mo, with elevated As (105 ppm) and W (37 ppm). Cu was quite low (48 ppm). Unmineralized but pervasively sericitized granodiorite just west of this sample returned low Mo (10 ppm), but still elevated As (90 ppm) and W (14 ppm), and even lower Cu (20 ppm).

About 1.3 kilometres east of these outcrops, a boulder of well mineralized, lithologically identical biotite-hornblende granodiorite was located in an area of heterogeneous creek float boulders. This boulder, which was cut by numerous quartz, quartz-pyrite and quartz-molybdenite veinlets, returned 706 ppm Mo (sample 148080), with elevated Cu (189 ppm), As (89 ppm) and W (19 ppm).

About 835 m southeast of sample 148080, and 2 kilometres southeast of the outcropping weak Mo mineralization, three boulders were sampled in a 50 m wide boulder field in which the majority of boulders contained significant alteration, quartz veining and/or Mo mineralization. These samples included:

- biotite altered (quartz?) diorite (granodiorite?) with well mineralized quartz veins and 1-2% disseminated pyrite (sample 147594: 1487 ppm Mo, 168 ppm Cu);

- feldspar-phyric granodiorite with strong fine-grained biotite-magnetite alteration, 1% disseminated pyrite, and quartz veinlets with moly along vein margins (sample 147348: 223 ppm Mo, 61 ppm Cu);
- pervasively biotite-magnetite altered fine-grained volcanic(?) cut by narrow quartz stringers with fine-grained moly as well as weakly disseminated moly (sample 147349: 195 ppm Mo, <1 ppm Cu).

In contrast to both outcrop and boulder samples to the west, these samples are characterized by the presence of strong biotite(-magnetite) alteration and much lower As (16 ppm or lower) and W (<5 ppm).

About 60 metres southwest of this boulder field, a diorite boulder with strong pyrite-pyrrhotite returned negligible Mo (8 ppm) but anomalous Cu (357 ppm).

About 320 metres south of the boulder field discussed above, a boulder field adjacent to Snowdrift Creek contained a homogeneous boulder assemblage dominated by quartz-phyric biotite granite. These boulders were large and generally quite angular, giving the appearance of being possibly frost heaved and *in situ*. Most of the boulders contained weak to moderately disseminated chalcopyrite and some contained molybdenite. A character sample (147347) from several of these boulders returned 390 ppm Cu but only 35 ppm Mo. As and W were both below detection limit (<5 ppm).

Stream Sediment Geochemistry

Regional geochemical survey (RGS) sampling of two tributaries of Snowdrift Creek returned among the highest Mo values in all of B.C. Five silt samples were taken in 2007 in order to provide verification of these two anomalies. Four samples were taken from the northern creek, where RGS sample 104I951469 returned 122 ppm (AAS), and one from the southern creek, where the RGS sample 104I951491 returned 280 ppm Mo (AAS). Samples of sandy silt were taken by hand without seiving from active creek beds and placed in cloth bags. Sample shipment and analytical procedure is as discussed above under Rock Geochemistry. Samples are dried to 60 C and seived to -80 mesh up to 100 grams. Silt sample descriptions and analytical results are in Appendix C. Sample locations are plotted on Figure 4.

Three samples were taken from the northern creek well west of (upstream from) the RGS anomaly. The highest (westernmost) sample was taken above the outcrops of sericite altered and quartz veined granodiorite, and returned 38 ppm Mo, 32 ppm Cu, 115 ppm As and 13 ppm W (sample 148075). About 400 metres to the east in the same drainage, the next sample below these outcrops returned 47 ppm Mo, 81 ppm Cu, 111 ppm As and 11 ppm W (sample 148078). The next sample was taken a further 725 metres to the east, and returned 45 ppm Mo, 52 ppm Cu, 115 ppm As, and 6 ppm W (sample 148079). The final sample in the northern creek (148081) was a further 1465 metres east of sample 148079

and is located less than 30 metres from RGS sample 104I951469. These samples can be compared as follows:

- 148081: 246 ppm Mo, 65 ppm Cu, 88 ppm As, 81 ppm Pb, 198 ppm Zn, 19 ppm W
- 104I951469: 122 ppm Mo, 41 ppm Cu, 1 ppm As, 7 ppm Pb, 155 ppm Zn, 5 ppm W (Mo, Cu, As, Pb, Zn by AAS, W by INAA).

Although the ICP analysis gives higher values in all of these elements, it can at least be said that the data supports the presence of a significant Mo anomaly in this drainage and a significant increase in strength in the gap between 148079 and 148081. It is unclear whether this increase is due to mineralization in underlying bedrock as there are no outcrops in the drift covered area between the two silt samples.

One silt sample (148082) from the southern drainage sampled by the RGS was from a location about 200 metres east of the RGS sample. The two samples compare as follows:

- 148082: 921 ppm Mo, 450 ppm Cu, 60 ppm As, 55 ppm Pb, 143 ppm Zn, 28 ppm W
- 104I951491: 280 ppm Mo, 180 ppm Cu, 2 ppm As, 5 ppm Pb, 76 ppm Zn, 1 ppm W (Mo, Cu, As, Pb, Zn by AAS, W by INAA).

Again the ICP values are much higher, but both the RGS and Paget samples indicate an increase in the strength of the Mo and Cu anomaly from the northern creek to the southern creek, and a corresponding decrease in Pb and Zn. This suggests a north to south transition from a more distal to a more proximal porphyry environment.

Soil Geochemistry

Soil samples were taken from five pits scattered across 700 metres within the soil anomaly defined by previous work by Kennco (Assessment Report 4645) and Serrana (10356 and 10923). Pits were dug to depths of 70 cm to 1.0 metres and the soil profile and boulder lithologies examined. Soil samples were taken at measured depths below surface and placed in kraft paper bags. Sample shipment and analytical procedure is as discussed above under Rock Geochemistry. Samples are dried to 60 C and sieved to -80 mesh up to 100 grams. Soil sample descriptions and analytical results are in Appendix C. Sample locations are plotted on Figure 4.

Results are as follows:

- Sample location A, 100 metres east of 190 ppm Mo sample from historical data
 - 15 cm depth, A horizon: 20 ppm Mo, 79 ppm Cu (147851)
 - 35 cm depth, B horizon: 39 ppm Mo, 163 ppm Cu (147852)
 - 70 cm depth, B-C horizon, angular intrusive cobbles: 61 ppm Mo, 239 ppm Cu (147853)

- Sample location B, 80 metres southeast of 500 ppm Mo sample from historical data
 - 20 cm depth, B horizon (no A horizon): 33 ppm Mo, 197 ppm Cu (147589)
 - 50 cm depth, B horizon: 42 ppm Mo, 258 ppm Cu (147590)
- Sample location C, on top of 500 ppm Mo sample from historical data
 - 30 cm depth, A horizon mixed clay and organics: 70 ppm Mo, 53 ppm Cu (147591)
 - 60 cm depth, B horizon, abundant volcanic cobbles: 43 ppm Mo, 106 ppm Cu (147592)
- Sample location D, on top of 395 ppm Mo sample from historical data
 - 15 cm depth, deep A horizon: 254 ppm Mo, 125 ppm Cu (147854)
 - 40 cm depth, B horizon: 71 ppm Mo, 107 ppm Cu (147855)
 - 70 cm depth, B-C horizon, subangular diorite and volcanic cobbles: 40 ppm Mo, 52 ppm Cu (147856)
- Sample location E, on top of 460 ppm Mo sample from historical data
 - 10 cm depth, A horizon: 16 ppm Mo, 50 ppm Cu (147857)
 - 60 cm depth, B horizon: 14 ppm Mo, 72 ppm Cu (147858)

Conclusions and Recommendations

The 2007 evaluation of the MO property has established that weak molybdenum mineralization occurs in granodiorite outcrop in the western part of the property, and has verified the RGS stream sediment Mo anomalies. The discovery of a relatively homogeneous boulder field (possible *in situ* frost-heaved boulders) with chalcopyrite and moly in granite boulders adjacent to Snowdrift Creek represents a previously undocumented mineral occurrence. More heterogeneous boulder fields to the north of this occurrence also contain boulders with strong biotite-magnetite alteration and molybdenum mineralization in a variety of rock types. This occurrence is also previously undocumented. These two areas are about 320 metres apart and are located within a strong Mo in soil anomaly documented by previous workers.

The rock and stream sediment data, although sparse, does suggest a possible geochemical zonation from west to east and north to south. Rock outcrops in the western part of the property contain higher As and W values not found in boulders sampled further to the east, suggesting a possible As-W halo to a Mo-Cu system. The southernmost relatively homogeneous granite boulder field contains persistent chalcopyrite not found in the more heterogeneous boulder fields to the north. In addition, the stream sediment data suggests a major jump in Cu and Mo from the northern creek to the southern creek, and a

corresponding decrease in Pb and Zn. These data support a transition to a more proximal porphyry environment from north to south.

Limited soil sampling data fails to support previously reported high molybdenum values, although most of the 2007 samples are certainly anomalous in Mo, based on the author's prior experience with Cu-Mo porphyry systems in B.C. The relationship between depth and geochemical values is equivocal, with Mo and Cu increasing with depth at locations A and B, decreasing with depth at locations C and D, and at location E showing no significant change. Locations A and B are the southernmost locations and location A is only 65 metres west of the granite – dominated boulder field with chalcopyrite mineralization.

The 2007 exploration program, together with historical data, provides sufficient support for the possibility that a major porphyry moly system underlies the extensive drift covered area west of Snowdrift Creek that further work is recommended. Probably the most thorough approach to evaluating this area would involve a combination of geophysics and overburden drilling. The presence of biotite-magnetite alteration associated with mineralization in some float boulders suggests that magnetics could be an effective exploration tool. IP effects could be largely masked by drift, but a deep penetrating survey could be effective in locating a possible pyrite halo. A few test soil lines would help to re-evaluate the historical soil geochemical anomaly, which appears to be an order of magnitude too high in some localities. Overburden drilling is recommended as a cost-effective way to evaluate a large drift-covered area and provide target support for future diamond drilling.

Appendix A Statement of Qualifications

STATEMENT OF QUALIFICATIONS

I, John Bradford, P.Geo., certify that:

1. I am presently Vice President Exploration for Paget Resources Corporation with a business address located at:
1160-1040 W. Georgia St.
Vancouver, BC, Canada
V6E 4H1
2. I am a member in good standing of the Association of Professional Engineers and Geoscientists of B.C.
3. I graduated from the University of British Columbia in 1985 with a Bachelor of Science in Geology and from the University of British Columbia in 1988 with a Master of Science in Geology.
4. Since 1988 I have been continuously employed in exploration for base and precious metals in North America, South America and China.
5. I supervised and participated in the 2007 exploration program in 2007 and am therefore personally familiar with the geology of the MO Property and the work conducted in 2007. I have prepared all sections of this report.

Dated this 7 Day of January, 2008
