Summary

The Crack Moly property is comprised of eight contiguous mineral claims all of which are owned (100%) by Pacific Cascade Minerals Inc, in the New Westminster Mining Division. The property is centred at 49°52' North latitude and 121° 49' West longitude, on the east side of Harrison Lake, approximately 55 kilometres west-northwest of Hope, B.C., and 28 kilometres west from Boston Bar, B.C. Several Forest based communities within a 2-hour drive of the property can supply most materials, heavy equipment, and personnel for mining development in addition to basic exploration supplies.

The terrain is steep and rugged, with thick, dense west coast forest cover comprising cedar, hemlock, spruce and fir at the lower elevations. The tree cover fades with elevation to stunted shrubs and grasses to bare rock. The area of work is mainly bare rock in a cirque bowl.

The exploration program comprised nine diamond drill holes totaling 2,437.49 metres from seven setups. The program included camp construction, the first camp, referred to as the 'lower camp', was positioned too far down the mountain slope and was subsequently moved to a higher elevation. The program was conducted from July 1, 2007 to Dec. 28, 2007, with the bulk of the work done in August and September 2007, at a cost of \$996,228.90. Crews were weathered in by snowfall late in the program resulting in considerable standby time for both crews and equipment.

1. Introduction

The Crack Moly property is located approximately 28 kilometres southwest of Boston Bar, BC. The property covers a gossanous area within granodiorite and quartz monzonite, the Late Cretaceous Scuzzy Pluton and represents a porphyry molybdenum target. Within the gossan three mineralized zones have been identified, the Central Moly, Sericite Fracture and Quartz-Moly Breccia.

Molybdenum mineralization has been observed as coarse-grained rosettes along selvages of larger quartz veins, as disseminations in the selvages of quartz veinlets and lining the walls of cavities in some breccias. Historic rock sample assays from programs in the 1980's range from 0.004% Mo in pyrite rocks to 8.27% Mo from a 10 centimetre wide quartz vein. In addition a 50 centimetre sample across a rusty weathering zone assayed >0.1% tungsten, the source of the tungsten was not identified. Soil geochemical sampling outlined a large zone of greater than 20 ppm Mo measuring 1500 x 500 metres with peripheral anomalous W geochemical values. Fracture controlled molybdenite mineralization was observed within the geochemical anomaly.

In 2005 field crews under the direction of United Exploration Management Inc. completed line cutting, rock sampling and 3D-Ip surveys on two grids, the Scuzzy grid (7.45 line-kilometres) and the Alt grid (7.6 line-kilometres). This work lead to the planning and execution of the drill program described in this report.

2. Location Access and Topography

The Crack Moly property is centred on a north-south trending ridge line about five kilometres east of the north-south valley occupied by Big Silver Creek, which drains into Harrison Lake. The claims are centred at 49° 52' North latitude and 121° 49' west longitude on NTS map sheet 92H/13 (Figure 1). The nearest community is Boston Bar, B.C., approximately 28 kilometres to the east on Highway #1, the Trans-Canada Highway. Helicopter service from Hope (65 kilometres to the south) provides convenient access to the property on which landing sites are numerous. Helicopter access can also be gained from Boston Bar, however there is no helicopter base there.

Elevations on the property range from 760 metres (2,500') in the southeast portion of the claims to 1,950 metres (6,500') near the Scuzzy showing. The eastern, western and southern portions of the property are above timberline. The northern and central portions of the property lie on moderate to steep slopes that are forested with a variety of tree species. Local areas within the property are very steep and inaccessible.

Logging activity has created several road systems that pass within a few kilometres of the property, two of the roads actually enter the property boundaries. The Nahatlatch River logging road passes within 10 kilometres of the northern property boundary. To the east, along Kookipi Creek, recent logging activity provides a good road passing within the property at the south. As well, logging roads extend to the headwaters of Big Silver Creek in the valley hosting the Scuzzy showings. Roads here are within 1-2 kilometres of the showings. Both the Nahatlatch Main and Kookipi roads provide access to Boston Bar, approximately 30 kilometres by the road to the east. Boston Bar is serviced by Highway #1, and both the CN and CP railways.

Heavy equipment is available at any of the logging communities within 90 minutes drive of the property, principally Hope or Boston Bar. As well full services – police, hospitals, supplies, schools, restaurants and hotels are available. Vancouver, three hours drive west, has drilling and assay facilities.

Major power transmission lines are 20 kilometres east along Highway #1 and several river power-generating facilities have been built or are proposed within 30 kilometres of the

project area. Small creeks and lakes within the property are suitable to support exploration activities.

Figure 1. Location Map

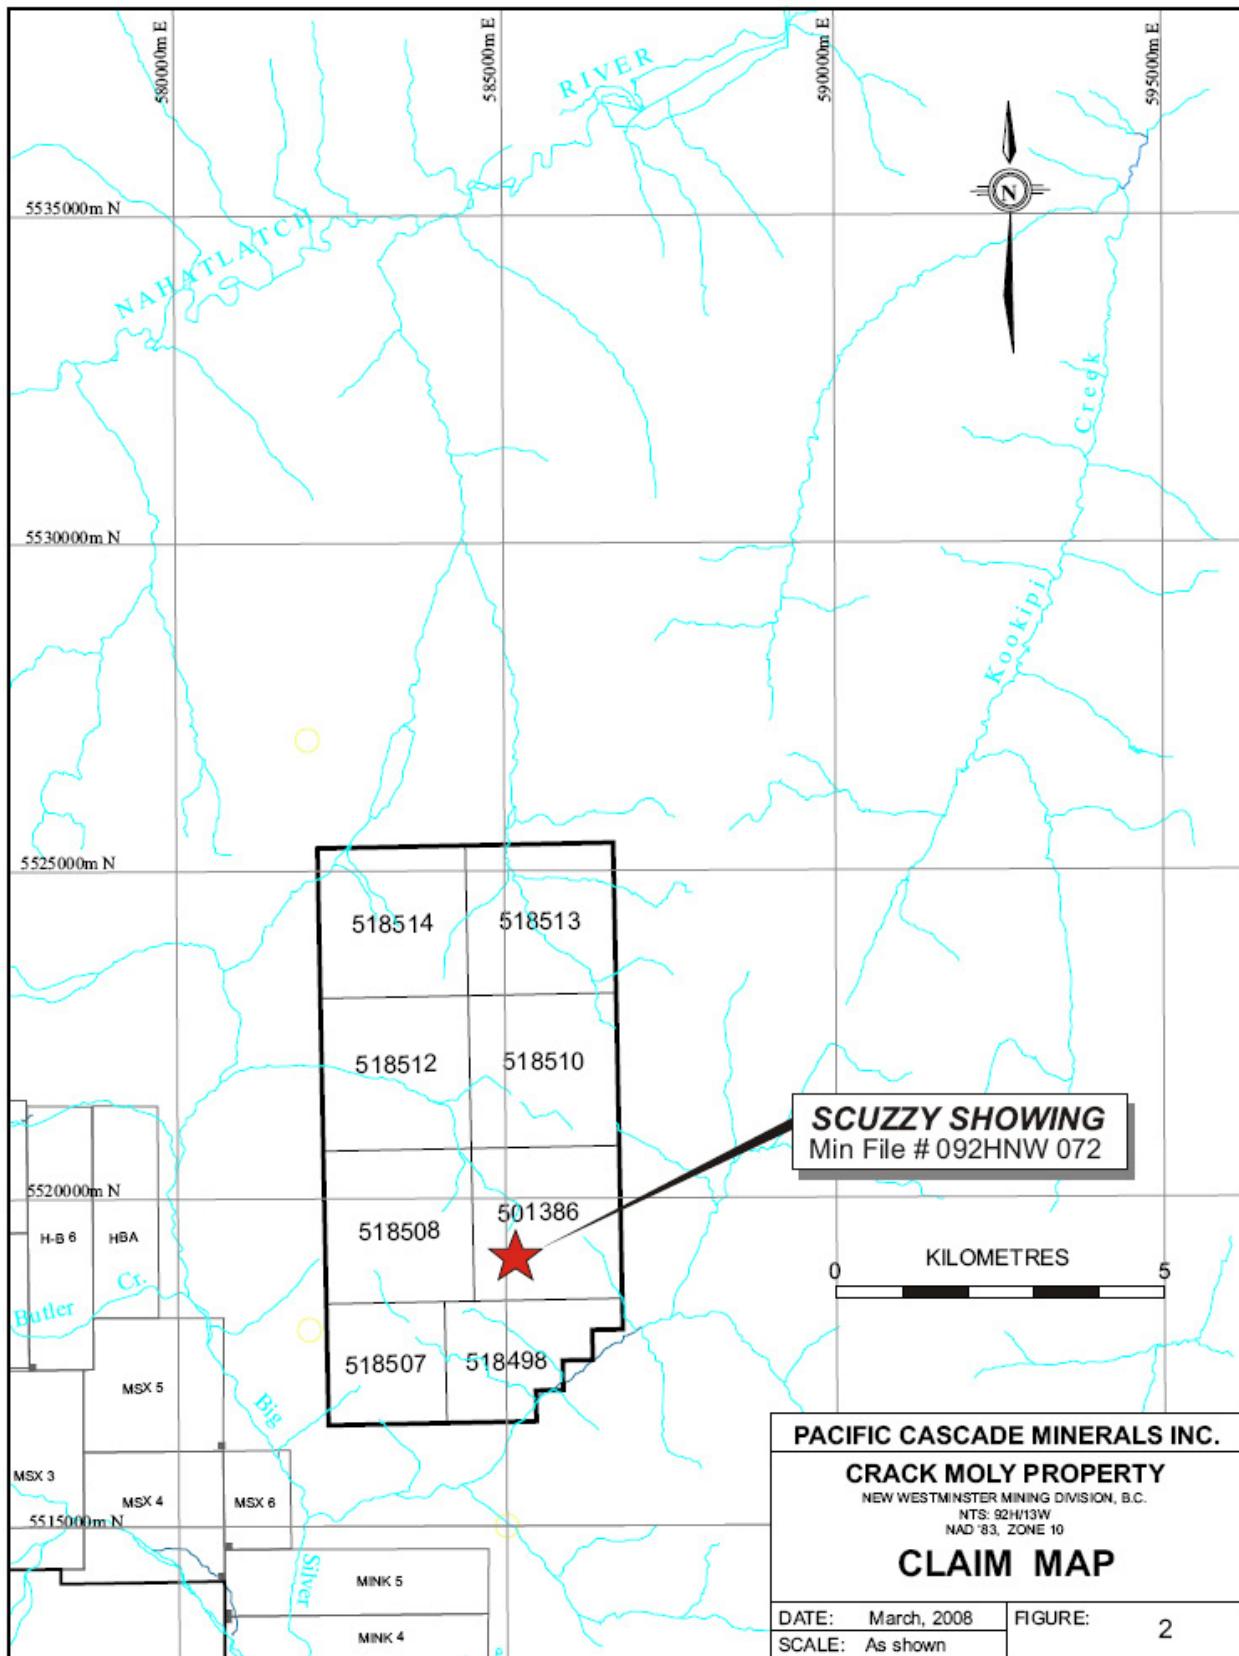

3. Claim Status

The Crack Moly property is comprised of the SCH 1 to SCH 7 claims and the Scuzzy 1 claim, located in the New Westminster Mining Division. The claims are centred at 49° 52' North latitude and 121° 49' West longitude on NTS map sheet 92H/13 and are shown on Figure 2. All claims are registered (100%) to Pacific Cascade Minerals Inc. Claim details are shown in Table 1 and reflect assessment credits claimed from the 2007 drill program, the work for which is described in this report.

501386	Scuzzy 1	Jan 12/05	Jan. 12, 2013	521.079	Pacific Cascade Minerals
8 claims				3338.332	

In British Columbia mineral claim assessment requirements are \$4.00 of work per hectare per year, or cash in lieu, plus \$0.40 filing fees per hectare per year for the first three years, thereafter rising to \$8.00 of work per hectare per year plus \$0.40 filing fees per hectare per year.

4. History

The area was first recognized in August 1980 when molybdenite was discovered in a float sample at the headwaters of Big Silver Creek. Follow-up prospecting discovered molybdenite-bearing quartz veins in an area of strong gossan staining. The area was staked and work commenced in September of the following year, 1981. From 1981 to 1984 the property was worked on by JMT Services Corp.

In the 1981 program JMT Services Corp. undertook a preliminary mapping and rock chip-sampling program on two claims, which covered the gossanous ridge. A total of 157 rock chip samples were collected and analysed for Cu, Mo, Pb, Zn, W and F. Contouring of the rock sample data showed the 5 ppm Mo contour corresponded closely to the outer limit of quartz veining. The >20 ppm Mo contour defined an area measuring about 1,500 metres x 500 metres lying within the breccia complex. Molybdenum values ranged from 1 to >250 ppm, visible molybdenite was observed in some rock samples. Tungsten data outlined anomalous zones outward from the molybdenum zone and were roughly centred on the northwest boundary of the breccia complex. Values ranged from 1 to 750 ppm tungsten. An east-west trending copper anomaly (>20 ppm Cu) flanks the southern margin of the breccia complex with a north-trending lobe on the west side of the breccia complex. Copper values ranged from 1-3,300 ppm with chalcopyrite observed in hand samples. Zinc values outlined an anomalous area (>50 ppm) centred on the north-central border of the breccia complex. Zinc values ranged from 1-3,200 ppm zinc.

A limited program (3 days) was completed in September 1982. This work included mainly a study of fracture patterns on an enlarged air photo of the claims and study of the intensity of mineralization within the molybdenum rock geochemical anomaly. This was achieved by comparing air photo linears with the mineralized fractures seen in the field. In addition seven rock chip samples were collected from molybdenite-bearing veins and assayed for base and precious metals content. Molybdenum values ranged from 0.004% to a high of 8.27%, the latter from a 10 centimetre wide quartz-molybdenite vein. Tungsten values ranged from 5 to >1,000 ppm, the latter a 0.5 metre chip sample across a rusty weathering zone; no significant precious metals assays were returned.

The objective of the 1984 program was to test previously collected rock samples for precious metals and additional elements to aid in spotting drill holes. A total of 150 rock chip sample pulps were analysed for Au, Ag, Co and Ni by US Borax Research Corp., USA.

Only silver produced a contourable pattern, a few samples were anomalous in gold and generally correspond to the highest silver assays. Cobalt and nickel were quite flat. Silver values ranged from 0.2 ppm to 32.4 ppm, only three samples returned gold assays exceeding analytical detection limits, those sampled ranged from 0.05 ppm to 0.18 ppm. The ≥ 1.0 ppm silver contour flanks the south and west margins of the ≥ 20 ppm molybdenum contour. A smaller area of ≥ 1.0 ppm silver lies on the northeast portion of the breccia complex. Of interest were the two highest silver assays, 32.4 and 6.3 ppm occur near the 050° trending sericite fracture zones.

In 2005 field crews under the direction of United Exploration Management Inc. completed physical work (camp building, grid establishment), geochemical (rock sampling) and geophysical (IP) surveys on the Crack Moly project. The work was completed on two grids, the Scuzzy grid and the Alt grid. At the Scuzzy grid surveys included grid establishment, (7.45 line-kilometres), geochemical, (133 rock samples) and a 3D IP survey (7.45 line-kilometres). At the Alt grid surveys included grid establishment (7.6 line-kilometres) and a 3D IP survey (7.6 line-kilometres). No rock samples were collected from the Alt grid.

5. Regional Geology

The property is situated near the axis of the Cascade Range which is underlain by broad areas of granitoid intrusions: the Spuzzum and Scuzzy Plutons, flanked on the west by pendants of Custer gneiss and dark pelitic schists of probable Paleozoic age, and on the east by meta-sediments of possible Triassic age (Figure 3). The Spuzzum Pluton is dated at 74 My. and the Scuzzy Pluton at 70 M.y. Younger (Late Tertiary) intrusions are known in the Hope area – 18 M.y. and a number of early Tertiary volcanic centres exist north of the prospect.

Numerous molybdenite occurrences are present in an arcuate pattern following the central axis of the Cascade Range, and include AM breccia 40 kilometres southeast of Hope, the “Pipe” prospect on Sawmill Creek near Yale, the “Gem” deposit on Clear Creek, 28 kilometres south of the claims, the Cataract deposits 35 kilometres northwest, and several other occurrences extending north-westward to Salal Creek, 150 kilometres northwest.

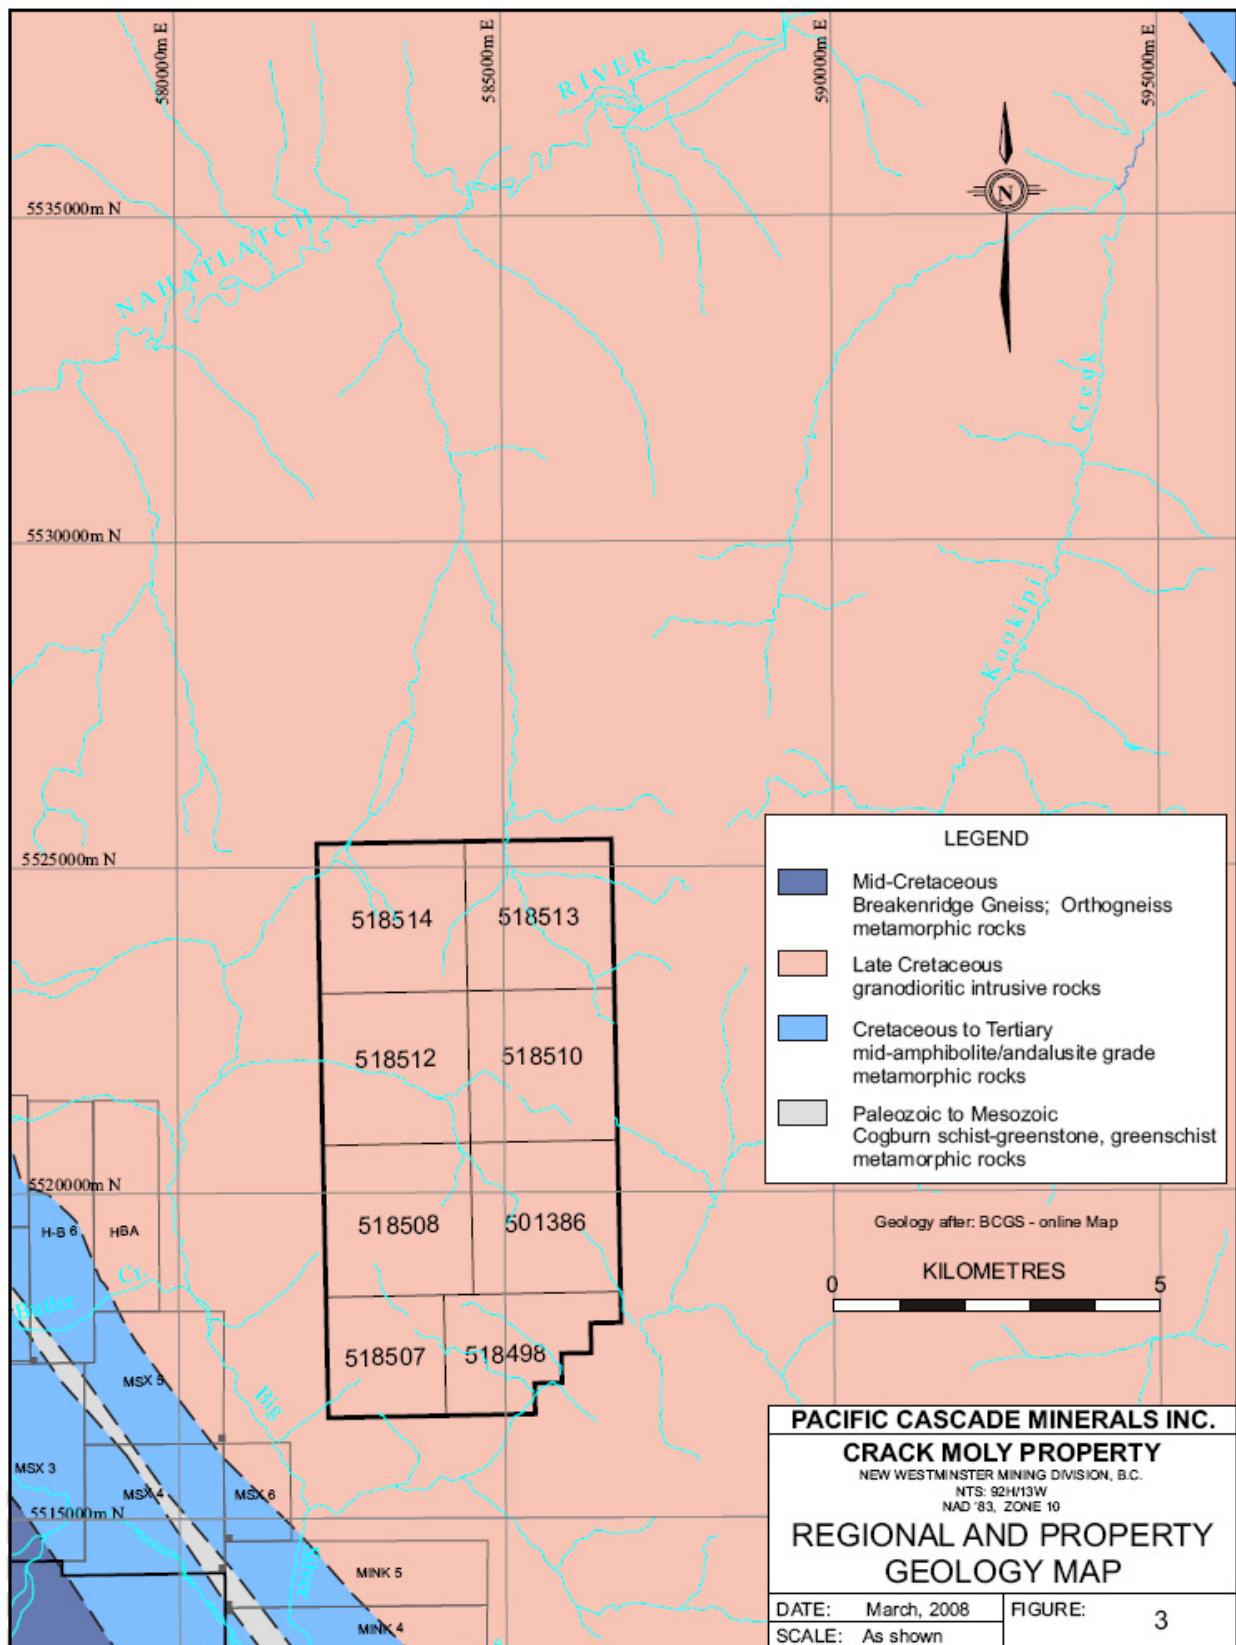

Figure 3. Regional Geology

6. Property Geology

The Scuzzy showing covers a rusty, weakly altered and mineralized phase of the Scuzzy Pluton; the subtle gossan stands out well against the uniform grey barren appearance of the large plutonic mass. Detailed geology of the showing is shown on Figure 4.

The barren country rock is medium grained, quartz-rich granitoid – probably a granite or quartz monzonite, with approximately 5% mafics (biotite exceeds hornblende) and abundant subhedral quartz phenocrysts. Minor but noticeable muscovite is present.

Traversing across the Scuzzy showing the first noticeable change in the rock is rusty coloration. At this point no mineralogical or textural difference exists. Continuing into the zone, the rock becomes slightly pyritized and mafics are destroyed, giving the rock a leucocratic appearance. Zones of silicification occur where clay alteration is noticeable as greenish colouration and quartz veins are common. Chloritic alteration is present where mafics are still present. In the centre of the zone of interest a prominent dark coloured feldspar porphyry dyke occurs. This forms a sharp rusty coloured ridge that forms the western limit of a small cirque. Another elongate section of the dyke is seen in the south-central area of the cirque, and a prominent lineation trending northeastward through the cirque probably has offset the dyke by several hundred metres. The dyke contains fresh biotite, pyrite and has quartz veins (barren) and inclusions of quartz monzonite. The rock may be a variety of lamprophyre and is thought to be pre-mineral.

The fault zone mentioned previously is marked by a topographic depression trending north-eastward and cuts off the western limb of the lamprophyre dyke. The fault zone contains a quartz vein 30 centimetres wide. South of the fault, alteration is stronger and the rock is slightly coarser-grained.

The best mineralization is present within the cirque area and may be related to the intersection of the dyke and the fault. The south limit of alteration and mineralization is marked by the northeast trending ridge that forms the south wall of the cirque. The actual zone of interest is roughly 600 metres in diameter.

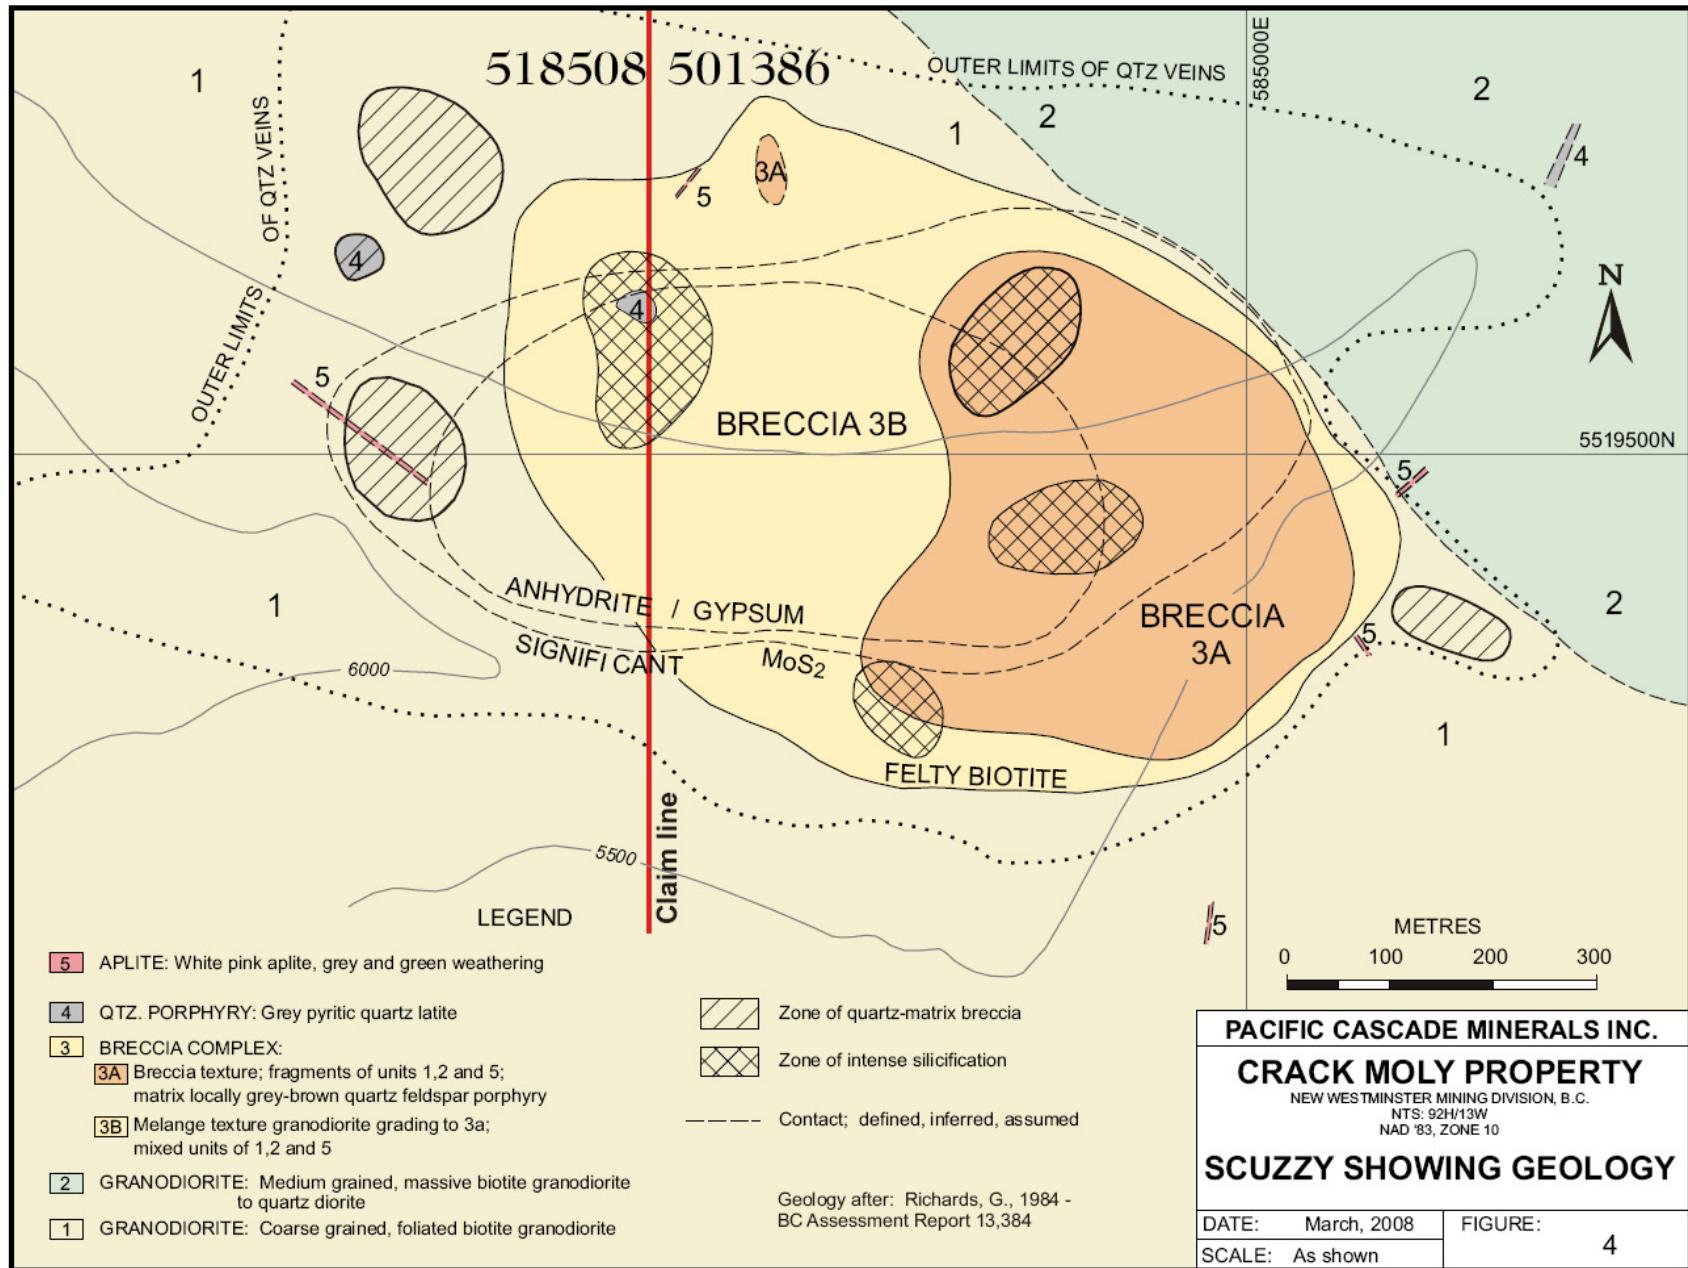

Figure 4. Property Geology – Scuzzy Showing

The molybdenite and very sparse chalcopyrite mineralization is confined to quartz veins and siliceous zones and is mostly fine-grained. Nowhere is the mineralization particularly abundant. Nevertheless, molybdenite is scattered over the altered and rusty zone and this covers a significant area that is worthy of further exploration.

Past mapping programs have outlined three zones within the area of interest. These zones are named the Central Moly Zone, the Sericite Fracture zone, and the Quartz-Moly Breccia zone.

At the Central Moly Zone fracture controlled molybdenite is the predominant sulphide although minor pyrite, chalcopyrite and pyrrhotite are associated. The molybdenite occurs in spectacular coarse-grained rosettes along the selvages of the large quartz veins as much as 10 centimetres in width. Finer grained platy and disseminated molybdenite occur on the selvages of narrow quartz stringers, ribbon quartz veins, and along the walls of the interstitial cavities in some breccias, occasionally forming thick blebs of solid molybdenite.

Molybdenite also occurs with other sulphides as fine coatings along tight fractures. Conspicuous molybdenite is restricted to approximately the innermost 200 metre central core of the molybdenite zone. Outwards, molybdenite becomes harder to detect visually.

In the Sericite Fracture Zone about ten very prominent fractures occur along the cliff face. They trend 050°, are spaced about 10 metres apart, and contain abundant coarse sericite in zones approximately one-half metre wide with quartz veinlets containing pyrite, molybdenite and chalcopyrite. In the field they extended at least 200 metres southwest where they disappeared over the ridgeline. To the northeast they continue some distance.

The Quartz-Moly Breccia Zone is a brecciated intrusive unit comprised of a quartz matrix breccia containing occasional blebs of coarse molybdenite up to 10 centimetres wide but generally two to four centimetres across. The molybdenite occasionally has minor associated pyrite and heavy Mn staining. Otherwise the quartz is white and free of other minerals. The breccia fragments are angular and measure one-half to five metres in maximum dimension often displaying only minor rotation.

7. 2007 Exploration Program

7.1 DRILLING

General Parameters

A drill program was initiated on the Crack Moly program to test both surface mineralization and IP chargeability and resistivity targets at depth. Drill pad construction was completed by ISE Blasting Ltd of North Vancouver, B.C., who constructed pads from a combination of 6"x6" and 8"x8" timbers for cribbing with 2"x10" decking. Some blasting was required for pad construction and anchor bolts were placed at key points around the setup to anchor to drill to. Drill site reclamation was also done by ISE Blasting with two of seven pads reclaimed in 2007, the balance to be finished in 2008. The drill contract was awarded to Westcore Drilling of Hope, B.C. The program was completed with an Atlas Copco 250 helicopter portable diamond drill, core size was BQTK (equivalent to B-thinwall). Nine holes totaling 2,437.49 metres were completed from seven setups (Figure 5). The actual drilling portion of the program commenced on August 9, 2007 with the casing of hole CM07-01 and finished on September 23, 2007. Drill hole collar information is shown in Table 2, Crack Moly Project Drill Hole Information. UTM coordinates are NAD 83, Zone 10. Collar locations were derived by handheld GPS until an accuracy of +/- 3 metres was attained. The core is stored on site, with holes CM07-01 to 03 at the lower camp and holes CM07-04 to 09 at the upper camp.

Sample intervals were selected by the onsite geologists and generally ranged from 1.0 to 3.0 metres depending upon lithology and mineralization. All core submitted for analysis was sawn in half with a diamond saw, placed into a 12"x20" plastic sample bag with an assay tag number from the lab and the same number written on the outside of the bag with black felt marker, and the bag sealed with a "zap" strap. An analytical molybdenum standard purchased from CDN Resource Laboratories Ltd., Delta, B.C., was randomly inserted into the sample sequence with several standards per hole. A blank was used on occasion but it was not a true analytical blank and the practice was discontinued when several samples selected as a blank returned appreciable molybdenum. Samples were shipped from camp on a hole-by-hole basis to Valley Helicopters operations base in Hope, B.C., and from there transported by Greyhound bus to Eco Tech Laboratory Ltd. in Kamloops, B.C. All samples were subject to a 29- element ICP analysis (method BICP-12), for Mo exceeding 500 ppm a more precise assay method was employed (BOGA-27) and the results expressed in percent. The molybdenum assays reported in this report are for Mo, not MoS₂.

7.2 GENERAL GEOLOGY AND MINERALIZATION

The drill holes all encountered similar lithologies over varying lengths, the age relationships of the various units described below is uncertain. The lithologies are classified into three general categories:

1 Granodiorite;

- 1.1: Unaltered-coarse grained, massive granodiorite;
- 1.2: Weakly foliated-coarse grained granodiorite with weak foliation defined by biotite flakes;
- 1.3: Altered granodiorite through fine-grained infiltration of granitic rock. May contain molybdenite rosettes and crystals and plates and chalcopyrite crystals;

2 Breccia;

- 2.1: Monolithic breccia consisting of granodiorite angular inclusions in a finer-grained groundmass. Molybdenite is associated with quartz veinlets cutting or filling spaces;
- 2.2: Heterolithic breccia (melange) consists of angular fragments of granodiorite, quartz-porphyry, and absorbed granitic “clasts.” Molybdenite in fractures, quartz veins and in quartz-porphyry fragments;

3. Quartz-Porphyry;

- 3.1: Unaltered; very much aplitic in texture, white to light grey to very pale green colour. Aphanitic with porphyritic feldspar crystals, contains pyrite and chalcopyrite. Very quartz-rich and competent;
- 3.2: Red stain altered; this is a penetrating alteration that often has a alteration envelope surrounding it with a dark grey to black colouration. The alteration tends to follow fractures and then penetrates beyond the walls of the fractures into the rock. Molybdenite does not appear to be associated with the alteration;
- 3.3: Fractured quartz-porphyry, may be altered or not. The fractures are very fine to 20 centimetres in width, are quartz filled and contain very fine-grained molybdenite and chal-

copyrite, though rarely together. Coarser molybdenite rosettes can be seen but usually in larger quartz filled cracks;

The molybdenite mineralization is classified into three styles as follows:

- 1: - As coarse rosettes within vuggy quartz veins that have well developed quartz crystals. These are found within the breccias and altered granites.
- 2: - As well developed grains within the quartz porphyry and proximal to quartz veins in any material and also as interstitial material in the breccia units.
- 3: - Fine-grained molybdenite within veinlets that cut through all lithologies. These veins are from sub-millimeter to up to centimetre width and also may contain chalcopyrite within a quartz matrix. These cut the core at various angles and are the most common form of molybdenite mineralization.

Alteration in the intrusive body drill tested is relatively minimal and is comprised chiefly of biotite, sericite and silica. Biotite is the most abundant and is common in the granodiorite and biotite-hornblende granodiorite. Silicification is commonly present in the quartz porphyry and this same unit exhibits minor sericite as well.

7.3 DRILL HOLE DESCRIPTIONS

CM07-01 and 02 (Figures 6 and 7)

These holes were collared at the same setup, hole CM07-01 testing a chargeability high and CM07-02 testing a resistivity high. Hole CM07-01 collared in granodiorite, then an intermixed succession of heterolithic breccia, quartz porphyry, granodiorite and hornblende-biotite granodiorite, ending in mainly granodiorite and hornblende-biotite granodiorite. Hole CM07-02 also collared in granodiorite, then a thicker succession of intermixed mono- and heterolithic breccias, granodiorite, and minor quartz porphyry and ended in granodiorite. Molybdenite was scattered throughout both holes but was strongest in hole CM07-01, particularly in the lower portion of the hole where the interval from 187.41 to 343.51 metres averaged 0.035% molybdenum over 156.10 metres. In hole CM07-02 molybdenite was more concentrated in the upper portion of the hole with the interval 25.70 to 32.84 metres aver-

aging 0.037% molybdenum over 7.14 metres with scattered anomalous results over narrow intervals down to 130.15 metres.

CM07-03 (Figure 8)

This hole was collared to test the eastern flank of a chargeability zone at depth with associated moderate resistivity. The hole intersected a thick succession of granodiorite and hornblende-biotite granodiorite with intercalated sections of quartz porphyry; no breccia units were logged. The hole had molybdenite mineralization throughout the hole and was one of the best holes of the program, assaying 0.042% molybdenum over 233.25 metres from 1.25 to 234.5 metres. Within this section the interval from 140.22 to 155.63 metres assayed 0.216% molybdenum over 15.41 metres.

Figure 7. Drill Section CM07-02

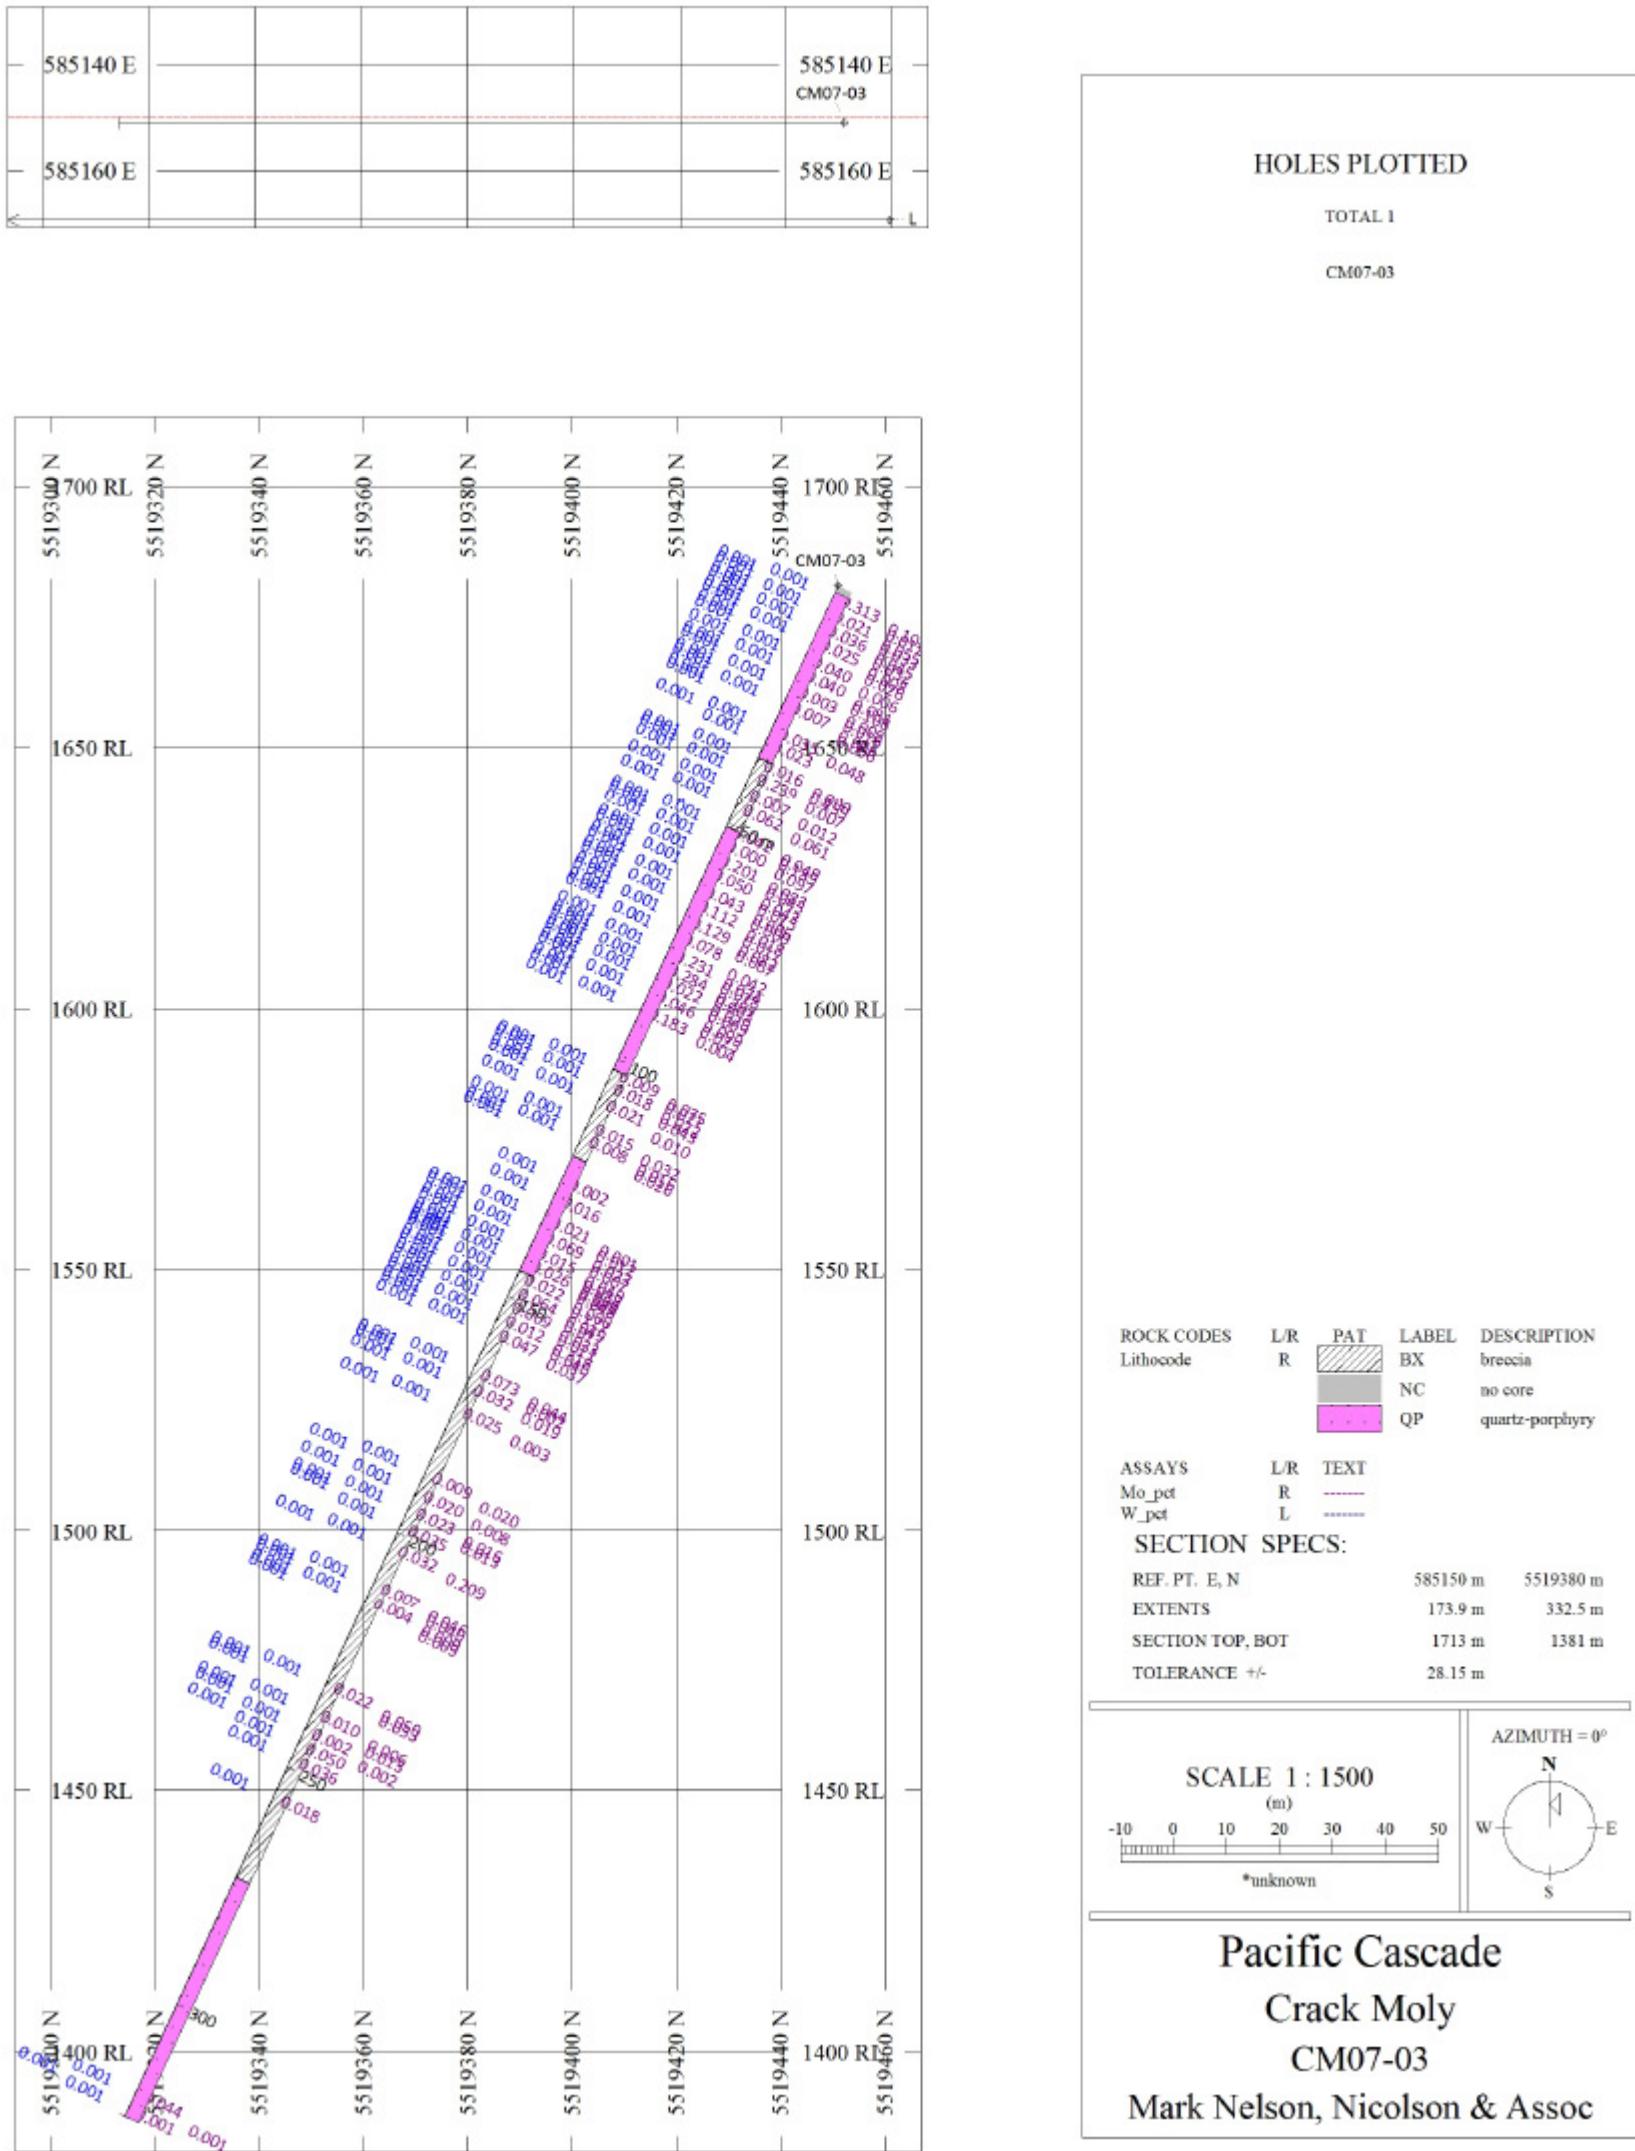

Figure 8. Drill Section CM07-03

CM07-04 (Figure 9)

This was a short hole collared to test a zone of low chargeability. It encountered the same general lithologies as the others but no significant results were returned.

CM07-05 and 06 (Figure 10)

Both holes were collared from the same setup. Hole CM07-05 was testing a chargeability anomaly at depth; hole CM07-06 was a vertical hole testing lower chargeability and resistivity. Hole CM07-05 intersected a thick section of granodiorite to 131.45 metres, then intermixed quartz porphyry, breccia, and granodiorite to the bottom of the hole at 320.95 metres and returned the best assays of the program. The hole returned 0.053% molybdenite over 195.05 metres from 84.57 to 279.62 including 0.196% molybdenite over 44.60 metres. Hole CM07-06 intersected much more quartz porphyry and lesser granodiorite, monzonite and breccia units. The results were not as good as in CM07-05 with the interval from 1.52 to 110.00 metres averaging 0.029% molybdenum over 108.48 metres including 41.00 metres of 0.049% molybdenum.

CM07-07 (Figure 11)

Hole CM07-07 was collared approximately halfway between holes CM07-03 and CM07-05 to test the same chargeability feature at depth and intersected narrower intervals of monzonite and granodiorite near the top of the hole and then a broad zone of intermixed mono and heterolithic breccia with local sections of quartz porphyry. Traces of molybdenite were encountered throughout the hole but of insufficient density to form any broadly anomalous zones except at the top of the hole, which assayed 0.025% molybdenite over 44.18 metres from 1.82 to 46.00 metres.

CM07-08 (Figure 12)

The hole was collared in granodiorite and encountered no other lithologies, ending at 331.93 metres. The hole was collared in a high chargeability zone and attempted to test a high chargeability zone at depth, it did not fully reach the deep target as the depth capability of the drill was reached. Molybdenite was consistently present throughout the hole but in low concentrations, usually one or two narrow quartz-molybdenite veinlets per 1-3 metres. This low density veining was reflected in the assay results. Silver assays were elevated relative to

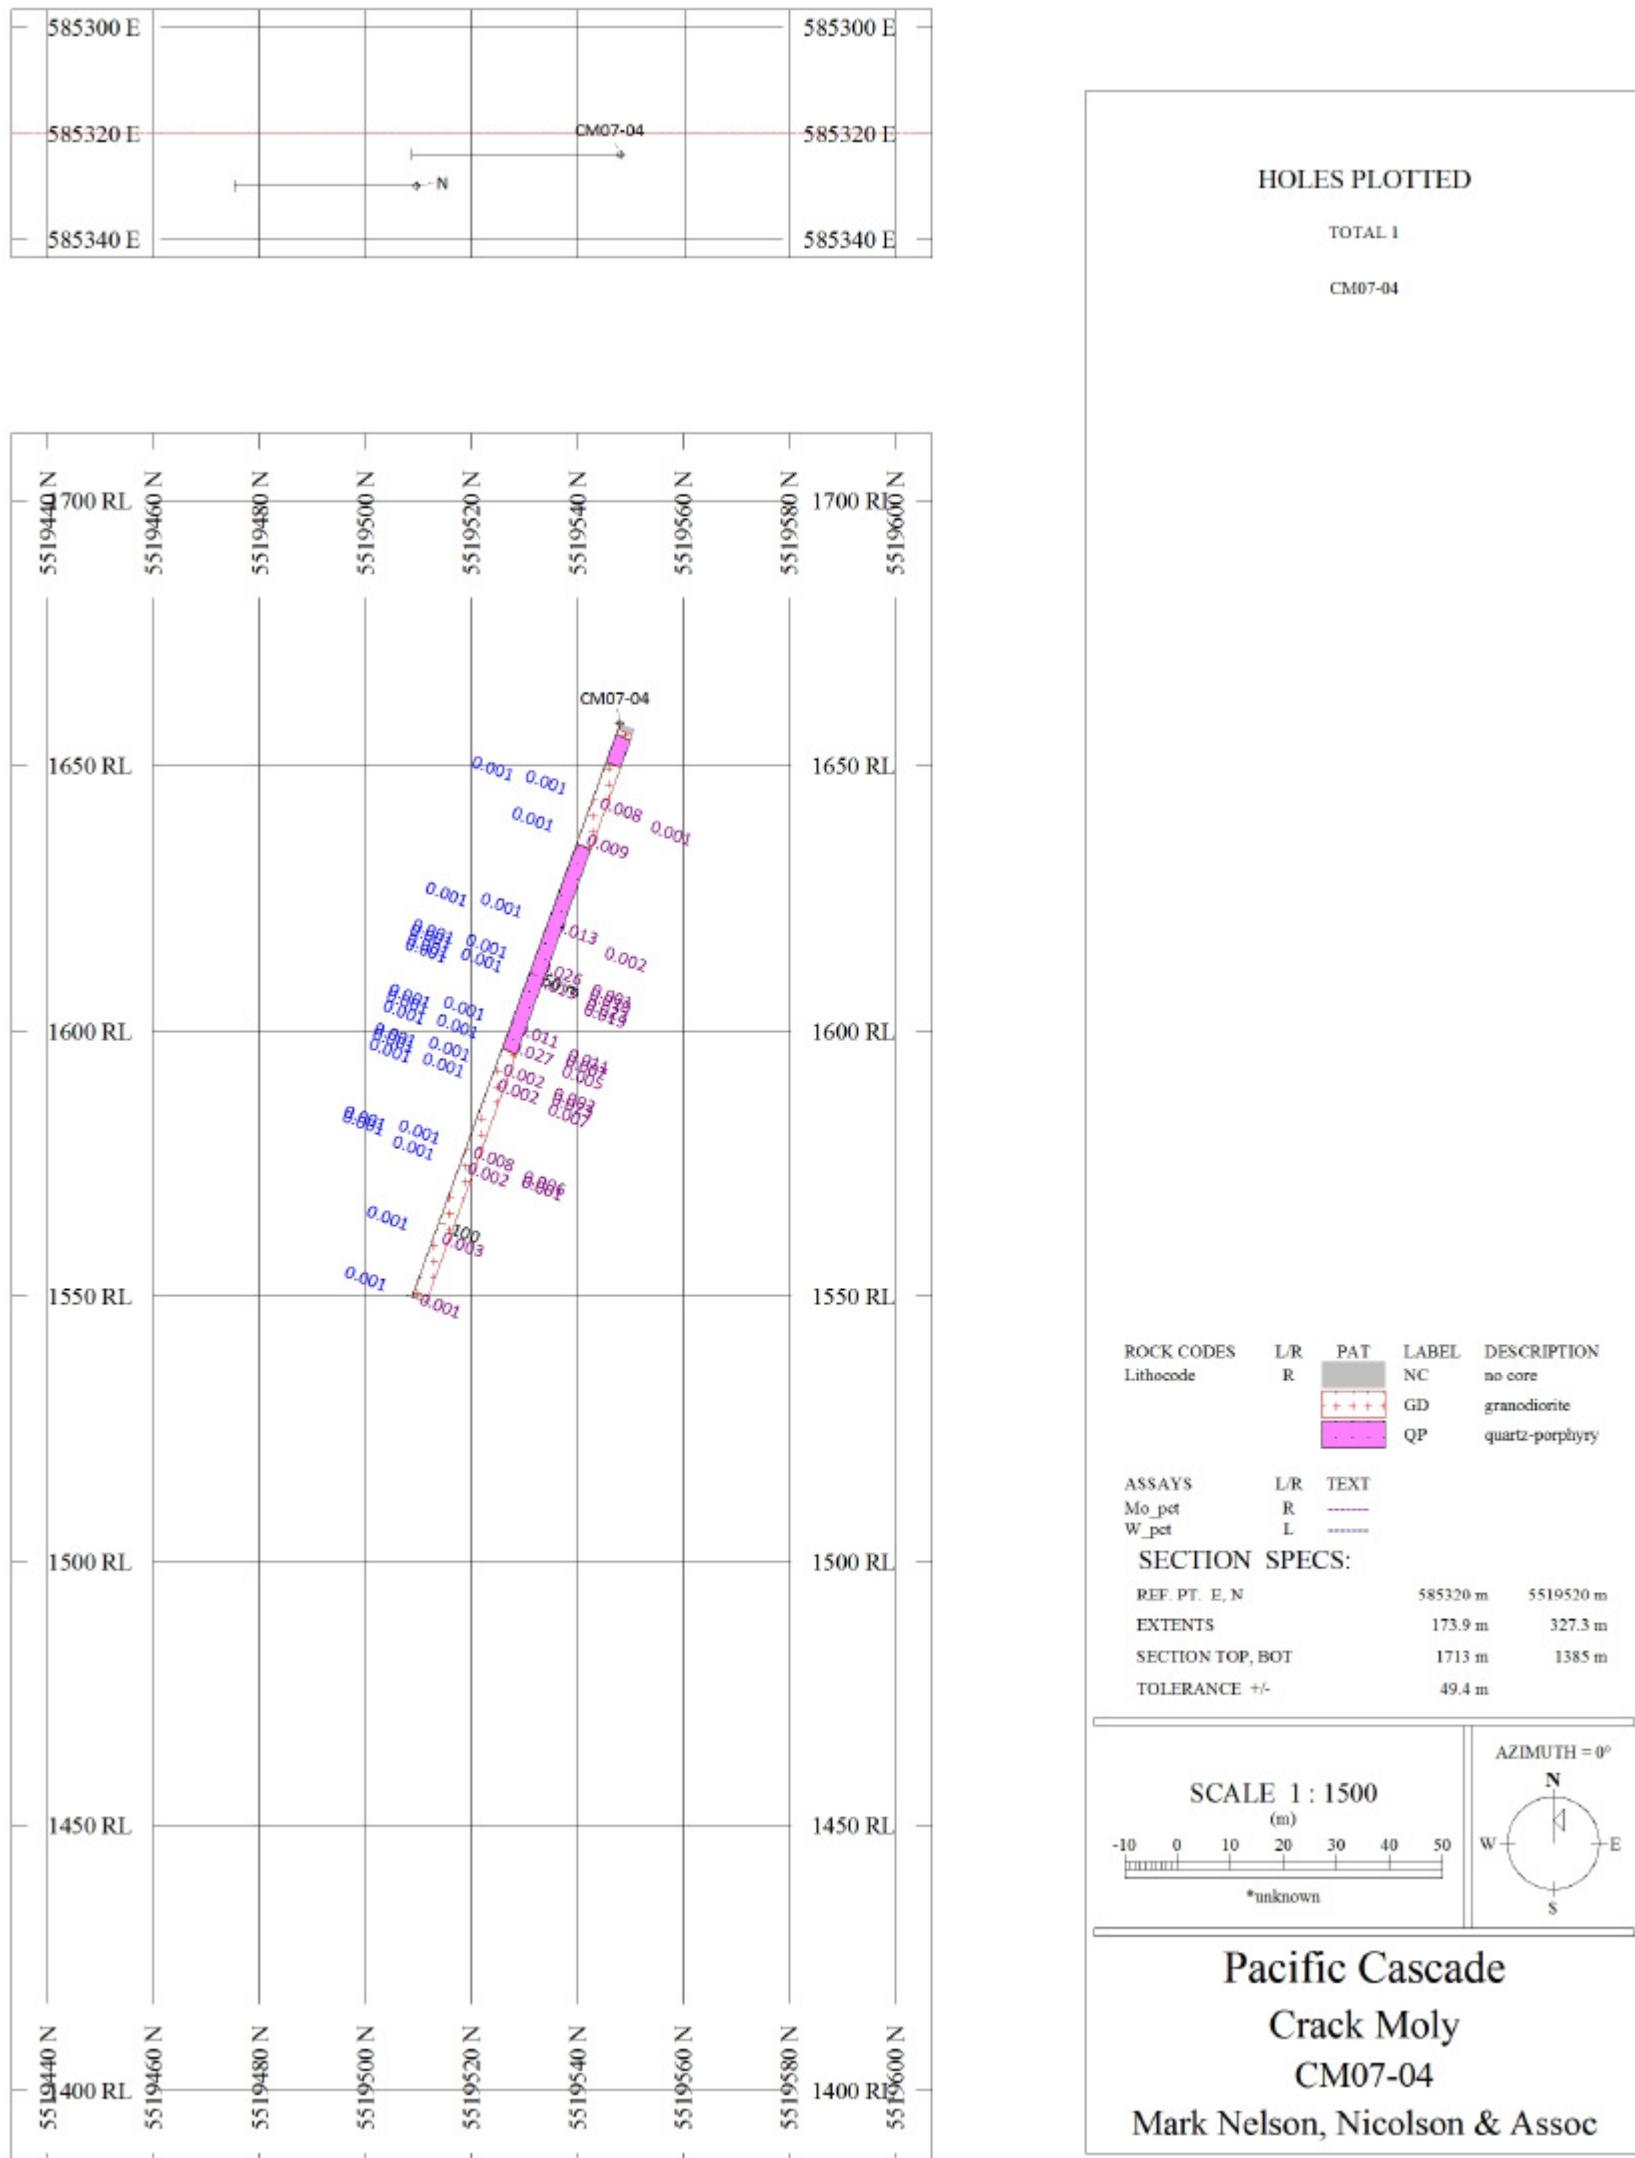

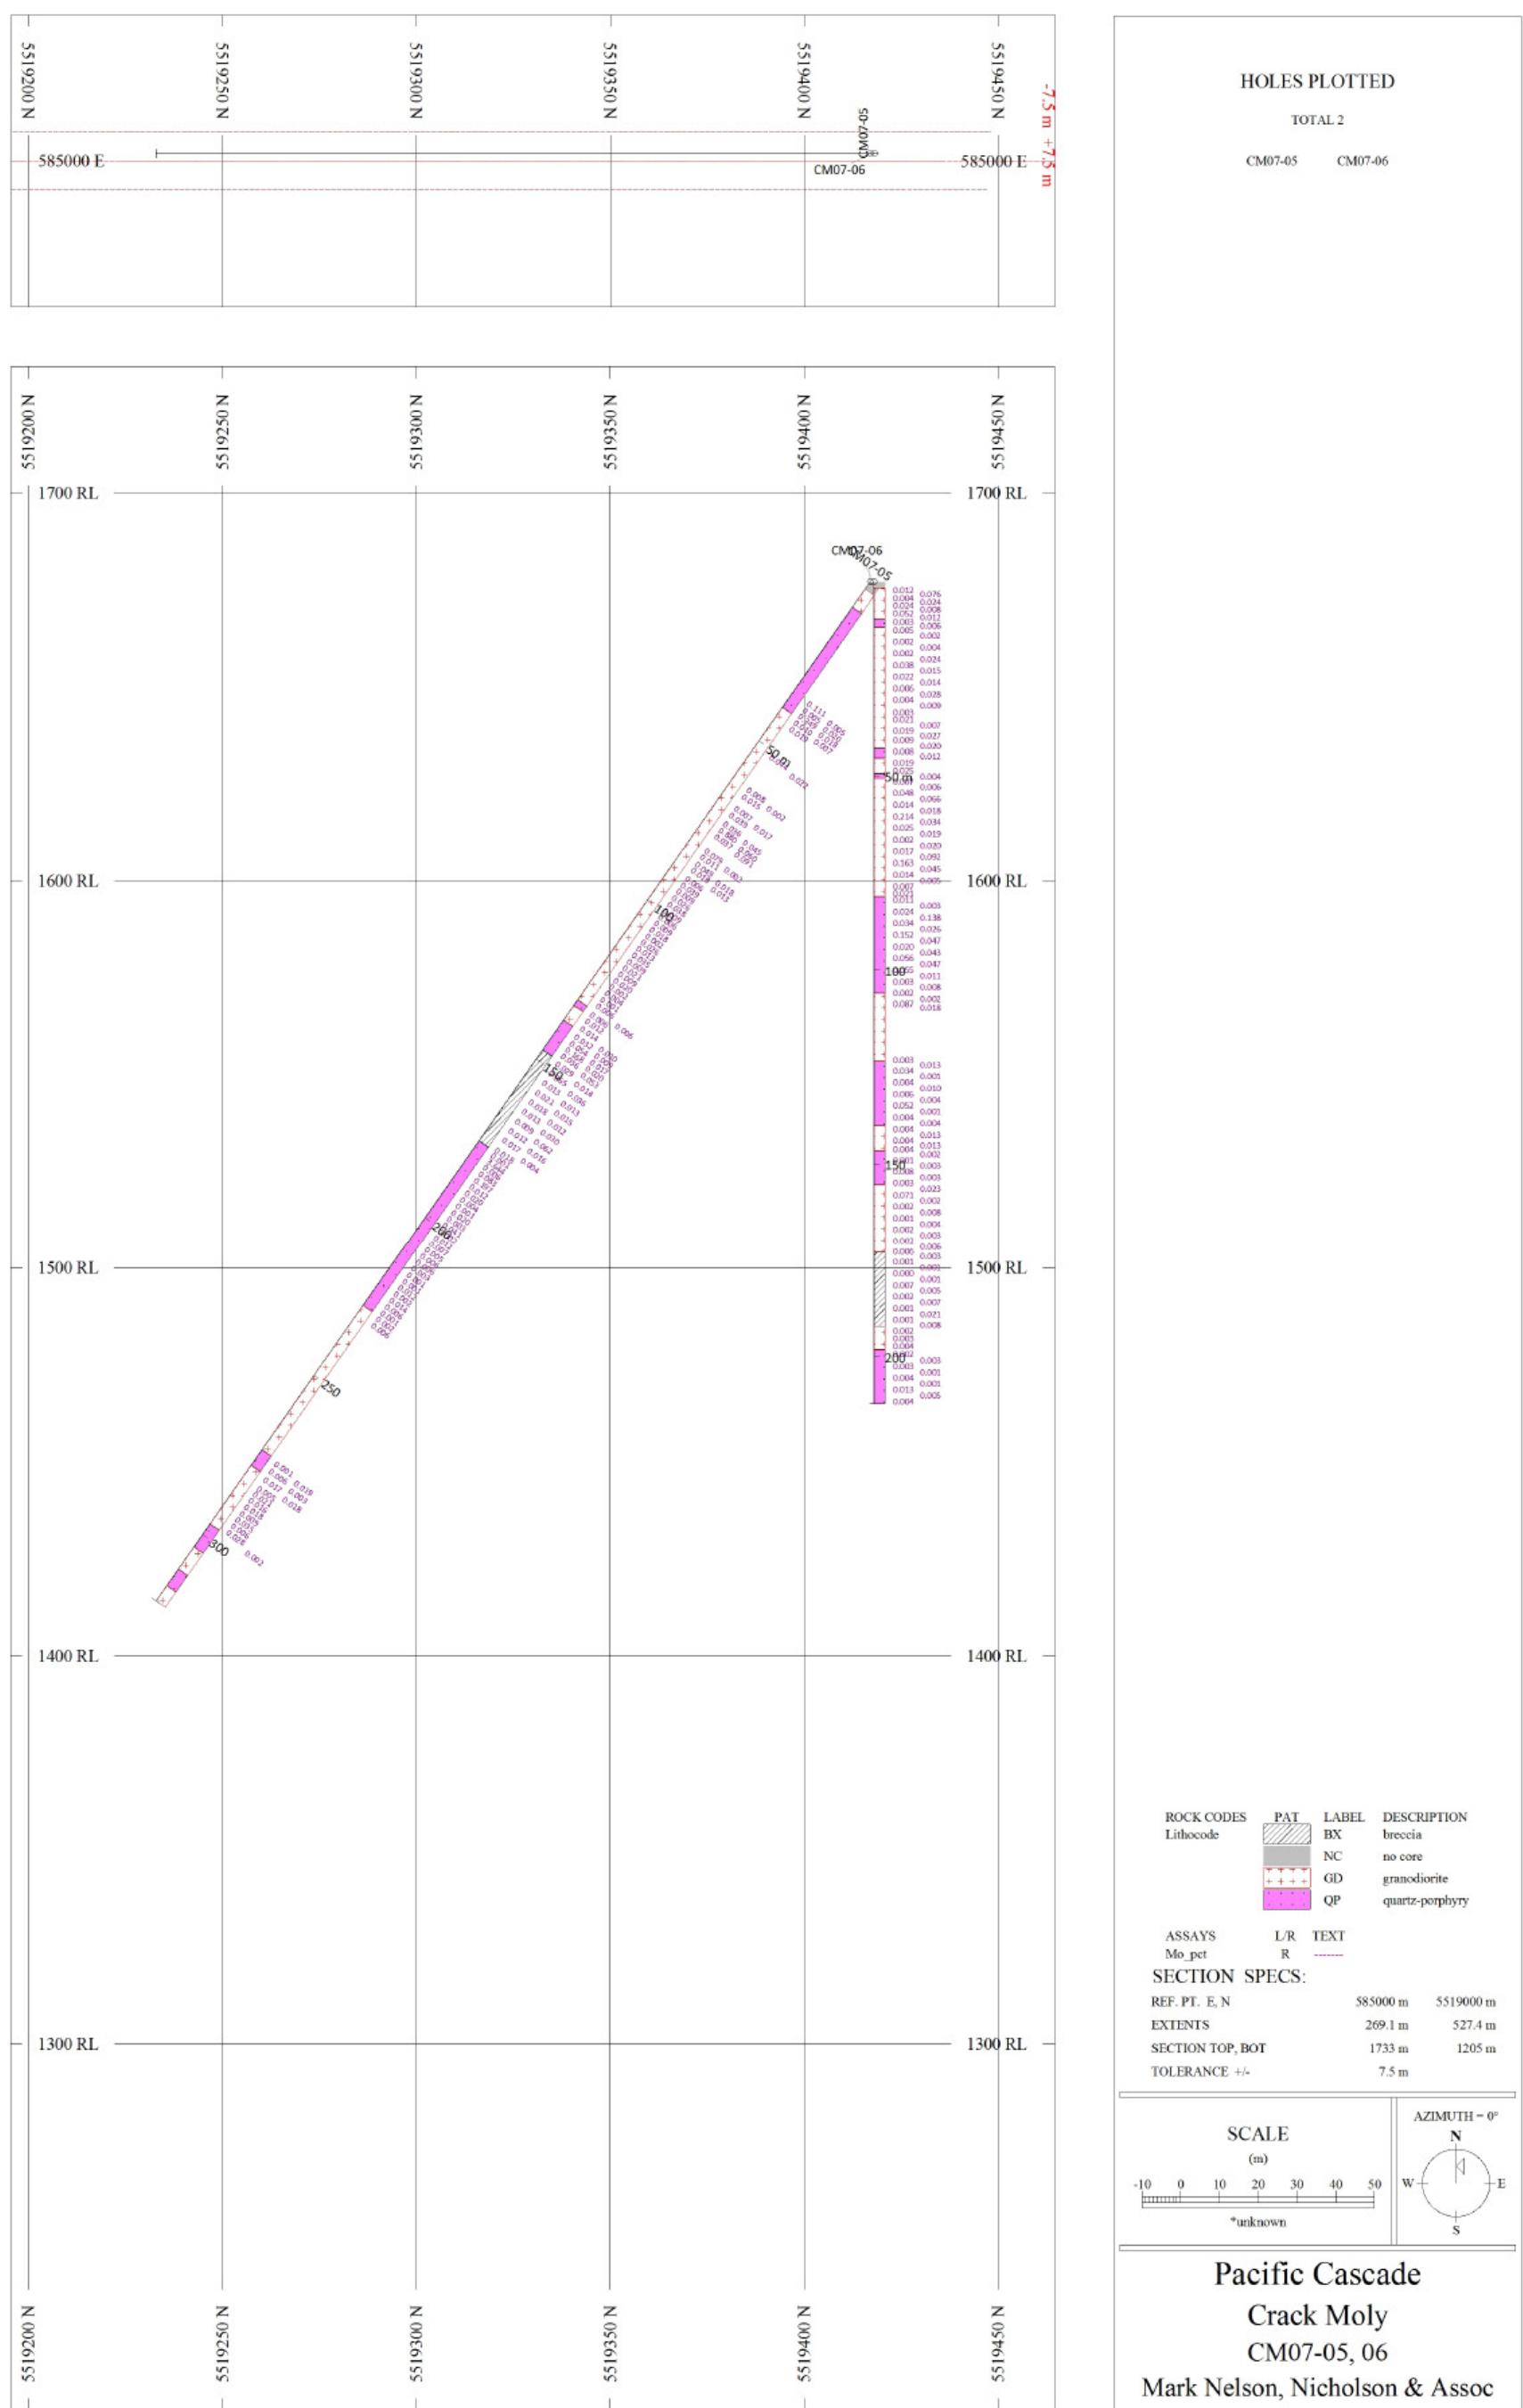

Figure 9. Drill Section CM07-04

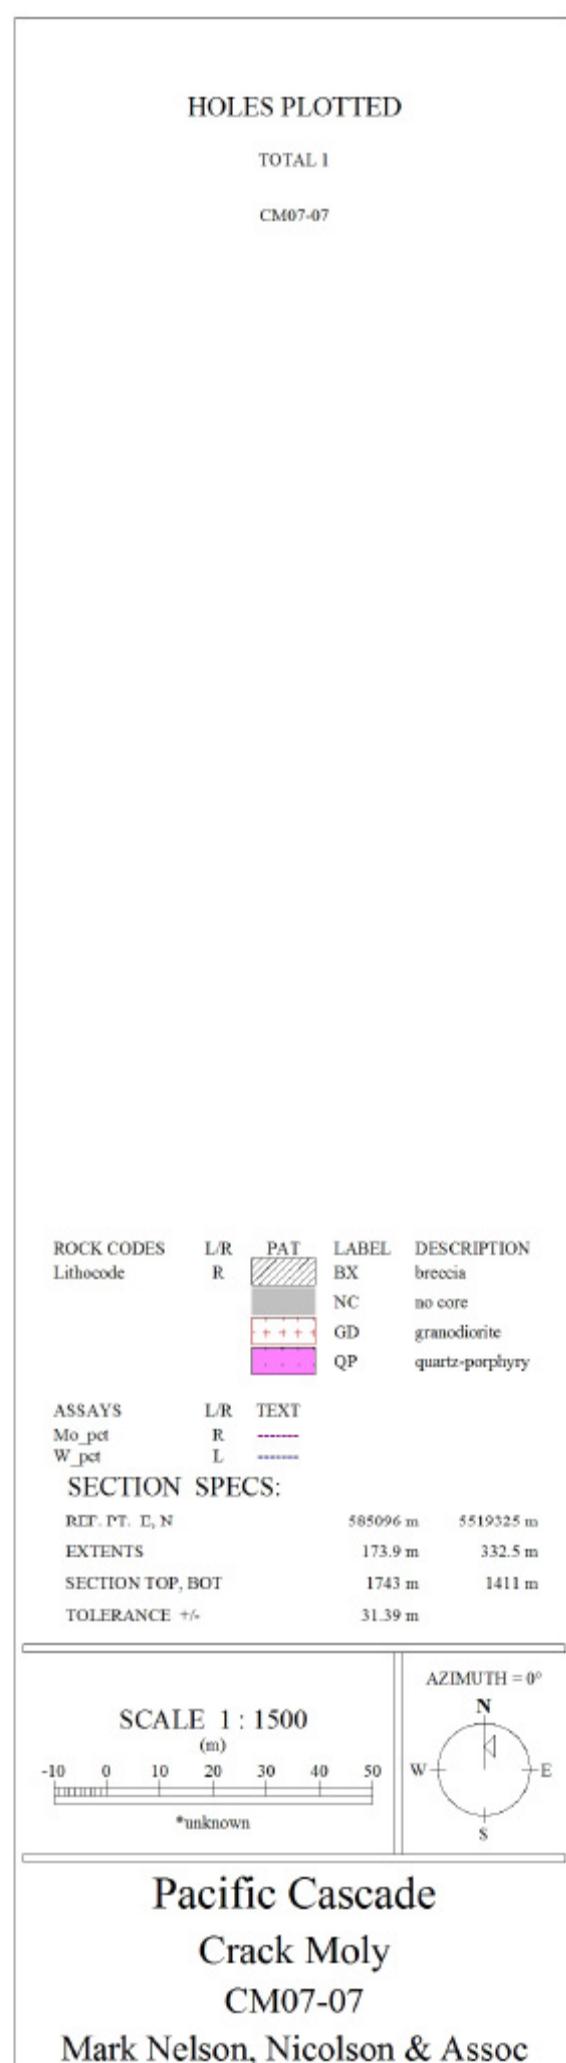

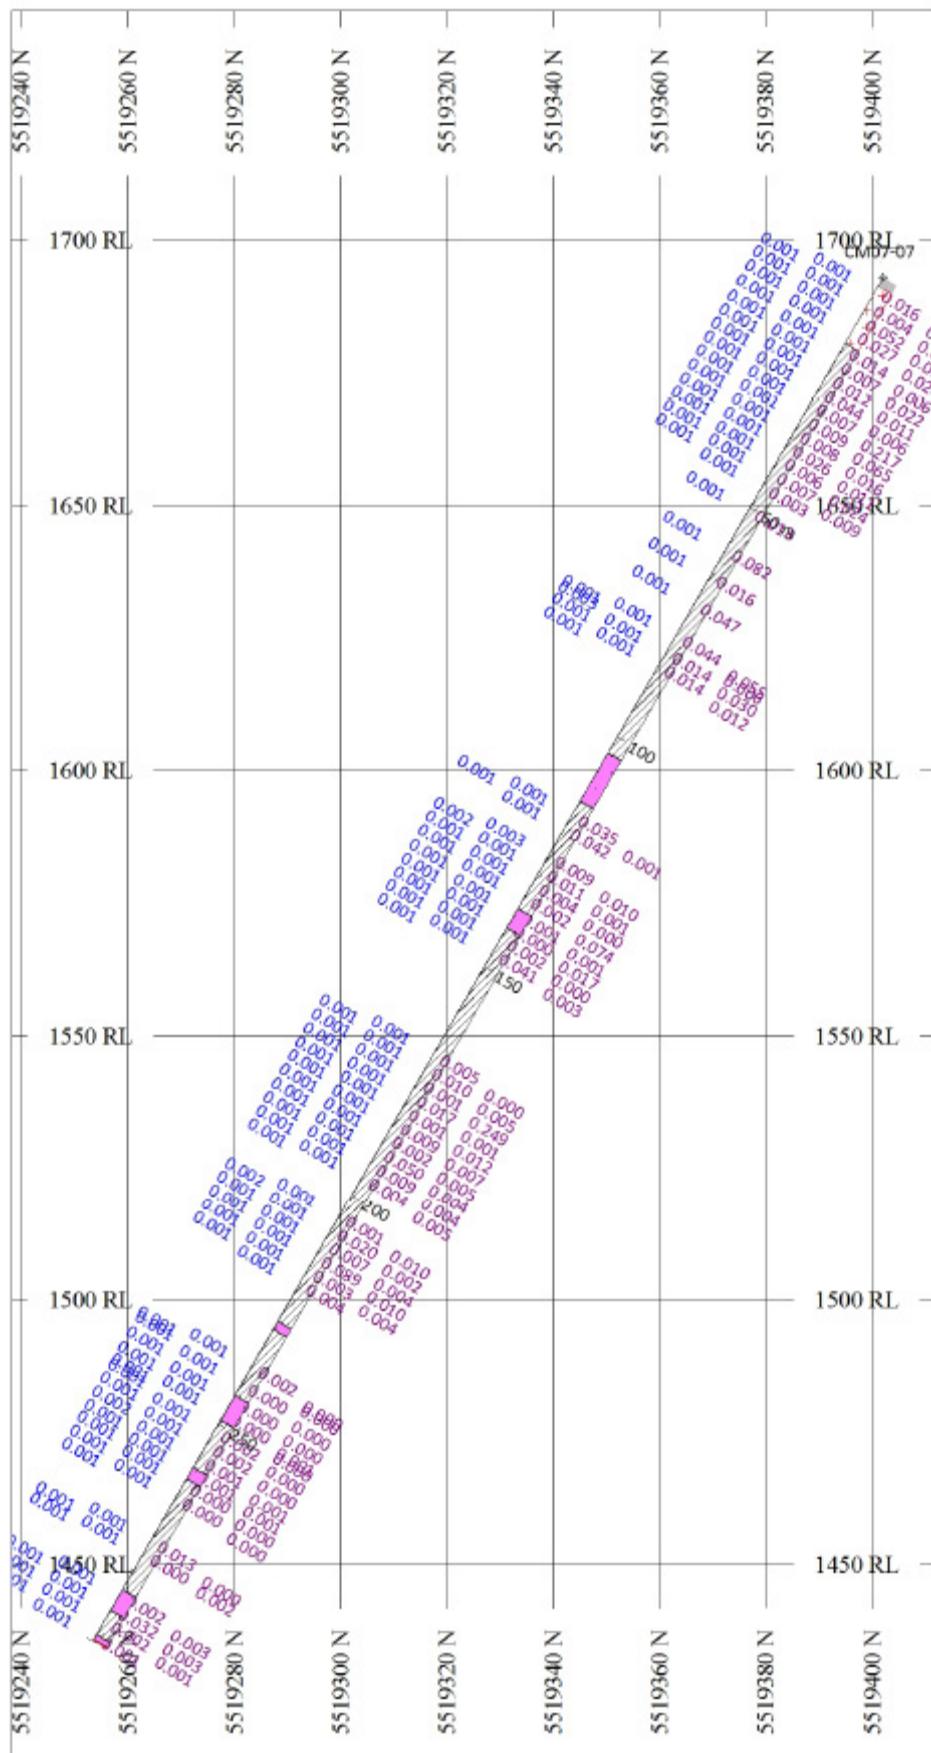

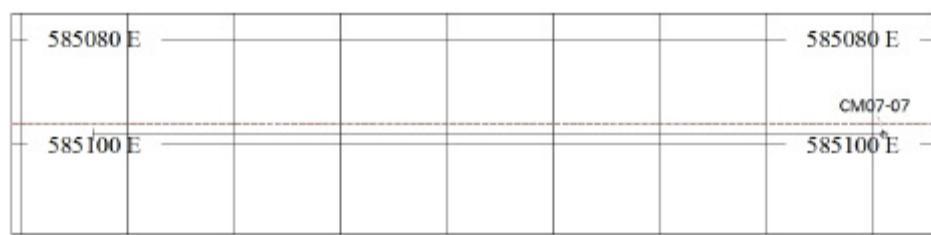

Figure 11. Drill Section CM07-07

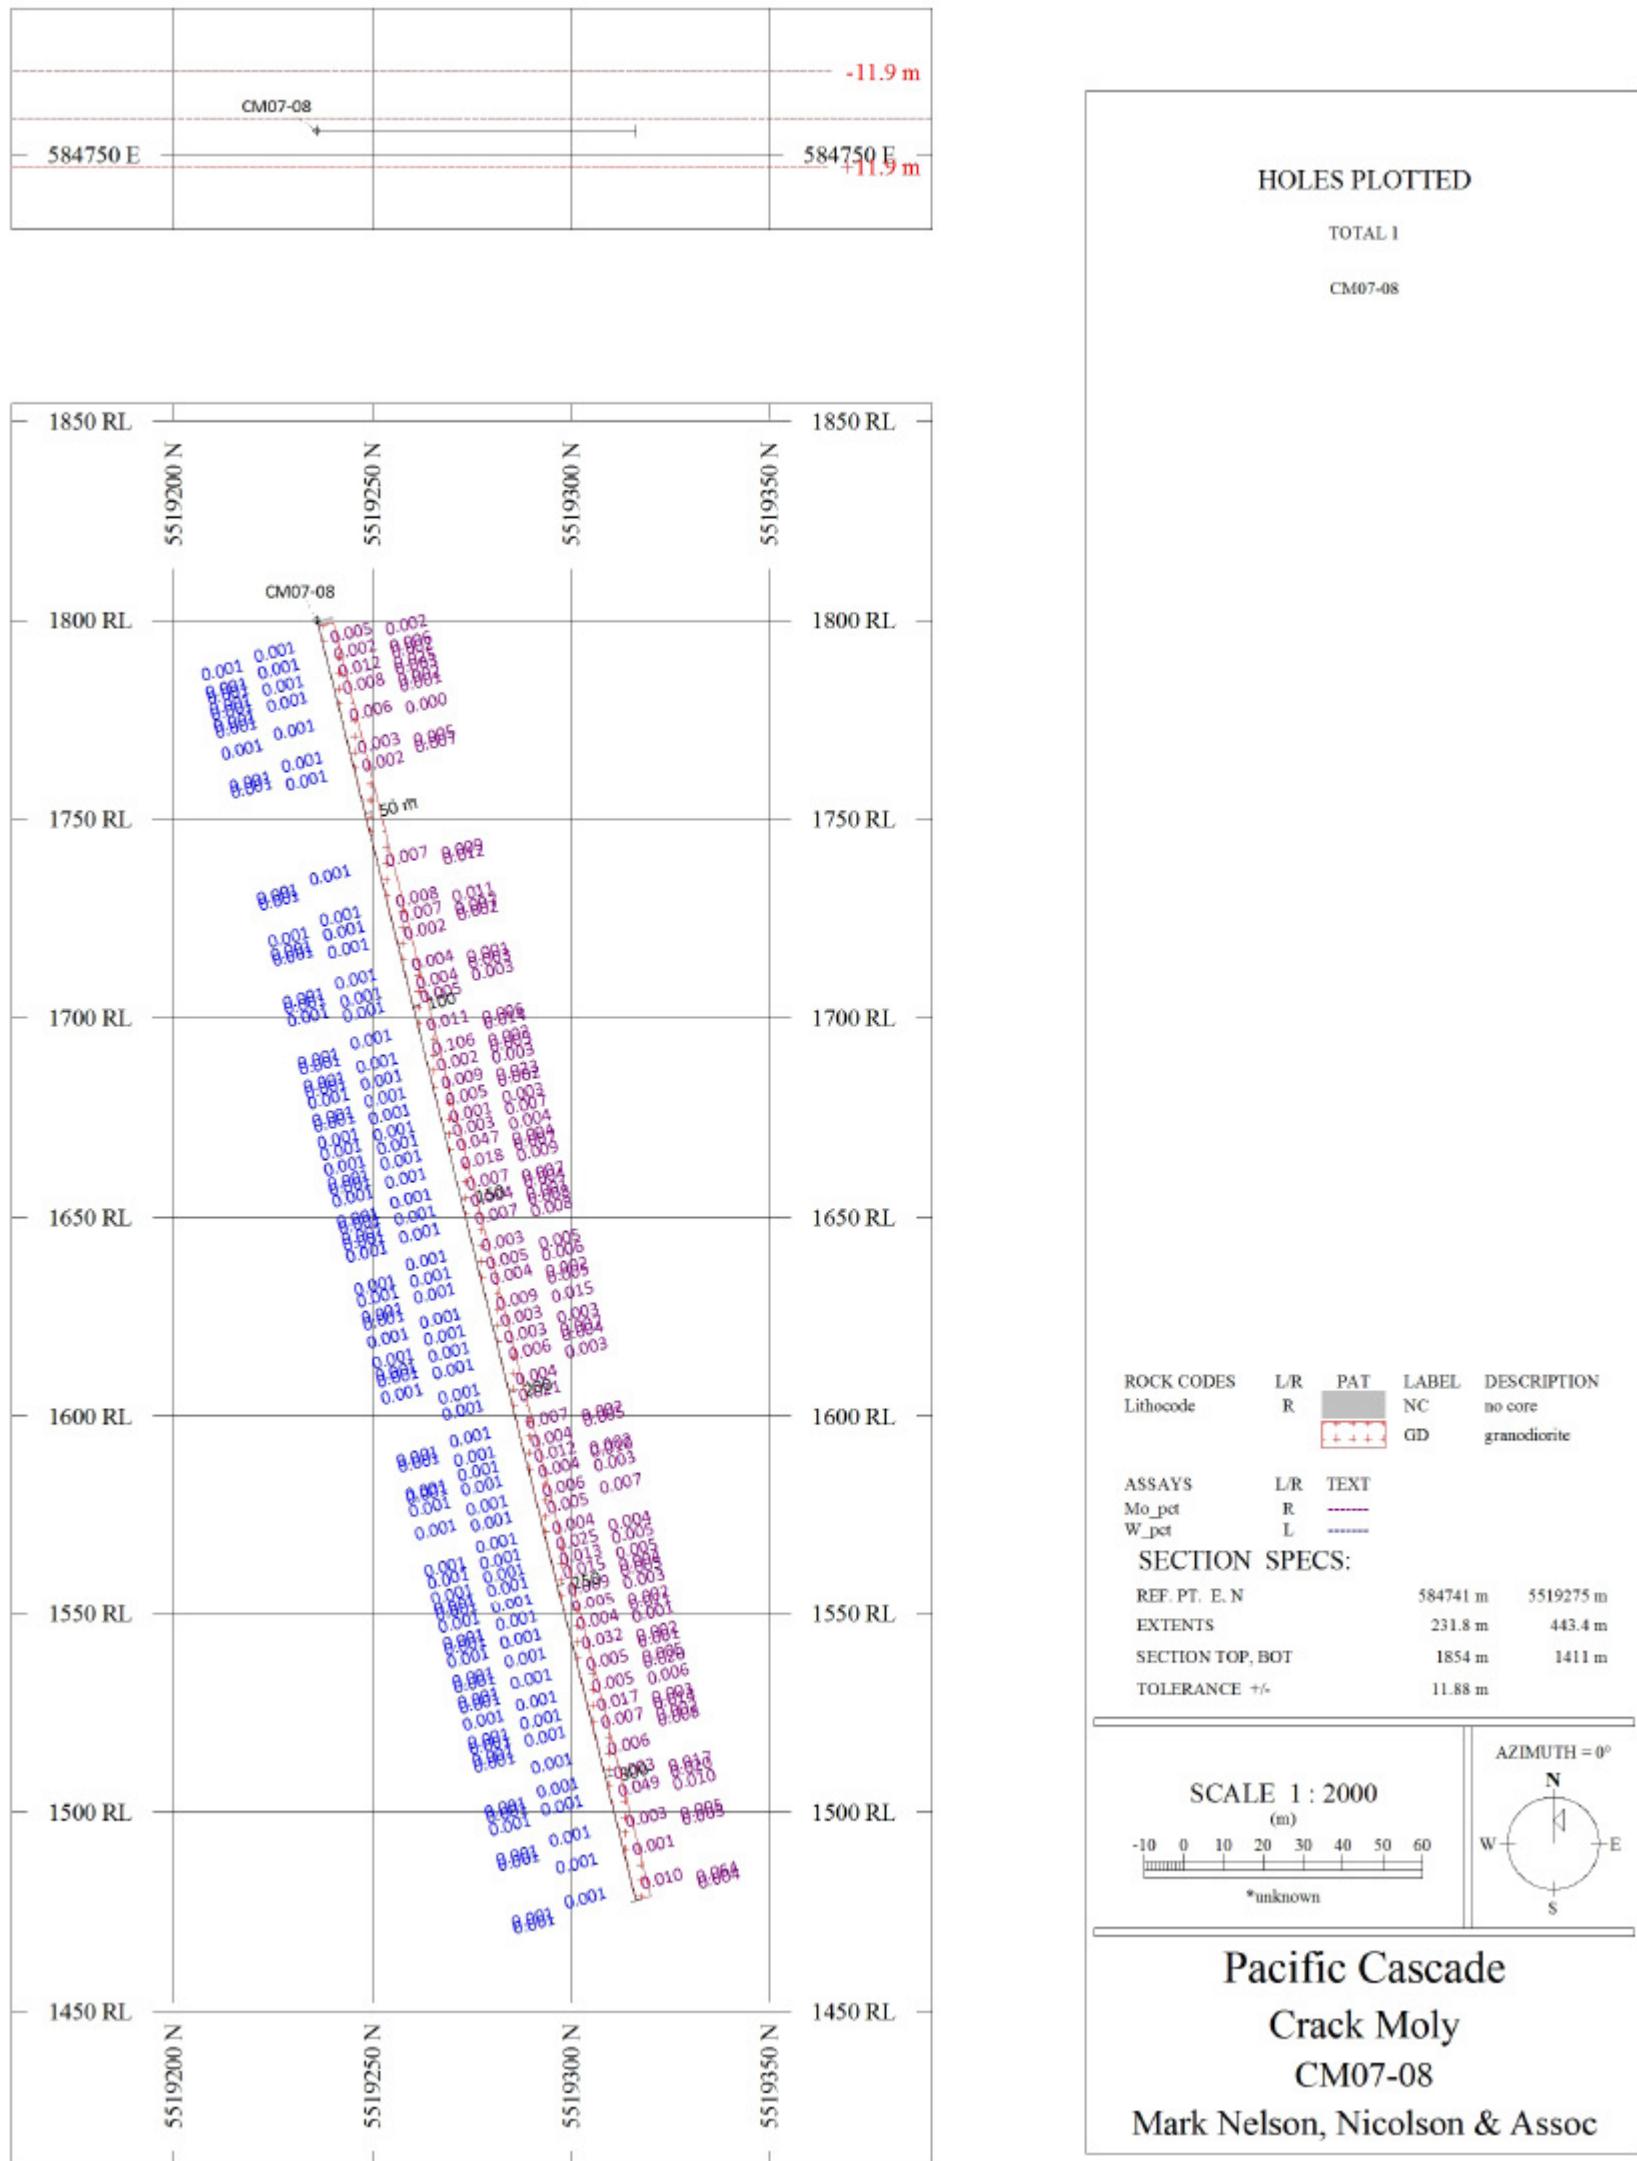

Figure 12. Drill Section CM07-08

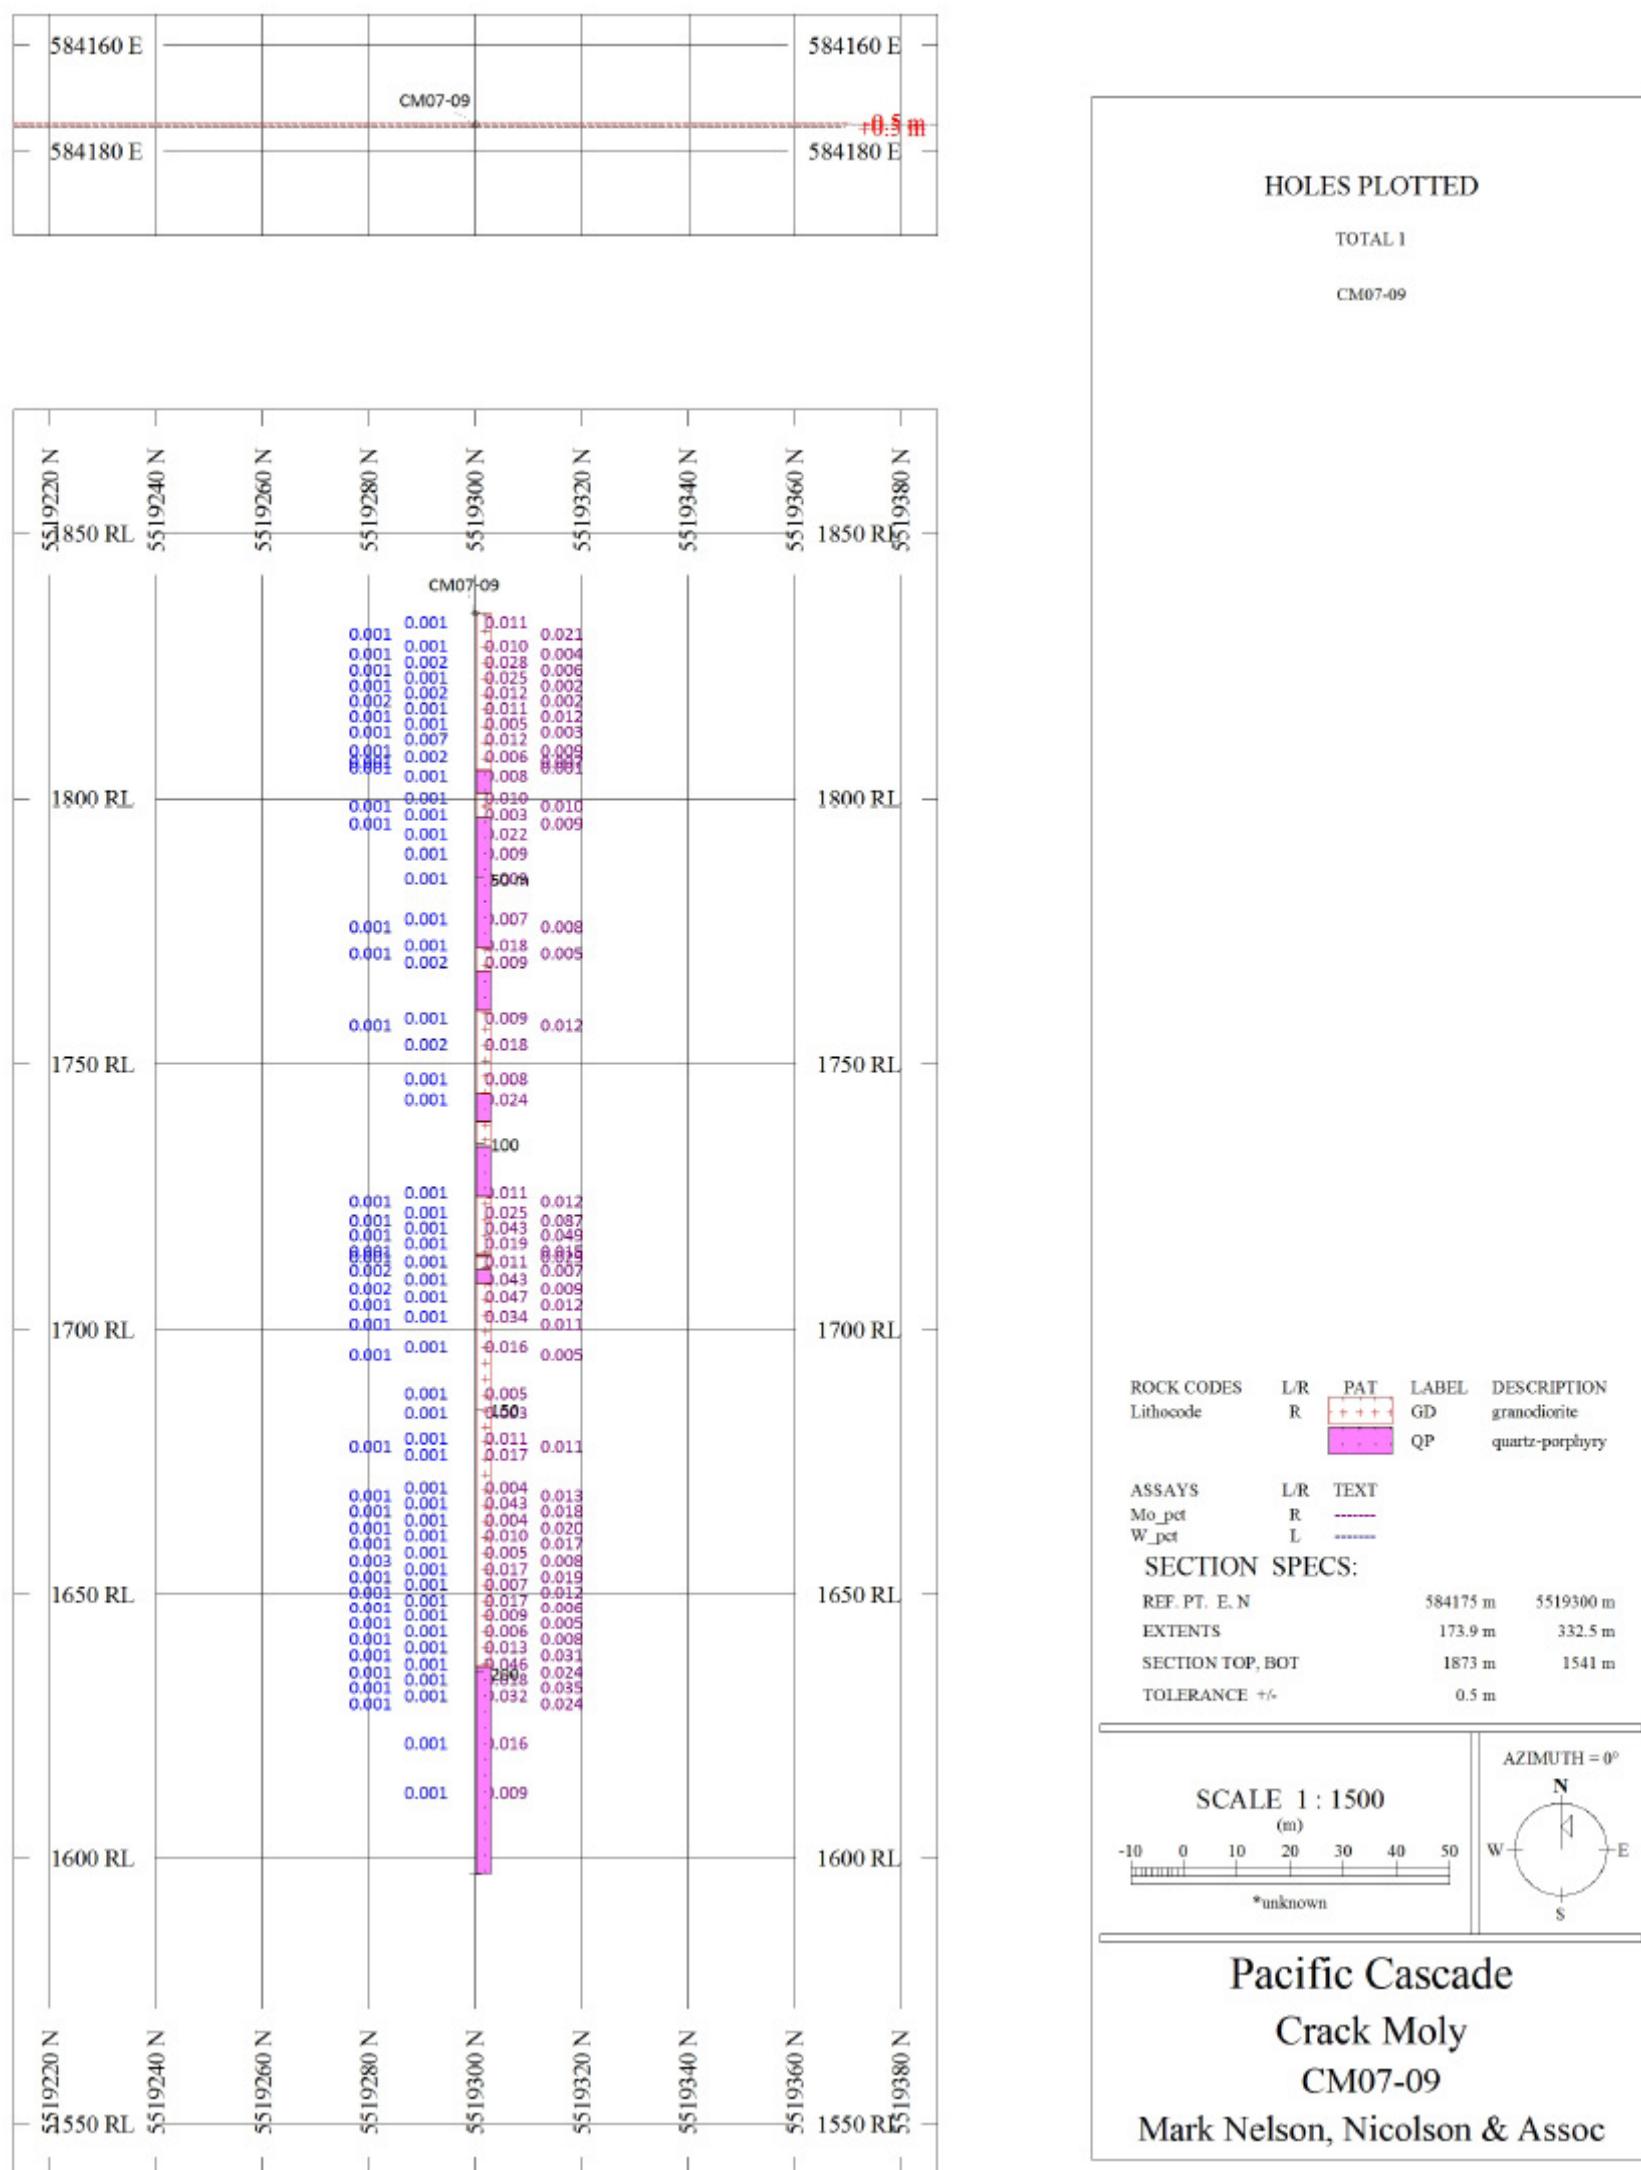

Figure 13. Drill Section CM07-09

any other hole with several intervals near the top of the hole reporting about 2.0 g/t silver over lengths of approximately seven metres.

CM07-09 (Figure 13)

The last hole of the program was also the westernmost hole drilled in 2007. It tested a strong surface chargeability feature but failed to fully test the deeper chargeability zone. The upper half of the hole intersected alternating granodiorite and quartz porphyry units followed by a thicker succession of granodiorite then quartz porphyry to the bottom of the hole. Assay results were low; the longest intercept was 42.63 metres averaging 0.017% molybdenite from 163.68 to 206.31 metres.

A summary of drill hole intercepts is presented in Table 3 - 2007 Drill Hole Intercepts

7.4 DRILLING SUMMARY

The results of the program were encouraging. Several of the holes returned anomalous molybdenum assays over broad intervals of 100's of metres with local high-grade intercepts within. The drill was incapable of testing a very deep chargeability feature at an interpreted depth of 400-500 metres below surface so most of the drilling focused along the eastern margin of the deep-seated chargeability feature. The drilling tested an area nearly 700 metres in length with work focused along a ridge top due to the lack of helicopter support. There are targets to the north and west that remain untested as well as a deep-seated strong chargeability zone.

8. Conclusions and Recommendations

The drill program successfully tested various IP targets, including chargeability and resistivity highs, as well as areas of surface mineralization. An approximate length of 700 metres was drill tested with holes at variably spaced intervals along this trend, largely confined to sites along the ridge top. Casing was left in select holes so that they could be extended to depth to fully test the IP chargeability target.

Drilling has confirmed the presence of molybdenite mineralization over a widespread area. Locally higher grades over 10's of metres were received within broad (100's of metres) areas of lower grade material. Continuity of mineralization from hole to hole is not consistent, with lower grade zones separating higher-grade material. The best result of the program was from hole CM07-05, which assayed 0.053% molybdenite over 195.05 metres from 84.57 to 279.62 including 0.196% molybdenite over 44.60 metres.

The Company was not able to test a deep-seated IP chargeability anomaly interpreted at a depth of 400 to 500 metres below surface, as the onsite drill was too small. This target area occurs just west of the last hole completed, CM07-09 and remains a significant, untested target for 2008. The geophysical survey done in 2005 indicates possible extensions to the mineralization in the form of chargeability responses west of the last line surveyed, the survey should be expanded for coverage an additional 500 metres west and south to fully resolve both chargeability and resistivity targets.

9. Statement of Qualifications

9.1 WESLEY RAVEN

I, Wesley Raven, of 108-1720 West 12th Avenue, Vancouver, British Columbia hereby certify:

1. I am a graduate of the University of British Columbia (1983) and hold a BSc. degree in geology.
2. I have been employed in my profession with various companies since 1983.
3. I am a member of the Association of Professional Engineers and Geoscientists of British Columbia, and have been registered since 1992. I am also a Fellow of the Geological Association of Canada and have been a member since 1989.
4. I am responsible for preparation of all sections of this report utilizing data summarized in the References section of this report and from my time spent at onsite management and core logging on the property.
5. I have had no direct involvement with Pacific Cascade Minerals Inc. on the Crack Moly Property except for my time spent in preparing an 43-101 report and an assessment report.
6. I am not aware of any material fact or material change with respect to the subject matter of the report that is not reflected in the report, the omission to disclose which makes the assessment report misleading.
7. I am independent of Pacific Cascade Minerals Inc. and act as their "Qualified Person".
8. I consent to the use of this report by Pacific Cascade Minerals Inc. for any corporate use normal to their business.

Wesley Raven, P. Geo.

DATED at Vancouver, British Columbia, this 7th day of April, 2008

CERTIFICATE OF ASSAY AK 2007-1624

Pacific Cascade Resources
520 - 700 W. Pender Street
Vancouver, BC
V6C 1G8

26-Nov-07

No. of samples received: 132

Sample Type: Core

Project: Crack Moly

Submitted by: Wesley Raven

CERTIFICATE OF ASSAY AK 2007-1510

Pacific Cascade Resources
520 - 700 W. Pender Street
Vancouver, BC
V6C 1G8

18-Oct-07

No. of samples received: 141

Sample Type: Core

Project: Crack Moly

Submitted by: Wesley Raven

Submitted by: Pacific Cascade Resources

ICP CERTIFICATE OF ANALYSIS AK 2007- 1264

Pacific Cascade Resources
520 - 700 W. Pender Street
Vancouver, BC
V6C 1G8

Phone: 250-573-5700
Fax : 250-573-4557

No. of samples received: 125
Sample Type: Core
Project: Cracis Moly
Submitted by: Pacific Cascade Resources

Values in ppm unless otherwise reported
