PROPERTY GEOLOGY KEYWORDS (lithology, age, stratigraphy, structure, alteration, mineralization, size, attitude)  
The claims are largely underlain by Cretaceous Spences Bridge Group volcanics and volcaniclastics. These rocks are being explored for epithermal precious metal mineralization. Small soil grids and mechanical trenching were completed over the Kelsch and Double D showings on the Fame Group. The best bedrock intervals were 400 ppb Au over 4 metres in trench FM-07-04 and 460 ppb Au over 5 metres in trench FM-07-06. A soil grid was completed over the Hamm vein on the Stobart Group. Five sub-parallel zones were identified. Bedrock vein sampling returned values to 1480 ppb Au.

## SUMMARY

Low sulphidation type mineralization was discovered within a road cut on the Fame property in 1986. From that time until 2006 this area had been the subject of various exploration programs that included diamond and rotary drilling, trenching, geological mapping and prospecting and soil geochemistry. Similar type mineralization was discovered in the Hungry Creek area on the Stobart property in 1991. Appleton Exploration acquired the Stobart - Fame property in 2006 and proceeded to do reconnaissance type exploration in selected areas of the property. In 2007 Appleton continued exploration with soil geochemical grids on the Kelsch and Hungry Creek grids, excavator trenching on the Double Diamond and Kelsch Zones and geological mapping and prospecting in the Kelsch - Twilight Zone area and in the Hungry Creek area respectively.

The 2007 exploration program confirmed the presence of low sulphidation type mineralization and located additional quartz vein in the area of the initial discovery. Excavator trenching in the Double Diamond - Kelsch Zone area was only partially successful in further delineating these mineralized localities. Short intervals with anomalous gold values were obtained in trenches FM-07-04 and FM-07-06.

Soil geochemistry completed on the Kelsch and Hungry grids returned only a few high or anomalous gold values on the Kelsch Grid and a series of north-northeast trending gold anomalies on the Hamm Grid in the Hungry Creek area. These anomalies are most abundant in the northwest corner of the grid where quartz veining has been observed in outcrop. Overburden on the Stobart - Fame property is generally deep and may have had a significant impact on the soil geochemistry.

Additional work is required in both the Hungry Creek area and on the Fame claims. This work should consist of expanding the Hungry Creek soil geochemical grid, mapping and prospecting in the Hungry Creek area and excavator trenching in both the Fame and Hungry Creek areas.

## **INTRODUCTION:**

In 2006 Appleton Exploration acquired the Stobart claims from 665777 B.C. Ltd. and optioned the Fame claims from John Kemp and Justin Turner of Grand Forks, B.C. The company proceeded with reconnaissance exploration that included soil geochemistry on the West and Alex grids and on the Twilight Zone. In 2007, Appleton completed soil geochemical grids over the Kelsch Zone and on the Hamm Grid in the Hungry Lake area. In addition, excavator trenching was done in the vicinity of the Kelsch and Double Diamond Zones.

The author was responsible for supervising much of the 2007 exploration program. This report compiles and summarized the data from the 2007 exploration program as well as previous work and makes recommendations for ongoing exploration.

## **RELIANCE ON OTHER EXPERTS:**

Certain opinions expressed in the report are based on data and information supplied by Appleton Exploration Inc., assessment reports and various other sources. Unless expressly stated otherwise, any such data and information have not been verified or audited by the author and the author makes no representation as to its accuracy and disclaims all liability with respect thereto.

The ownership of the claims comprising the property has been taken from the Minerals Online Database maintained by the British Columbia Ministry of Energy and Mines. The data on this site are assumed to be correct.

## **PROPERTY DESCRIPTION AND LOCATION:**

The Stobart - Fame property is located in the Chilcotin Plateau area of central British Columbia approximately 94 kilometres northwest of Clinton and approximately 85 kilometres southwest of Williams Lake (Figure 1).

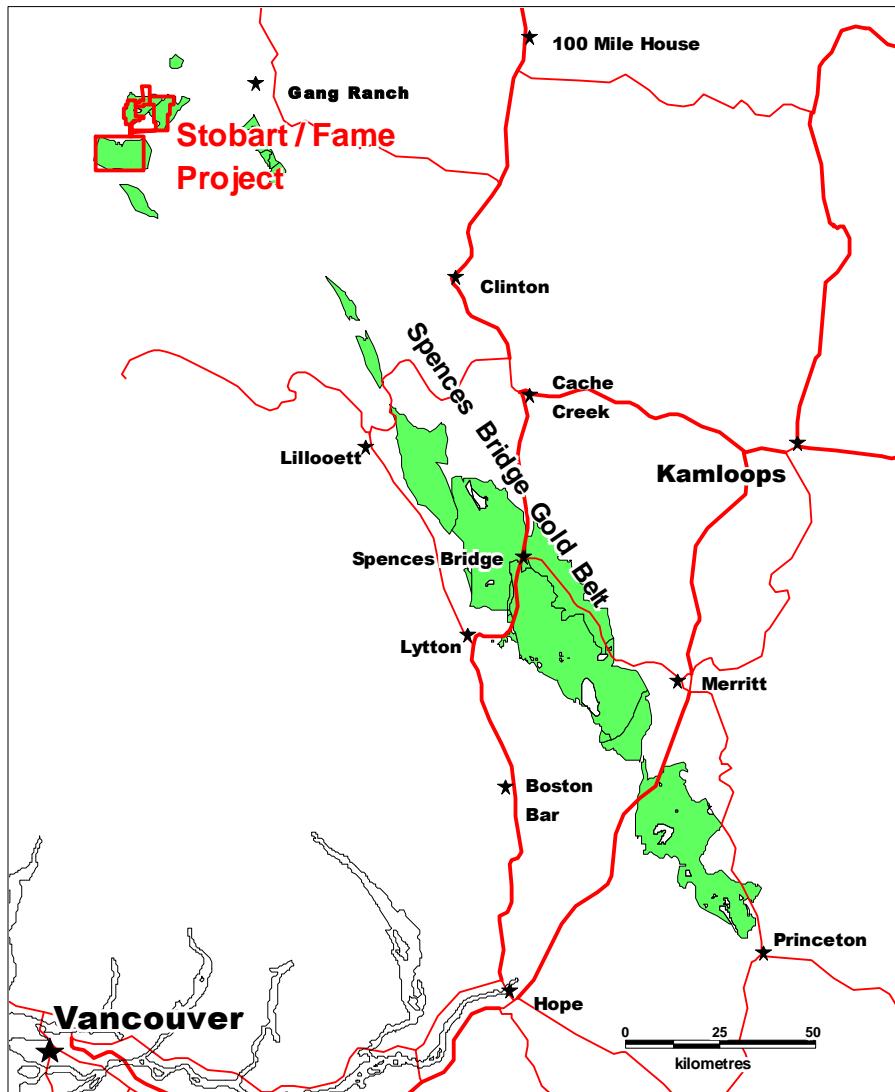

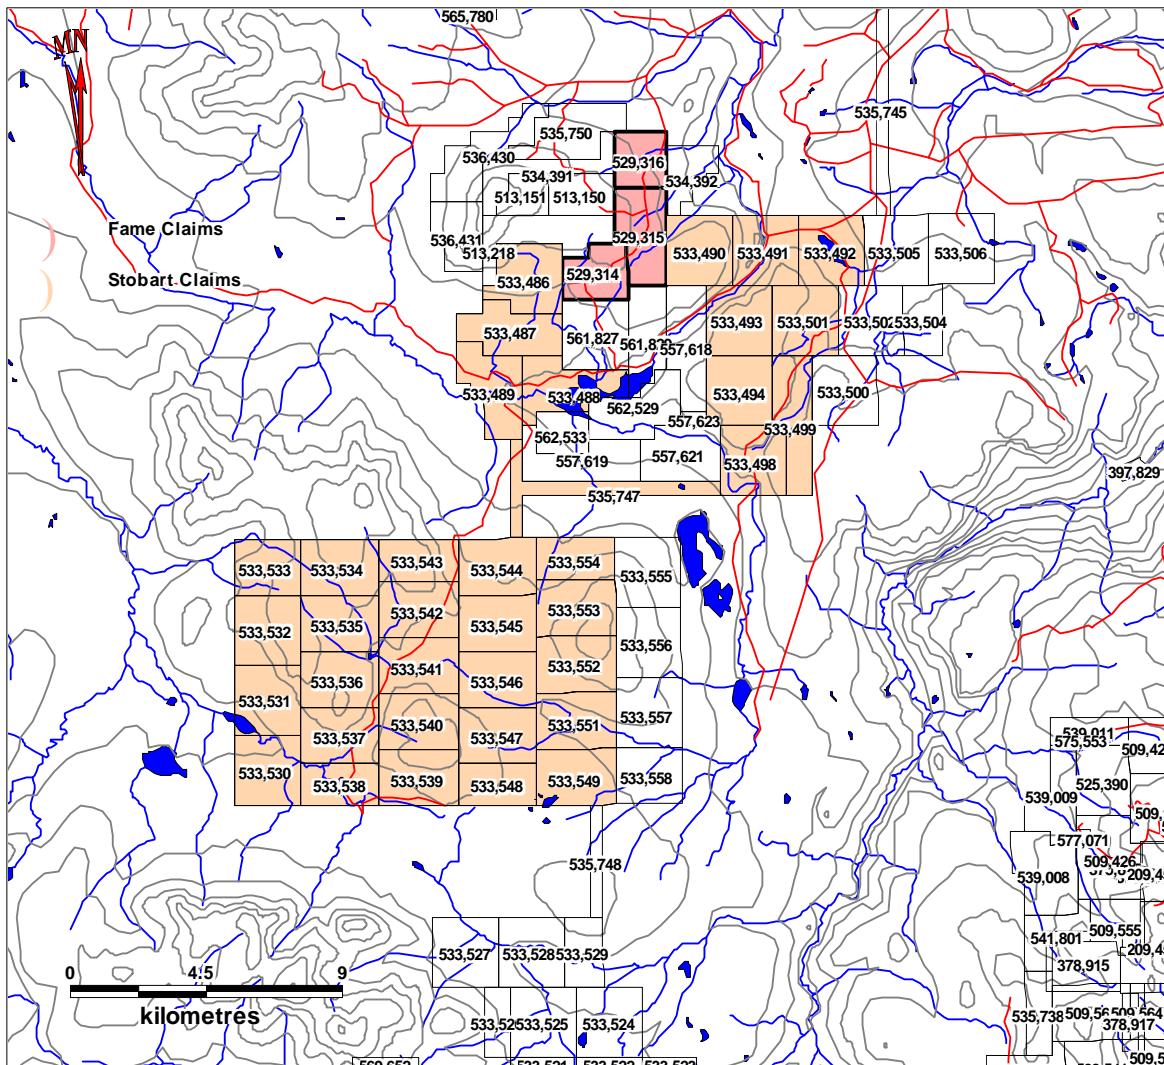

FIGURE 1: Location Map for Fame-Stobart property.

The Stobart Group consists of 37 claims totaling 17,578.49 hectares. The Fame Group consists of 3 claims comprising 1186.76 hectares (Figure 2). Complete details of the claims are summarized in Table 1.

**FIGURE 2:** Tenure map for Fame-Stobart property.

The Stobart claims are registered in the name of Appleton Exploration Inc. (owner 207126) These claims are subject to a 1.5% NSR with 665777 B.C. Ltd., a private British Columbia Corporation controlled by two of Appleton's Directors. Appleton has the right to purchase 0.5% of the NRS for \$1,000,000.

The Fame 1-3 mineral claims are held under an option agreement with John A. Kemp and Justin J. Turner (owners 113908 and 145292, respectively) of Grand Forks, B.C. According to the terms of the agreement Appleton Exploration has the right to earn a 100% interest in the property subject to a 2.5% NSR by making cash payments totaling \$65,000, by issuing 300,000 common shares and by completing work commitments of \$160,000 by August 15, 2010. Appleton has the right to purchase up to 1.5% of the NSR at the rate of \$250,000 for each 0.5%.

## **ACCESSIBILITY, CLIMATE, LOCAL RESOURCES, INFRASTRUCTURE AND PHYSIOGRAPHY:**

The Stobart - Fame property lies 94 kilometres northwest of Clinton. Access is via Highway 97 north from Clinton for 16 kilometres to Meadow Lake Road. The Meadow Lake, Canoe Creek road system crosses the Fraser and continues to Gang Ranch and through to the 2800 Road which provides access to the various claim blocks. The claim blocks are 36 kilometres southwest of Gang Ranch. Local accommodations are available at Gaspard Camp at km 16 on 2200 Road or Meadow Camp at km 31 on 2800 Road. Secondary roads from the 2200, 2800, and 2900 roads provide access to the claim blocks. A considerable portion of the blocks are only accessible by foot. The Hungry Block of the Stobart project is subject to road access restrictions along the 3100 Road during migration periods in the fall of the year.

From Williams Lake the property is accessible via Highway 20 to Riske Creek and then southward by logging road across the Chilcoutin River. From here, access is via the 2000 Forest Access road, south and west on the 2200 Road and then southeasterly on the 2900 Road to the main showing area on the Fame property. Access from here to the area of Hungry Creek geochemical grid is by an old trail that is only suitable for 4-wheel drive vehicles.

All of the claim blocks are covered with open stands of pine, with lesser spruce and fir. Much of this area is being actively logged because of the pine beetle infestation. Underbrush is generally thin except along creeks.

Climate conditions are typical for this part of central British Columbia. The summer field season is generally warm and dry and runs from mid-April through to late October. Winters are relatively cold with moderate to significant snow accumulations. Temperatures can drop to minus 20 Celsius for extended periods.

The logistics of working in this area are good to excellent. A well established network of gravel logging roads provides access to most of the claim blocks. These roads allow for the movement of heavy equipment and supplies. Significant services are available in Williams Lake and Clinton.

The terrain on the Stobart - Fame property is moderate, with broad rolling hills that are transected by a few steep gullies. Total relief is in the order of 700 metres, varying from 1200 to 1900 metres ASL. Elevation ranges on the various blocks range from 1200 metres to 1500 metres on the northern Alex Group, 1300 metres to 1500 metres on the Gaspard and Fame Groups, 1500 metres to 1900 metres on the Hungry Group and 1400 metres to 1800 metres on the West Group. There are a few creeks, some of which are ephemeral, and one rare small lake on the property

## HISTORY:

The Fame claims and surrounding Stobart property have a long exploration history dating back to 1986 when B.K. Bowen discovered a gold-bearing alteration zone within a logging road cut (Discovery Zone). Follow-up exploration by Bowen and his partner in 1987 resulted in the discovery of additional mineralized zones. Grab samples of altered andesite from the Discovery Zone collected in 1987 returned values up to 1.02 opt Au and 5.83 opt Ag (Bowen, 1988).

In February, 1988, Canamax Resources Inc. optioned the Fame property and staked an additional 420 units in 22 claims. During 1988, the company completed a program of 1:20000 mapping over the entire property and mapping at a scale of 1:5000 over selected areas. This work resulted in the discovery of the Kelsch Zone. In addition the company completed a program of hand and excavator trenching on the Discovery, Kelsch, Double Diamond and Gas 1 showings, soil sampling on 3 detailed grids and 702 metres of diamond drilling in 9 holes on the Discovery and Kelsch Zones. Drilling on the Discovery Zone confirmed the presence of mineralized quartz veining at depth except that gold values were lower. Drilling on the Kelsch Zone failed to reach the planned target (Harris, 1988). In March, 1999, Canamax returned the property to the owners.

In 1989 the property owners completed a program of prospecting over an area of 30 square kilometres (Bowen, 1989). They also did reconnaissance soil sampling and an air photo interpretation study. This work resulted in the discovery of the Twilight Zone located approximately 700 metres southwest of the Discovery Zone. Samples collected from this new discovery in 1989 returned values up to 1860 ppb Au across 0.7 metres.

In 1990 they optioned the property to Goldsmith Minerals Limited. The company proceeded to conduct VLF, EM surveys on three grids covering the Fame showings, Gas 1, 9 and 18 areas (Cartwright and Petersen, 1990). This work revealed high resistivity zones in each of these areas that were thought to be indicative of the presence of quartz veins or silicified zones. Goldsmith subsequently drilled 6 NQ diamond drill holes totaling 817.9 metres to test resistivity anomalies on the Twilight, Discovery, Kelsch and Gas 18 grids (Petersen, 1990). This included two holes on the Twilight Zone that intersected epithermal quartz veining. Goldsmith then completed a two hole, 175.3 metre reverse circulation drilling program on the Twilight Zone (Bowen, 1991). These holes returned results similar to those obtained in the diamond drill holes. Goldsmith subsequently terminated its option on the property.

The entire property was allowed to lapse. The main showing areas were acquired by L.J. Caron in May, 1998. Peatfield (1999) completed a small prospecting and sampling program over these claims. These claims were forfeited during 2000 and 2001 and subsequently acquired by the present property vendors.

The north central part of the Stobart Group was explored in 1992 as the Ham Claims (Meyers, 1993). Prospecting discovered a 0.4m to 1.37m wide quartz vein within a well defined structural break. Assay results returned values up to 0.165 oz/ton gold over 1.37 metres. This showing was examined during the 2007 exploration program.

Appleton Exploration Inc. completed a preliminary evaluation of the Stobart Group in 2006 through a program of road soil sampling and follow-up coarse grid geochemistry and limited prospecting and bedrock sampling (Henneberry, 2007). Spot gold-in-soil anomalies were located on each of the grids.

## **GEOLOGICAL SETTING:**

(Summarized from MINFILE 092O, Green and Trupia, 1989).

The Spences Bridge Gold Belt lies within the Intermontane Tectonic Belt of Central British Columbia, proximal to its western boundary with the Coast Plutonic Belt. The Intermontane Belt is a region of relatively low topographic and structural relief, while the Coast Plutonic Belt is a region of high topographic and structural relief. The regional map (Figure 3) also shows small elements of Insular Belt to the extreme southwest and the Omenica Belt to the extreme northeast. The elements of these two belts have no relevance to the Spences Bridge Gold Belt and will be described no further.

The two primary belts are further divided into nine lithographic terranes in the map area: Coast Complex, Harrison, Cadwallader, Bridge River, Shuksan, Methow, Stikinia, Cache Creek and Quesnellia respectively from west to east. Each terrane is bounded by major faults.

The Harrison and Coast Complex terranes are not directly relevant to the Spences Bridge Group and its mineralization.

The Cadwallader Terrane lies to the west of the northern outliers of the Spences Bridge Group. It comprises a series of Cretaceous clastic sediments and the Powell River Group volcanoclastics. The Bridge River Terrane consists of Mississippian to middle Jurassic marine sedimentary and volcanic rocks. The Shuksan Terrane consists primarily of Cretaceous intrusives and high grade metamorphic rocks.

The Methow Terrane forms much of the boundary between the two belts. It comprises sequences of Jurassic through to Cretaceous, predominantly fine grained, clastic sediments.

The south end of the Stikinia Terrane includes Cretaceous clastic sediments and a series of Jurassic through to Cretaceous intrusives.

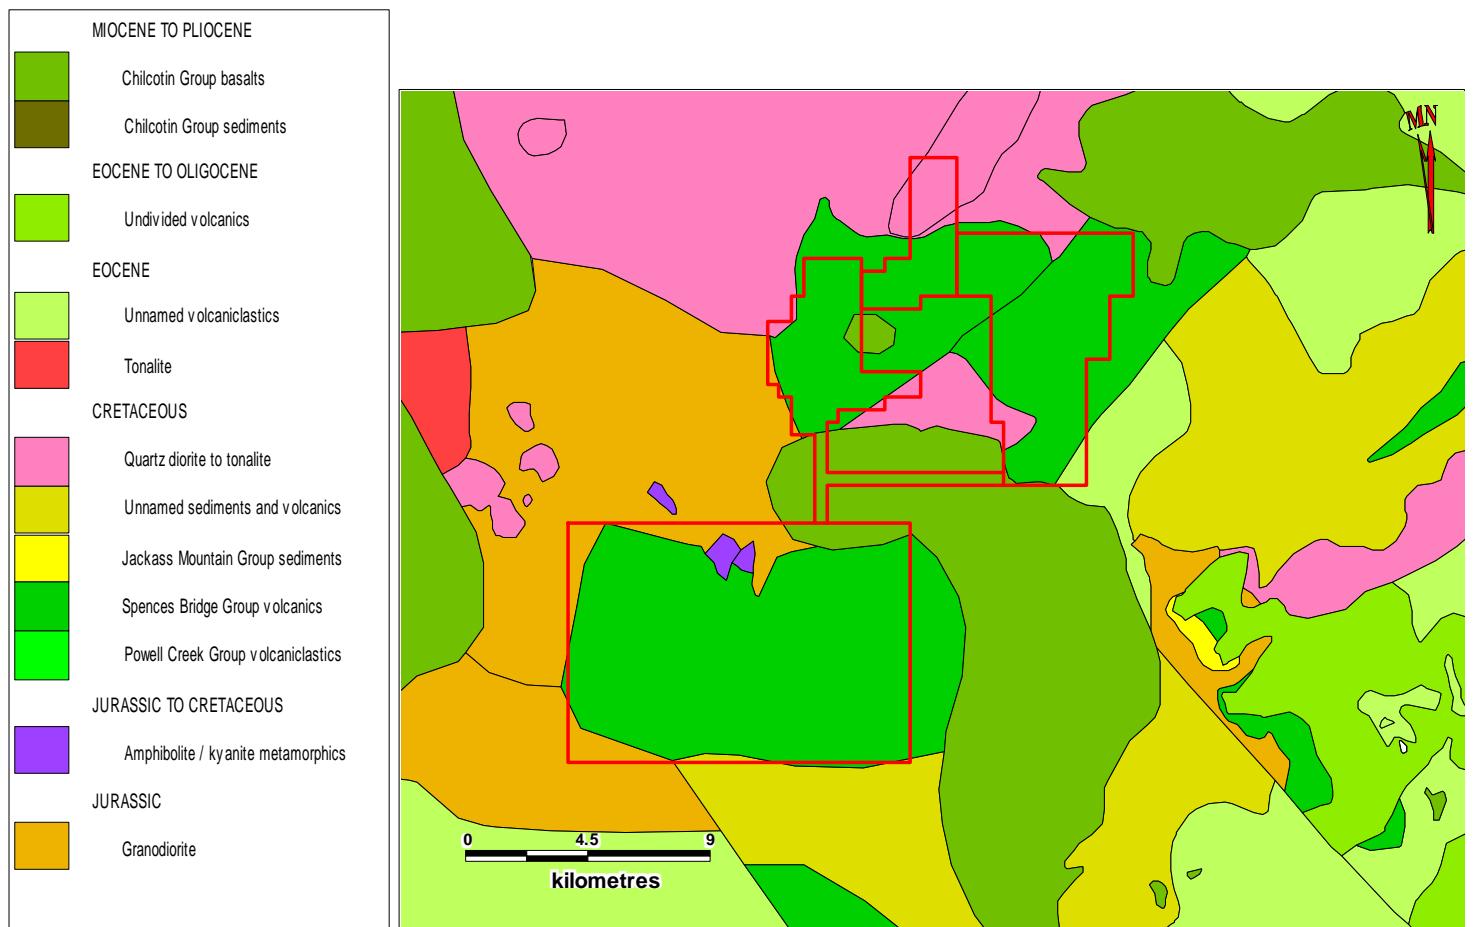

Figure 3: Regional Geology

The geology of the Cache Creek Terrane is complex with units ranging in age from Pennsylvanian to middle Jurassic. The rocks include a melange of Permian to Pennsylvanian carbonates with minor clastic sediments and volcanics in the eastern and central sections and a series of Permian to middle Jurassic clastic sediments with minor carbonates and volcaniclastics in the west.

The Quesnella Terrane consists primarily of the upper Triassic Nicola Group clastic sediments, and volcanic rocks with associated late Triassic - early Jurassic intrusions. The most important is the Guichon Creek Batholith, host to the Highland Valley copper deposits.

The Methow, Stikinia, Cache Creek and Quesnellia Terranes through much of the map area are covered by Cretaceous and/or Tertiary sedimentary and volcanic overlap assemblages. These include Miocene - Pliocene plateau basalts and coarse clastic sediments of the Chilcotin Group, Eocene to Oligocene volcanics and Eocene basalt and andesite, local rhyolite, breccia, tuff and sandstone thought to be related to the Kamloops Group. Spences Bridge Group flows and volcaniclastics occur as a series of outliers through the lower end of the Stikinia Terrane in the north and as a large belt within the Quesnellia Terrane in the south.

The middle to upper Cretaceous Spences Bridge Group has recently been identified as a significant target for epithermal precious metal mineralization. This group forms a northwest trending volcanic belt consisting of a thick sequence of gently folded volcanics with lesser sediments, dipping shallowly to the northeast. Rocks of the Spences Bridge Group are believed to have formed as a chain of stratovolcanoes associated with subsiding, fault-bounded basins (Thorkelson, 1985).

### **Geology of the Spences Bridge Group:**

The Spences Bridge Group (Figure 4) forms a northwest trending belt from 3 to 24 kilometres wide and up to 3400 metres thick from north of Princeton through to east of Lillooett (Duffel and McTaggart, 1952). A faulted extension of the belt lies in the Churn Creek/Empire Valley area west of 100 Mile House (Thorkelson, 2006).

The Spences Bridge Group as described by Thorkelson (2006) is thought to be the volcanic representation of the closure of the oceanic basin between Wrangellia to the west and the assemblage of intermontane terranes (the accreted part of ancestral North America) to the east. Spences Bridge rocks were deposited on two main basement types: west of the Village of Spences Bridge, they overlie the mainly Paleozoic Cache Creek terrane; to the east, they overlie plutonic and volcanic rocks of the late Triassic Nicola Arc, part of the Quesnellia terrane.

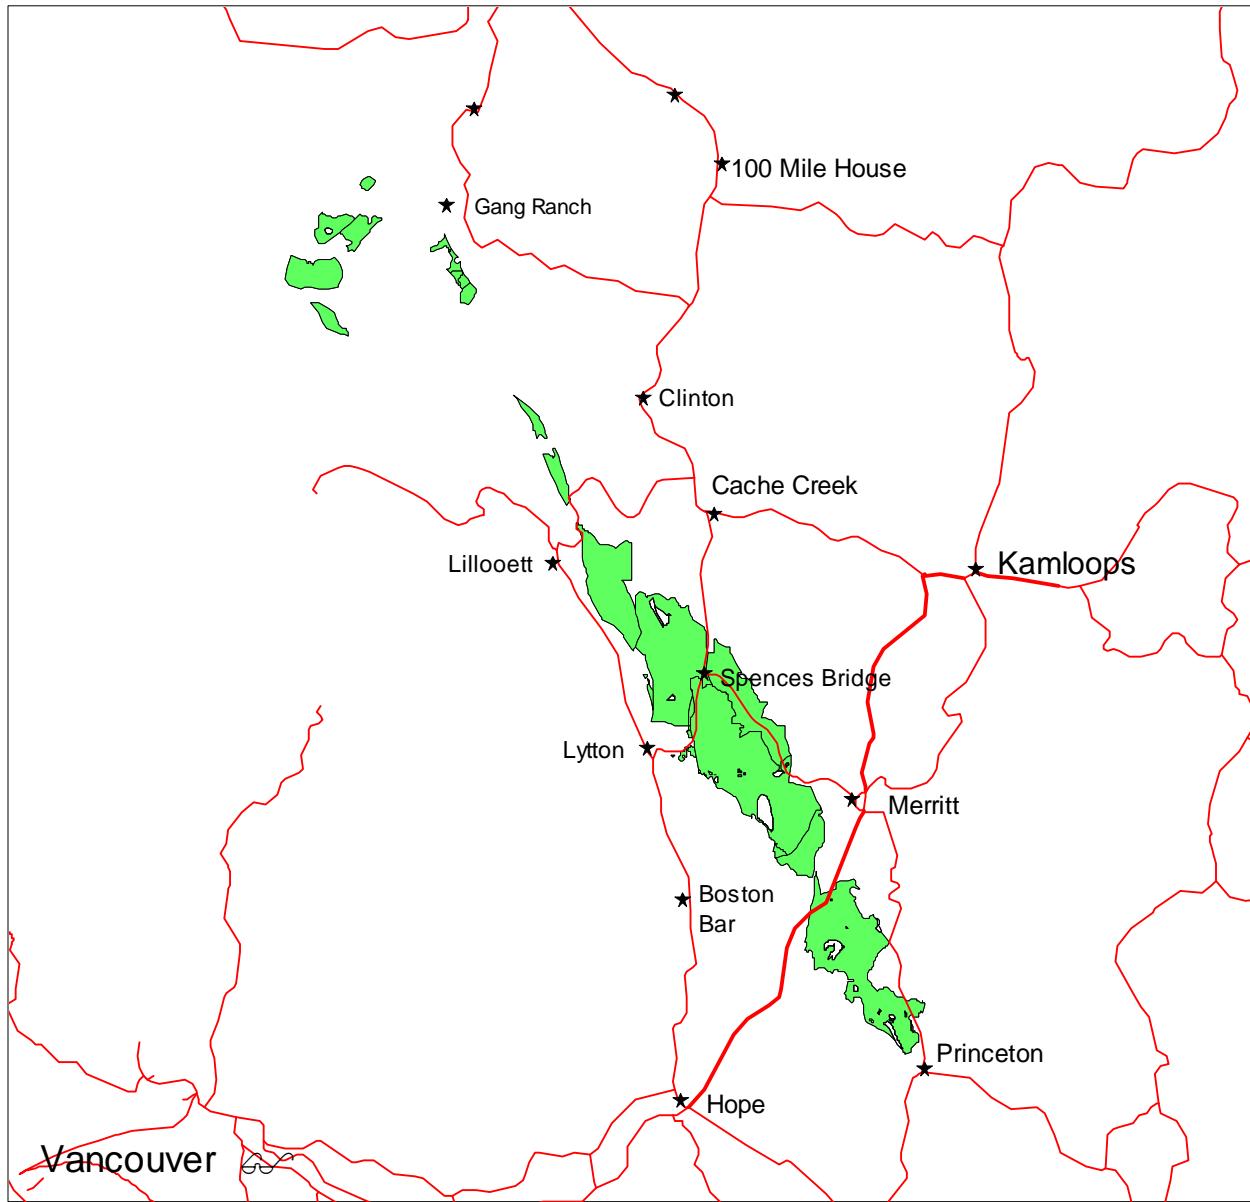

FIGURE 4: Distribution of the Spences Bridge Group

Shortly after eruption of the Spences Bridge Group began, tectonism led to the deposition of a near-basal conglomerate that contains clasts of Triassic granitoids and Nicola volcanic rocks. These rocks commonly show foliations and lower greenschist metamorphism which are not evident in the Spences Bridge Group, suggesting Spences Bridge rocks were deposited on the basement after deposition of the Nicola Group, deformation and metamorphism, and exhumation.

The Spences Bridge Group consists of two formations: The Pimainus Formation and the overlying Spius Formation. The Pimainus Formation is highly variable, containing lava, tephra, fanglomerate, lahar, sandstone, and coal. Volcanic compositions range from basalt to rhyolite. It is most reasonably thought of as a stratovolcano assemblage. The overlying Spius Formation consists almost entirely of amygdaloidal andesitic lava, ranging from pahoehoe to aa types. In some places, the contact is conformable and hard to identify, while in others, lacustrine beds separate two formations.

The Spences Bridge Group is preserved in the Nicoamen structural depression, a complex synclinorium crosscut by normal faults. This synclinorium may have been forming at the same time as the Spences Bridge Group. Presently, the Spius Formation is largely confined to the centre of the structural depression but appears to be the relic of an extensive shield volcano with a few cinder cones.

Structurally, the Spences Bridge Group is generally gently folded, with dips from  $10^{\circ}$  to  $40^{\circ}$ . Individual flows and beds do not appear to be widespread. There appears to be some faulting within the group but the lack of marker horizons makes measurement of any displacement difficult (Duffel and McTaggart, 1952).

### **Property Geology:**

The author spent one day and a portion of another mapping in the vicinity of Kelsch - Twilight Zone area. This area is primarily underlain by andesite interpreted by the author to belong to the Spius Formation of the Cretaceous Spences Bridge Group. Locally, some outcrops of volcaniclastic rocks are present (Figure 5).

Andesitic rocks are typically light green to grey weathering and varies from dark green to maroon to grey in colour. These rocks are generally massive and aphanitic to very fine-grained. Locally, the rock is porphyritic. Near known mineralized showings the rock is moderately fractured, sheared and brecciated and contains varying amounts of quartz stringers. Some vesicular andesite was observed in float but was not observed in outcrop.

Volcaniclastic rocks are grey weathering, grey, fine-grained tuffs that are fresh appearing and in places are porous and vuggy.

In the vicinity of the Discovery Zone there is an old quarry that is underlain by a tuff unit. This rock is buff to creamy white weathering and colour. It is very fine-grained with a bleached appearance. It contains moderate to strong pervasive clay and silica alteration.

Andesite is the main rock type in Hungry grid area on the Stobart property. It is very similar to rocks on the Fame claims. This area contains a network of north-south trending quartz veins that vary in thickness from a few centimetres to in excess of 1.0 metre and attains lengths up to 70 metres. Andesite adjacent to these veins exhibits varying degrees of alteration and is commonly sheared or foliated.

## **DEPOSIT TYPES:**

The Stobart property is being explored for low sulphidation epithermal precious metals deposits. The following summary is condensed from British Columbia Ore Deposit Models (Panteleyev, 1996).

Low sulphidation epithermal deposits are typically hosted in volcanic island and continent-margin arcs and continental volcanic fields with extensional structures. These deposits can form in most types of volcanic rocks, though calc-alkaline andesitic compositions predominate. Low sulphidation deposits can be any age. While Tertiary deposits are the most abundant, deposits of Jurassic age such as those in the Toodoggone region of British Columbia are also important.

Ore zones are typically localized in structures, but may occur in permeable lithologies. Upward-flaring ore zones centred on structurally controlled hydrothermal conduits are typical. Large (> 1 m wide and hundreds of metres in strike length) to small veins and stockworks are common with lesser disseminations and replacements. Vein systems can be laterally extensive but ore shoots have relatively restricted vertical extent. High-grade ores are commonly found in dilational zones in faults at flexures, splays and in cymoid loops.

In some districts the epithermal mineralization is tied to a specific metallogenic event, either structural, magmatic, or both. The veins are emplaced within a restricted stratigraphic interval generally within 1 km of the paleosurface. Mineralization near surface takes place in hot-spring systems, or the deeper underlying hydrothermal conduits. Normal faults, margins of grabens, coarse clastic caldera moat-fill units, radial and ring dike fracture sets and both hydrothermal and tectonic breccias are all ore fluid channeling structures. Through-going, branching, bifurcating, anastomosing and intersecting fracture systems are commonly mineralized. Hanging wall fractures in mineralized structures are particularly favourable for high-grade ore.

Veins are comprised of quartz, amethyst, chalcedony, quartz pseudomorphs after calcite, and calcite. They may contain lesser amounts of adularia, sericite, barite, fluorite, Ca-Mg-Mg-Fe carbonate minerals such as rhodochrosite, hematite and chlorite. Veins commonly exhibit open-space filling, symmetrical and other layering, crustification, comb structure, colloform banding and multiple brecciation.

Mineralization within the veins consists of pyrite, electrum, gold, silver and argentite, with lesser chalcopyrite, sphalerite, galena, tetrahedrite, silver sulphosalt and/or selenide minerals. Deposits can be strongly zoned both along strike and vertically. Deposits are commonly zoned vertically over 250 to 350 m from a base metal poor, Au-Ag-rich top to a relatively Ag-rich base metal zone and an underlying base metal rich zone grading at depth into a sparse base metal, pyritic zone. From surface to depth, metal zones contain: Au-Ag-As-Sb-Hg, Au-Ag-Pb-Zn-Cu, Ag-Pb-Zn.

Alteration is important in low sulphidation epithermal deposits. Silicification is extensive in ores as multiple generations of quartz and chalcedony are commonly accompanied by adularia and calcite. Pervasive silicification in vein envelopes is flanked by sericite-illite-kaolinite assemblages. Intermediate argillic alteration [kaolinite-illite-montmorillonite (smectite)] formed adjacent to some veins; advanced argillic alteration (kaolinite-alunite) may form along the tops of mineralized zones. Propylitic alteration dominates at depth and peripherally.

Prospecting for mineralized siliceous and silica-carbonate float or vein material with diagnostic open-space textures is an effective exploration method. VLF can be effective in tracing structure, while radiometric surveys may outline strong potassic alteration of wallrocks. Geochemical sampling is also an effective exploration method with elevated values in the ore metals: Au, Ag, Zn, Pb, Cu as well as elevated values for pathfinder elements: As, Sb, Ba, F, Mn and locally Te, Se and Hg. Finally, silver deposits generally have higher base metal contents and Au and Au-Ag deposits.

## **MINERALIZATION:**

Mineralization on the Fame claims was first discovered in 1986 in a road cut. Four areas have been defined: the Discovery Zone, Double Diamond Zone, Kelsch Zone and Twilight Zone. These mineralized areas occur along a northeast-southwest trend approximately 900 metres long (Figure 6). All exhibit similar morphologies.

At the Discovery Zone mineralization has been exposed in outcrop, angular float and surface trenching over an area measuring 100-200 metres wide and approximately 400 metres long. Brecciated quartz veins 3 millimeters to 20 centimetres wide and trending south-southeast occur in altered andesite (Harris, 1988). Adjacent to the veins the andesite has been moderately to strongly kaolinized. In places the kaolinized rock has been mineralized. Sampling by previous owners have returned values from 1 ppb Au to 31.7 grams per tonne (gpt) Au and 2 ppm Ag to 181.3 gpt Ag in grab samples (Bowen, 1988). Resampling of this zone by Peatfield (1999) returned a range of values from 101-13000 ppb Au and 1.0-104 ppm Ag.

**Table 2. Selected Historical Fame Sampling Results**

Sample Number	Report Number	Sample Location	Description	ppb Au	ppm Ag
98-02	AR #25983	Discovery area (east)	Vuggy quartz vein float	2130	3.4

Mineralization consisting of abundant quartz veinlets within a strong to very strong silicified and brecciated andesitic unit is exposed in a small trench near the bottom of a relatively steep slope on the north side of a northeast-southwest trending draw. This is the Double Diamond Zone. It is located approximately 400 metres east of the Discovery Zone. Moderate amounts of chalcedony are also present. This rock may have originally contained minor amounts of sulphides that have now been altered to hematite. Samples collected by previous owners returned values ranging from 30-50 ppb Au. Grab samples collected by Appleton personnel in 2006 returned similar results (35-160 ppb Au). Prior to 2007 this zone had only been partially tested by a single diamond drill hole.

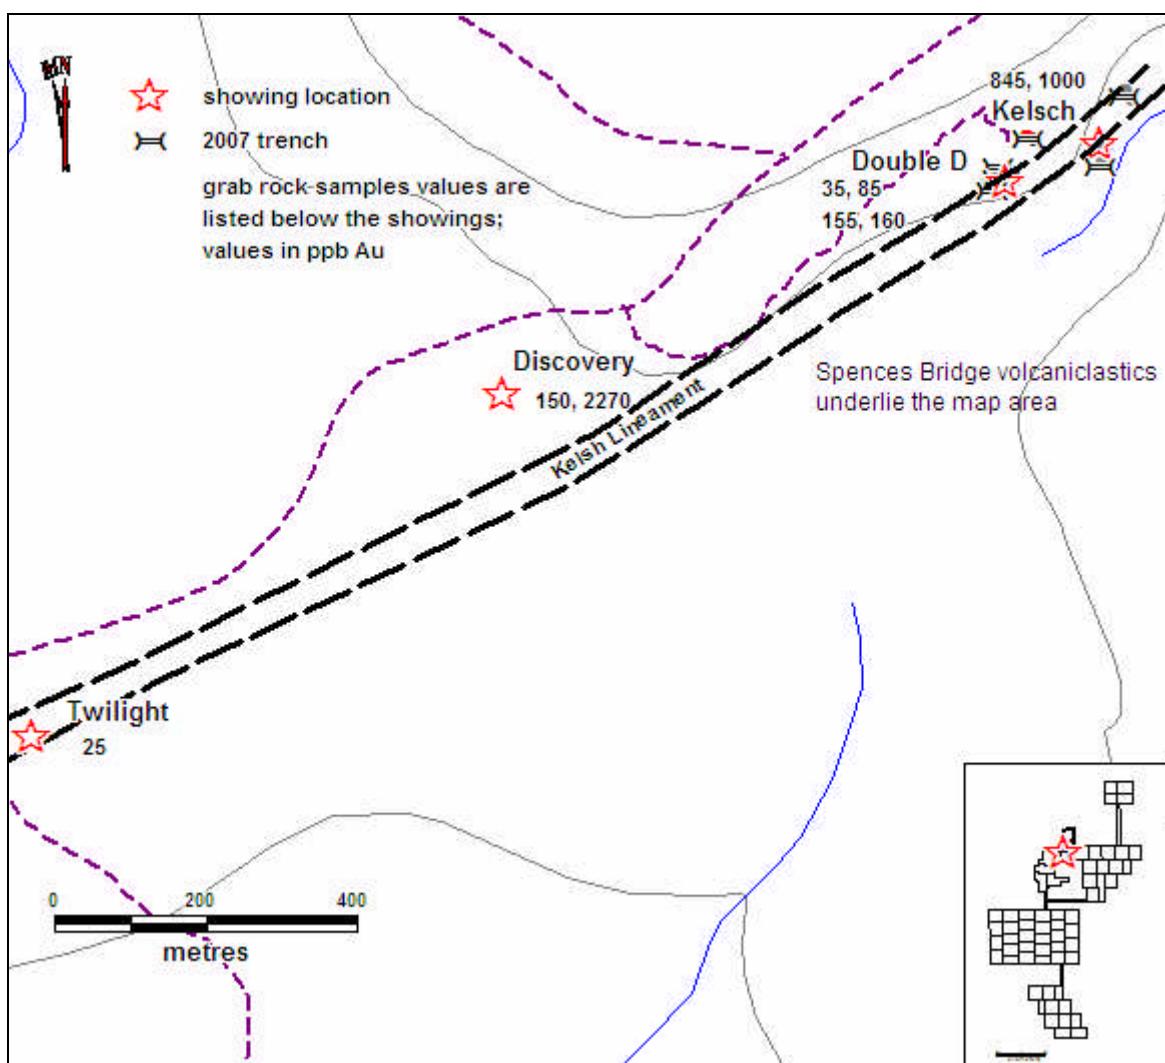

FIGURE 6: Mineralized Zones-Fame Property.

At the Kelsch Zone intensely altered rock is exposed in one main trench approximately 3 metres long and several short cross-cutting trenches. The rock contains very strong to intense pervasive silicification and contains abundant quartz stringers and veinlets. It was possibly originally an andesite. The rock is also brecciated, in part vuggy and contains moderate to relatively abundant chalcedony. Two grab samples collected by the author in 2007 returned values of 0.845 g/t Au and 1.65 g/t Au. A single diamond drill hole previously drilled in this area failed to reach its projected target.

At the Twilight Zone, very strongly silicified andesitic or pyroclastic rock is exposed in outcrop over an area of 2 by 4 metres. Abundant chalcedony is also present. A grab sample collected by Appleton personnel in 2006 returned a value of 25 ppb Au. Sampling by previous owners returned several values in excess of 400 ppb Au (Bowen, 1989).

This zone has been drill tested by both diamond drilling (2 holes) and reverse circulation drilling (2 holes). Both of the diamond drill holes intersected epithermal quartz veining (Petersen, 1990). Hole 90-2 contained 3 short intervals containing anomalous gold values: 31-32 metres @ 660 ppb Au, 57-58 metres @ 890 ppb Au and 79-80 metres @ 410 ppb Au. Drill hole 90-1 was intensely fractured and faulted. The reverse circulation substantiated the presence of gold that was obtained in the diamond drill program.

On the Stobart property, south of Hungry Lake, a set of north-northeasterly trending quartz veins have intruded andesite. These veins vary in thickness from a few centimetres to in excess of 1 metre and have been traced over lengths varying from a few metres to in excess of 60 metres. The original Hamm vein, discovered in 1992 returned gold values from 5 to 5031 ppb Au (Table 3). One metre chip sampling in 2007 at 4 separate localities along strike returned values of 380, <5, 380 and 1480 ppb Au from southwest to northeast. An additional sample 120 metres to the south returned a value of 1040 ppb Au from a vein that may represent the faulted southern extension of the Hamm vein. Another vein located 150 metres northwest of the Hamm vein is 1 metre wide and 15 metres long. Samples collected from this vein across 1 metre intervals returned values of 880 and 1180 ppb Au (Figure 7, Table 6).

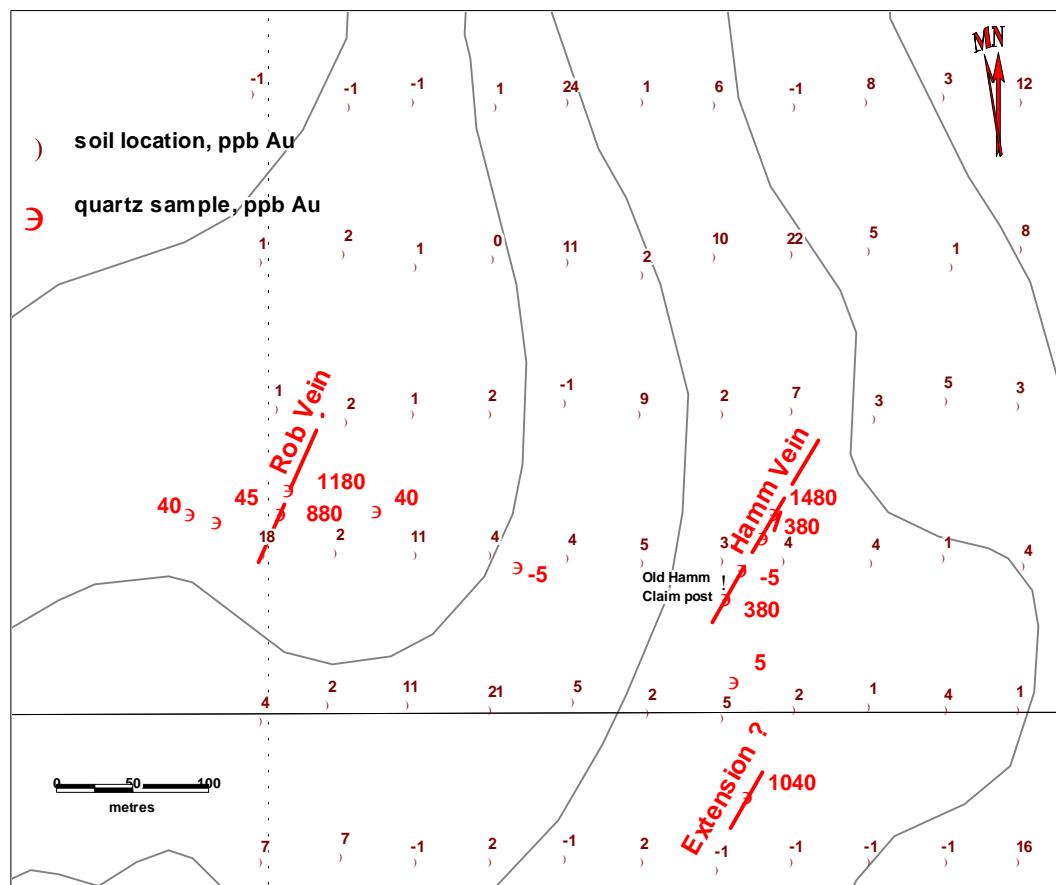

Figure 7. Hamm Grid Vein Sampling

**Table 3. Selected Historical Stobart Sampling Results**

Sample Number	Report Number	Sample Location	Description	ppb Au	ppm Ag
69851	AR #23040	Hamm vein trenches	Vuggy milky quartz	933	-0.2
69852	AR #23040	Hamm vein trenches	Glassy rusty quartz	715	-0.2
69857	AR #23040	Hamm vein trenches	Vuggy rusty quartz	5031	14.6
41157	2007 Appleton	Hamm vein trenches	Epithermal vein material	1480	6.6
41158	2007 Appleton	Hamm vein trenches	Epithermal vein material	380	2.3
41155	2007 Appleton	Hamm vein trenches	Epithermal vein material	5	-0.2
41161	2007 Appleton	Hamm vein trenches	Epithermal vein material	380	4.0
41159	2007 Appleton	Hamm vein extension	Epithermal vein material	1040	0.5
41164	2007 Appleton	Rob Vein	Epithermal vein material	1180	4.0
41165	2007 Appleton	Rob Vein	Epithermal vein material	880	2.0

Elsewhere on the Stobart property, a 170 by 50 metre strong kaolinized area is present in granodiorite (GAS 1). Trace amounts of disseminated pyrite containing an average of 333 ppb Au is present in this rock (Harris, 1988). Petrographic work done on specimens from this locality suggest the presence of alunite - a mineral that is characteristic of low sulphidation gold deposits.

## **EXPLORATION:**

Appleton Exploration Inc. completed exploration programs on the Fame and Stobart Groups in 2007. Fame exploration consisted of geological mapping in the Kelsch - Twilight Zone area, soil geochemistry over the Double Diamond and Kelsch Zones and excavator trenching in the vicinity of the Double Diamond and Kelsch Zones. Stobart exploration consisted of prospecting and soil geochemistry in the Hungry Creek (Hamm Grid) area. This work was done intermittently during the period August 23 to October 31, 2007. Results of the geological mapping and prospecting have been described in the sections Property Geology and Mineralization respectively.

A total of 93 linear metres of excavating in 8 trenches was completed in the vicinity of the Double Diamond and Kelsch Zones (Figure 7). This work was done utilizing a very small portable excavator (Plate 1). Of these, three trenches (FM-07-1, 07 and 08) adjacent to the Kelsch Zone failed to reach bedrock. Five trenches were excavated near the Double Diamond Zone. Analytical results for gold and silver values in these trenches are summarized in Table 3. A complete description of the analytical data for the trenching is given in Appendix 3. Short intervals containing significant amounts of gold were obtained in trenches FM-07-04 and FM-07-06. Trench FM-07-04 returned a continuous 4 metre sample interval of 0.400 g/t Au, including a 1 metre interval of 0.675 g/t Au; trench FM-07-06 returned a continuous 5 metre interval of 0.460 g/t Au, including a 1 metre interval of 0.810 g/t Au. Trench FM-07-04 is located above the main Double Diamond Zone and trench FM-07-06 is located along strike to the east.

**Table 4. Fame Trenching Results**

Trench	Zone	Length m	% bedrock	Au range	Zone gpt Au/m
FM-07-01	Kelsch	16	0%	no bedrock	
FM-07-02	Double D	13	69%	5 ppb to 15 ppb	
FM-07-03	Double D	13	62%	15 ppb to 0.195 gpt	0.195/1
FM-07-04	Double D	14	64%	15 ppb to 0.675 gpt	0.400/4
FM-07-05	Double D	11	45%	5 ppb to 95 gpt	
FM-07-06	Double D	14	86%	4 ppb to 0.81 gpt	0.460/5
FM-07-07	Kelsch	6	0%	no bedrock	
FM-07-08	Kelsch	5.5	0%	no bedrock	

Approximately 100 soil samples were collected on the Kelsch Grid. Samples were collected at 20 metre intervals along east-west trending lines spaced at 100 metre intervals. Analytical results are summarized in Appendix 2. With the exception of few spot highs, gold values were generally low (Figure 8).

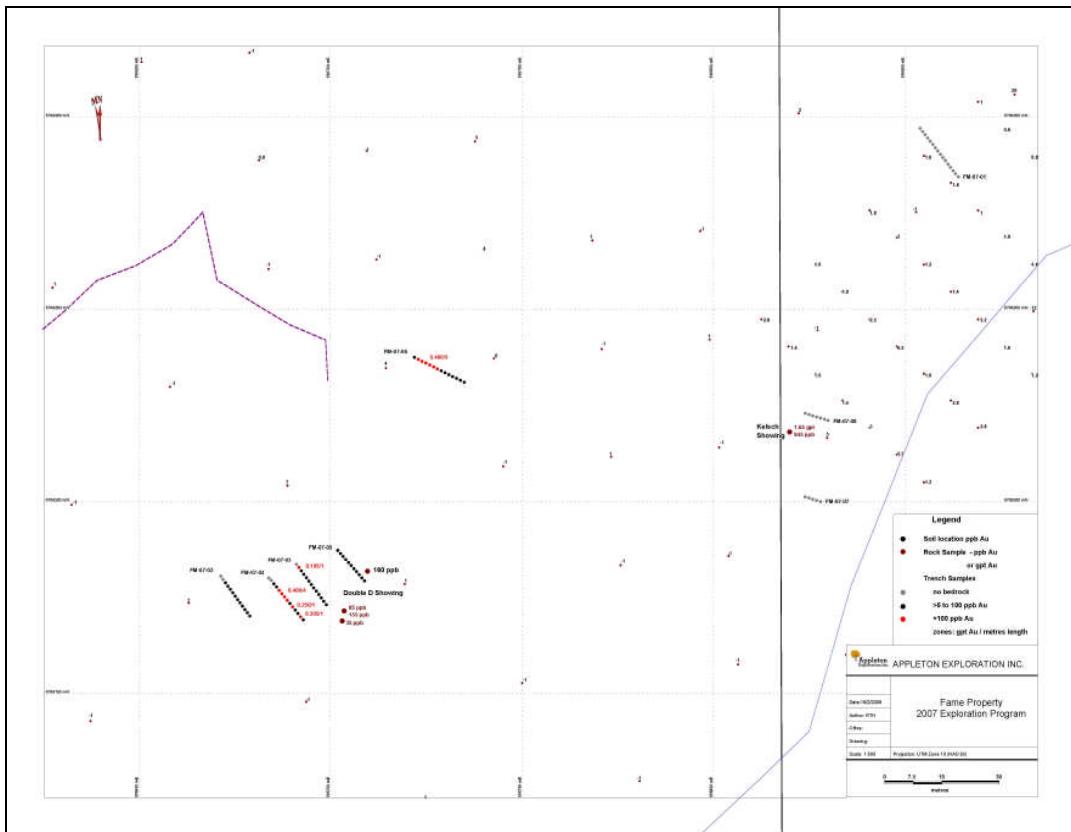

FIGURE 8: Trench locations and Kelsch Soil Grid (Full size in pocket)

PLATE 1: Trenching on the Fame claims

In the Hungry Creek area (Hamm Grid), approximately 450 soil samples were collected. Samples were collected at 50 metre intervals along east-west trending lines spaced at 100 metre intervals. Analytical results are tabulated in Appendix 3 and the distribution of gold values is shown in Figure 9. A large proportion of this grid was located outside of the area where quartz veining was observed in outcrop. Analytical results indicate the presence of a series of north-northeast trending gold anomalies that parallel the orientation of quartz veins observed in outcrop. Anomalous gold values range from 14-120 ppb Au. These anomalies are most abundant in the northwest corner of the grid where quartz veining has been observed.

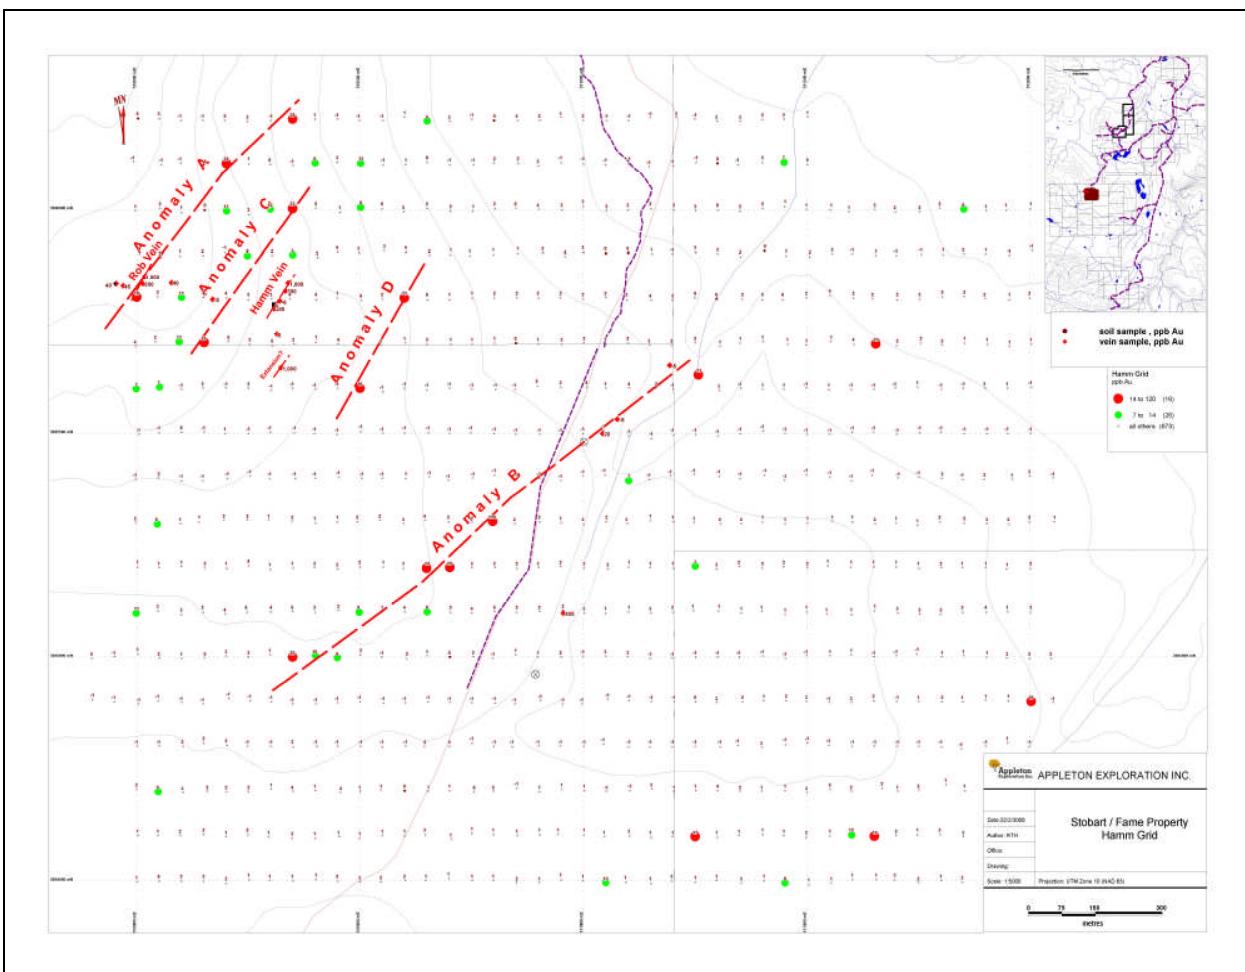

FIGURE 9: Gold geochemistry-Hamm Grid- Hungry Creek area. (Full size in pocket)

## **DRILLING:**

To date, Appleton Exploration has not done any drilling on the Stobart - Fame property. There has been historical drilling done on the property by Canamax in 1988 (Harris, 1988) and by Goldsmith Minerals in 1990 and 1991 (Peterson, 1990 and Bowen, 1991). These holes are summarized in Table 2.

**TABLE 5: Summary of Historical Drilling**

Reference	Size	NQ Metres	RC Metres	Discovery	Kelsch	Double Diamond	Twilight	Gas 18	Range of Results
Harris (1988)	NQ	602		8 holes					5 to 1160 ppb Au
Harris (1988)	NQ	110			1 hole				Short
Peterson (1990)	NQ	124.1		1 hole					1 to 120 ppb Au
Peterson (1990)	NQ	99.7			1 hole				1 to 410 ppb Au
Peterson (1990)	NQ	177.5				1 hole			1 to 12 ppb Au
Peterson (1990)	NQ	263.5					2 holes		1 to 890 ppb Au
Peterson (1990)	NQ	153.1						1 hole	Not assayed
Bowen (1991)	RC		175.3				2 holes		1 to 980 ppb Au
		1529.9	175.3	9 holes	2 holes	1 hole	2 holes	1 hole	

Appleton personnel have been unable to locate any of the drill hole locations. Most of the core has been vandalized and dumped making re-logging and re-sampling impossible. Many of these holes appear to not have adequately tested the downdip extensions of observed surface mineralization.

## **SAMPLE METHOD AND APPROACH:**

The sampling procedure for the soil samples were briefly mentioned in the exploration section. Each soil line was flagged and sampled at 20 metre intervals along the line on the Kelsch grid and at 50 metre intervals on the Hungry grid. Soil bags and tyvex tags were pre-numbered the day before. At each sample location a 500 to 1000 gram sample of the soil from the "B" horizon was taken and placed in the corresponding soil bag. The location was marked as a waypoint on either a Garmin 72 unit. The waypoint was also recorded in a field notebook at the corresponding sample location as back-up. Details on soil color and proximal rock outcrop were also recorded. The GPS data was downloaded daily into an Excel spreadsheet. The corresponding sample number and the soil color and proximal outcrop were also entered.

Rock samples were taken from areas of interest. 1-3 kilograms of rock were placed in a poly sample bag with a sequentially numbered assay ticket. The bag was then sealed with twist ties or flagging tape for transport to the lab. The sample location was recorded in a GPS unit, which was downloaded into a laptop computer on a nightly basis. Each sample location was flagged with the sample number, sampler and date.

Rock trench samples were taken by first cleaning the bottom of the excavator trench with a heavy duty leaf blower or broom. Continuous 1 metre intervals were painted on the bedrock and samples were taking in continuous chips over the one metre interval.

All soil, rock and rock trench samples were taken by 665777 B.C. Ltd. personnel under the supervision of the author. The samples were delivered to the laboratory by Appleton personnel.

## **SAMPLE PREPARATION, ANALYSES, AND SECURITY:**

All soil and rock samples were taken and immediately placed in sealed sample bags. The sample location was written on the outside of the kraft soil bag for soil samples. A pre-numbered assay ticket was placed in each poly sample bag for rock samples, with the corresponding part of the ticket filled out with date, time and location. Flagging was used to mark the sample locations, except for the excavator trenches were intervals were marked in spray paint directly on the bedrock. A fix of the position was obtained by a Garmin 72 Global Positioning System unit set to record NAD 83 coordinates for the soil samples.

All samples were sorted by number, bagged and delivered to Eco Tech Laboratory Ltd. In Kamloops, British Columbia, by Appleton personnel.

Eco Tech's sample preparation procedures are described below. Samples are first catalogued and dried. They are then prepared as follows:

Soils: Soils are prepared by sieving through an 80 mesh screen to obtain a minus 80 mesh fraction. Samples unable to produce adequate minus 80 mesh material area screened at a coarser fraction. These samples are flagged with the relevant mesh.

Silts: Stream silts are prepared by sieving through an 80 mesh screen to obtain a minus 80 mesh fraction. Samples unable to produce adequate minus 80 mesh material are screened at a coarser fraction. These samples are flagged with the relevant mesh. The entire sample of the stream heavies is used for analysis.

Rocks: Rock samples are two stage crushed to minus 10 mesh and a 250 gram sub-sample is pulverized on a ring mill pulverizer to -140 mesh. The sub-sample is rolled, homogenized and bagged in a pre-numbered bag.

Samples for gold geochemical analysis are weighed to 30 grams and fused along with proper fluxing materials. The bead is digested in aqua regia and analyzed on an atomic absorption instrument. Over-range values for rocks are re-analyzed using gold assay methods.

Appropriate reference materials accompany the samples through the process allowing for quality control assessment. Results are entered and printed along with quality control data (repeats and standards). The data is faxed and/or mailed to the client.

For multi element IcP analysis, a 0.5 gram sample is digested with 3 ml of a 3:1:2 (HCl:HN03:H2O) which contains beryllium which acts as an internal standard for 90 minutes in a water bath at 95<sup>0</sup>C. The sample is then diluted to 10 ml with water. The sample is analyzed on a Jarrell Ash ICP unit.

Results are collated by computer and are printed along with accompany quality control data (repeats and standards). Results are printed on a laser printer and are faxed and/or mailed to the client.

## **DATA VERIFICATION:**

The quality control measures for the 2007 exploration program on the Stobart - Fame property consists of resplits, rechecks and standards. Eco Tech runs three quality control measures. First they insert standards in to the sample stream. Second, they complete a repeat analysis on every tenth sample. Thirdly, they complete a resplit and analysis on every 25<sup>th</sup> sample. The author feels this was a sufficient quality control measure.

To establish further confidence in the results standards were obtained from CDN Resources Laboratories Ltd. of Delta, B.C. Three standards were obtained: P1-100 ppb Au, P3-300 ppb Au and P5-500 ppb Au. The standards were placed in small Ziploc bags within kraft soil sample bags. The sample bags was given the same coordinates as one of the samples along the soil line, but also identified as "B" sample. These were then inserted into the sample strings and submitted to the lab at an interval of approximately 1 standard for every 20 samples. Standards were also submitted at an approximate interval of 1 to 20 for the rock and excavator trench sampling as well.

The assay results from the standards appear to show good reproducibility. The 100 ppb Au standard assayed at 115 ppb to 150 ppb. The 300 ppb Au standard assayed at 315 ppb to 350 ppb. The 500 ppb Au standard assayed at 520 ppb to 590 ppb.

The author feels confidence in the assay results from Eco Tech Laboratories Ltd. based on the labs in house resplits, rechecks and standards and also based on the CDN standards submitted with the sample stream.

### **ADJACENT PROPERTIES:**

This technical report is not relying on data from adjacent properties.

### **MINERAL PROCESSING AND METALLURGICAL TESTING:**

There has been no mineral processing or metallurgical testing undertaken on the Stobart - Fame property.

### **MINERAL RESOURCES AND MINERAL RESERVE ESTIMATES:**

There are presently no mineral reserves or mineral resources on the Stobart - Fame property.

### **OTHER RELEVANT DATA AND INFORMATION:**

There is no additional relevant data or information known that is not disclosed on the Stobart - Fame property.

## **INTERPRETATION AND CONCLUSIONS:**

The presence of low sulphidation type epithermal deposits has been identified in at least two localities on the Stobart – Fame property. Exploration to date has only partially tested these mineralized zones. In addition, large areas of the property have only been partially explored or have not had any exploration.

### **Fame Group:**

Much of the previous exploration has concentrated on prospecting and reconnaissance geochemical sampling. Because of the paucity of outcrop in this area and the depth of overburden these techniques may not have been totally successful in locating additional mineralization. Some of the previous drilling did not adequately test known mineralized zones.

The 2007 Double Diamond excavator trenching was successful in defining zones of bedrock mineralization. Thicker than expected overburden negated the Kelsch zone trenching and is the likely explanation for the lack of soil geochemistry responses in the small grid completed over the Kelsch zone.

The previously completed diamond drilling and reverse circulation drilling clearly shows there is gold in the system associated with the Kelsch Lineament. Geochemistry is the preferred method to narrow down potential targets within the lineament. The significant overburden depths encountered during the Kelsch excavator trenching suggest conventional soil geochemistry is not the best method. A mobile metal ion (MMI) geochemical survey should be able to see through the thicker overburden and help define targets for follow up excavator trenching and diamond drilling.

### **Stobart Group:**

Initial prospecting was successful in locating the Hamm vein first sampled in 1992 and also was successful in discovering the sub-parallel Rob vein. The Hamm soil grid was also successful in identifying several sub-parallel linear anomalies that may prove to represent additional veins. Further prospecting needs to be done in this area and should continue to the northwest.

The present northwest section of the Hamm soil grid needs to be tightened from a 50m by 100m spacing to a 25m by 50m spacing. The soil grid also needs to be expanded to the northwest at the same 25m by 50m spacing.

A follow-up program of excavator trenching in advance of diamond drilling will be required to follow up on the final soil survey results.

## **RECOMMENDATIONS:**

Further work is required to fully evaluate known mineralized occurrences and to search for additional mineralization on the Stobart - Fame property.

A soil geochemistry and excavator trenching program is recommended for the Stobart – Fame property for 2008.

A small MMI soil survey is recommended for the Fame property covering the Kelsch Lineament from the Twilight showing in the southwest to the Kelsch showing in the northeast. A grid 1800 metres long by 200 metres wide will yield 198 samples at a 100 metre line by 20 metre sample interval along the line.

Conventional soil geochemistry is required to tighten the northwest corner of the Hamm Grid and also to expand the Hamm Grid to the northwest. A 1500 metre by 1500 metre grid at 50 metre line spacing and 25 metre sample spacing along the lines will cover the target area. A total of 1800 soil samples will result. Ten days of prospecting is also budgeted for the Hamm Grid.

A twenty day excavator trenching program will test the Hamm Grid gold-in-soil anomalies once they are better defined by the 2008 soil survey. A total of 180 hours of excavator time is budgeted. The program should result in approximately 250 samples.

soil geochemistry	\$130,000
excavator trenching	\$72,000
<hr/>	
Phase I total budget	\$202,000

## **CERTIFICATE OF QUALIFIED PERSON**

I, Stephen B. Butrenchuk, P. Geol., do hereby certify that:

I am the independent Qualified Person of:

Appleton Exploration Inc.  
580 – 550 Hornby Street  
Vancouver, B.C., V6C 3B6

I earned a Bachelor of Science degree majoring in geology from the University of Manitoba (1996) and a Master of Science degree in geology from the same university in 1970.

I am registered with the Association of Professional Engineers, Geologists and Geophysicists in the Province of Alberta as a Professional Geologist.

I have practiced my profession continuously for 37 years since graduation.

I have read the definition of "qualified person" set out in National Instrument 43-101 ("NI 43-101") and certify that by reason of my education, affiliation with a professional association (as defined in NI 43-101) and past relevant work experience, I fulfill the requirements to be a 'qualified person' for the purposes of NI 43-101. My relevant experience for the purpose of this Technical Report is:

- 37 years of exploration experience for base and precious metals in the Canadian Cordillera

I am responsible for the preparation of the technical report titled "Geological and Geochemical Report on the Stobart Fame Property" and dated April 26, 2008, relating to the Stobart Fame property. I completed site visits to the Stobart Fame property on August 22 -26 and November 2-4, 2007.

As of April 25, 2008, to the best of my knowledge, information and belief, the Technical Report contains all scientific and technical information that is required to be disclosed to make the Technical report not misleading.

I am independent of the issuer after applying all of the tests in section 1.4 of NI 43-101.

I have read NI 43-101 and Form 43-101F, and the Technical Report has been prepared in compliance with that instrument and form.

Dated this 25<sup>th</sup> day of April, 2008.

"signed and sealed"

---

Stephen B. Butrenchuk, P. Geol.
