1.0 Summary of Field Program and Results

The SPN property, consisting of nineteen Mineral Titles Online (MTO) tenures totalling 95 square kilometres, was staked on September 12th, 2006 to cover relatively elevated precious and base metals values in the British Columbia Regional Geochemical Survey (RGS) database. The following June, an eight person crew collected 1066 follow-up stream sediment samples from creeks draining the SPN property. The samples confirmed the polymetallic potential of the property, with consistently highly anomalous samples, as well as highs of up to 8.7 ppm Ag, 1435 ppm Zn, 502 ppb Au, and 732 ppm Cu from creeks draining the property.

Based on the elevated silt geochemistry, a large soil geochemical grid centred on Mt. Leslie was established. In total, 1266 soil samples were collected from the grid in two stages, one at the end of July and the other in October.

Using the results of extensive soil geochemical programs undertaken over the nearby Rea Gold, Samatosum and Homestake deposits (on the Adams Plateau) for comparison, it is clear that the soil and stream sediment geochemistry of the SPN property is highly anomalous, particularly with respect to silver, copper and gold, because the geochemistry compares very favourably with that from the surveys conducted in the immediate vicinity of known deposits. Anomalous silver-in-soils generally outlines northwest to west-northwest trends on the SPN property, while anomalous copper and gold results are supportive, although somewhat less consistent. Zinc geochemistry is also anomalous, but also somewhat inconsistent in distribution, although the zinc geochemistry outlines a highly anomalous northwest trending zone, approximately 500 metres long, and with values which range between 500 and 1,230 ppm Zn. This anomaly is coincident with a silver-in-soil geochemical anomaly in which silver values average greater than 2 ppm. Using geochemical pathfinder elements that were employed successfully on the Homestake

property (Ag, Cd, Cu, Mo, Pb, and Zn), a soil geochemical index was plotted which outlines a broad zone of high prospectivity toward the northern and eastern sides of the Mt. Leslie soil grid.

There is good potential on the SPN property for VMS-style mineralization. This is evident not only from the highly anomalous multi-element soil and stream sediment geochemistry, but also from the observation that local proximal mafic volcanic and sulphide-bearing (pyrite, subordinate chalcopyrite) felsic volcanic rocks outcrop on the property. The occurrence of precious metals-enriched VMS deposits with similar geochemistry in the nearby Adams Plateau area, as well as along trend to the northwest at Mt. Armour, further highlights this potential.

The total cost of year 2007 exploration on the SPN property was \$104,052. Further exploration is highly recommended, and should initially include infill soil geochemical work on the grid as well as further reconnaissance soil sampling, geological mapping, and prospecting. If the results are encouraging, a geophysical program consisting of EM, magnetometer, and gravity surveying, should be conducted in the 2008 season.

2.0 Location, Access, and Physiography

Bitterroot Resources' SPN property is located approximately 19 kilometres southeast of Barriere, a small community on the North Thompson River, and 9 kilometres north of the Sun Peaks Ski Resort (figs. 1 & 2). Bitterroot's property has excellent road access. Highway 5 between Kamloops and Barriere gives access to the gravel Heffley-Louis Creek road, which borders the SPN claims on their west side, from the Agate Bay and Sun Peaks roads, which yield access to the claims from the north and south, respectively (fig. 2). From the Heffley-Louis Creek road there are three well maintained forest service roads (FSR) that can be used to visit the property: the Fadear FSR on the north, the Cahilty FSR on the south, and the McKnight FSR between them (fig. 3).

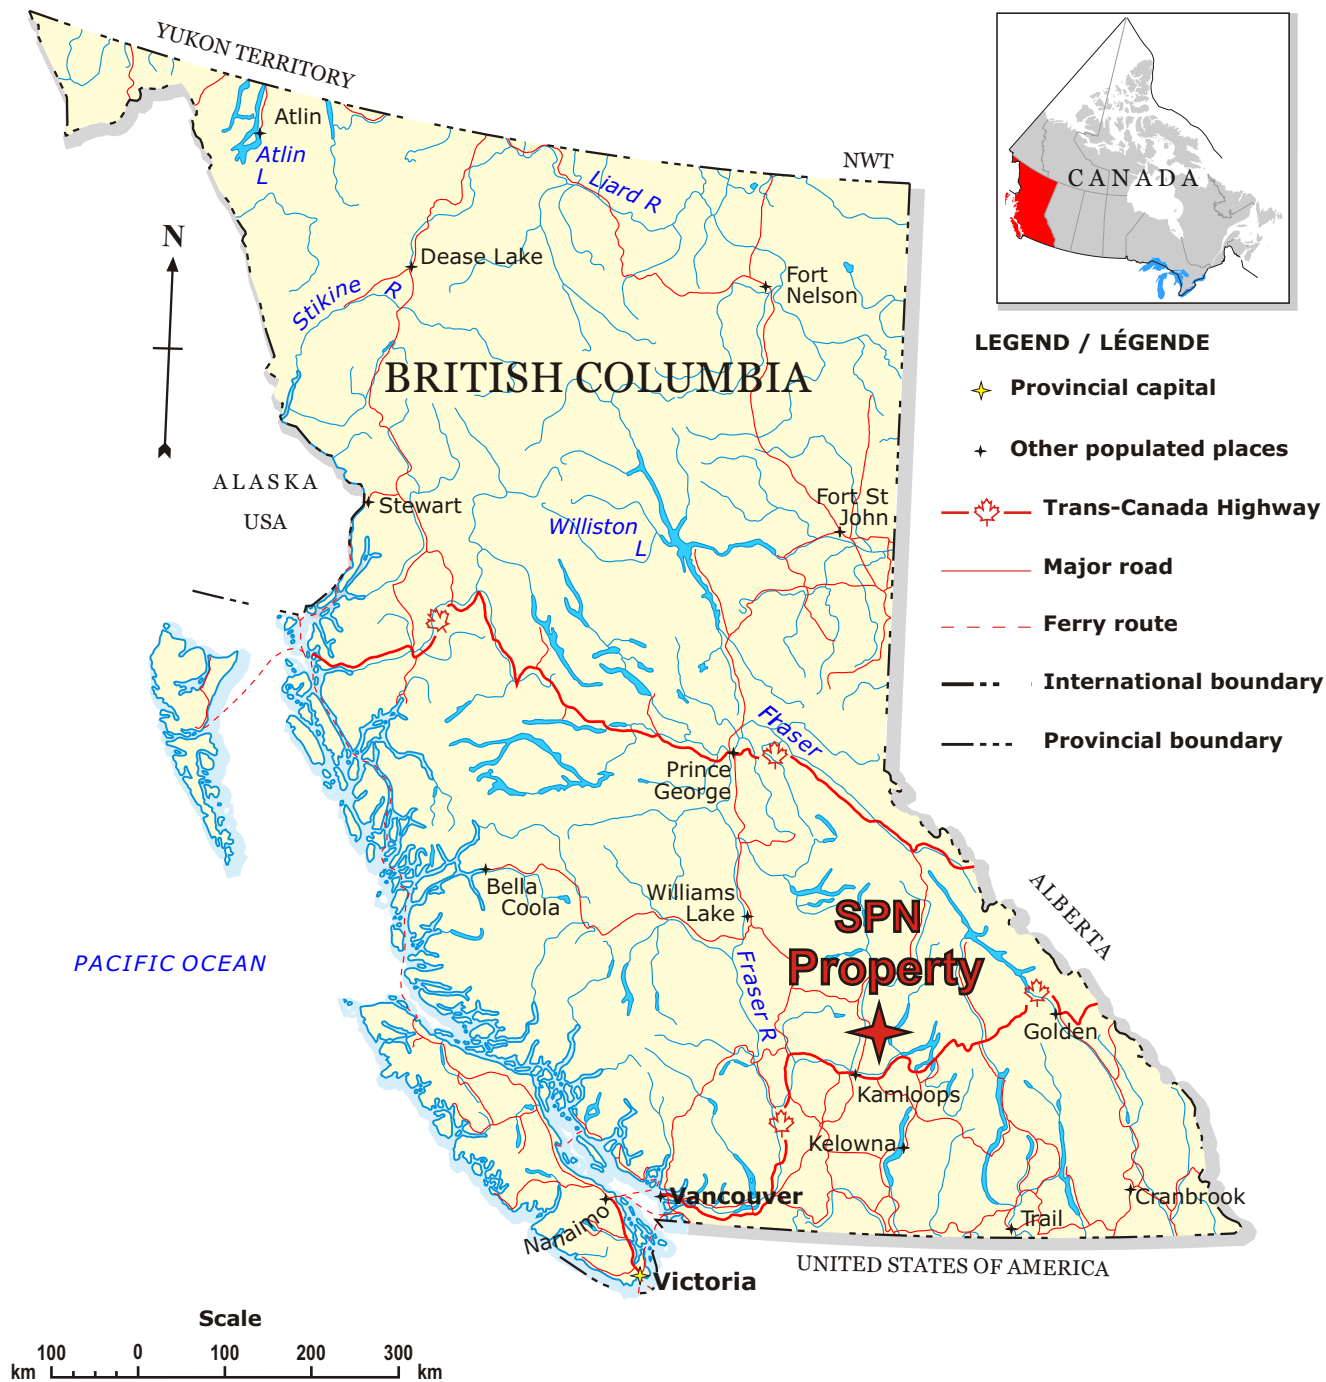

Figure 1. Location of the SPN Property, southern British Columbia.

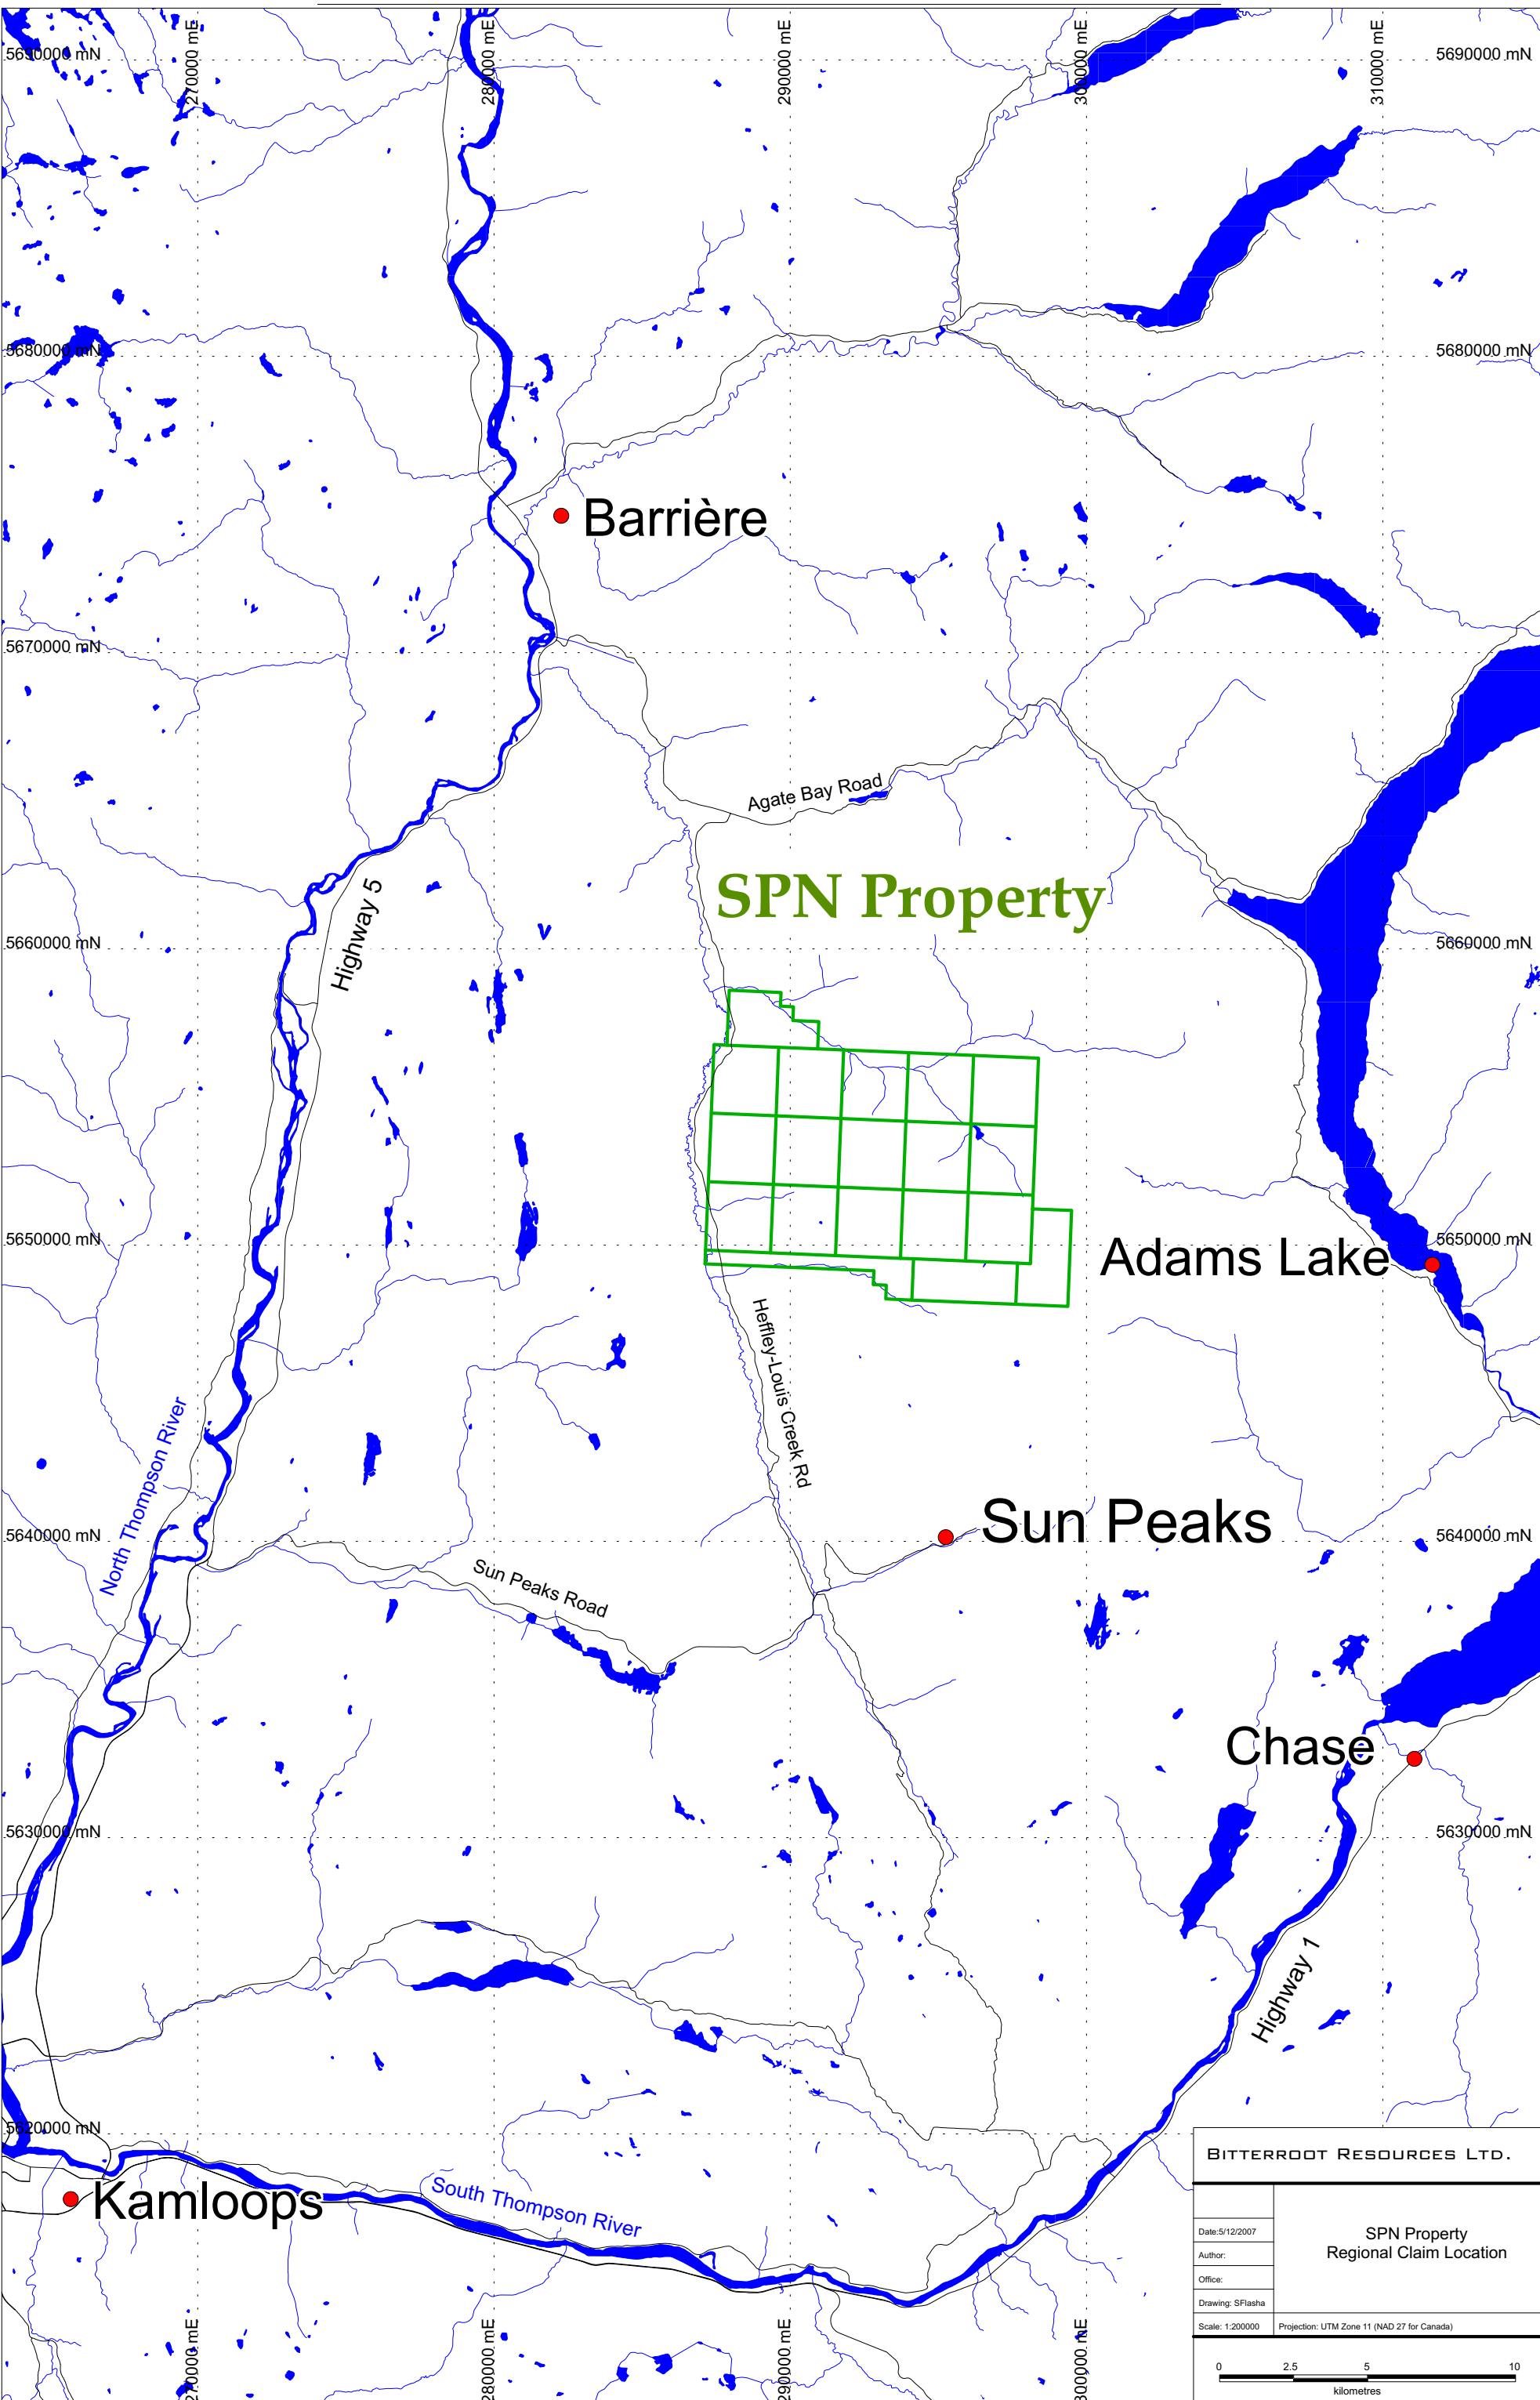

Figure 2. Location of the SPN Property, showing selected significant mineral occurrences in southern British Columbia.

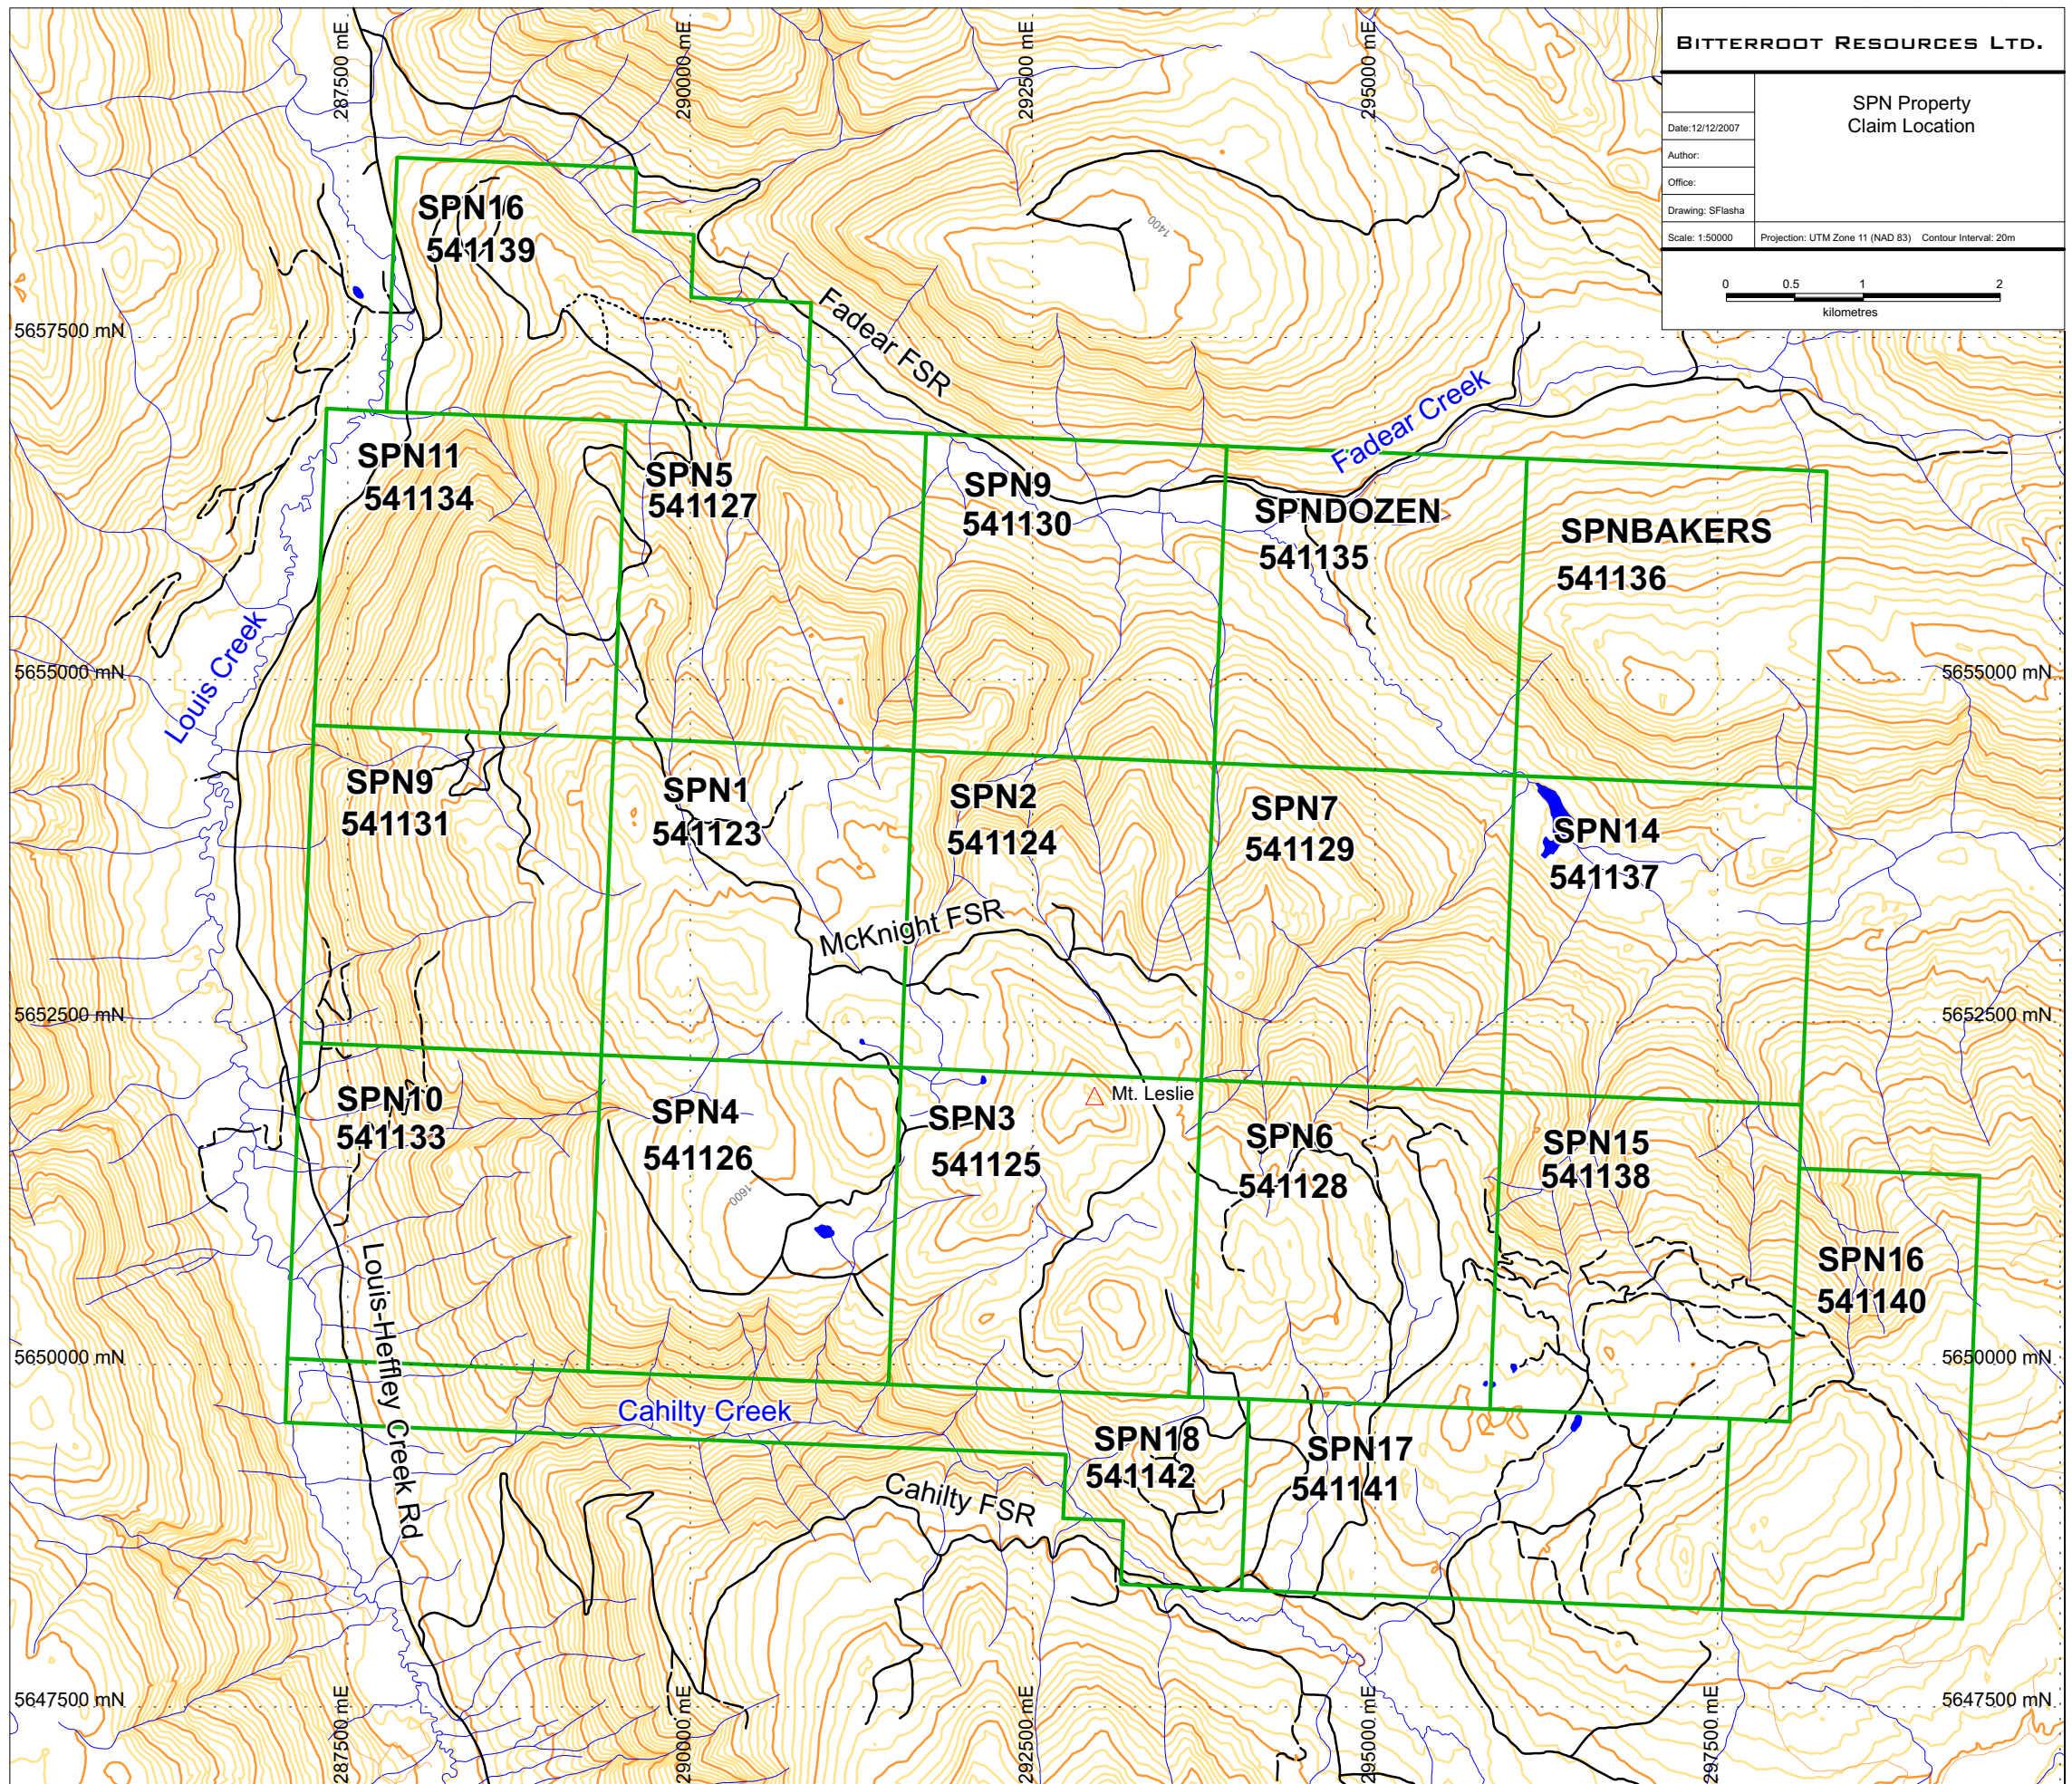

Figure 3. SPN property claim location, Kamloops Mining Division, southern British Columbia.

The SPN property is centered on Mt. Leslie (1840m; fig. 3). It receives a considerable yearly snowfall, as it lies within the same belt as Mt. Tod (2131m), which is the site of the popular destination ski resort at Sun Peaks. Even so, the property is workable for at least 7 or 8 months of the year. Elevation on the property ranges between 650 metres and 1840 metres, with steep slopes into the valleys that are generally thickly forested with pine, balsam fir, and spruce, depending on local drainage. Deciduous trees are also common in the valley bottoms. Approximately twenty percent of the property has been logged, mainly in the past 20 years, and with second growth developed to variable degrees. Overburden is considerable, and outcrops are best found along road cuts. Cattle are commonly ranged throughout the property in the summer months, as there are major ranches along most of the major valleys in the Barriere region .

3.0 Claims

Bitterroot Resources Ltd.'s SPN property (Table 1, fig.3) consists of nineteen claims covering a total of 95 square kilometres. The tenures were staked online by Charles Greig in September 2006, and were optioned to Bitterroot Resources Ltd. in March 2007. They lie within the Kamloops Mining Division and are in good standing until September 12, 2008.

4.0 Geologic Setting & Mineral Occurrences

According to geology maps available on the Ministry of Mines website, the SPN property is underlain on the east by Mississippian clastic sedimentary rocks of the Eagle Bay Assemblage, and on the west by undivided Upper Triassic to Lower Jurassic volcanic rocks of the Nicola Group (fig. 4). The Nicola Group includes intermediate and mafic plagioclase- and augite-plagioclase-phyric flows, sills, tuffs, and breccias that are intercalated with volcanic

Figure 4. Regional geology, showing location of the SPN property and selected producing mines and significant mineral occurrences in southern British Columbia.

conglomerate, sandstone, and mudstone (Ministry of Mines Online). Cursory geologic observations during the course of the silt and soil sampling programs suggest that the SPN property is underlain predominantly by sedimentary rocks, but our observations also indicate that local mafic and pyritic felsic volcanic rocks do outcrop on the property, at least in the vicinity of Mt. Leslie.

The SPN property lies near the western margin of a very prospective belt of rocks which includes the Discovery or Rea Gold massive sulphide deposit and the nearby Samatosum deposit. These deposits are precious metals-enriched base metals deposits that were discovered in the mid-1980's and which are hosted by folded and faulted rocks of the Paleozoic Eagle Bay Assemblage (fig. 4).

Both the Samatosum and original Discovery or Rea Gold zone, which is located only 500 metres to the southwest of Samatosum, have similar sulphide mineral assemblages and are hosted by similar rocks, although they are considered to represent different deposit types. The deposits occur within a westward-overturned package of mixed sedimentary rocks, predominantly argillite, siltstone, and wackes, as well as fine-grained intermediate to mafic tuffaceous rocks and their sericitized equivalents. The well-stratified rocks are structurally overlain by mafic pyroclastic rocks (stratigraphic footwall), while graphitic argillite, graywacke, and intermediate to felsic fine tuff typically overlie the mineralized sequence in the immediate stratigraphic hangingwall (structural footwall). Locally, the massive sulphide horizons at the Discovery or Rea Gold zone (there are at least two lenses) are capped by massive barite. Farther southwest in the hangingwall are felsic volcanic rocks, presumably related to the felsic rocks common at the Homestake deposit, which occurs approximately 4 kilometres southward along trend.

4.1 Rea Gold Zone (from B.C. Minfile)

The Rea Gold zone mineralized horizon hosts conformable bedded massive and semi-massive sulphides but also includes graphitic chert, pyritic siltite, and local pyritic graywacke. .

Mineralization within the sulphide lenses include pyrite, sphalerite, galena, arsenopyrite, chalcopyrite and tetrahedrite-tennantite. The sulphides range from fine-grained to medium-grained and banded, but locally display breccia textures. Precious metals are associated with massive sulphides and barite. The massive sulphides are underlain by a footwall feeder and alteration zone, characterized by intense silicification, pervasive pyrite and the development of sericite development.

The northern lens (L100 or Discovery lens) at the Rea Gold property has a surface strike length of about 50 metres, a width of about 4 metres, and a down dip projection of at least 120 metres. The lens strikes 140 degrees and dips 50-60 degrees to the northeast. Measured geological reserves are estimated at 242,849 tonnes grading 6.51 grams per tonne gold, 73.37 grams per tonne silver, 2.14 per cent lead, 2.24 per cent zinc and 0.52 per cent copper (B.C. Minfile; George Cross News Letter #8, 1987). The southern or L98 lens contains measured geological reserves of 133,536 tonnes grading 61.71 grams per tonne silver, 5.41 grams per tonne gold, 0.69 per cent copper, 2.4 per cent lead and 2.4 per cent zinc (B.C. Minfile; Northern Miner - November 30, 1987).

4.2 Samatosum (from B.C. Minfile)

The Samatosum deposit was mined for a period of approximately three years between 1989 and 1992, mainly by open pit. Like the Rea Gold zone, it trends northwest and dips to the northeast.

The area of the deposit has been divided into several northwest trending, northeast dipping panels of rocks. From northeast to southwest these include: 1) the Tshinikan Limestone, which forms steep, massive cliffs which dominate the topography of the area; 2) a mixed sequence of interbedded chert and argillite; 3) mafic volcanic rocks; 4) rocks of the "Mine Series," which consists largely of mixed sedimentary rocks and mafic volcanic rocks, but which also includes minor but significant interbedded felsic to intermediate volcanic rocks that form the immediate host rocks for both the Samatosum and Rea Gold deposits; and finally 5) a thick unit of argillite and wacke and a package of felsic volcanic rocks which lie in the structural footwall of the Mine Series.

The generalized ore stratigraphy reveals the stratabound nature of the Samatosum orebody, which lies near the hangingwall side (in stratigraphic terms) of the highly altered and intensely strained Mine Series. The mixed sedimentary rocks proximal to the deposit are characterized by the presence of yellow to white sericite, but contain lenses of chert or quartz that range up to 30 per cent by volume. The structurally underlying altered argillite is characterized by light silvery grey muscovite and sericite. Both units represent altered lithologies, and their protolith was probably a sequence of argillite, wacke, and fine tuff. The altered rocks also commonly contain fine-grained pyrite, which may range in abundance up to 60 per cent. The altered pyritic rocks may yield low base and precious metals grades.

The Samatosum deposit likely represents an early-formed, highly deformed quartz vein system containing massive to disseminated tetrahedrite, sphalerite, galena and chalcopyrite. The upper portion of the orebody is tabular, averages about 5 metres in thickness, strikes northwesterly for about 500 metres, and dips at an average of 30 degrees to the north northeast, for a total down-dip distance of approximately 100 to 150 metres. In the northern half of the

deposit, the tabular nature of the orebody gives way down dip to an apparent synformal structure, which is interpreted to have been formed through imbrication and local overturning along local contractional faults.

Tetrahedrite was the main economic mineral in the Samatosum orebody, followed in order of importance by sphalerite, chalcopyrite and galena. Tetrahedrite also appears to have been the most uniformly distributed of the ore-bearing minerals, while the sphalerite, galena and chalcopyrite were distributed more erratically, particularly in the northern part of the orebody. The tetrahedrite contained 36 per cent copper, 25 per cent sulphur, 23 per cent antimony, 5 per cent zinc, 4 per cent silver, 3 per cent arsenic and 2 per cent iron. The principal gangue minerals in the ore body were quartz (30 per cent), dolomite (19 per cent) and pyrite (11 per cent).

Sericite and muscovite are by far the dominant alteration minerals in the Mine Series rocks at Samotosum. They are interpreted, in part, to be products of the deformation and metamorphism affecting the original ore-related alteration products. All units from the lower portion of the structurally overlying mafic volcanic rocks through the entire Mine Series stratigraphy contain abundant sericite, although remnants of relatively unaltered protoliths are also common. Other significant alteration zones immediate to the deposit include: silicification or silica flooding of portions of wallrock surrounding the orebody; dolomite, the bulk of which is believed to be a late-stage fault-related overprint; pyritization, as a replacement feature of lapilli in the structurally-overlying mafic pyroclastic sequence; and fuchsite, almost entirely restricted to a several metre thick shear zone near the footwall of the ore zone.

Underground mineable reserves remaining at Samatosum are 80,278 tonnes grading 1.2 per cent copper, 2.9 per cent zinc, 1.7 per cent lead, 1021.5 grams per tonne silver and 1.7 grams per tonne gold (B.C. Minfile; Northern Miner - August 5, 1991).

4.3 Homestake (from B.C. Minfile)

The Homestake deposit is hosted by quartz-talc-sericite schists, sericite-quartz phyllite and sericite-chlorite-quartz phyllite derived from felsic to intermediate volcanic rocks of the Eagle Bay Formation. The rocks are structurally(?) overlain by intermediate to felsic volcanic and volcanoclastic rocks which host the Rea Gold deposit to the north, and the Rea Gold correlatives are in turn overlain by metasedimentary rocks consisting of argillites, siltstones and grits, which are themselves structurally overlain to the east by mafic volcanic rocks.

The Homestake deposit lies on the southern limb of a northwest trending, tight, overturned syncline. An east dipping thrust fault is inferred to separate the felsic to intermediate metavolcanics from more mafic metavolcanic rocks to the east.

At the Homestake deposit, several barite-rich lenses containing variable amounts of sulphides occur near the top of a bleached, rusty-yellowish weathering zone of pyritic sericite-quartz schist which is interpreted to be a highly altered felsic tuff. The schistosity and compositional layering dip at shallow to moderate angles to the northeast, and the mineralization occurs as two tabular horizons separated by 4 to 5 metres of schist. The largest mineralized body, referred to locally as the "barite bluff", is 5 to 6 metres wide on surface and contains most of the sulphides. A lower horizon, 1 to 2 metres thick, contains only minor sulphides.

Underground, the barite-sulphide lenses have been traced intermittently for several hundred metres.

The main horizon consists of massive to banded barite, metallic minerals and quartz-sericite schist. It is commonly cut by veins and lenses of quartz. The metallic minerals include tetrahedrite, galena, sphalerite, pyrite, chalcopyrite, argentite, native silver, trace ruby silver and native gold.

Probable reserves at the Homestake mine are 249,906 tonnes grading 226.6 grams per tonne silver, 36.7 per cent barite, 0.28 per cent copper, 1.24 per cent lead, 2.19 per cent zinc and 0.58 grams per tonne gold (B.C. Minfile; Statement of Material Facts 06/06/86, Kamad Silver Company Ltd.). Several small sulphide lenses also occur between 500 metres and 2 kilometres southeast of the Homestake deposit, while several conformable quartz lenses containing pyrite, chalcopyrite, galena, and sphalerite occur approximately 1 kilometre to the northwest.

All of the known lenses occur within a belt, up to 600 metres wide, of sericite and quartz-sericite schist which extends for at least 7 kilometres northwest from the Squaam Bay area on Adams Lake. The sericite schist is fine-grained, fissile and commonly weathers a distinct yellow colour due to coatings ferric sulphate coating.

Other silver-lead-zinc copper prospects in the Rea Gold-Samatosum-Homestake region include the K-7 occurrence, only 500 metres south of the Samatosum mine, and the Elsie occurrence, another structurally controlled showing, approximately 18 kilometres east of the SPN property (fig. 4).

As for gold, BC Minfile indicates that placer gold has been recovered from the North Thompson River and McGillivray Creek, which flows west, parallel to the Sun Peaks Road, although there are no active placer workings in the area. No documentation has been found to confirm these locations and findings by BC Minfile.

According to records on the Ministry of Mines website, the only previous documented and systematic exploration work completed on the SPN property was undertaken by INCO in 1984 (Debicki 1985). The work included mapping, gridding, and rock and soil sampling, with work centred on the southeast part of the present SPN property. The only mineralization reported by Debicki (1985) were minor gossans formed by oxidation of cubic pyrite (between 1

and 3%) hosted in sedimentary rocks (phyllite, argillite, schist). Debicki (1985) noted that the soil geochemistry on the property was anomalous with respect to silver, zinc, and copper, with only weakly anomalous gold and lead. Although he was unable to find a source for the anomalies, Debicki (1985) recommended further exploration, including an expanded soil grid, prospecting, and more geologic mapping.

5.0 Stream Sediment Geochemistry

In June 2007, two separate trips were made to the SPN property to collect stream sediment samples from creeks draining Bitterroot's SPN property. In total, twenty-one creeks were sampled and over 1100 silt samples were collected (fig. 5; Appendix I). Spacing between samples ranged from 50 to 100 metres.

The results of the stream sediment sampling were encouraging, with several creeks averaging greater than 1 ppm Ag, 200 ppm Zn, and 200 ppm Cu over distances of between 200 meters and 1.5 kilometres (figs. 6 to 8). The gold-in-stream sediment values were also encouraging, although less consistent from sample to sample (fig. 9). Overall, the most consistently anomalous creeks appear to be sourced from the Mt. Leslie area, near the center of Bitterroot's SPN landholdings.

Zinc-in-stream sediment values were highest to the north-northeast of Mt. Leslie, in creeks draining in that direction toward the Fadear Creek valley. The highest individual value was 1,435 ppm Zn (fig. 6), and the upper reaches of the creeks north-northeast of Mt. Leslie consistently yielded 90th percentile (>183 ppm Zn) values, which are comparable to 95th percentile values (>165 ppm Zn) in the Provincial Regional Geochemical Survey (RGS)

database, which has a sample population of over 44,000. For comparison, the RGS sample collected downstream from the Homestake Mine yielded 2,600 ppm Zn.

In contrast to zinc, the highest copper-in-stream sediment results tend to be concentrated in creeks draining southward from Mt. Leslie, while the drainages north of Mt. Leslie yielded highly anomalous Cu values only in their uppermost reaches (fig. 7). As with zinc, copper-in-stream sediment values are extremely high relative to those in the RGS database, with the property sample population yielding a 90th percentile value of 177 ppm Cu, and the RGS database yielding a 95th percentile value of 75 ppm Cu. The high for Cu-in-stream sediment values for the property is 732 ppm Cu, from a stream draining southward into Cahilty creek, and several supportive +500 ppm values occur upstream and downstream from this sample site (fig. 7).

Silver values correlate well with both zinc and copper, and are highly anomalous in streams both to the north and south of Mt. Leslie (fig. 8). Silver-in-stream sediment values range up to a high of 8.7 ppm Ag, with the 90th percentile value being 1.2 ppm Ag (fig. 8). For comparison, RGS samples collected from the vicinity of the Homestake and Samatosum deposits yielded values of only 0.1 ppm Ag, and the 95th percentile value for the Provincial RGS database is only 0.6 ppm Ag.

Gold-in-stream sediment values from the SPN property confirm the presence of highly anomalous RGS samples from the area, with over 10% of the samples returning gold values greater than 95th percentile RGS values (>20 ppb Au). (fig. 9). The high for gold-in-stream sediment from the property was 502 ppb Au, from a stream near the southern boundary of the SPN property. Unfortunately, that sample appears to have little in the way of supporting values, with no highly anomalous Au-in-stream sediment values occurring immediately upstream or

downstream. This phenomenon appears to be common for gold-in-stream sediment results on the property, as there are highly anomalous Au values from most creeks, but the values are spotty, and frequently lack support in immediately adjacent samples. This may make it difficult to directly target anything but a very general source area for gold (fig. 9).

As for other elements in the SPN stream sediment database, molybdenum values were anomalous in the uppermost reaches of all drainages in the immediate vicinity of Mt. Leslie, and interestingly, molybdenum was an element employed as a geochemical tracer on the Homestake property (Bristow 1971). Lead values from stream sediment samples collected from the SPN property are typically less than 10 ppm Pb, and are low in comparison to the local RGS database. For example, the RGS site from the drainage near the Homestake deposit yielded 1060 ppm Pb and those collected from the drainage of the Elsie occurrence yielded 840 ppm and 55 ppm Pb.

Stream sediment geochemical samples, which were collected from active drainages, were sent to ALS Chemex Labs in Vancouver for analysis and were analyzed for gold and a 34 element ICP exploration package (Appendix I). Material collected included fresh silt, silty sand, or locally, silty mud using either bare hands or the help of a mattock. The material collected was placed within Kraft paper sample bags and dried before shipping to the lab. Blank sample material, also collected from the property, was also sent for analyses with the stream sediment samples to test the accuracy and reproducibility of the results; analyses of blank samples show that the work is of good quality (Appendix II).

6.0 Soil Geochemistry

After receiving the results of the second stream sediment sampling program in June of 2007, a 3.5 kilometre long flagged baseline was laid out. The baseline was oriented northwest (310

degrees), and was centred on the area of most highly anomalous Ag-Cu-Zn stream sediment geochemistry, on the Mt. Leslie plateau. The baseline was chained using a hipchain, with stations marked every 50 metres. In late July and early August 2007, soil geochemical samples were collected on 200 metre northeast to southwest oriented crosslines on the Mt. Leslie grid, with samples collected every 50 metres. A total of 926 samples were collected in this first soil-sampling program, and based on the first round of soil sample results, a second trip was made in October to run a number of lines marginal to the original grid. In total, almost 1300 soil samples were collected on the SPN property (fig. 10; Appendix III).

Silver-in-soils on the Mt. Leslie grid were as anomalous as they were in the stream sediments, ranging up to a high of 8.7 ppm Ag (fig. 11). The results are also comparable to soil geochemical anomalies defined in the vicinity of the Homestake and Samatosum deposits, where in the immediate vicinity of the deposits anomalous thresholds were set at 0.5 ppm Ag, and where values ranged up to 10.5 ppm Ag (for Homestake, Bristow 1971; for Samatosum, Croft et al. 1981). The results for other elements, as well as for other surveys conducted in the Rea Gold-Samatosum-Homestake area, are also generally very much comparable (see Table 2). Croft et al. (1981) noted that the silver-in-soil geochemical values at Samatosum closely outlined known mineralization and that they also correlated very well with zinc geochemistry. On the SPN property, silver-in-soils outline several northwest to north-northwest trends, some of which are more than a kilometre long, with all values exceeding 1 ppm Ag (fig. 11).

Zinc values in soil on the Mt. Leslie grid are highest on the north-northeast side of Mt. Leslie, which helps to explain the most highly anomalous stream sediment geochemistry in that area (figs. 7 and 12). Zinc values on the grid range up to 1,230 ppm in this area, and within the immediate area of this particular sample are many supportive values, including those returning

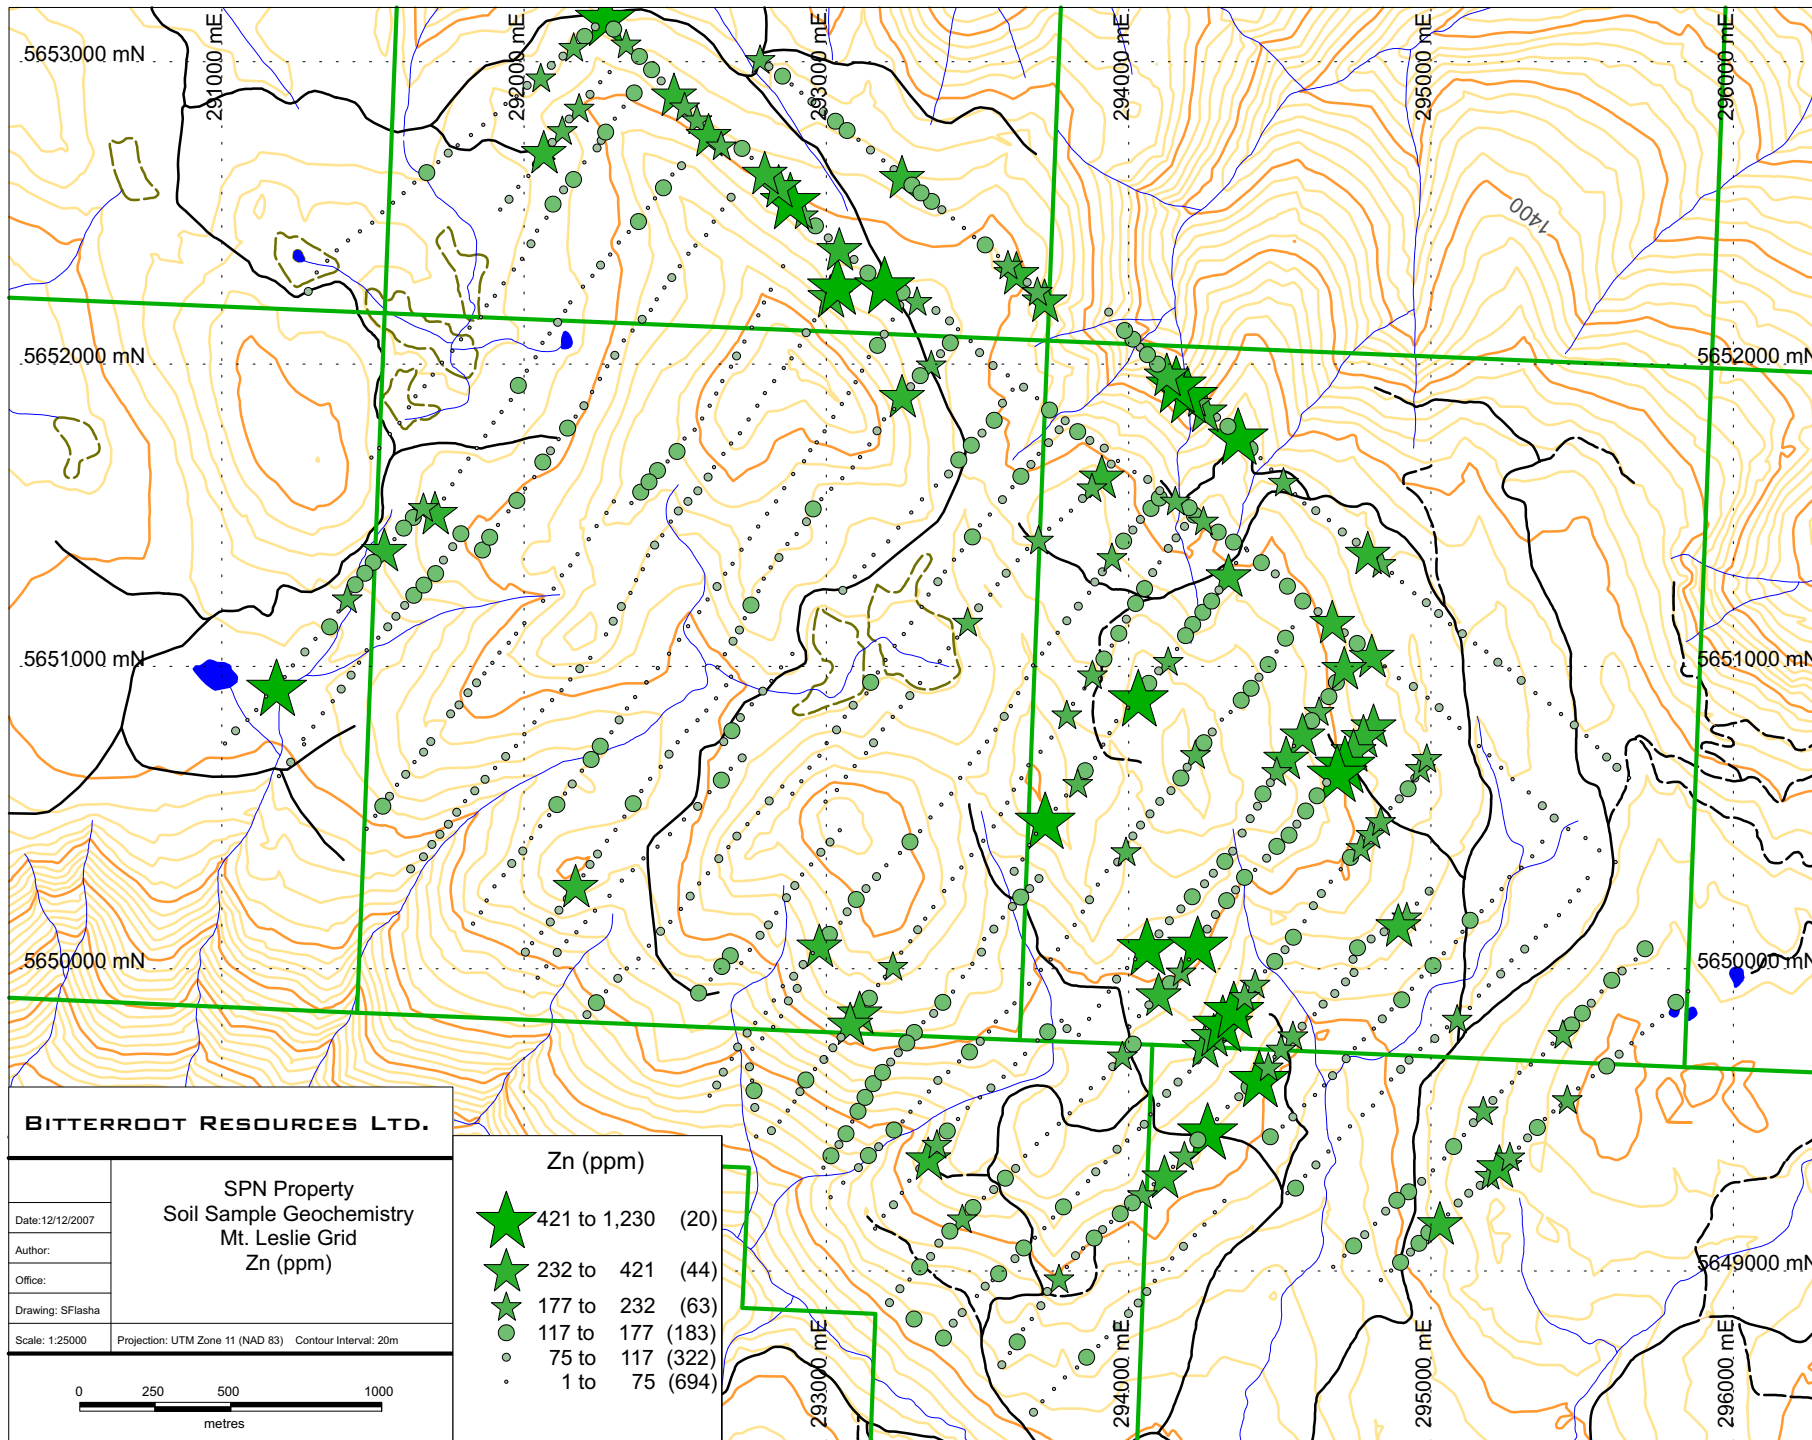

Figure 12. Zinc geochemistry in soil samples, Mt. Leslie grid, SPN property.

values of 999 ppm, 775 ppm, and 514 ppm Zn; silver geochemistry in this area is also highly anomalous, with all sites returning more than 2.1 ppm Ag (figs. 11& 12). With the exception of this area, however, zinc values in soil on the SPN property are not as highly anomalous as those found on the Homestake property, where the anomalous threshold was 600 ppm Zn, and where values range upwards of 4,000 ppm Zn (Bristow 1971). One must note, however, that mineralization is exposed at surface at the Homestake deposit, and that the sample database in Bristow's (1971) study is somewhat limited in numbers and in extent.

Many of the SPN property copper-in-soil values are anomalous, but they are widely and somewhat inconsistently distributed throughout the Mt. Leslie soil grid (fig. 13). The highest copper value obtained was 668 ppm Cu, and 38 samples exceed the anomalous threshold of 240 ppm Cu determined by Bristow (1971) for the immediate vicinity of the nearby Homestake massive sulphide occurrence. Another intriguing characteristic of the SPN Cu-in-soil values, is that while they are elevated, they are in general not as elevated as many of the Mt. Leslie area stream sediment values. For example, the upper reaches of one creek draining southward from Mt. Leslie returned values between 500 to 700 ppm Cu, while the surrounding Cu-in-soil values average less than 300 ppm Cu, and they do not exceed 400 ppm Cu (fig. 13). This may in part reflect remobilization of Cu in near-surface waters and precipitation in the drainages.

In some ways, gold values for soil geochemical samples from the Mt. Leslie grid yield results similar to copper in that they are commonly anomalous, yet erratically distributed (fig. 14). Croft et al. (1981) reported similar results for gold on the Samatosum property, where anomalous threshold gold values (>20 ppb for the sample population) were erratically distributed. The mostly highly anomalous gold value on the soil grid, 362 ppb Au, remains open, as it was taken on the line farthest to the west--it should be followed-up with in-fill sampling.

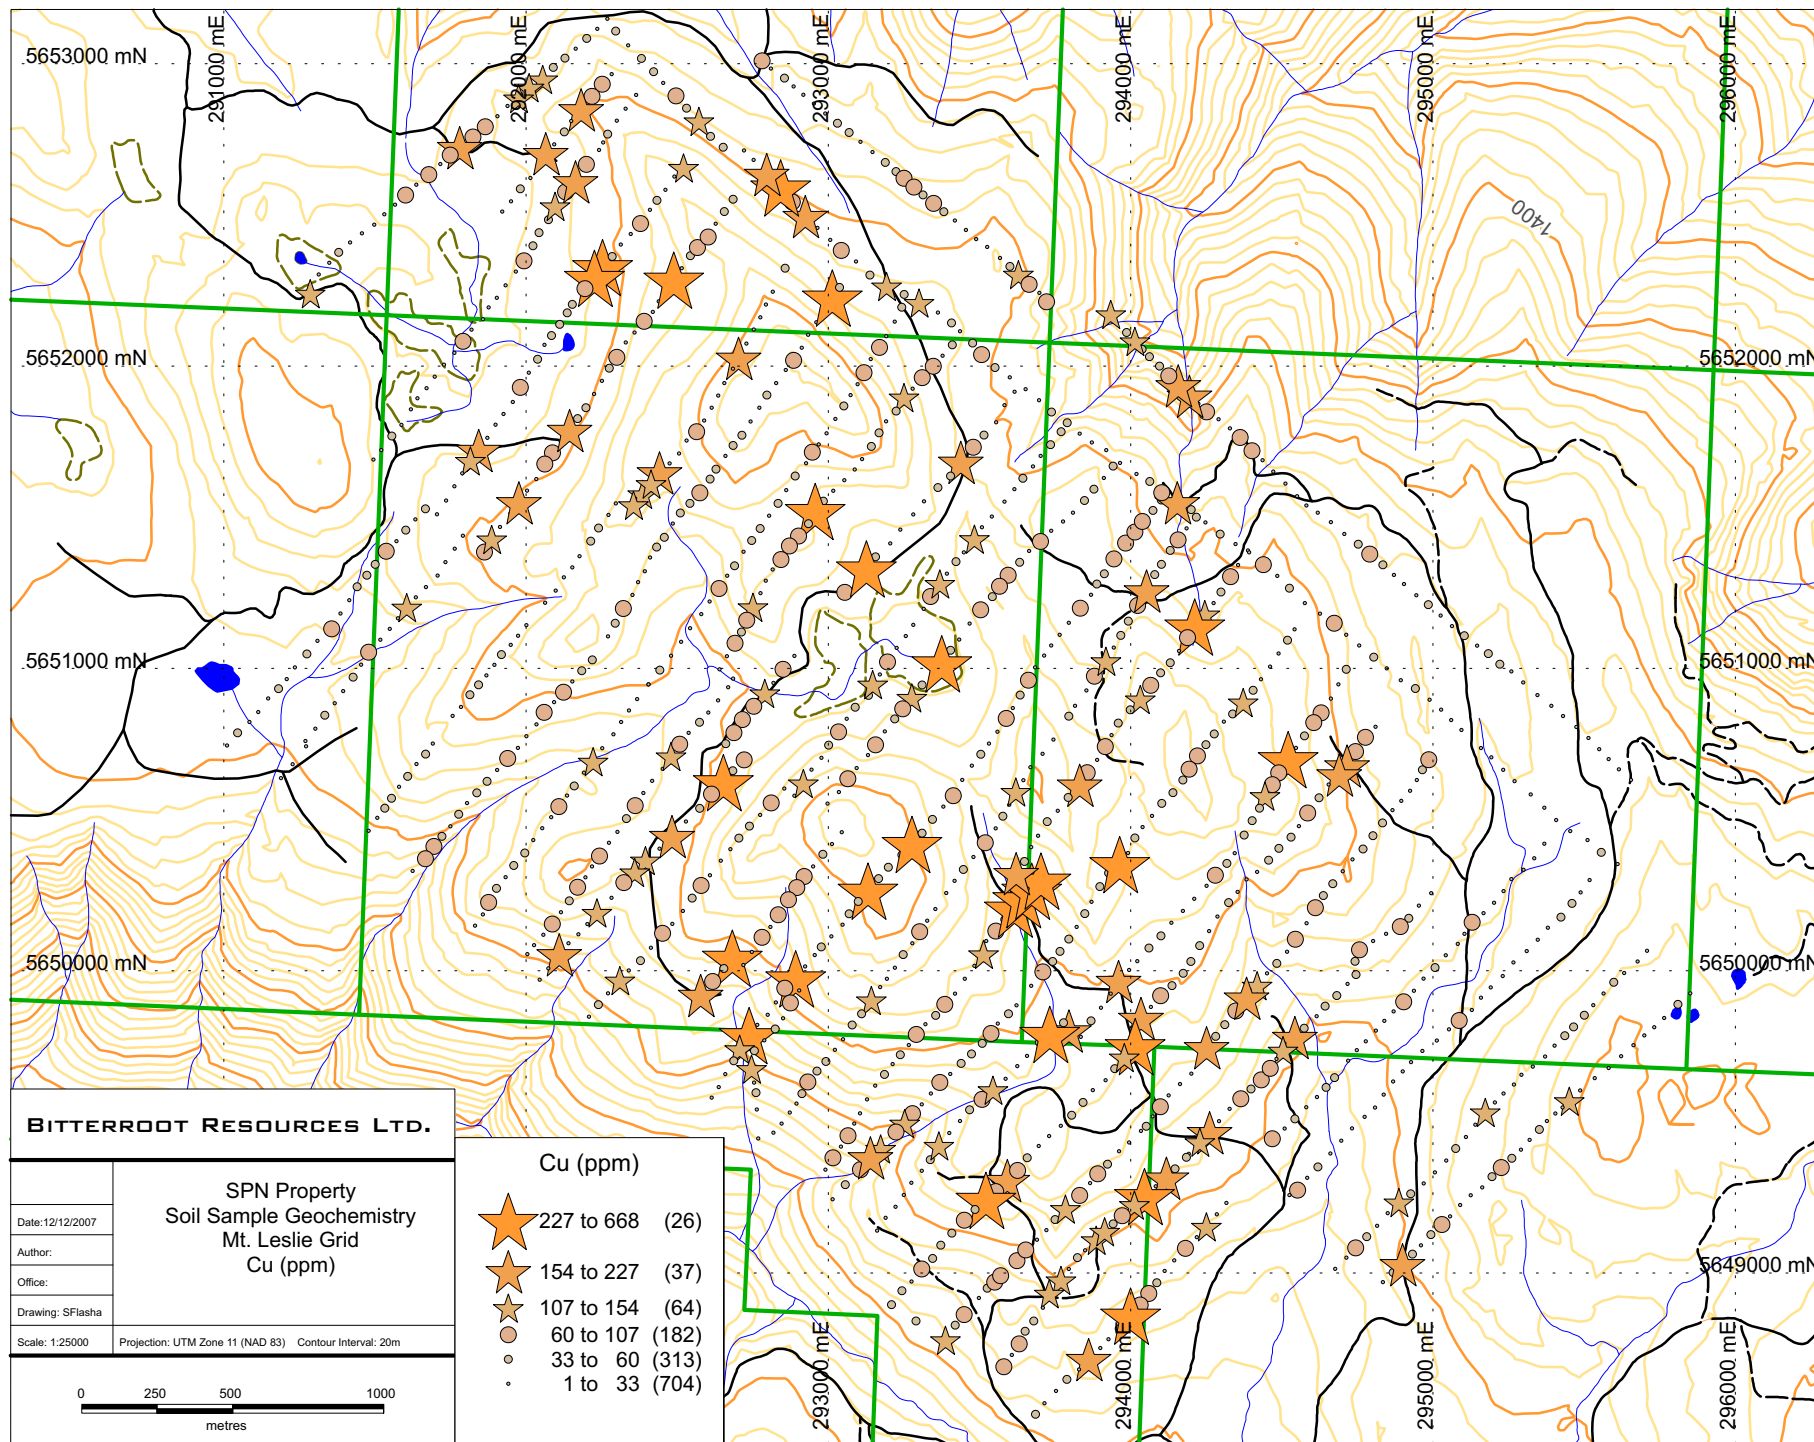

Figure 13. Copper geochemistry in soil samples, Mt. Leslie grid, SPN property.

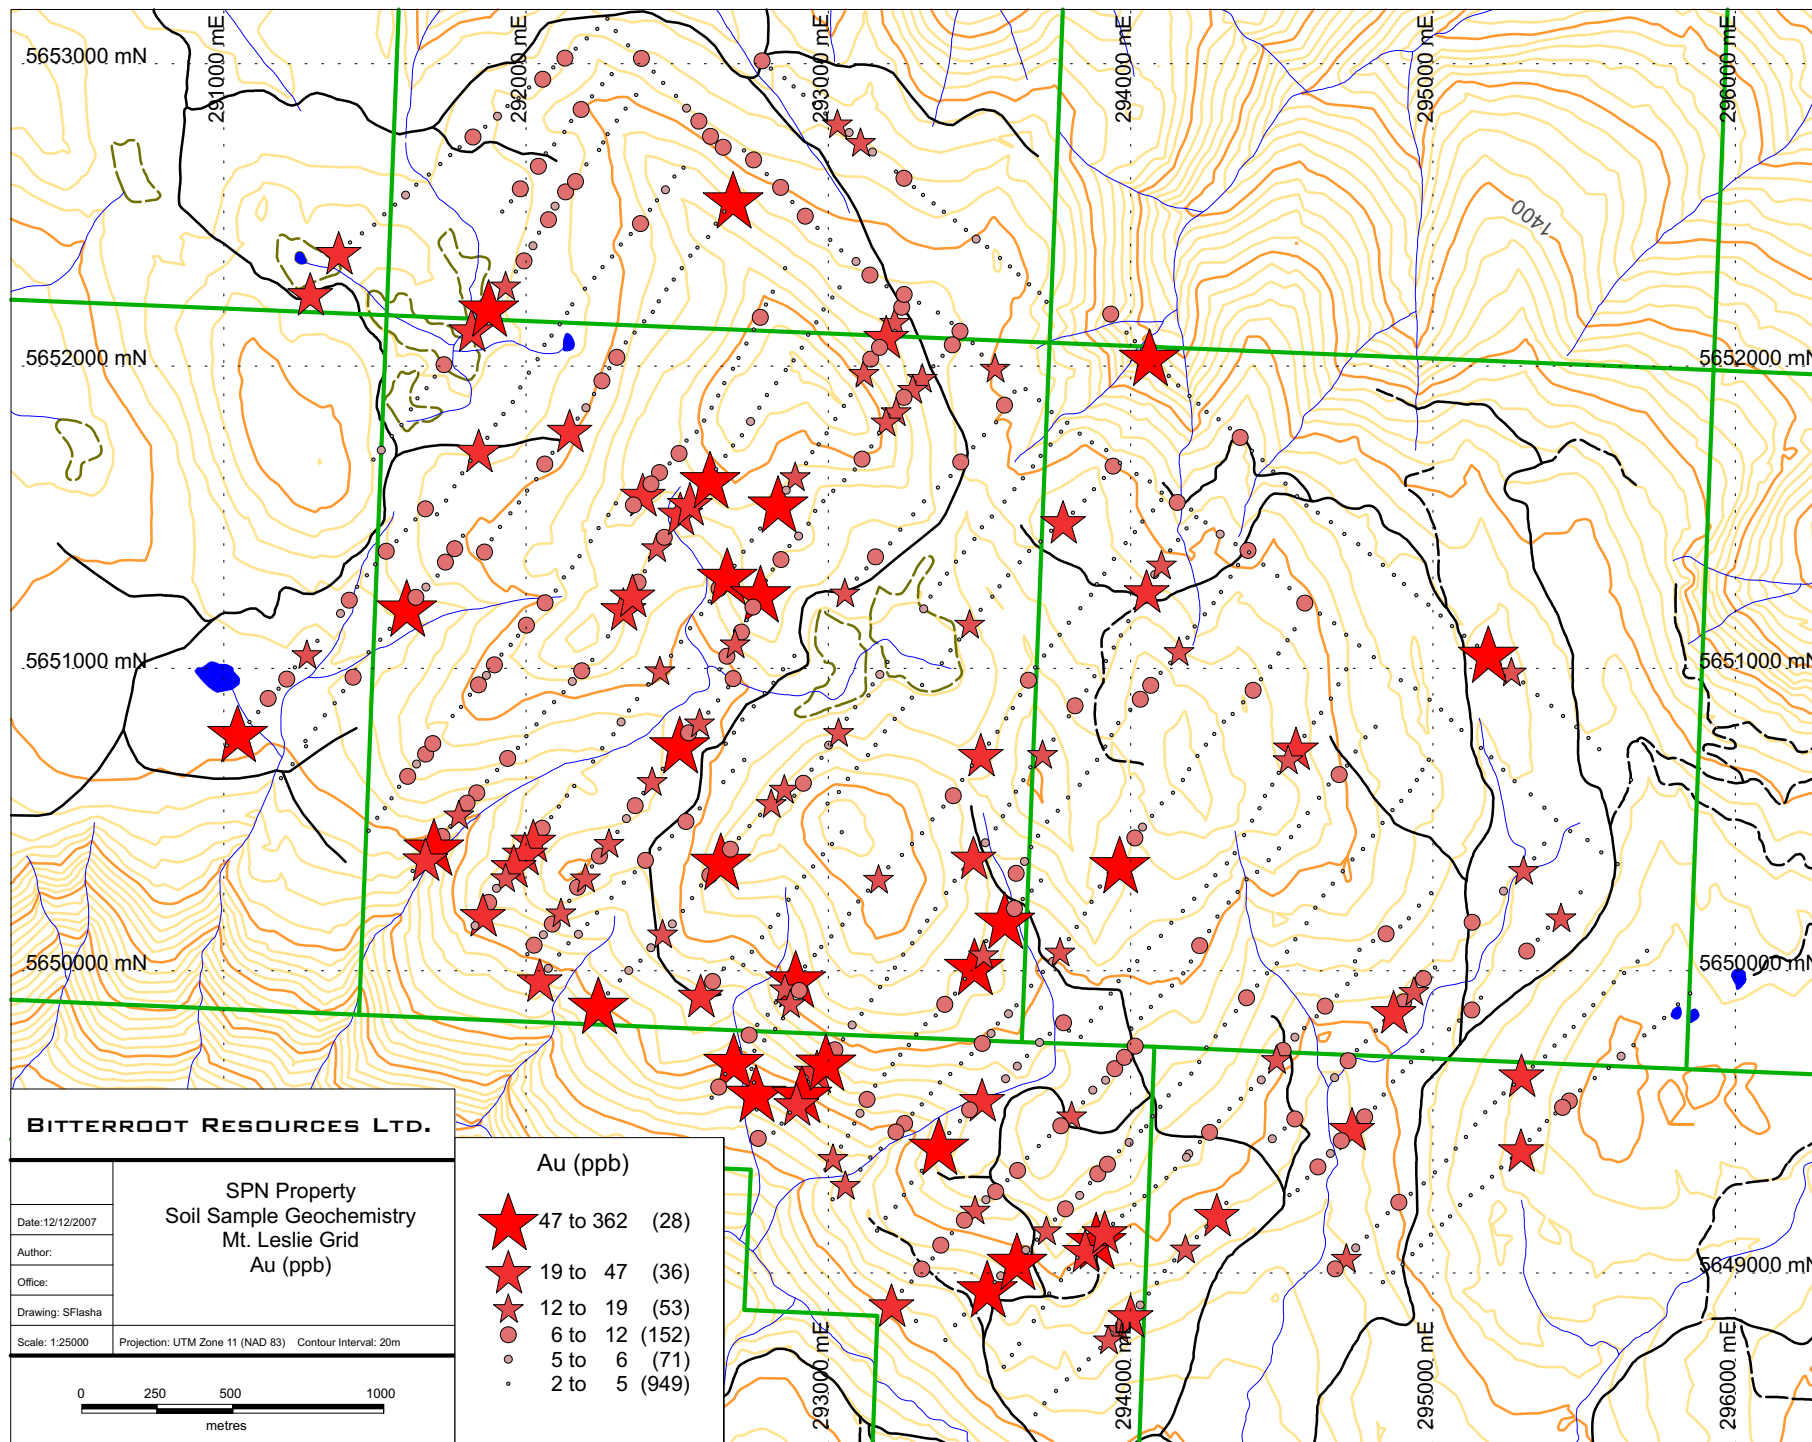

Figure 14. Gold geochemistry in soil samples, Mt. Leslie grid, SPN property.

The second highest gold-in-soil sample from the grid, which returned 345 ppb Au, was collected near the southern end of the grid, and shows good support, with nearby values returning 226, 90, and 40 ppb Au (fig. 14). No obvious trends in gold geochemistry were outlined in grid sampling and as a consequence completing the grid with 100 metre spaced lines and more tightly-spaced samples might be advised.

Using the same tracer elements as were used on the Homestake property (Ag, Cd, Cu, Mo, Pb, and Zn; Bristow 1971), figure 15 shows a contoured log-product soil index (i.e., $\log(\text{AgxCdxCuXMoxPbxZn})$) for the Mt. Leslie grid. This was plotted in an attempt to better define prospective areas on the SPN property. The figure suggests that there are paired geochemically anomalous highs, or trends, which sweep around both the eastern and western flanks of Mt. Leslie. The eastern trend includes the aforementioned zone of highly anomalous zinc and silver. The western trend is not as highly anomalous, and it is not certain whether or not the two trends connect at either end.

As with the stream sediment samples, all soil samples were sent for analysis to ALS Chemex Labs in Vancouver, where they were analyzed for gold and a 34 element ICP exploration package (Appendix III). Soil samples were generally collected from the B horizon, where available. The material collected was placed within Kraft paper sample bags and dried prior to shipping to the lab. Blank samples were also included in the samples sent to the lab, with the purpose of assessing accuracy and reproducibility of results; Analysis of the results for the blank samples shows that the work is of good quality (Appendix II).

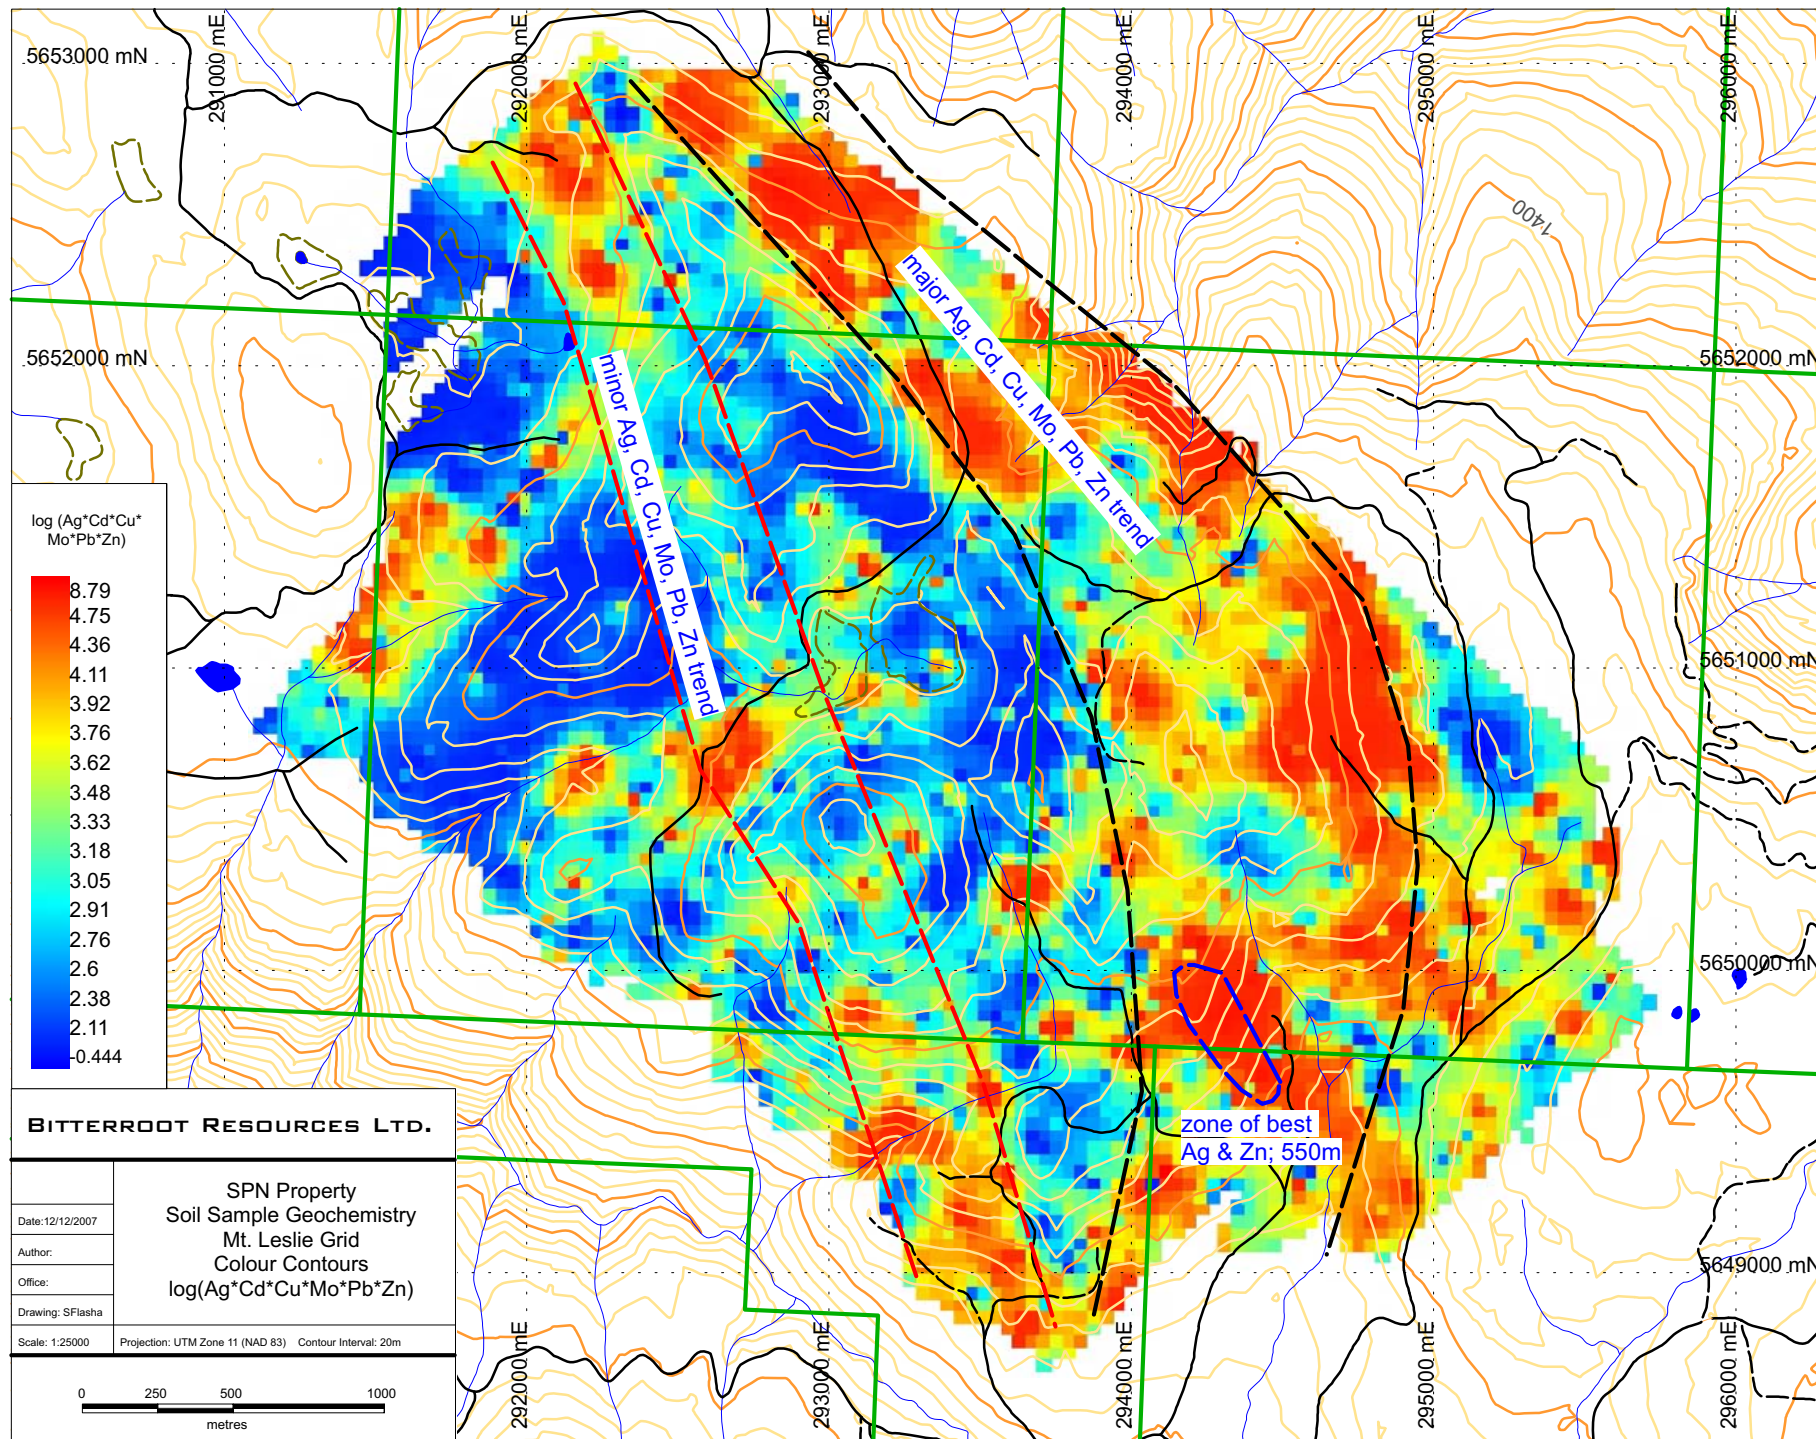

Figure 15. Colour contoured log products of pathfinder elements Ag, Cd, Cu, Mo, Pb, Zn, Mt. Leslie grid, SPN property.

7.0 Recommendations

The results of stream sediment and soil geochemical work on the SPN property in the 2007 season compare favourably with those from nearby known deposits. The suggestion, from the geochemistry, and from the observation of local proximal mafic volcanic and sulphide-bearing (pyrite, subordinate chalcopyrite) felsic volcanic rocks, is that there is good potential on the property for VMS-style mineralization. The occurrence of precious metals-enriched VMS deposits with similar geochemistry in the nearby Adams Plateau area, as well as along trend to the northwest at Mt. Armour, further highlights this potential. As a consequence, a multi-stage exploration program for the upcoming field season is strongly recommended. The first stage, to be initiated when the snow cover comes off, typically in late May, should consist of geological mapping, prospecting, and in-fill soil sampling on the Mt. Leslie grid.

The geologic mapping could be undertaken concurrently with prospecting and should yield a more complete understanding of the geological setting of the property, as well as of the potential styles of mineralization which may be found. The in-fill soil sampling, at 100 and locally 50 metre line spacings, with samples collected on 25 metre centres, should initially focus on the northern and eastern edges of the grid, where the best multi-element geochemical anomalies are situated (fig. 15). This would better test whether or not the soil geochemical anomalies are continuous, and would help to delimit trends of mineralization. A more tightly-spaced grid should also be centred on the Ag-Zn soil anomaly at the eastern edge of the grid, to better establish its size, to test whether or not the presently outlined trends are indeed continuous, and to help define areas for possible trenching. Similarly, the anomalous Au values on the grid, particularly if they occur in clusters, should be resampled, surrounded by infill samples, and prospected, in order to help find a source. If the findings of this next phase of work on the

property prove encouraging, then a logical follow-up phase of work would include line-cutting of a grid across at least the most prospective areas of the present Mt. Leslie grid. Establishment of the cut grid would mainly be for control of ground geophysical surveys, which may include Horizontal Loop EM, magnetics, and gravity, depending of course on the mineral potential identified and interpreted in the first phase of recommended work. If the geophysical work provides further encouragement, and targets are identified, then trenching and/or diamond drilling programs are recommended.

Shipping samples - Greyhound			\$ 601.44	\$	38,148.44

Grand Total **\$ 104,052.00**

Appendix V. Statement of Qualifications

Statements of Qualifications

I, Charles James Greig, of 250 Farrell St., Penticton, British Columbia, Canada, hereby certify that:

1. I am a graduate of the University of British Columbia with a B.Comm. (1981), a B.Sc. (Geological Sciences, 1985), and an M.Sc. (Geological Sciences, 1989), and have practiced my profession continuously since graduation.
2. I have been employed in the geoscience industry for over 25 years, and have explored for gold and base metals in North, Central, and South America, and Africa for both senior and junior mining companies, and have several years of experience in regional-scale government geological mapping.
3. I am a member in good standing of the Association of Professional Engineers and Geoscientists of British Columbia (license #27529).
4. I am a “Qualified Person” as defined by National Instrument 43-101.
5. I am not aware of any material fact or material change with respect to the subject matter of the technical report that is not reflected in the technical report, the omission to disclose which makes the technical report misleading.
6. I own shares of Bitterroot Resources Ltd., who is the optionee of the SPN Property. I am the optionor of the SPN Property.
7. I am an author of the report entitled; “2007 Exploration, SPN Property” dated December 2007. I worked on and supervised the work program reported on herein. I have been involved with exploration on behalf of Bitterroot Resources Ltd. since 1996.
8. I have read National Instrument 43-101 and Form 43-101F1 and the technical report has been prepared in compliance with National Instrument 43-101 and Form 43-101F1.

Dated at Penticton, British Columbia, this 29th day of December, 2007

Respectfully submitted,

“Charles James Greig” - signed

Charles James Greig, P.Geo

I, Susan Teresa Flasha, of #303 - 764 Government St, Penticton, British Columbia, Canada, hereby certify that:

1. I am a graduate of the Okanagan University College with a B.Sc. (Earth & Environmental Science, 2003), and have practiced my profession continuously since graduation.
2. I have been employed in the geoscience industry for 4 years, and have explored for gold and base metals in Canada for junior mining companies.
3. I am not aware of any material fact or material change with respect to the subject matter of the technical report that is not reflected in the technical report, the omission to disclose which makes the technical report misleading.
4. I am an author of the report entitled; “2007 Exploration, SPN Property” dated December 2007. I worked on the program reported on herein. I have been involved with exploration on behalf of Bitterroot Resources Ltd. since March 2004.

Dated at Penticton, British Columbia, this 29th day of December, 2007

Respectfully submitted,

“Susan Teresa Flasha” - signed

Susan Teresa Flasha, B.Sc.
