1.0 SUMMARY

A rock sampling program was performed on the River Jordan Property ("Property") from August 8 to 24, 2008. The Property is owned by Silver Phoenix Resources Inc. ("Silver Phoenix"). The Property consists of seven MTO mineral claims.

The Property is located 19 km northwest of Revelstoke and covers Copeland Ridge between Copeland and Hiren Creeks as well as the Copeland Creek valley to the north.

The Property covers the River Jordan deposit, which is a metamorphic rock-hosted massive sulphide deposit. Exploration work has been carried out on the River Jordan deposit since the 1890s and has defined Pb-Zn-Ag-Ba±Cu zones. This "Shuswap-type" zinc-lead deposit can be considered as a subdivision of the larger class of clastic and carbonate hosted sedimentary exhalative deposits. The Shuswap deposits are a transitional type in that they are hosted by both clastic and carbonate rocks, often within a single deposit. The deposit consists of a sulphide layer ranging up to 6 metres in thickness within calc-silicate gneiss.

More recent work in the 1990s has defined a light-rare-earth bearing extrusive carbonatite layer beneath the massive sulphides. At the present time the carbonatite layer is only of geologic rather than economic interest.

Exploration carried out between August 8 and August 24, 2008 included minor geological mapping, and rock sampling. A systematic channel sampling program was done on all the major mineralized zones. All zones have channels with Pb-Zn-Ag mineralization and anomalous copper and gold values. Galena, sphalerite, pyrite, pyrrhotite and magnetite are the common minerals. Best intervals are:

- 9.1% Pb, 10.4% Zn and 58 g/t Ag across 3.5 m
- 3.4% Pb, 2.4% Zn and 27 g/t Ag across 5.0 m
- 15.6% Pb, 2.7% Zn and 128 g/t Ag across 1.0 m

Preliminary geological mapping visually confirmed both the general accuracy of historical mapping and the presence of a mineralized horizon on the Property.

2.0 INTRODUCTION

This assessment report has been prepared by Discovery Consultants ("Discovery"), at the request of Mr. William Murray of Silver Phoenix, the owner/operator of the Property.

Discovery was retained by Silver Phoenix to:

- Systematically rock channel sample the known mineralization to verify previous work
- Report on results of rock sampling program for assessment purposes

This report describes the 2008 rock sampling program, sampling procedures, analytical results and conclusions.

3.0 LOCATION AND ACCESS

The Property is situated within the central Monashee Mountains in south-central British Columbia. It is roughly centred at latitude 51° 07' 30" N and longitude 118° 24' 44" W within BCGS Map Sheets 82M.018 and 019 and National Topographic System (NTS) Map Sheets 082M/01W. The Property is located 19 km northwest of the town of Revelstoke, BC. Figure 1 shows the regional location of the Property.

Access to the Property can be gained via helicopter from the town of Revelstoke. A road providing access to the former Mount Copeland molybdenum mine along Hiren Creek lies within 10 km of the River Jordan Deposit. A pack trail leads off this road at Hiren Creek and proceeds up the Jordan River and Copeland Creek to the River Jordan Deposit. Both road and trail have long since fallen into disrepair.

4.0 TOPOGRAPHY

The claim area is mostly rugged mountainous landscape rising above east-west steeply walled valleys, with the majority of the claims along Copeland Ridge in alpine terrain. Elevations range from around 1,130 m in the Copeland Creek valley to in excess of 2,530 m at Mount Copeland. The Jordan River on the southeast side of the Property is at an elevation of 670 m. The claims are drained to the north and south by Copeland and Hiren Creeks, respectively. These creeks drain east into the Jordan River, which flows south to join the Columbia River just north of Revelstoke.

River Jordan Property	Property Location

Date: December 5, 2008	Project: 802	Scale: as shown	N.T.S.: 82M.018	Mining Div: Revelstoke	Figure: 1

The treeline is at approximately 1700 to 1800 m in elevation (Goggle Earth). Above this are alpine conditions, with glaciers and with snowpack on the shaded north-facing slopes remaining all year. The area is subjected to heavy snowfall during the winter months.

5.0 PROPERTY DESCRIPTION

The Property comprises seven mineral claims containing 3123.6 hectares (Table 1 and Figure 2). The MTO mineral claims are owned 100% by Silver Phoenix. The mineral cell titles were acquired online and as such there are no posts or lines marking the location of the Property on the ground.

6.0 EXPLORATION HISTORY

This section has been taken with minor changes from Carpenter (2008).

The earliest reported work in the River Jordan - Mt. Copeland area was carried out in the 1890s, following the discovery of placer gold in the Jordan River. Brief mentions of work in the area are contained in the BC Ministry of Mines reports for 1895, 1896 and 1898.

No further work was carried out until 1956 when American Standard Mines Ltd. optioned the property and carried out a sampling and trenching program. In 1958 the property was optioned to Bunker Exploration Ltd., which carried out a trenching program.

In 1961, C. Riley mapped the mineralization (West, Cliff and East Zones). He reported a measured geological reserve of 2.6 million tonnes grading 37.7 grams per tonne silver, 5.1 per cent lead and 5.6 per cent zinc at ten per cent dilution (Riley, 1961). This historical estimate predates NI 43-101 legislation.

In 1963, the property was under option to Bralorne Pioneer Mines Limited which carried out a 5-hole diamond drilling program totaling 1502 m. The deepest hole completed was 457 m in length. The company continued exploration in 1965, by completing a mapping program and drilling an additional 904 m in two holes. This work was followed in 1966 by a further 2,432 m with four holes drilled in the western part and one in the eastern part of the mineralized area.

In 1970, the Property as well as the Mount Copeland molybdenum deposit, located 300 m to the west, was geologically mapped by government geologist Fyles (1970). The Mount Copeland deposit was subsequently mined from 1971 to 1974. Fyles mentioned a further drill hole on the River Jordan deposit which encountered “encouraging grades”. No mention was made however of when or by whom this program was carried out or a definition of “encouraging grades”.

In 1990, First Standard Mining Ltd. carried out a limited geological mapping and prospecting program (AR 20513). A light rare-earth bearing extrusive carbonatite layer was recognized, located stratigraphically below the sulphide horizon, and several new Pb-Zn-Ag-Ba zones were identified. The company continued in 1991 with a program of mapping, sampling and geophysical surveying on various mineralized zones on the property, including the West, Cliff, and East Zones. The company also examined two new zones of mineralization named the Northeast and Lake Zones (AR 22029).

The current Property was acquired in 2006 by William J. Murray, who subsequently transferred title to Silver Phoenix later that same year.

7.0 GEOLOGY

7.1 Regional Geology

The regional geology of the Property is shown on the Geological Survey of Canada (GSC) Map 1964-12, mapped by J.O. Wheeler at a scale of 1:253,440, (Wheeler, 1965). J.T. Fyles, of the British Columbia Geological Survey, mapped the area at a scale of 1:24,000 (Fyles (1970). Recent work includes a regional correlation study of the Sedex-Broken Hill-type deposits in the area by Höy (2001).

The area of the Property is part of the Monashee Metamorphic Complex within the Omineca Terrane, comprising regionally metamorphosed rocks of amphibolite grade. The Monashee Complex, as described by Höy (1987), consists of a series of granitic gneissic domes of probable Aphebian age overlain unconformably by a succession of mainly metasedimentary rocks.

The Property lies on the south-eastern flank of the northernmost of these domes, the Frenchman Cap gneissic dome. This dome consists predominantly of medium to dark grey, medium-grained, granitic biotite-feldspar gneiss. Within the granitic gneiss are found inclusions of biotite-hornblende gneiss and light grey granitic gneiss.

The overlying metasedimentary rocks consist of a basal sequence of quartzites, calcareous and pelitic schists. These rocks are in turn overlain by layers of marble, a carbonatite layer and micaceous schists and gneisses (Höy, 2001). These units are described in detail below. In the area of the River Jordan deposit, vertical fault structures host pods and lenses of high-grade Pb-Zn-Ag mineralization within these sequences.

The youngest rocks recognized in the area are Tertiary-aged lamprophyre dykes. These range from less than 1 m to over 3 m in thickness and tend to fill northerly trending faults and structures.

Most of the rocks have been regionally metamorphosed to amphibolite grade and underwent several phases of folding. Compressive tectonics from Late Paleozoic to Jurassic time was followed by extensional faulting in the Cretaceous and Early Tertiary. These events have

produced an exceedingly complex structural setting, making correlation of units difficult.

Figure 3a shows the regional geology of the Property.

River Jordan Property

Regional Geology

Date:	December 5, 2008	Project:	802	Scale:	1:100,000	N.T.S.:	082M.018,019	Mining Div:	Revelstoke	Figure:	3a

7.2 Property Geology

The following geology has been largely excerpted and adapted from Clarke and Laird (1991), who carried out geological mapping and prospecting program for First Standard Mining in 1991, and by Fyles, who also mapped the area at property scale (1:4800) in 1970.

The River Jordan (King Fissure) deposit lies within a southeasterly trending, southwesterly dipping syncline with an overturned southern limb, known as the Copeland Synform (Fyles, 1970). Folding is open and concentric at the western end, but tightens considerably towards the east. The synform has approximate dimensions of 2.5 km long by 0.8 km wide. Stratiform massive sulphides are seen on both limbs of the fold. Several zones within the deposit have been established by Riley (1961); the West, Cliff, and East Zones as well as the Northeast, Peak and Lake Zones, which were established in the 1991 exploration program.

7.2.1 Lithology

Fyles (1970) described 10 distinct metamorphic units, along with various intrusive rocks, as present in the River Jordan area. The River Jordan deposit contains biotite sillimanite schist (Fyles Unit 4), at the center of a synform, followed by marble (Unit 5) and quartzite/gneiss (Unit 6), as shown on Figure 3b. It is important to note that the 1991 program by First Standard ("FS") appears to have reversed the number sequence, going from unit 4 at the outside of the synform to unit 6 at the centre.

At the bottom of the sequence, Fyle's Unit 6 (FS's unit 4), grey-green gneiss, quartzites and quartz-biotite schists, form virtually inaccessible cliffs along the overturned southern limb of the deposit. Commonly weathering to grey and black, these rocks are unusually rusty above the Cliff Zone.

Above Unit 4, the Unit 5e (FS's unit 5m) basal marble is commonly less than l m thick. In gradational contact with the basal marble is the extrusive 5a carbonatite unit (FS's unit 5c). Best exposures of the carbonatite occur in the Cliff and Northeast Zones. In the Cliff Zone the carbonatite is approximately 5 m thick and almost entirely tuffaceous in nature. Rare fragments less than 2 cm in size tend to occur along discrete horizons. Repetitive centimetre-scale interlayering of fine and medium grain sizes indicates several episodes of deposition. In the Northeast Zone, the carbonatite is highly fragmental and reaches 10 m in thickness. Poorly sorted, matrix-supported fragments up to 25 cm in size form approximately 20% of the volume, and are interpreted to be indicative of a proximal source

vent. Light-rare-earth element content is markedly higher in the Northeast Zone samples than in the Cliff Zone samples, particularly with respect to Ce, La, and Nd.

Discontinuous medium to coarse-grained amphibolite layers are often present within the immediate carbonatite stratigraphy, and probably represent metamorphosed basic volcanics and related intrusives (Höy, 1987). Amphibolite samples from the River Jordan Deposit are chemically similar to basic metavolcanic rocks near Blais Creek in the Cottonbelt area (Höy, 1987).

The marker marble, Unit 5e (FS's unit 5m), ranging from 3 to 10 m in thickness, is composed almost entirely of coarse-grained white calcite, and may also be of exhalative origin.

Above the marker marble lies feldspar-porphyroblastic grey mica schist with lesser calc-silicate schist, Unit 5b, (FS's unit 5). This unit is uniformly nondescript, notable only in that it directly underlies the massive sulphides.

The massive sulphide horizon (FS's Unit 5s) can be traced throughout the entire River Jordan deposit with the exception of talus and snow covered intervals. Greatest known primary massive sulphide thicknesses occur in the West and Cliff Zones. Mineralogy consists mostly of fine to coarse grained pyrrhotite, sphalerite, galena and pyrite, often within a siliceous or calcareous matrix. Massive barite occurs with sulphides in the Northeast and West Zones.

Directly overlying the sulphide horizon are more grey mica schists and calc-silicate gneisses, in turn overlain by interlayered quartzites and mica schists of Fyle's Unit 5c (FS's unit 5q). The quartzites are generally white to tan coloured and have well-developed micaceous partings. Most of the mica is muscovite, although green mica (fuchsite?) is often present. Biotite schist layers become more prevalent up section, leading into biotite-sillimanite schist and quartzite of Fyle's Unit 4 (FS's unit 6) occurring in the core of the Copeland Synform. This highly tectonized and locally migmatitic unit weathers to a strongly Fe-oxidized surface. Chaotic ptygmatic folding is common, and displacement along foliation planes may be significant, but is difficult to measure.

Several northerly trending late stage lamprophyre dykes cut through the deposit, particularly in the central and eastern regions of the Copeland Synform. These dykes, which often occur in swarms, weather to a dark brown colour. Textures consist of fine-grained

biotite and subordinate amphibole within an aphanitic groundmass. Thickness of individual dykes range from less than 0.5 m to 3 m.

7.2.2 Structure

The River Jordan deposit lies within a southeasterly trending, southwesterly dipping syncline, which is approximately 2.5 km long by 0.8 km wide in area. The fold has been named the Copeland Synform by Fyles (1970).

The Copeland Synform is open and concentric in the western end, but tightens considerably to the east. In the western end, an anticline superimposed on the keel of the Copeland Synform has created a "W" shaped folding pattern, effectively raising the structural level of the keel and establishing easterly plunges to folds. Structural measurements in the West Zone indicate that the Copeland Synform plunges approximately 30° towards 150° southeast (Fyles, 1970). The central antiform, plunging more steeply than the Copeland Synform, diminishes in magnitude towards the east, at some point disappearing entirely as three fold axes coalesce into one. Near this point on the surface a major northerly trending fault zone, known as the Camp fault, cuts across the synform with a dextral offset of approximately 20 m. This late structure may be related to stress created at the junction of the earlier folding. East of the Camp Fault, the Copeland Synform is assumed to have a near horizontal keel. East of the River Jordan deposit, structural mapping by Fyles indicates that fold axes in Unit 4 rocks plunge approximately 15° to the west.

In the East Zone area, massive sulphides on each limb of the Copeland Synform are approximately 150 m apart. Geological mapping and magnetic survey data indicate that the closure of the synform probably lies under talus and thick bush further to the east.

7.2.3 Mineralization and Alteration

Historic exploration on the River Jordan deposit has focused primarily on stratiform base-metal (Pb-Zn-Ag) massive sulphides that occur near the top of a carbonate sequence. The sulphide horizon is well exposed along both limbs of the Copeland Synform. Numerous trenches and shallow adits occur in the Cliff, East, and Northeast Zones. The following descriptions of the zones are taken from AR 22029.

<u>Cliff Zone</u>

In the Cliff Zone, massive sulphides range from 1.5 m to more than 3 m thick. A vertical zonation within the massive sulphide layer is recognizable; at the base is a dark weathering 0.2 to 1.0 m layer of mostly sphalerite and galena, with minor pyrrhotite. This is overlain by

0.5 to 2 m of rusty weathering, massive, fine-grained pyrrhotite containing eyes of grey quartz and fine-grained sphalerite and galena. Above the pyrrhotite-dominant middle layer is a 0.2 to 1.0 m siliceous horizon hosting coarse grained pyrite with galena, sphalerite, and minor pyrrhotite. This siliceous upper layer is most easily distinguished by its abundant pyrite and light grey to white weathered surfaces. Brecciation and footwall sulphide stockworks were noted in this zone. Barite has not been recognized.

East Zone

In the East Zone, massive sulphide layers are approximately 0.5 to 1.0 m thick, consisting mostly of sphalerite and galena with lesser pyrrhotite and pyrite within a siliceous matrix. Barite has not been noted. On the north limb is a pyrrhotite-rich zone containing wall rock breccia fragments. This zone is similar in mineralogy and appearance to the middle layer of the Cliff Zone massive sulphide unit. Multiple layering over an interval of 3 m occurs on the north limb. The extrusive carbonatite layer is also present in the East zone.

West Zone

Massive sulphides layers in the West Zone consist of galena, sphalerite, pyrite and pyrrhotite. Massive barite is interbedded with the sulphides and contains a fine-grained mesh of galena. The mineralized horizon also contains brecciated fragments of wall rock, up to 10 cm in size, in a massive sulphide-barite matrix. The extrusive carbonatite is also present in this zone.

Northeast Zone

In the Northeast Zone, up to three massive sulphide layers are separated by calcareous and siliceous layers containing barite; in total the layers reach 1.5 m to 3.0 m in thickness. Three sulphide layers were intersected in diamond drill holes by Bralorne Pioneer Mines Ltd., and were interpreted to be structural repetitions of the same unit. The carbonatite layer is well exposed here and reaches about 5 m in thickness. Large fragments exceeding 25 cm are present.

Lake Zone

Mineralization in this zone consists of galena, sphalerite and pyrite; pyrrhotite is notably absent. The massive sulphide layer does not exceed one metre in thickness. A rare green silicate mineral, identified as gahnite, a zinc-bearing spinel, has been observed. The carbonatite layer is well exposed in this zone.

7.2.4 Deposit Type

The River Jordan deposit, along with other similar deposits to the northwest (Ruddock Creek, Cottonbelt) and to the south (Big Ledge) have been variously described as Broken Hill type (Lefebure and Höy, 1996) and Sedex type deposit (Höy, 2001). The River Jordan deposit appears to be more closely related to Sedex deposits.

Sedex type deposits are found in intracratonic or continental margin environments. The deposits are stratabound, tabular to lens shaped, normally shale-hosted sedimentary deposits of zinc, lead and silver with minor copper and barite. They normally comprise many beds of sulphide laminae. Frequently the lenses are stacked and more than one horizon is economic.

Ore lenses and mineralized beds often are part of a sedimentary succession up to hundreds of metres in thickness with a horizontal extent much greater than the vertical extent. Individual laminae or beds may extend over tens of kilometres within the depositional basin.

The major metallogenic Sedex events occurred during the middle Proterozoic, early Cambrian, early Silurian and middle to late Devonian to Mississippian. The middle Proterozoic and Devonian-Mississippian events are recognized world wide. One of the type examples of a Sedex deposit is the former world-class Sullivan Mine near the town of Kimberly in southeast BC.

"Shuswap-type" zinc-lead deposits can be considered as a subdivision of the larger class of clastic and carbonate hosted sedimentary exhalative deposits. The Shuswap deposits are a transitional type in that they are hosted by both clastic and carbonate rocks, often within a single deposit.

River Jordan Property

Property Geology

Date:	December 5, 2008	Project:	802	Scale:	1:15,000	N.T.S.:	082M.018,019	Mining Div:	Revelstoke	Figure:	3b

8.0 WORK PROGRAM

8.1 Method and Approach

Between August 8 and August 24, 2008, a rock sampling and mapping program was carried out on the River Jordan Property by personnel of Discovery Consultants. The program comprised the mapping of the sulphide zone on the Jordan River deposit where exposed and the sampling of the sulphide layer(s) over the major previously-delineated zones on the Property.

The sulphide horizon was mapped where outcropping and rock chip and grab samples were collected. The rock chip samples were collected across the sulphide horizon to a maximum of one metre in width. Where the thickness of the sulphides was greater than one metre, more than one sample was collected at that showing. In areas of glacially polished outcrop, sampling was achieved with the use of a chainsaw-type rock saw equipped with a diamond blade. With the diamond saw parallel cuts were made across the outcrop and the intervening material was chipped out with the aid of a rock chisel. Where not glacially polished, the rock was sampled by continuous chip sampling across the horizon. Samples were also collected from the units bounding the sulphide horizon. In total, 126 channel samples were collected within and adjacent to the mineralized zone and within the underlying carbonatite unit. Channel sampling of the massive sulphide layers was done in all the main areas, or zones. Channel sampling provides a reliable estimate of true grade across widths of the sulphide horizons, as well as grades into the adjacent units on either side.

Rock grab samples were also collected at selected localities. The majority of the grab samples were taken from outcrop within small sulphide horizons; a few were taken from float talus rock. Grab sampling is a useful prospecting tool as it represents the best mineralized rock present. In total, 26 grab samples were collected.

In total, 152 rock samples, including field blanks, were collected and sent for analysis. Rock descriptions are summarized in Appendix I. The samples collected during the program were stored in secure premises at the end of the program before being submitted for analysis to Acme Analytical Laboratories Ltd (“Acme”) in Vancouver, BC.

8.2 Sample Preparation, Analysis and Quality Control / Assurance

The samples were crushed to 70% passing 10 mesh and a 250 g split was pulverized to 85% passing 250 mesh. A 0.5 g sub-sample was leached with 180 ml of aqua regia (HCl-HNO_3-H_2O) at 95˚C for one hour, and diluted to 600 ml, and analyzed by ICP-MS

techniques (Acme's Group 1DX, 36 elements).

Twenty-nine of the samples were submitted to over-limit assays for Pb and Zn. A 1.0 g sub-sample was leached with 180 ml of aqua regia (HCl-HNO_3-H_2O) at 95˚C for one hour, and diluted to 600 ml, and analysed by ICP emission spectrometry (Acme's Group 7AR method). Appendix II lists the analytical results. Four samples were over-limit on silver; these were fire assayed using Acme's Group 6 method on a 30 g sample. The analytical results of the rock samples are shown in the Appendix II. Note that ppm silver is equivalent to g/t silver.

Quality control by Acme involves the routine use of laboratory blanks, duplicates and standards, added to the sample sequence during analysis. In addition, four field blank samples were added to the rock samples sent from the field. Appendix III lists the QA/QC results.

Acme inserted blank rock samples (G1) at the start of each batch and also within the batch. These samples went through the same preparation and analysis as the regular samples. Field blank samples comprised younger, post-mineralization lamprophyre dykes. The analyses of the rock field blanks and rock lab blanks show no problems with contamination in the sample preparation. In addition, an analytical blank (BLK) was regularly inserted to check for analytical problems; there were none noted.

Acme regularly analyzed duplicate sub-samples, approximately every 30 samples. The sample is another sub-sample of the pulverized rock. Less commonly, duplicate reject samples were analysed. These comprised the pulverization of another 250 g spilt of the crushed sample. The results show good precision.

The laboratory also inserted a standard (DS7), after about every 35 samples, to monitor for errors in the analytical process. The analyses of the inserted standards show acceptable results.

8.3 Results

The sulphide layer was sampled in all major zones, as shown on the index map (Figure 4).

Prospecting

One channel sample and six mineralized grab samples were collected northwest of the

Silver Phoenix Resources Inc.

River Jordan Property

Index Map

Date:	December 5, 2008	Project:	802	Scale:	1:10,000	N.T.S.:	082M.018,019	Mining Div:	Revelstoke	Figure:	4

Northeast Zone, two from outcrop and four from float, as shown on Figures 5 and 6.

A 0.5 m channel was sampled along the main sulphide layer; values run 2.19% Pb and 2.75% Zn and 19 g/t Ag.

The two outcrop samples (802RGB121 and 122) are disseminated sulphides taken from siliceous schist. Best lead and zinc values are 224 ppm Pb and 410 ppm Zn. Quartz veins were sampled from a narrow sulphide layer (802RGB029 and 030); however, lead and zinc values are not significant.

Prospecting and rock grab sampling also occurred in the major zones; these samples are described within each section below.

Cliff Zone (Figures 7-11)

72 samples were collected in the Cliff Zone, including eight continuous channel samples. Channels taken from the sulphide layer in this zone are among the highest grade on the Property.

The main sulphide layer was sampled in two locations (802RGB031-035 and 036-038). One channel, from sample 802RGB-032-035, ran 9.06% Pb, 10.37% Zn and 58 g/t Ag across 3.5 m. Copper values averaged 218 ppm Cu and iron averaged 16.2% Fe. Further east by 60 m, a channel within sulphides contains 3.54% Pb, 2.77% Zn and negligible silver across 2.5 m.

Rusty zones within the calc-silicate gneiss unit lying stratigraphically above the sulphide layer were also sampled (039-041, 042-043 and 044-045). This unit, stratigraphically adjacent to the sulphide layer, is also mineralized, running 0.88% Pb and 2.47% Zn across 3.0 m.

Continuing stratigraphically up section into the quartz mica schist of Unit 5C, several channels were cut across rusty zones (802RGB051-053, 055-64, 067-068). These channels contain up to 3% disseminated pyrite, and have no significant Pb-Zn values. Rock grab samples in this area are also not significantly mineralized.

The carbonatite layer was sampled 802RGB149; however, REE analysis was not done on it.

Peak Zone (Figures 12-16)

Channel sampling along the massive sulphide layer at 802RGB070-073 consisted of a 2.0 m massive to semi-massive sulphide layer bounded by 1.0 m wide samples of gneissic layers having disseminated sulphides. The 2.0 m interval runs 1.2% Pb, 4.5% Zn and 14 g/t Ag and 43 ppb Au.

A second channel stratigraphically higher in the section and about 20 m to the north consisted of rusty calc-silicate gneisses (Unit 5b or 5c) and disseminated 1-5% pyrite. Values average 87 ppm Pb and 1.02% Zn with negligible silver.

Continuing 250 m north, two 3.0 m wide channels were collected within a rusty layer of quartz mica schists and gneisses (Unit 5c). These channels return negligible Pb-Zn-Ag values.

Sample 802RGB108, located along the sulphide layer between the Peak and West Zones, consists of two small lenses of massive sulphide separated by a layer of schist. This channel sample runs 8.19% Pb, 21.46% Zn and 91 g/t Ag over a 1.0 metre thickness. It also has a gold value of 186 ppb.

West Zone (Figures 17-21)

One channel was taken across the main massive sulphide layer (802RGB103-107). The sulphide layer at this location is 5 m wide, with narrow interlayered horizons of schist. This channel runs 3.4% Pb, 2.4% Zn and 27 g/t Ag across 5.0 m. Copper is also elevated, averaging 385 ppm Cu across the interval.

A second channel was taken within rusty biotite sillimanite schists and minor calc-silicate gneisses (Unit 5b) about 100 m to the southeast (802RGB093-099, 145). Mineralization consists of 1-3% disseminated pyrite and trace pyrrhotite; however it contains no significant geochemical values.

A float sample of micaceous quartzite containing malachite was sampled north and east of the main sulphide layer (802RGB092). Although lead-zinc values are low, it contains 8,700 ppm Cu with minor silver (1.8 g/t Ag).

Lake Zone (Figures 22-26)

A grab sample of massive galena (802RGB109), taken from outcrop, assays 19.83% Pb, 30.74% Zn, 289 g/t Ag and 73 ppb Au. Channel sampling from the sulphide layer out into

the host schist and gneiss (802RGB110-114) shows a gradational decrease in Pb and Zn mineralization. The sulphide layer runs 3.02% Pb and 4.23% Zn across 1.0 m.

A grab sample (802RGB118) from a 5 cm wide galena vein assayed 11.86% Pb, 30.71% Zn and 169 g/t Ag. A channel from the nearby sulphide layer yielded 3.92% Pb, 2.69% Zn and 44 g/t Ag.

Channels within rusty sections of the nearby calc-silicate gneiss do not carry anomalous lead-zinc values.

Northeast Zone (Figures 27-31)
A 2.4 m channel (802RGB123-125) was collected along the 0.4 m sulphide layer and the adjacent gneisses. The sulphide layer runs 12.79% Pb, 0.18% Zn, 71 g/t Ag, 58 ppb Au and 982 ppm Cu. A further 140 m along the sulphide layer to the southeast, a channel sampling of an inter-layered sulphide layer and micaceous quartzite (802RGB128-130) yielded 1.96% Pb, 0.90% Zn and 17 g/t Ag over a 3.0 m interval.

Two grab samples from outcrop, sampling massive galena with lesser sphalerite and pyrrhotite yielded 14.73% Pb, 0.44% Zn and 75 g/t Ag. A second grab, consisting of massive pyrrhotite and minor quartz, yielded 1.68% Pb, 10.10% Zn, 18% Ag and 1,613 ppm Cu.

East Zone (Figures 32-36)
On the south limb of the synform, a 3.0 m channel within the sulphide layer and adjacent schist/gneiss (802RGB134-136) yielded 5.25% Pb, 0.99% Zn and 43 g/t Ag. Sample 135 also has 173 ppb Au and 599 ppm Cu.

On the north limb of the synform, a channel was taken along the sulphide horizon. A 2.0 m channel (802RGB140-141) ran 1.74% Pb, 4.24% Zn, 18.5 g/t Ag, 16 ppb Au and 115 ppm Cu; these samples are fault displaced from each other by 20 m. The adjacent schist (802RGB139), channelled for 1.0 m, does not have elevated Pb, Zn or Ag values.

9.0 DISCUSSION and CONCLUSIONS

Channel samples having signification mineralization are summarized in Table 2. These channels are from semi-massive to massive sulphide beds and lenses, bounded by marbles (calc-silicates) and quartzites. All major zones have samples with significant Pb-Zn-Ag mineralization and anomalous copper and gold values. Galena, sphalerite, pyrite, pyrrhotite

and magnetite are the common minerals. Preliminary geological mapping visually confirmed both the general accuracy of historical mapping and the presence of a mineralized horizon on the Property.

Table 2: Significant Mineralization

East Zone				
802RGB135	1.0	15.6	2.7	128
802RGB140 - 141	2.0	1.7	4.3	19

A strong correlation exists between lead and silver mineralization, even stronger than lead and zinc mineralization. Silver mineralization is likely to occur as included grains within galena; thin section work could confirm this.

10.0 RECOMMENDATIONS

Further work on the property should include detailed structural mapping to aid in the definition of fold zones that would represent zones of thickening of mineralization and potential targets for drill testing. Detailed mapping of the property by a trained structural geologist would allow the accurate placement of drill holes for a later program.

A new detailed topography/orthophoto map of the Property should be produced.

A magnetometer VLF-EM survey would help to map the area.

13.0 STATEMENT OF QUALIFICATIONS

I, Agnes Koffyberg, PGeo of Discovery Consultants, 201-2928 29th Street, Vernon, BC V1T 5A6

DO HEREBY CERTIFY that:

1. I am a geologist in mineral exploration and am employed by Discovery Consultants, Vernon, BC.

2 I graduated with a B.Sc. degree in combined Geological Sciences/Chemistry from the Brock University in 1987. In addition, I have obtained a M.Sc. in Geology from the University of Alberta in 1994.

3. I am a member of the Association of Professional Engineers and Geoscientists of British Columbia, registration number 31384.

4. I have worked as a geologist for a total of 12 years since graduation from university.

5. This report is based upon knowledge of the Property gained from a review of existing industry and government reports.

Dated this fifth day of December, 2008 in Vernon, BC

Acme Analytical Laboratories Ltd

Method 1DX Aqua regia digestion, ICP-MS analysis, 0.5 g subsample
Method G6 Ag by Fire Assay, 30 g subsample
Method 7AR Aqua regia digestion, ICP-ES finish, 1.0 g subsample
Method 7AR.1 Aqua regia digestion, ICP-ES finish, 0.1 g subsample

Discovery Consultants
