GEOCHEMISTRY, TRENCHING AND DIAMOND DRILLING REPORT FOR THE GAR PROPERTY (NORTH)

1.0 Introduction

The Gar property is a large block of north to northeast-oriented claims covering the upper portion of the Angus Creek drainage (a tributary to Hellroaring Creek which flows into the St. Mary river) and east and west from it. The total core area is about 5500 hectares. Approximately centered on UTMs 5484000N and 562000E for the entire property, the 2008 work was focused on the north end of the property around UTMs 5488137N and 562516E. Tenure numbers for the area of work are: 512232, 512229, 512231, and 512233.

Access is gained from the St. Mary river logging road or the St. Mary Lake road west from Highway 95, up the major St.Mary river valley. Secondary logging roads leave the above roads into the Angus Creek and Hellroaring Creek drainages. The property is accessed most readily by 4x4 truck, a total of 50 to 60 kilometres from Cranbrook. Relief is from 1500 to 2500 metres ASL.

2.0 Property Definition, History, and Background Information

The Gar claims cover an area that has not been extensively explored at any time. Active exploration, particularly for gold has been more confined to the adjacent Perry Creek drainage where placer gold and gold indications in bedrock have been pursued at various times. Exploration in the St.Mary/Angus/Hellroaring Creek drainage system has been for lead/zinc of the Sullivan deposit type and therefore in older rocks of the Purcell Supergroup. Recorded exploration work has focused mostly on the Leader Group which occurs on the north end of the Gar Property. The geology and focus here is as follows. A granodiorite stock has intruded rocks of the Creston and Kitchener Formations. The intrusion is a leucocratic, porphyritic and non-porphyritic body with only modest alteration noted in outcrop. The main interest was the Leader quartz vein a 15cm to 1 metre thick vein traced over 600 metres in length. (Assessment report# 8163, 14112) Individual samples ranged from trace to 4.8 oz/ton gold with associated galena, sphalerite and chalcopyrite. The vein appears to occupy a shear zone which juxtaposes Creston against Kitchener Formation rocks with the intrusion proximal. The vein strikes approximately north-south and dips east at 68 to 80 degrees.
The Gar claims were acquired as part of a prospecting/rock sampling campaign conducted by Super Group Holdings Ltd. in the East Kootenay region. Recognition of a geological environment permissive for gold mineralization and encouraging analytical results for grab samples led to staking.

3.0 Summary of Work Done

Work in 2008 concentrated on the north end of the property around and in the Leader stock in an effort to source gold in float and in soils. Work continued on a soil grid from 2007 and trenching was used to follow-up on gold-bearing quartz vein boulders found in a float train south from the drilling completed last year. Additionally three drill holes were completed to test: an area where soil geochem anomalies intersect; down-dip on the gold bearing shear zone drilled last year; and thirdly a short hole in the area of trenching to test for shear zones and the source of the quartz vein float.

4.00 Geological Setting for the Property

4.10 Regional Geology

The Gar claims are within the Moyie structural block which is a northeast-trending block of ground between two major reverse faults – the St.Mary and Moyie faults. This block, moreso than others in the Purcell Anticlinorium, has apparently been rotated clockwise exposing the deepest stratigraphic level of Lower Aldridge Formation rocks in a northeast-southwest orientation. Overall the sedimentary rocks young to the northwest/west but at various stratigraphic levels the sequence is repeated by reverse faults. Across the Gar alone there a number of younging sequences from east to west. The Gar is underlain by predominantly Mesoproterozoic sedimentary rocks of the Creston and Kitchener Formations. These are dominantly light colored, grey to green, fine clastic rocks succeeded by darker colored, silty argillaceous rocks mixed with carbonates. Granitic intrusions were known to be present in the area and now more have been located. These form small stocks and elongate bodies trending northeast on the property. Structurally the geology is dominated by northeast-trending fault panels. The faults are predominantly reverse faults sympathetic to the bounding major faults. There is small to medium-scale folding which seems restricted to ground adjacent to faults.

The sedimentary sequence is worthy of discussion, as the nature of the rocks does influence the potential for mineralization along with other factors. The lowest sedimentary rocks exposed on the property are close to the base of the Creston Formation. The Middle Creston is a grey to greenish weathering sequence dominated by thin to thick bedded, fine-grained quartzitic wackes to quartz wackes. Interbedded argillites are laminated to thin-bedded rocks. Sedimentary features include flame structures, graded bedding, cross-bedding and lenticular bedding. On a fresh surface the quartzites vary from grey to green to mauve colors with shallow water depositional conditions dominant. The overlying Upper Creston is greenish-grey to green argillite sequence with some intermixed siltstones. Thin and wavy bedded, these rocks form a transition to the rocks above. The Kitchener Formation has basically two divisions. The lower division is not as well exposed but is green weathering argillites and siltstones which are thin bedded. Characteristic of Kitchener is presence of carbonate and this shows as buff weathering interbeds of dolomitic siltsone. The upper portion of the

Kitchener is a darker grey to black or buff weathering thin bedded succession of argillite, carbonate, and dolomitic siltstone.

These sedimentary rocks have been intruded by granitic-type intrusions such as the Leader stock in the north and the Angus Creek stock in mid-property. Other similar but smaller bodies of intrusive rocks have been located on the property. It is important to note that the intrusions are aligned along the northeast structural fabric as if emplaced along some of the faults. The Leader stock has been dated as Cretaceous. The intrusions are granodiorites or quartz monzonites which are leucocratic, medium to coarse-grained, containing plagioclase, quartz, orthoclase, biotite, and sericite in order of abundance. Petrographic work on a few samples shows lesser epidote, chlorite, apatite and zircon with minor pyrite, hematite, and leucoxene. Near the contact with the sediments locally, these intrusions can be more altered including: coarse phases (almost pegmatitic)with increased K-feldspar; sericitization of the plagioclase; muscovite; and chlorite after biotite. There is an increase in quartz veining, silicification, and alteration of the sediments as well.

4.20 Intrusions

There are now five separate intrusive plugs/stocks along the Gar structural trend/zone of about 12 kilometres. These are similar granodiorites to quartz monzonite intrusions which have their long axes oriented northeast-southwest along the structural belt described previously. These likely Cretaceous-aged intrusions vary from homogeneous, medium crystalline to quite coarse, pegmatitic rocks. The amount of outcrop is limited so determination of any zoning within the individual intrusions has not been possible.

Petrographic work indicates the intrusions are quite altered along the contacts. Described as granodiorite, medium to coarse leucocratic, with plagioclase, K-feldspar, quartz, biotite and chlorite (after mafics), and muscovite. Traces of apatite and zircon. Magnetite is present but in very minor amounts (<1%). Sericite alteration of the plagioclase is common.

Structure within the intrusions has not been studied but detail will be limited due to a lack of outcrop, especially a lack of large outcrops. However, smaller structures such as faults and fractures are notable with quartz veins occupying them in at least three orientations – north to northeast; southwest-northeast; and northwest-southeast. Sheeted quartz veins are known along the eastern and northern margins of the Angus Creek stock. Trenching of the Leader stock exposed faults of several orientations with quartz veins containing gold, limonite and sulphides.

The Gar property covers a linear array of small intrusions which together with aeromag anomalies indicate a major pluton underlies the property at depth.

4.30 Mineralization

Gold is the primary target commodity on the Gar property. The presence of gold is indicated by a variety of features including: anomalous gold in stream silts collected by the RGS program; anomalous gold was also confirmed by stream silts and heavies done by National Gold in 2001/2002; prospecting and selected rock geochem sampling yielded multigram gold in 10% of the rock samples collected over the 12 kilometre length of the property; and soil geochem anomalies for gold and associated elements have now been defined in several locations. In addition, historical work on the Leader showing at the north end of the property demonstrated gold with galena and chalcopyrite was present in a quartz vein occupying a shear zone. The potential for gold is also reflected by the geological setting where significant faults/shears have been the locus for granitic intrusions into a varied sequence of sedimentary rocks from quartzites to carbonate-rich argillaceous rocks.

In 2008 minor geological mapping and additional rock geochem sampling was completed. The mapping around the margins of the Leader stock now document a much more irregular contact than had been originally interpreted from regional work. This is particularly true in the area where the drilling has been done. Prospecting located a quartz vein float train south from the landing showing which was drilled in 2007. Quartz boulders with scattered sulfide and visible gold were located over about 150 metres along a float train. Analyses of these rocks yielded seven of ten samples as very anomalous in lead and silver with gold up to 11.5 grams. The gold values are accompanied by a variety of elements (based on core samples, float boulder samples, and soils) including the primary pathfinders of copper, lead, silver, ± zinc, arsenic and the secondary (limited association) pathfinders of antimony, bismuth, molybdenum, and tungsten. Minerals identified visually include free gold, pyrite, galena, chalcopyrite, and sphalerite.

5.00 Geochemistry, Trenching and Diamond Drilling Report

5.10 Geochemistry

The 2007 soil grid was extended to the south and north to further define the lead and gold anomaly. Nine lines with samples every 25 metres were completed on the south and three lines to the north. The samples were placed in kraft paper bags for temporary storage and shipped to Acme Laboratories Ltd. Of Vancouver, B.C. Samples were 15 grams run under Group 1DX with 1:1:1 aqua regia digestion ICP-MS analysis.

The results demonstrate the anomaly continues to the south with two actual trends emerging – the Leader vein is reflected in the soils trending about 010 to 020° azimuth. It appears to terminate to the north about 500 metres. A second anomalous trend is reflected particularly by lead and gold along about 340 to 350° azimuth for 1.3 kilometres. Closure to the north and south is suggested but not confirmed by the amount of sampling.

5.20 Trenching and Diamond Drilling

The road which exposed the original Landing showing drilled last year was extended in 2008 about 140 metres to the south (on the contour) because prospecting had identified a float train of quartz vein boulders (to 0.5m dimensions) carrying visible gold. Two apparently separate shear structures were cut by the road/trench and these were in turn trenched across with a small backhoe. After viewing and some sampling the road was re-contoured.

The shear zones are approximately 1.5 to 2.0 metres wide and trend about 350° azimuth. They contain only narrow, very irregular quartz veins or lenses of quartz. Pyrite and minor galena are the only sulphides of note. Alteration is sericite and chlorite in the sheared and broken sediments. No source for the large quartz vein blocks was found in the exposures created.

Diamond drilling included three drill holes drilled in separate locations on three different targets. Totalling 562.5 metres the drilling was not successful in locating economic grades or intervals of gold mineralization. However, significant gold, silver, and lead mineralization was intersected in different lithologies along shear zones. The core was analyzed by AcmeLabs crushing the samples to minus 200 mesh then using 1:1:1 aqua regia digestion then ICP-MS analysis on a 0.5 gram sample.

Drill hole Gar-08-1 was collared at a lower elevation towards the south end of the intrusion. It was designed to test beneath the intersection of the two soil geochem trends. Drilled at 0562500E and 5487620N at -45° to 090° to a total depth of 401 metres. The first 142 metres was leucocratic, salt and pepper textured quartz monzonite. There are narrow coarse to pegmatitic zones which cut and replace the intrusion. There are very few true quartz veins. One interval with sericitized feldspars, limonite, and pyrite was sampled but was only weakly anomalous in gold. Dominantly argillaceous sediments continue to the end of the hole with highly foliated argillite appearing near the bottom of the hole with skarnification starting. This is interpreted as the down-dip extension of the Leader structure. Three intervals were sampled but none contain gold.

Drill hole Gar-08-2 was designed to test down-dip of the Landing Shear zone drilled last year (1.27m of 3.0g Au and 394g Ag). This -80° hole drilled at 270° azimuth was entirely in quartz monzonite intrusion. There were a few narrow alteration zones of sericite/muscovite± quartz vein – seven over 76 metres so not very abundant. The shear zone was intersected from 77.0 to 88.6 metres but core core recovery was poor. Some of the recovered material was quartz vein. Sericite alteration is widespread along fractures, particularly below the main shear. Weakly anomalous gold occurs within the core zone of 77 to 80.4m at 168ppb Au, 2.8ppm Ag, and 640ppm Pb. The hole ended in fractured quartz monzonite.

Drill hole Gar-08-3 was located on the trench south of the Landing shear zone about 75 metres. Collared in a shear zone, core loss from the first 4.5m was excessive so this wasn't a good test of this zone. The hole remained in quartzitic Creston rocks to 49.0 m

then entered altered intrusion and sediment mixed to 58.5m then fractured quartz monzonite to the end at 70.5m. The sediment/intrusion contact is interesting with alteration and some shearing – best 54.85 to 58.5m - 3.65m of 102.5ppb Au, 0.5ppm Ag, and 811ppm Pb.

6.00 Summary and Conclusion

Work during 2008 was limited to minor geological mapping, extension of the pre-existing soil grid, and drilling of three drill holes. The work from the last two years demonstrates that the likelihood of a large, low grade gold deposit is poor. The intensity of quartz veining with alteration is too low – volumetrically there isn't enough mineralized rock. However, there are several shear zones within the quartz monzonite intrusion and surrounding sediments that are gold bearing. Trenching and drilling of some of these shears indicates the zones are narrow (<2 metres) and grades low to marginal. Sampling of float material yields good gold grades in individual samples so the possibility exists that the better shear-hosted gold has not yet been located.

In 2008, the expanded soil grid continues to define a long (1.3 kilometre) gold and lead soil anomaly which has only been partly tested. The first drill hole tested below the soil anomaly at a substantial depth due to the steep topography. When the hole reached the down-dip projection of the Leader zone, the shear was in argillaceous rocks contrasting with the quartzites at surface. This may account for the lack of mineralization. The second drill hole tested the Landing shear zone at greater depth (about 25 metres) but excessive core loss was encountered. The third hole demonstrated again that there are multiple shears in the area and they do contain anomalous gold.

7.00 Summary of Costs

Geology – Anderson Minsearch Consultants - at $400/d plus 4x4 truck at $75/d and 0.75/km	8883.75
Pighin's Welding – trench; make drill sites;move drill – D6 cat and small backhoe	7728.90
Acme Labs (rocks and soils)	1290.85
EK Expediting – moving of core and storage ($250/d)	2095.00
Lone Peak Drilling – three holes totaling 562.5m	82048.93
Drafting and report writing – 5 days at $400/d	2000.00
Sub-total	104047.43
Administration fee (Ruby red Resources) – 12%	12485.69
Total Costs	$116533.12

8.00 Author's Qualifications

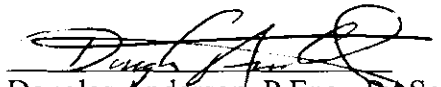
I, Douglas Anderson, Consulting Geological Engineer, have my office at 3205 6th. St. South in Cranbrook, B.C., V1C 6K1.

I graduated from the University of British Columbia in 1969 with a Bachelor of Applied Science in Geological Engineering.

I have practiced my profession since 1969, predominantly with one large mining company, in a number of capacities all over Western Canada and currently within southeastern B.C. as a mineral exploration consultant.

I am a Registered Professional Engineer and member of the Association of Professional Engineers and Geoscientists of B.C., and I am authorized to use their seal which has been affixed to this report.

I am also a Fellow of the Geological Association of Canada.



Douglas Anderson, P.Eng., BASc., FGAC

GAR PROPERTY

DRILL HOLE GL-08-1

Location – Above Angus Creek road at 9.5 kilometres. 0562500E; 5487620N
Started: September 13 Completed: September 17, 2008 Length=401m
Contractor: Lone Peak Drilling Elevaton = 1610m Dip=-45° Azimuth=090°
NQ core stored at the Vine Property at Peavine Creek Overburden=3.25m
Objective: to test the Leader stock and margins for quartz vein stockworking and or shear-hosted mineralization.

3.25 – 142.0m Quartz monzonite – medium to coarsely crystalline; leucocratic salt and pepper textured intrusion. 15 to 18% biotite and pyroxene (hornblende) with 25%+ grey quartz.; white plagioclase feldspar. No structure excepting hairline fractures with bounding sericite alteration of feldspars.There are coarse to pegmatitic zones of quartz-feldspar-muscovite 22.85 to 24.80m; 68.6 – 69.7m; 91.8 – 92.5m. 59 to 62.2m alteration with two short limonitic intervals with green sericitized feldspars. Scattered pyrite with magnetite shells. Very few true quartz veins – some zoned, pegmatitic "veins". Increasing numbers of sedimentary xenoliths below 123m.

142.0 – 181.5m Contact with sediments – appears faulted with 25cm of limonitic rubble with micas then into vaguely bedded sediments wih apophyses of quartz monzonite and two intervals of coarsely crystalline Q-F-M 144.4 – 146.5m; 150.5 – 153.15m; 168 – 174.2m light colored pinkish green – some pyrite. Bedding at 50° to ca. Contact meta seds are thin to barely medium bedded, highly biotitic/sericitic.

181.5 – 194.1m Mixed zone of contact meta sediments with black and white QM intrusion. 75%intrusion/25%sediment remnants. Grey wackes/quartzitic wackes with argillaceous interbeds isolated within the intrusion.

194.1 – 224.2m Mottled, contact metamorphosed sediment – rare quartzite bed, mostly argillaceous with some laminated intervals. Bedding at 45 to 65°. Grey to dark grey. Three narrow quartz veins below 215m – thickest 5cm with magnetite patches.

224.2 – 229.2m Still sediments but more pale green due to a shear in the 226 to 227m interval. A few short Q-F segregations/highly altered intrusion. Bedding vague.

229.2 – 325.6m Sediments well represented as grey to dark grey laminated to thin bedded to medium bedded QcW to subwackes. Start seeing a few quartz veins, some with darker green chlorite/mica alteration zones. Intrusion 246.2-247.2m which is altered with qv. ;246.6-247.1m with magnetite patches; 266.75 – 266.9 last intrusion in hole. Bedding at 55 to 65 then back to 55° deeper in hole. By 263 to 273m to 70°. Bedding less identifiable with depth – at 296m at 30 to 40°; 20 to 25 around 315m; last bedding at 325m at 50 - 60°. No fault zones. Chlorite and mica cross-cutting zones to 10cm with quartz boundaries are interesting but of low overall distribution. 256m 7cm qv with magnetite. 261.2m 5cm Q-chlorite with massive pyrite and chalcopyrite. Not many QV overall.

325.6 – 358.3m Simply more altered section with quartzitic beds silicified and argillaceous intervals pale green, spotted schistose rocks. Transitional sediment Creston to Kitchener? Bedding not recognizable due to metamorphism and structural overprinting. Stretching/shearing at 20 to 40° to ca. No QV.

358.3 – 401m Somewhat arbitrary boundary to more consistently dark grey contact meta sediments of Kitchener? Certainly skarnification starts, particularly below ~375m. Bedding obliterated. Shearing within argillaceous section foliated starting around 374m . 380.5- 383.5m; 399-400.5m strongly foliated argillite at 10° to ca. Skarny patches are silica-epidote-garnet-chlorite. There are only a few narrow qv but there are siliceous zones also. Some disseminated pyrite, minor chalcopyrite, galena, sphalerite.

DRILL HOLE GL-08-2

Location – Above the Angus Creek road at 9.5km. UTMs 0562560E 5488112
Started Sept. 18 Completed Sept.19. Length = 91.0 metres.
Contractor – Lone Peak Drilling Elevation = 1720m Dip = -80° Azimuth = 270°
NQ core stored at the Vine Property in Peavine Creek. Overburden=1.83m
Objective – To test the Landing shear zone drilled last year down-dip.

1.83 – 77 m Coarse grained Quartz Monzonite. Get some segregation compositionally over short lengths (<0.5m) of quartz and feldspars. Large, light grey feldspars feldspars and grey quartz in the intrusion. 10 to 15% mafics. Not much structure with low fracture intensity (at 45-60° to ca); at ~70m the intrusion becomes more broken up with a pervasive greenish-yellow coloration due to weathering. Alteration restricted to small sericite zones (of feldspars) proximal to fractures – may be narrow qv associated – examples 20.6-20.9; 25.4-26.10;35.78-36.10;43.5-43.6;47.6-47.9;55-55.6;57.9-58.7m. Minor pyrite in some alteration zones.

77.0 – 88.6m Shear Zone in Quartz Monzonite – only rubble recovered. Less than 50% recovery with 77 to 80m yielding ~1.2m of qv material. Hangingwall alteration is moderate back to ~ 70m ; footwall alteration is more intense, extending down to about 88.5m. Shear known to be high angle, east-dipping.Green sericitization of the plagioclase feldspars. Microcline fresher. Quartz vein not overly suphidic but such poor recovery. Limonite stainingb widespread, more developed in fractured intrusion.

88.6 – 91.0m Quartz monzonite to granodiorite – fresher, medium to coarse crystalline. Only modest fracturing, a large proportion of which have limonite and muscovite coatings and greenish feldspars. Limonite on fracture, no sulphides.

DRILL HOLE GL-08-3

Location - Above the Angus Creek road at 9.5km. UTMs 0562574E 5487963N
Started Sept.19 Completed Sept.20. Length=70.5m
Contractor – Lone Peak Drilling Elevation=1705m Dip -45° Azimuth= 090°
NQ score stored at the Vine Property in Peavine Creek. Overburden=1.7m
Objective – To test east of the trench for more shearing and quartz veining.

1.70 – 49.0m Sediments – Creston Fm. Grey, f.g. quartzitic wackes to quartz wackes. Metamorphically spotted with micas with paler alteration rims. Minor intervals of f.g. intrusion (4.7-5.2; 12.2-12.5;26.7-27.2;42.8-43.5) Some f.g. alteration phases as well. Bedding present but not generally obvious – visible as 50 to 60° to ca. Started hole in trenched shear zone – cored was rubble from 1.5 to 4.5m with excessive core loss; 4.7-5.2 m intrusion then fractured sediment to 7.5m with limonitic fractures. Small xc intrusive phases. Probable shear 43.5 0 44m with rubble and sheared seds at 50° to ca.Spotting due to mica clotting. Small amount of qv recovered around 3.5 – 4.0m with pyrite. 42.8-45.0m fracture zone (shear probable) with intrusion then limonite on fractures.

49.0 – 70.5m First 20cm is foliated/sheared argillite then altered intrusion and sediment 49.2 – 53.3m then sheared dark argillite 53.3 to 54.35m then altered intrusion to ~58.5m then fresher granodiorite below to 70.5m. Coarse-grained intrusion with large microcline crystals. Mixture of two sediment types and intrusion along a sheared altered contact. Altered intrusion from 49-51.2m is mostly white albite then spotted, altered sediment as above in hole then white, altered intrusion with pyrite and vugs. Only a minor amount of true qv. Pyrite and limonite after it are present within the altered intrusionbut not in the quartzite or argillite.

EOH

CLIENT JOB INFORMATION

Project: GAR
Shipment ID:
P.O. Number
Number of Samples: 223

SAMPLE DISPOSAL

DISP-PLP Dispose of Pulp After 90 days
DISP-RJT Dispose of Reject After 90 days

Acme does not accept responsibility for samples left at the laboratory after 90 days without prior written instructions for sample storage or return.

SAMPLE PREPARATION AND ANALYTICAL PROCEDURES

Method Code	Number of Samples	Code Description	Test Wgt (g)	Report Status
SS80	223	Dry at 60C sieve 100g to -80 mesh		
Dry at 60C	223	Dry at 60C		
RJSV	223	Save all or part of soil reject fraction		
1DX15	223	1:1:1 Aqua Regia digestion ICP-MS analysis	15	Completed
DIS-RJT	223	Warehouse handling / Disposition of reject
