## SUMMARY

MMI soil sampling was carried out within three grids within the Logan Lake Property belonging to SNL Enterprises. The property is located on and around Logan Lake which is about 43 km north of the town of Merritt within the Kamloops Mining Division of B.C.

The main purpose of the MMI geochemical surveys was to locate mineralization similar to that of the nearby porphyry copper deposits, which occur about 8 km to the west within the Guichon Creek Batholith within the Highland Valley, as well as to locate any other possible deposits that may occur within other rock types. The Highland Valley mineralization consists of disseminated copper, zinc, and molybdenite sulphides as well as other disseminated sulphides with associated gold and silver. In addition to the Highland Valley mines, the Craigmont mine occurs about 23 km south-southwest of the southern property boundary and occurs within the Nicola volcanics very close to the Guichon Creek batholith.

The property is mostly underlain by the oldest rocks in the area, which are andesites and basalts of the Nicola Group which is of Upper Triassic age. The west side of the property is underlain by the east side of the Guichon Creek batholith which on the property consists of diorite, quartz diorite and granodiorite of Late Triassic to Early Jurassic age. Six Minfile showings or past producers occur on the property while eight others occur on the property boundary or very close to it. Two of the six occur within the Guichon Creek batholith while the remaining four occur within Nicola volcanics.

The MMI samples were picked up every 25 or 50 meters on lines 50 or 100 meters apart and the sample taken at a 10-to 25-cm depth. The total number of samples was 1,223 taken on 48 lines. These were bagged and sent to SGS Laboratories in Toronto, Ontario for analysis where they were tested for 46 elements.

Eleven elements were chosen out of the 46 reported on and these were copper, zinc, molybdenum, gold, silver, lead, cobalt, cadmium, nickel, and cerium. Two stacked histograms were then made to show the correlation of the results with each other. In addition, eleven contour plan maps were made for the same eleven metals, that is, copper, zinc, molybdenum, gold, silver, lead, cobalt, cadmium, nickel, and cerium, respectively.

## CONCLUSIONS

1. The MMI surveys over the three grid areas revealed two main anomalous zones that have been labeled the Central Anomaly and the Valley Anomaly.
2. The Central Anomaly, which contains the Dansey showing, consists of very strong copper values that reach an extreme high of 333,329 ppb. It also correlates with anomalous molybdenum, gold, and silver values. This copper-molybdenum-gold-silver anomalous area extends 1,700 meters in a northerly direction by 800 meters in a westerly direction, and is open to the west. Cobalt, suggestive of pyrite, also correlates with the anomaly as well as occurring to the north.
3. Zinc, cadmium, with some anomalous lead values correlate with the main copper-molybdenum-gold-silver anomaly but also occur around its perimeter. If the zinc anomaly is included with the copper anomaly then the extent of the Central Anomaly increases to 3,000 meters in a north direction, being open to both the north and south, by 1,200 meters in a west direction, being open to both the east and west.
4. The MMI signature of the Central Anomaly is strongly suggestive of a porphyry copper type deposit such as occurs within the Highland Valley.
5. The Valley Anomaly occurs within the northeast part of the Noname Grid and is a minimum 700 meters in a northerly direction, being open to the north, by a minimum 400 meters in an east direction, being open to the east. It also is a copper-molybdenum anomaly with gold and silver anomalous values. The molybdenum values are especially strong. However, the copper and molybdenum anomalies do not correlate directly but occur adjacent to each other with the copper anomaly occurring to the north and the molybdenum anomaly occurring to the south.
6. The Valley Anomaly contains very strong uranium values that correlate with both the copper and molybdenum anomalies and that are up to 3300 ppb which is 260 times background. This is very significant for uranium and thus may indicate uranium mineralization.
7. The MMI data, especially the zinc, suggests a lithologic contact striking north-northwesterly through the center of the Noname grid and to the immediate west of the Valley Anomaly. The MMI data also suggests a possible lithologic contact to the immediate east of the Central anomaly.
8. Three additional copper anomalies with associated molybdenum, gold, and silver values were located within the three grid area. However, they were somewhat weaker than the two main anomalies which may be a result of the possible mineralization being at a greater depth.

## **RECOMMENDATIONS**

The positive results from the MMI soil sampling strongly warrant further work within the area of the three grids as follows:

- 1.** Carry out geologic mapping and/or prospecting throughout the area of the three grids in order to help determine causative sources of the MMI anomalies as well as to aid in the determining the underlying rock-types.
- 2.** Extend the MMI sampling as follows: (1) to the east and north of the Noname grid in order to determine the extent of the Valley Anomaly, (2) to the west and north of the Dansey grid in order to determine the extent of the Central Anomaly, and (3) between the Dansey and Last SNL grids in order to determine whether anomalies on the edge of the two grids are connected to each other.
- 3.** Carry out IP and resistivity surveying over the Central and Valley anomalies in order to help determine the depths of the causative sources as well as to optimize drill targets. This should be done with the dipole-dipole array using a dipole length of 50 meters and an 'n' separation up to 12 in order to read as deep as possible.
- 4.** Diamond drill the subsequent targets as suggested by the MMI and IP/resistivity surveys.

**INTRODUCTION AND GENERAL REMARKS**

This report discusses survey procedure, compilation of data, interpretation methods, and the results of MMI soil sampling carried out on the Dansey, Noname, and Last SNL grids which occur within the Logan Lake Property belonging to SNL Enterprises Ltd. The property is located at and around the village of Logan Lake within the Kamloops Mining Division, British Columbia.

The MMI soil sampling was carried out by a nine-man crew from June 29<sup>th</sup> to July 20<sup>th</sup>, 2008.

The general purpose of exploration on this property is to locate sulphide mineralization especially similar to that of the nearby Highland Valley mines, which occur within the Guichon Creek batholith, as well as to locate any other possible deposits that may occur within the Nicola volcanics. The Highland Valley mineralization consists of disseminated copper, zinc and molybdenite sulphides as well as other disseminated sulphides with associated gold and silver values.

## **PROPERTY AND OWNERSHIP**

SNL Enterprises Ltd.'s Logan Lake Property is comprised of 92 mineral claims within the Kamloops Mining Division as shown on the Claim Maps (Fig. 3, 3a, 3b, and 4). It is a huge property that extends 39 km in a north-south direction and 26 km in an east-west direction covering an area of 41,312 hectares, or 102,082 acres.

The property is entirely owned by SNL Enterprises Ltd. of Delta, BC.

## **LOCATION AND ACCESS**

The Logan Lake property is located at and around the village of Logan Lake which is located 43 km north of the town Merritt and 40 km southwest of the city of Kamloops (see figs 2 to 4). It is also located within the eastern part of the Highland Valley and to the immediate west of Chuwels Mountain. The center of the three grids discussed within this report are located 6.5 km west-northwest of the town of Logan Lake.

The Logan Lake Property is located within NTS maps 92I/7 and 92I/10 and BCGS maps 092I.036, .037, .046, .047, .048, .056, .057, .058, .066 and .067. The UTM coordinates, NAD 83, Zone 10U, extend from 5580400 northing at the southern boundary of the property, to 5613600 northing at the north end, and from 643600 easting at the western edge to 970600 at the eastern edge. The center of the property is 5596000N, 658000E in UTM coordinates and 50° 30' latitude and 120° 46' longitude.

The access is good with numerous logging roads and other bush roads throughout the entire property. Highway 97C runs in a southeasterly direction from Ashcroft almost to Logan Lake and then southerly along Guichon Creek to Merritt. From Ashcroft by road, Logan Lake is 42 km, and from Merritt it is 48 km. From Kamloops along the paved Meadow Creek road which runs westerly through the center of the property and which connects to the Coquihalla Highway, Logan Lake is 58 km.

## **PHYSIOGRAPHY**

The Logan Lake Property is found within the Thomson Plateau, which is a physiographic unit of the Interior Plateau System. The Thomson Plateau consists of gently rolling upland of low relief for the most part.

The elevations on the Logan Lake Property vary from 965 meters (3170 feet) at the southwest corner of the property on Guichon Creek to 1,820 meters (5,970 feet) along the eastern edge of the property on the western slope of Chuwels Mountain. Since the property is so large, the terrain is highly variable with much of the property covered by gently rolling hills as well as steep to moderate slopes covered with variable soil cover.

Numerous lakes and creeks occur throughout the property. However, the main creek is the Guichon Creek which flows southerly along the western side of the property. Another major creek is Meadow Creek which flows westerly into Guichon Creek south of Logan Lake.

Tree cover is generally that of open to medium thick forest with some thick second growth.

Glaciers occupied the Thomson Plateau and thus much of the property area is covered by glacial drift, which can become quite deep over the flatter areas.

The climate in the Logan Lake area is semi-arid, and thus the precipitation is low, about 25 to 28 centimeters (10 to 11 inches). Temperatures vary from the high extreme in summer of around 35°C to the low in winter of around -30°C, though the usual temperature during the summer days would be 15°C to 25°C and that in winter would be -10°C to 5°C.

## **HISTORY OF PREVIOUS WORK**

Much work has been carried out throughout the property area, and because of the sheer volume is beyond the scope of this report. Much of the work would have been done in the late sixties when the Highland Valley was the hottest mining exploration area in Canada (and probably the world).

However, the writer has taken the following description from the MapPlace web site from work carried out over the Dansey property since it is relevant to the MMI surveying described within this report.

Deerhorn Mines Ltd. held the Witches Brook group of 24 claims in the vicinity of the JB showing in 1956. Noranda Exploration Company Limited held the PG group of 99 claims along and mainly west of Guichon Creek to the north of Witches Brook in 1962. This property was partly a relocation of the claims held by Deerhorn Mines Ltd. Geological, geochemical and geophysical surveys were carried out during 1963. The CL group, apparently staked by C.W. Dansey in 1964, was located partially on ground formerly part of

the PG group. North Pacific Mines Limited carried out a program of trenching, soil sampling, magnetometer and geological surveying on the property during 1964.

In 1965, North Pacific Mines Ltd. carried out an induced polarization survey which outlined an anomaly about 914 metres long over a width of 244 metres. Other work consisted of trenching, road building and 8 diamond-drill holes totalling 1280 metres. In 1968, an airborne magnetometer survey (202 kilometres) was flown on behalf of North Pacific Mines Ltd. and Comet-Krain Mines Ltd. In 1969, Noranda Exploration Company Limited conducted a soil geochemical survey and induced polarization surveys over the Mike, Bill, Tom and JB claims. In 1974, North Pacific Mines Ltd. conducted percussion drilling in 5 holes totalling 384 metres on the Tom claims.

## **GEOLOGY**

### **a) Regional**

The following regional geological description is derived in part from Owsiaci (2003).

The Logan Lake Property is situated within the Quesnel Trough, a 30 to 60 km wide belt of Lower Mesozoic volcanic and related strata enclosed between older rocks and much invaded by batholiths and lesser intrusions (Campbell and Tipper, 1970). The southern part is the well known Nicola belt, continuing nearly 200 km to its termination at the U.S. border. The Nicola belt is enveloped by the Guichon Creek Batholith to the west which is host to the major porphyry copper mines of the Highland Valley; the Wild Horse Batholith to the east; and the Iron Mask Batholith to the north northeast which is host to the former Afton Mine,.

The Nicola Group which is of Upper Triassic Age is the oldest rocks of the property area and consists of a predominantly subaqueous island arc assemblage of sedimentary and volcanic rocks. The Nicola Group is broken into three blocks that are separated by two northerly-trending sub-parallel faults with the eastern one being partly defined by Cherry Creek and the western one by Guichon Creek and Deadman River.

The Nicola Group has been divided into four lithologic assemblages:

1. a steeply dipping, east-facing 'western volcanic belt' consisting predominantly of subaqueous felsic, intermediate and mafic volcanics of calcalkalic affinity that grade upward into volcanoclastic rocks;
2. a 'central volcanic belt' composed of both subaqueous and subaerial basalt and andesite flows, volcanic breccias and lahars of both alkalic and calcalkalic (both plagioclase and augite-phyric) affinities;
3. an overlying, westerly dipping 'eastern volcanic belt' composed of predominantly subaqueous and subaerial alkalic (both augite and hornblende-phyric; shoshonites and ankaramites) intermediate and mafic volcanic flow,

fragmental and epiclastic rocks; and an 'eastern sedimentary assemblage' that is overlapped by,

4. the eastern volcanic belt and is composed predominantly of greywackes, siltites, argillites, alkalic intermediate tuffs and reefal limestones.

The Nicola Group has been cut by Late Triassic and Early Jurassic alkalic intrusions such as the Guichon Creek batholith. These consist of medium to small, commonly fault-bounded stocks and dyke swarms of diorite, monzodiorite, monzonite and syenite.

The Guichon Creek batholith of Late Triassic to Early Jurassic age is a semi-concordant dome that is elongated slightly west of north. It consists of several nearly concentric phases which have sharp contacts locally, but are generally gradational. The main phases number four and consist of the following:

1. Hybrid Phase – consists of fine- to medium-grained mafic-rich diorite or quartz diorite.
2. Highland Valley Phase – consists of the Guichon variety which is quartz diorite to granodiorite with usually 15% mafic minerals, and the Chataway variety which is granodiorite with 12% unevenly distributed mafic minerals.
3. Bethlehem Phase – consists of granodiorite with 8% mafic minerals.
4. Bethsaida Phase – consists of quartz monzonite to granodiorite with 6% mafic minerals.

The Highland Valley ore-bodies of the Guichon Creek batholith are not restricted to any one phase. The Bethlehem Copper JA deposit occurs in and adjacent to a quartz plagioclase aplite stock which intruded rocks of the Guichon variety and Bethlehem phase of the Guichon Creek Batholith. The largest deposit of the camp, the Valley Copper deposit, is entirely in quartz monzonite of the Bethsaida phase and is west of the Lornex fault.

The youngest rocks of the area are Eocene arc volcanics and sediments of the Kamloops Group, extensive Miocene-Pliocene plateau basalts of the Chilcotin Group, as well as scattered minor Pleistocene and Recent flows. The Kamloops Group unconformably overlies the Nicola rocks and the Guichon Creek batholith and other similar-aged intrusives. Rocks of this group consist of tuffaceous sandstone, siltstone, and shale with minor conglomerate, as well as basaltic to andesitic flows and agglomerate with minor dacite, latite, and trachyte.

## **b) Property**

(This section is mostly taken from the BC government's web site, the Map Place.)

Almost the entire Logan Lake property is underlain by Nicola Group volcanics. The eastern part is underlain by basalts and to the west of the basalts is a 4-km wide band of

andesites striking north-northwesterly through the center of the property. The western part is underlain by undivided volcanics, probably a mixture of andesites and basalts.

The Guichon Creek batholith occurs to the west of the Nicola volcanics underlying the westernmost part of the property being a width of up to 10 km. This area of the property overlies the contact between Hybrid phase and Guichon variety rocks. Three main rock types are evident and comprise diorite, quartz diorite and granodiorite. Fracturing and shearing are abundant in the diorite and quartz diorite but markedly less in the granodiorite.

The northwestern corner of the property is underlain by young volcanics, mostly basalts, of the Kamloops Group.

Much of the contact between the Nicola volcanics to the east and the Guichon Creek batholith to the west is a regional fault, as mentioned above, that strikes north-northwesterly along Guichon Creek and thus through the western part of the property.

### **c) Mineralization – Nearby Mines**

The ore-deposits of the Highland Valley are structurally controlled. Movements on the Lornex and Highland Valley faults occurred simultaneously and alternatively in the final phases of intrusion of the Guichon Batholith. The fault planes provided the openings for the admission and deposition of mineral and igneous matter.

Highland Valley Copper operates two distinct mines, the Valley mine and the Lornex mine, and between the two has measured and indicated ore reserves of 761 million tonnes of 0.408 per cent copper and 0.0072 molybdenum. The ore reserves of each mine are: Valley mine – 627 million tonnes at 0.418 per cent copper and 0.0056 per cent molybdenum; Lornex mine – 135 million tonnes at 0.364 per cent copper and 0.0144 per cent molybdenum. The individual mine reserves are calculated at an equivalent cut-off grade of 0.25 per cent copper using a molybdenum multiplying factor of 3.5 (CIM Bulletin July/August 1992, pages 73,74).<sup>1</sup>

The Lornex and the Valley Copper ore-bodies in the Highland Valley are located at the low edge of an airborne magnetic high. The magnetic high traces the Highland Valley and the Lornex fault systems and clearly indicates the fault pattern of the system and the ore-bodies occurring within a magnetic low due to the supergene and dynamic related destruction of magnetite.

All of the following summary descriptions of the nearby mines to the Logan Lake property are taken from the BC government's web site "MapPlace". Only three of the deposits of the Highland Valley are chosen below as an example of Highland Valley Mine geology. The fourth is the Craigmont deposit which occurs in Nicola rocks.

### ***1. Lornex Mine***

The Lornex deposit lies in the central core of the Late Triassic-Early Jurassic Guichon Creek batholith and occurs within Skeena variety granodiorite to quartz diorite. This rock is medium to coarse-grained and slightly porphyritic. The Lornex property straddles the north trending, west dipping Lornex fault which juxtaposes Skeena rocks on the east side with Bethsaida phase quartz monzonite on the west. A pre-mineral quartz porphyry dyke probably related to the Bethsaida phase, trends northwest and pinches out in the Lornex deposit.

Mineralization is controlled by the distribution and density of fracture sets. Three major sets of copper-molybdenum veins strike north-northeast to east and dip moderately southeastward. There are two sets of post-mineral fault and fracture systems; one which roughly parallels the mineralized veins and another which offsets the first up to 2 metres. The most prominent structural feature is the Lornex fault which dips 55 degrees to the west in the southern part of the orebody, and steepens to nearly vertical in the north. This fault truncates the northwestern part of the deposit. It is characterized by a 10-centimetre to 1.5-metre wide black gouge on the footwall and discontinuous mylonite pods 1 to 50 metres wide in the hanging wall.

Five main types of hydrothermal alteration are related to quartz and sulphide mineralization. Pervasive silicification, consisting of close spaced quartz veins with associated quartz alteration, is hosted by the Skeena rocks. The quartz porphyry dyke is only weakly affected by hydrothermal alteration. Potassium feldspar veinlets and hydrothermal biotite are erratically distributed. Argillic alteration is pervasive throughout the ore zone and is characterized by quartz, sericite, kaolinite, montmorillonite and chlorite. Copper grades generally correspond to the intensity of argillization. Within the argillic zone, phyllic alteration consists of grey quartz-sericite envelopes on mineralized veins. Pervasive propylitization, consisting of epidote (zoisite), chlorite and carbonates (calcite), is peripheral to the argillic zone. There is also an irregular zone of late-stage gypsum.

The Lornex deposit is 1900 metres long, 500 metres wide and plunges northwest to a depth of at least 750 metres. Chalcopyrite, bornite and pyrite constitute 1.5 per cent of the ore zone and occur in three roughly concentric sulphide zones respectively. Sulphides occur mainly with quartz as fracture-fillings and coatings. Veins average 5 to 15 millimetres in width. Molybdenite occurs as thin laminae in banded quartz veins and less often as rosettes in vuggy quartz veins. The oxide zone averages 3 to 30 metres in thickness and thins toward the east. Supergene minerals are malachite, limonite, pyrolusite, azurite, cuprite, chalcocite, covellite, and native copper.

### ***2. Valley Copper Mine***

The Valley deposit lies within the Late Triassic to Early Jurassic Guichon Creek batholith and is hosted by Bethsaida phase porphyritic quartz monzonite and

granodiorite. Feldspar porphyry and quartz feldspar porphyry dykes 0.6 to 35 metres wide dip steeply eastward in the western and central areas, and northward in the southern area of the deposit. These dykes are cut by mineralized fractures and quartz veinlets, and have been dated at 204 Ma +/- 4 Ma. The Bethsaida granodiorite is also intruded by aplite dykes up to 30 centimetres wide, tan-coloured felsite dykes up to 4.5 metres wide, and three types of lamprophyre dykes (spessartite, hornblende vogesite, vogesite).

The most prominent structural features are the north-trending, west-dipping Lornex fault and the east-trending Highland Valley fault. Faults and fractures in the deposit comprise four main sets. Quartz veinlets are subparallel to two of the earlier formed fault and fracture sets.

Silicic, potassic, phyllic, argillic and propylitic alteration are intimately associated. Stockworks of quartz veinlets 1 to 2 centimetres in width are common. Vuggy veinlets have envelopes of medium-grained sericite and/or potassic feldspar, and contain minor amounts of sericite, plagioclase, potassium feldspar, calcite, hematite, bornite, chalcopryrite, molybdenite, digenite and covellite. These veinlets are moderately abundant within the 0.3 per cent copper isopleth. An area of well-developed barren quartz veinlets, generally 0.5 to 1.3 millimetres wide, without alteration envelopes, occurs in the southeastern part of the deposit.

In the west-central part of the deposit, potassium feldspar is associated with vein sericite in some replacement zones, as veinlet envelopes along fractures, and disseminated in quartz veinlets. Hydrothermal biotite occurs in small amounts. Flaky sericite and quartz, both as replacement zones and as envelopes around quartz veinlets, constitute the most common type of alteration associated with copper mineralization. Strong phyllic alteration coincides with the 0.5 per cent copper isopleth. Phyllic alteration is closely associated with pervasive argillization, which is strongest where fractures are most closely-spaced. Feldspars are altered to sericite, kaolinite, quartz and calcite. The phyllic-argillic zone grades outward to a peripheral zone of weak to moderate propylitization, characterized by clay, sericite, epidote, clinozoisite and calcite replacing plagioclase, and chlorite and epidote replacing biotite. The age of hydrothermal alteration is approximately 191 Ma.

At the Valley deposit, gypsum is interpreted to be secondary and post-ore. It is commonly fibrous and white to orange but locally it forms large platy crystals or may be massive. Anhydrite, which is also present, provides indirect evidence for the secondary nature of the gypsum. It is apparently the same age as and associated with sericitic and potassic alteration. Quartz-gypsum veins and quartz-potash feldspar veins in which gypsum fills interstices provide more direct evidence for its secondary nature. Gypsum is believed to have formed at the expense of anhydrite which was deposited from the ore-forming fluids. Gypsum veins are common in the lower portion of the orebody (Open File 1991-15).

Sulphides occur chiefly as disseminations in quartz veinlets, and in phyllic (bornite) and potassic (chalcopyrite) alteration zones. Mineralization includes bornite and chalcopyrite, with minor digenite, covellite, pyrite, pyrrhotite, molybdenite, sphalerite and galena. The oxide zone averages 4.5 metres in thickness, and contains limonite, malachite, pyrolusite, digenite, native copper, and tenorite(?).

### ***3. Bethlehem Copper Mine***

The Bethlehem property lies within the Early Jurassic-Late Triassic Guichon Creek batholith and straddles an intrusive contact where younger Bethlehem phase rocks form an irregular embayment in older Guichon variety rocks. The Bethlehem phase is medium-grained granodiorite to quartz diorite which ranges from equigranular to hornblende-biotite porphyry. The Guichon variety is medium-grained granodiorite. Igneous breccias are postulated to have been forcefully emplaced. Clasts up to 20 centimetres in diameter are subrounded and sit in a generally compact, but sometimes vuggy matrix. The granodiorites and breccias are intruded by north trending, steeply dipping dykes which are compositionally similar to the enclosing rocks; contacts are chilled. Most of the dykes are dacite porphyry and range in width from less than 1 metre to 60 metres.

The Bethlehem ore deposits (East Jersey (092ISE002), Huestis (092ISE004), Iona (092ISE006), and Snowstorm (092ISE005) are controlled by north-trending faults and are localized in zones of closely-spaced fractures. Mineralization is concentrated in breccia bodies, faults and highly fractured areas. The Jersey fault cuts through the centre of the Jersey pit.

Hydrothermal alteration is restricted to the immediate area of the ore zones. The distribution of secondary biotite defines an inner potassic zone, sericite with kaolinite and montmorillonite define an intermediate phyllic zone, and epidote defines a peripheral propylitic zone. There is an outer halo of chloritized mafic minerals.

Metallic mineral zoning is very similar to alteration patterns. Bornite and chalcopyrite occur in the hydrothermal biotite zone, specularite in the epidote zone and minor pyrite in the outer halo. Molybdenite, chalcocite and magnetite occur in minor amounts. Malachite, azurite, chrysocolla, cuprite, native copper, hematite, goethite and manganese oxides occur to shallow depths. An age date from a sample of a mixture of magmatic and hydrothermal biotite from the Iona ore zone (092ISE006) returned 199 Ma +/- 8 Ma (Canadian Institute of Mining and Metallurgy Special Volume 15).

The Jersey orebody hosts disseminated mineralization and occurs in an area of relatively evenly distributed and variously oriented pervasive fracturing. Irregular, discontinuous quartz veins also hosts mineralization. Production from the Jersey pit began in 1964 and from the Jersey pit extension in 1977.

#### ***4. Craigmont Mine***

The Craigmont Mine is 23 km south-southwest of the southern boundary of the Logan Lake Property and is not one of the Highland Valley mines.

The Promontory Hills area is underlain by a complex east- northeast trending, steeply dipping volcanic pile of Upper Triassic Nicola Group rocks, bounded to the north by the multistage Early Jurassic-Late Triassic Guichon Creek batholith and unconformably overlain by the Middle and Upper Cretaceous Spences Bridge Group. Most of the area is covered by extensive gravel overburden.

In the vicinity of Craigmont mine, the Border phase of the Guichon Creek batholith varies in composition from quartz diorite to granodiorite. These rocks intrude the Nicola Group, a thick volcanic and sedimentary series of agglomerate, breccia, andesitic flows, limestone, argillite and greywacke.

Attitudes parallel the intrusive contact zone. Sediments immediately adjacent to the batholith are hornfelsed quartzofeldspathic greywackes. Spences Bridge Group agglomerates and flows dip approximately 15 degrees to the south and outcrop in the areas south and west of the mine.

The mine lies adjacent to the southern margin of the Guichon Creek batholith. Host rocks to the mineralization are calcareous sedimentary rocks of the Nicola Group comprised of limestones, limy tuffs, greywackes and argillites.

The gross structure at the mine is a large anticline with ore- bearing drag folds on the north limb. These folds plunge 60 to 70 degrees eastward and are often occupied by diorite dykes. The anticline is cut off by a northwest trending fault on the west and an east trending fault on the south. Orebodies lie within a block bounded by these regional faults and the Guichon Creek intrusive.

Alteration mineralogy indicates thermal zoning. Within the hornfelsed zone, greywackes contain biotite and actinolite and limestone is altered to marble. Immediately to the south is a massive actinolite skarn which, in places, is further altered to epidote and garnet (grossularite, andradite).

Three types of alteration are present. First is a zone of potassic alteration with a related (second) distal hornfels. Third is skarn alteration which overprints the potassic alteration and some of the hornfels. The skarn is garnet-epidote-amphibolite in composition with some chlorite, tourmaline and sericite.

Semi-continuous ore is found over a strike length of 900 metres and a vertical depth of 600 metres. The five main orebodies are confined to the limy horizon between walls of greywacke and andesite.

Mineralization consists of magnetite, hematite and chalcopyrite and occurs as massive pods, lenses and disseminations extending through the calc-silicate horizon. The body is roughly tabular, trends east and dips near vertically. Minor folding and faulting is

present but do not significantly distort the mineralization. Chalcopyrite is associated with, but post-dates the magnetite and commonly encloses the magnetite.

Chalcopyrite is the principal ore mineral and occurs as veins, streaks, patches and coarse disseminations. It was first deposited with magnetite during the development of the actinolite skarn and later with specularite as fracture-fillings and veins. Bornite is present in small amounts. Pyrite is confined to areas of heavy garnet alteration. Approximately 20 per cent of the ore (by weight) is comprised of magnetite and hematite and along with actinolite, epidote, grossularite, andradite, pyrite and minor diopside, occur in the skarn. Supergene minerals, native copper and chalcocite, occur in a narrow oxidized zone immediately above the orebody. The apparent ore controls are favourable host rock, folding and brecciation of host rock, and proximity to the batholith.

#### **d) Mineralization – Property**

The Logan Lake Property contains six Minfile showings, the following descriptions of which are taken in whole or part from the BC government's web site "MapPlace". All UTM coordinates given below are NAD 83 and within zone 10U.

##### ***1. Dansey Showing– 92INE034***

(UTM coordinates 5598877 northing, 650393 easting, which is within the northern part of the Dansey grid)

The Dansey property is located at the eastern edge of the Late Triassic-Middle Jurassic Guichon Creek batholith and overlies the contact between Hybrid phase and Guichon variety rocks. As mentioned above, diorite, quartz diorite and granodiorite are evident in the area with fracturing and shearing abundant in the diorite and quartz diorite but markedly less in the granodiorite.

Mineralization on the Dansey property is associated with diorite and quartz diorite. Most of the mineralization occurs along fractures but the majority of it is associated with a second group of fractures that strike from 040 to 080 degrees. The main minerals include chalcopyrite and pyrite, with minor amounts of molybdenite, specularite, chalcocite and bornite. Malachite, azurite and chrysocolla occur as secondary minerals. Areas of moderate copper-molybdenum mineralization (>0.1 per cent copper) occur near the contact between diorite and quartz diorite with weak zones of copper-molybdenum mineralization scattered throughout the diorite.

Trenching has exposed disseminations and blebs of chalcopyrite, pyrite, bornite, hematite, magnetite and molybdenite mineralization in and adjacent to several northeast faults and shear zones in quartz diorite. The faults and shears mostly dip northwest at moderate to high angles. The shears are characterized by intensely chloritized and sericitized quartz diorite and vary from 1.5 to 9 metres wide. Near the shears are random fractured zones with pyrite and minor chalcopyrite on fracture planes.

## **2. *Dab Showing– 92INE040***

(UTM coordinates 5599883 northing, 649911 easting, which is about 1 km north of the Dansey grid)

The Dab property lies close to the northwest trending contact between Upper Triassic Nicola Group volcanics to the east from intrusive rocks of the Late Triassic-Middle Jurassic Guichon Creek batholith to the west. In this area Guichon rocks appear to be quartz diorite of the Hybrid phase.

Very low grade copper mineralization (inferred to be disseminated chalcopyrite) occurs in mafic intrusive rocks (Nicola?). The mineralization was found by drilling but is not reported in assessment reports (W.J. McMillan, 1970).

## **3. *Tunkwa Lake Past Producer– 92INE039***

(UTM coordinates 5608605 northing, 654363 easting, which is 11 km north-northeasterly of the Noname grid)

Mercury showings of the Savona Mercury Belt are associated with faulted, carbonate and/or silica altered zones within Triassic or Jurassic metasediments or metavolcanics and are spatially related to Tertiary intrusions. The Tunkwa Lake mercury prospect is believed to cap one of these Tertiary bodies and is thought to represent the upper, low temperature horizon of an epithermal system that could carry precious metal values at depth. Most of the recent work on the showing has focused on this potential.

The Tunkwa Lake property is underlain by north striking and moderately east dipping Upper Triassic Nicola Group andesitic metavolcanics with intercalated siltstone, sandstone, argillite and occasional limestone units. The volcanics comprise andesitic agglomerates, and amygdaloidal and feldspar porphyry andesite flows. The Nicola rocks are locally cut by diorite dikes and later rhyodacite dikes. Several faults are believed to pass through the property. Wide zones of brecciated rock or gouge, pervasively carbonate and/or silica replaced, mark the trace of the larger faults on surface. Elevated mercury, antimony and arsenic values accompany late ankerite, dolomite and quartz veinlets and pervasive low temperature silica replacement to depths of at least 125 metres within one major fault zone, but precious metal values are uniformly low.

The most intense carbonate/silica alteration occurs at the Tunkwa Lake showing where the metavolcanics have been highly fractured and brecciated by a fault zone. A banded andesitic tuff is altered to ankerite and veined with dolomite. The carbonate zone is mineralized with disseminated stibnite, tetrahedrite, chalcopyrite, malachite and azurite with cinnabar occurring as thin films and small masses in dolomite and quartz veins. Zones of silica replacement occur up to 5 metres in width with several small silicified breccia zones mended with chalcedony.

#### **4. *Bertha-Molly Past Producer– 92ISE190***

(UTM coordinates 5590427 northing, 662497 easting, which is within the northeast corner of the Molly grid)

The Dupont Lake area is underlain mainly by Upper Triassic Nicola Group intermediate volcanics and derivatives. Approximately 8 kilometres to the west, Nicola Group rocks are in contact with the Lower Jurassic Guichon Creek batholith. Quartz diorite outcrops southwest of Dupont Lake.

The Bertha-Molly showing is hosted by purplish amygdaloidal andesites with intercalated reddish tuffs. These rocks are strongly fractured and chloritized. The original shaft was sunk at a point where patches of cuprite occur in fractures. Small shipments were made.

In 1942, George Campbell did some surface-stripping on a copper showing, about 457 metres west of an old shaft. Production from this occurrence, known as the Lost group, was 31 tonnes, yielding 218 grams of silver and 626 kilograms of copper.

Recent development has exposed malachite, azurite, chalcopyrite, cuprite and pyrite hosted by shears and fracture-fillings in vesicular volcanics and red tuffs. Mineralization is structurally controlled with an apparent north trend. A common alteration is calcite and epidote with silicification becoming stronger at depth

#### **5. *Ford Showing – 92ISE009***

(UTM coordinates 5595161 northing, 660635 easting, which is 5,800 meters north-northwesterly of the Molly grid)

The Ford occurrence occupies the area north of Meadow Creek, which is underlain by dark grey to purplish red porphyritic amygdaloidal flows of the Upper Triassic Nicola Group. The lavas are typically amygdaloidal and vary in composition from olivine basalt to augite andesitic basalt. Alteration consists of albitization of plagioclase and propylitization of pyroxene to epidote, zoisite and calcite, with or without chlorite. The rock is locally shot through with sericite and epidote. Flows averaging 1.8 metres thick strike 050 degrees and dip 30 degrees northeast.

The original open cuts (pre-1915) expose copper carbonate ore with occasional flecks of bornite and chalcocite along fracture planes in amygdaloidal flows. The adit follows a mineralized shear zone striking 040 degrees and intersects an east trending set of faults.

Chalcocite(?), bornite and some malachite occur in amygdules and associated veins in flow tops. Gangue minerals include chlorite, sericite, clinozoisite, zeolite and calcite. Some mineralization also occurs in calcite veins, calcite-epidote-sericite veins, sericite-zoisite veins and chlorite veins. Carbonate-zeolite veins are barren.

Drill core assays range from 0.22 to 2.8 per cent copper over an interval of less than one metre (Minister of Mines Annual Report 1973).

#### **6. *Quen Showing – 92ISE190***

(UTM coordinates 5587148 northing, 662420 easting, which is 3,000 meters south of the Molly grid)

The Quen occurrence is underlain by augite and plagioclase porphyritic andesitic flows and red volcanic conglomerate of the Upper Triassic Nicola Group. Chalcopyrite, bornite, pyrite, native copper, molybdenite, chalcocite, malachite and azurite occur in the andesitic flows.

### **MMI SOIL SAMPLING**

#### **a) Sampling Procedure**

The samples were picked up within three grids as described in the following table.

<b>GRID</b>	<b>LINE DIRECTION</b>	<b>LINE SPACING</b>	<b>NUMBER of LINES</b>	<b>SAMPLE SPACING</b>	<b>NUMBER of SAMPLES</b>
Dansey	north	100 meters	10	25 meters	402
Last SNL	north	100 meters	19	50 meters	571
Noname	east	50 meters	18	25 meters	250
<b>TOTAL</b>			47		1,223

The sampling procedure was to first remove the organic material from the sample site (A<sub>0</sub> layer) and then dig a pit over 25 cm deep with a shovel. Sample material was then scraped from the sides of the pit over the measured depth interval of 10 centimeters to 25 centimeters. About 250 grams of sample material was collected and then placed into a plastic Zip-loc sandwich bag with the sample location marked thereon. The 1,223 samples were then packaged and sent to SGS Minerals located at 1885 Leslie Street, Toronto, Ontario. (This is only one of two labs in the world that do MMI analysis, the other being in Perth, Australia where the MMI method was developed.)

#### **b) Analytical Methods**

At SGS Minerals, the testing procedure begins with weighing 50 grams of the sample into a plastic vial fitted with a screw cap. Next is added 50 ml of the MMI-M solution to the sample, which is then placed in trays and put into a shaker for 20 minutes. (The MMI-M solution is a neutral mixture of reagents that are used to detach loosely bound ions of any of the 46 elements from the soil substrate and formulated to keep the ions in solution.) These are allowed to sit overnight and subsequently centrifuged for 10

minutes. The solution is then diluted 20 times for a total dilution factor of 200 times and then transferred into plastic test tubes, which are then analyzed on ICP-MS instruments.

Results from the instruments for the 46 elements are processed automatically, loaded into the LIMS (laboratory information management system which is computer software used by laboratories) where the quality control parameters are checked before final reporting. Quality control consists of retesting every 12<sup>th</sup> sample as well as continuously carrying out testing on standards. Accepted geochemistry standards are repeats within 10% of each other.

**c) Compilation of Data**

Eleven elements were chosen out of the 46 reported on and these were copper, zinc, gold, molybdenum, silver, lead, cobalt, cadmium, nickel, cerium, and uranium. The mean background value was calculated for each of these 11 elements and this number was then divided into the reported value to obtain a figure called the response ratio. However, because it was thought that the Noname Grid was underlain by a different rock-type than that of the Dansey and Last SNL grids, the mean background values were calculated separately for the Noname grid from that of the other two grids. The mean background values in parts per billion (ppb) were calculated as follows:

<b>Grid</b>	<b>Ag</b>	<b>Au</b>	<b>Cd</b>	<b>Ce</b>	<b>Co</b>	<b>Cu</b>	<b>Mo</b>	<b>Ni</b>	<b>Pb</b>	<b>U</b>	<b>Zn</b>
Dansey, Last SNL	7	0.1	5.8	41	24	613	4.6	149	29	7.6	118
Noname	1.7	0.1	2.9	12	18.6	348	4.3	222	8	13	10.3

Two sets of stacked histograms were then made for each of the eight lines of samples of the response ratios as shown on figures #6 through to #101, respectively. The one stacked histogram set consisted of the following elements, in order, copper, gold, arsenic, silver, cobalt, and molybdenum, and the second stacked histogram consisted of copper, nickel, lead, zinc, and cerium.

A plan map was made for each of eleven metals, being copper, zinc, molybdenum, gold, silver, lead, cobalt, cadmium, nickel, cerium, and uranium on maps GC-1 to GC-11, respectively. On each map, the response ratio data were plotted and contoured at a logarithmic interval.

**DISCUSSION OF RESULTS**

The MMI survey within the three-grid area revealed two main anomalous zones of strong exploration interest. These have been labeled the Central Anomaly and the Valley Anomaly.

### ***Central Anomaly***

The Central Anomaly consists of very strong copper values that reach 333,329 ppb, which is extremely high for MMI copper. This anomaly also correlates with molybdenum, gold, and silver anomalous values. This copper-molybdenum-gold-silver anomalous area extends 1,700 meters in a northerly direction by 800 meters in a westerly direction, and is open to the west. In addition, the gold anomaly is open to the north.

Zinc, cadmium, with some anomalous lead values correlate with the main copper-molybdenum-gold-silver anomaly but also occur around its perimeter. If the zinc anomaly is included with the copper anomaly then the extent of the Central Anomaly increases to 3,000 meters in a north direction, being open to both the north and south, by 1,200 meters in a west direction, being open to both the east and west.

Anomalous cobalt values occur throughout the area, especially within the northwest corner of the Dansey grid. This may simply be a reflection of pyrite that is associated with the causative source of the Central Anomaly.

A smaller uranium anomaly occurs to the immediate east of the Central Anomaly.

The Central Anomaly displays a typical geochemical signature of a porphyry copper mineral deposit – namely, anomalous copper values correlating with and surrounded by anomalous zinc values.

The historical Dansey showing occurs within the central anomaly, as shown on the plan maps, but not directly with any of the anomalous values. Either the location as taken from the BC government web site is wrong, or it is the average location for a number of mineral occurrences. However, the most interesting aspect of the Central Anomaly/Dansey Showing correlation is that the MMI survey has indicated that the mineralization may extend over a much wider area.

### ***Valley Anomaly***

The Valley Anomaly occurs within the northeast part of the Noname Grid. It is also a copper-molybdenum anomaly with gold and silver anomalous values though the molybdenum values are much stronger than those of the Central Anomaly. In addition this anomaly contains very strong uranium values that are up to 3300 ppb which is 260 times background. This is very significant for uranium and thus may indicate uranium mineralization.

The Valley Anomaly is a minimum 700 meters in a northerly direction, being open to the north, by a minimum 400 meters in an east direction, being open to the east. Of note, the copper part of the anomaly, which reaches a high of 33,500 ppb, is surrounded by the molybdenum part, which reaches a high of 1,210 ppb (a strong molybdenum response). That is, copper and molybdenum mineralization does not appear to occur

together. However, the uranium anomalous values occur with both the copper and molybdenum anomalous values.

### ***Possible Lithologic Contacts***

To the immediate west of the Valley Anomaly is a very strong zinc anomaly. In fact, the sharp edge of the zinc anomaly suggests the possibility that it may actually occur within a different rock-type, that is, the eastern edge reflects a lithologic contact. Therefore, the writer has drawn this possibility onto the 11 plan maps. As a result, it can be seen that this possible contact is also evident with several of the other metals. The high zinc values on the west side of the contact also correlate with high silver, lead, cadmium, and cerium values. On the other hand, the molybdenum and uranium anomalous values occur on the east side with copper occurring mostly on the east side but some also on the west side. In addition, a nickel anomaly occurs on the east side correlating directly with the copper part of the Valley anomaly.

According to the geology map (fig. 5) taken from the MapPlace web site, the entire grid occurs within the Guichon Creek batholith. However, there is also some indication that it may be underlain entirely by the Nicola Group. For example, the Dab showing, which is only 300 (?) meters northwest of the Noname grid, may contain Nicola rocks. Also, the MMI data, especially the copper, within the Dansey grid suggest the possibility of a northerly-trending contact to the immediate east of the Central Anomaly with Guichon Creek intrusives to the west and Nicola volcanics to the east.

However, the suggested contact within the Noname grid could also be a contact between Guichon Creek intrusives to the west and Nicola volcanics to the east. In support of this is the occurrence of the nickel anomaly east of the contact and cerium anomaly west. MMI nickel, besides reflecting nickel mineralization, also often reflects more basic rock types such as basalt, which is a rock-type within the Nicola volcanics. And cerium, besides reflecting rare earth mineralization, is often a reflection of more acidic rock-types, such as the rocks of the Guichon Creek batholith.

The MMI results indicate numerous possibilities and thus the area should be geologically mapped and/or prospected in order to sort the possibilities out.

### ***Other Anomalies***

A smaller copper/molybdenum/zinc/silver/gold/uranium anomaly occurs to the immediate east and south of the Central anomaly. It is about 400 meters in a north-south direction and about 300 meters in an east-west direction. The values are somewhat lower than the two main anomalies but this may simply be a result of sulphide mineralization at a greater depth.

A fourth anomaly with the same metals occurs to the south of the above mentioned anomaly and appears to extend onto the Last SNL grid. If this turns out to be the case, then this anomaly would be about 700 meters in a north-south direction by a few

hundred meters in an east-west direction (The exact size is difficult to say because of the large space between the two grids).

Within the Last SNL grid is a copper/molybdenum/cadmium/uranium anomaly that extends from the southeast corner of the Last SNL grid in a wide arc to the west central edge of the same grid. It is a narrower anomaly, about 100 meters wide, but it extends across the entire grid for a minimum strike length of 1800 meters being open to both the east and west. It is also a weaker anomaly but, as suggested above, may be reflecting deeper mineralization.

## **GEOPHYSICIST'S CERTIFICATE**

I, DAVID G. MARK, of the City of Surrey, in the Province of British Columbia, do hereby certify that:

I am registered as a Professional Geoscientist with the Association of Professional Engineers and Geoscientists of the Province of British Columbia.

I am a Consulting Geophysicist of Geotronics Surveys Ltd., with offices at 6204 – 125<sup>th</sup> Street, Surrey, British Columbia.

I further certify that:

1. I am a graduate of the University of British Columbia (1968) and hold a B.Sc. degree in Geophysics.
2. I have been practicing my profession for the past 40 years, and have been active in the mining industry for the past 43 years.
3. This report is compiled from data obtained from an MMI soil sampling survey carried out by a 9-man crew of Geotronics Consulting headed by me over the Dansey, Noname, and Last SNL grids within the western part of the Logan Lake Property June 29<sup>th</sup> to July 20<sup>th</sup>, 2008.
4. I do not hold any interest in SNL Enterprises Ltd, nor in any of its properties, nor will I receive any interest as a result of writing this report.

David G. Mark, P.Ge.  
Geophysicist

September 10<sup>th</sup>, 2008

## **AFFIDAVIT OF EXPENSES**

MMI soil sampling with grid emplacement was carried out over the Dansey Grid which is a portion of the Logan Lake Property belonging to SNL Enterprises Ltd, which occurs on and around the village of Logan Lake, located 40 km due north of the city of Merritt, B.C, from June 29<sup>th</sup> to the July 3<sup>rd</sup>, 2008, to the value of the following:

### **FIELD:**

Mob/demob share	\$ 1,200.00	
MMI Survey, 9-man crew, 4 days @ \$3,700/day	14,800.00	
Courier costs for sample shipping	<u>246.00</u>	
TOTAL	\$16,246.00	\$16,246.00

### **LABORATORY:**

Testing of 402 samples @ \$37/sample	\$14,874.00	\$14,874.00
--------------------------------------	-------------	-------------

### **DATA REDUCTION and REPORT:**

Senior geophysicist, 30 hrs @ \$60/hr	\$1,800.00	
Geophysical technician, 45 hours @ \$40/hour	1,800.00	
Report compilation and photocopying	<u>210.00</u>	
	\$3,810.00	\$3,810.00

**GRAND TOTAL**

**\$34,930.00**

Respectfully submitted,  
Geotronics Consulting Inc.

fig. 101

Note: Map data are lab data divided by the background which for uranium is 7.6 ppb for the Dansey and Last SNL grids and 12.7 ppb for the Noname grid.

 Lithological contact as suggested by MMI Data.

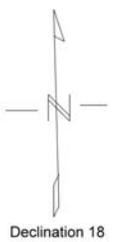

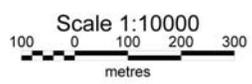

**X** Location of Dansey showing according to MapPlace web site

Dates Samples Picked Up:  
June, July 2008

Soils Tested By:  
SGS Laboratories, Toronto, Ontario

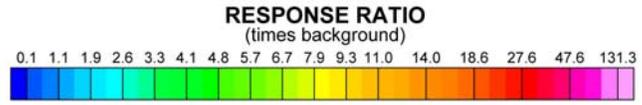

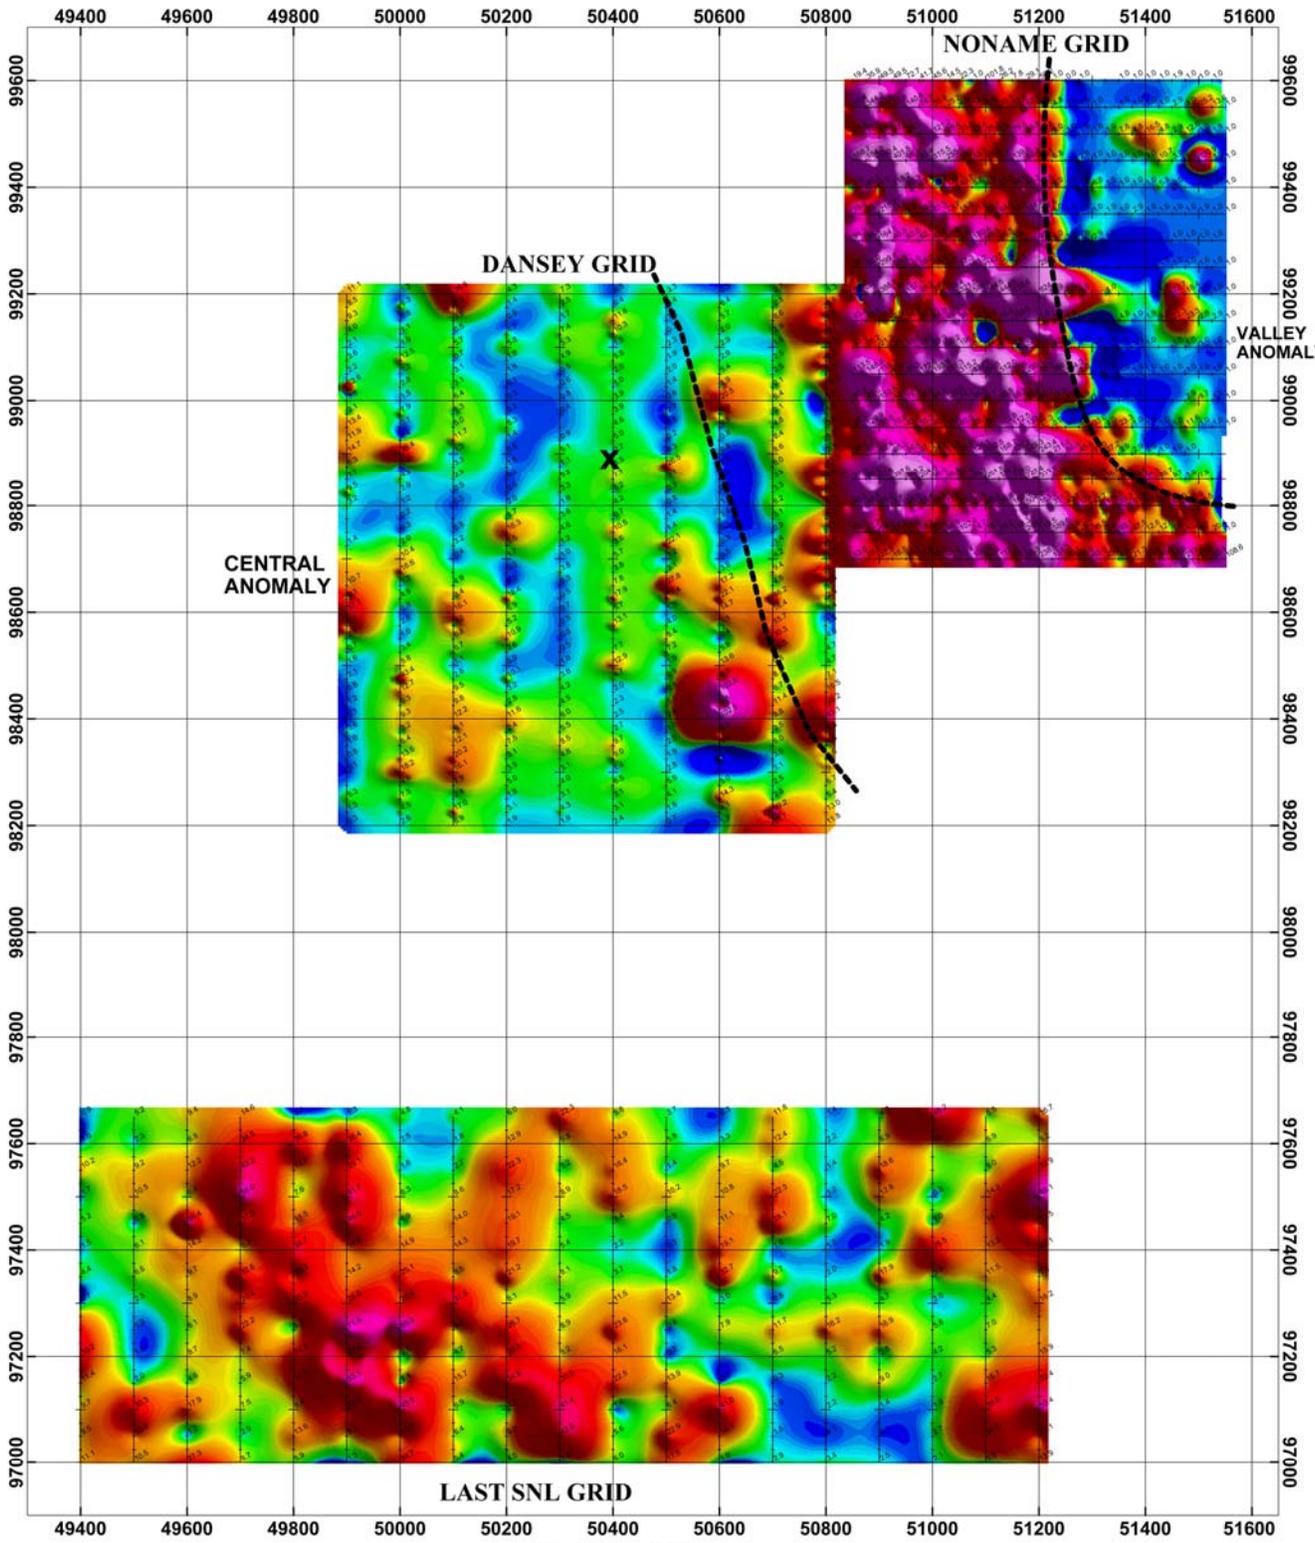

Grid:  
Last 5 digits of UTM grid, zone 10U, NAD 83  
ie., 50750 easting reads 650750 and  
98250 northing reads 5598250

Contour Interval:  
log base 10
