1.10 Location and Access

The Jacleg property is located in southeastern British Columbia, along the western edge of the Rocky Mountains and within the Fort Steele Mining Division, approximately 25 km northeast of Cranbrook (Fig.1). Access is via forestry roads north of Wasa and up Lewis Creek.

1.20 Property

The Jacleg property is part of a larger claim block (the "Rockies Block") within the Rocky Mountains held by Ruby Red Resources Inc. of Calgary, Alberta.

1.30 Physiography

The Rockies claim block is located east of the Rocky Mountain Trench in the Hughes Range of the Rocky Mountains and covers much of the area immediately east of the trench between the Wild Horse River and Lewis Creek (Figs. 1 & 2). Topography is generally steep with mainly wooded and locally rocky slopes. Elevation ranges from 1060 to 2060 meters. Forest cover includes mainly pine, fir and larch. Parts of the claim block have been logged and are in various stages of regeneration.

1.40 History of Previous Exploration

The Estella lead-zinc-silver deposit occurs on crown grants adjacent to the Rockies claim block. This small WNW oriented massive sulphide vein deposit was mined from 1953 to 1961 (Hoy, 1993). Exploration in the vicinity of the Estella has focused on finding similar deposits, and some work has also been done looking for sedimentary exhalative deposits like the world class Sullivan deposit near Kimberley, located about 15 kilometers west of the claim block. Cominco Ltd (Assessment Reports 20,175, 20,554 and 21,935) did extensive ground and airborne geophysics as well as soil and rock geochemistry and diamond drilling near the Estella, and Bakra Resources Ltd. (AR 16,337) did a program of surface geologic mapping and soil and rock geochemistry. Placer Dome Ltd. worked on what are now part of the Rockies block claims in the upper Wild Horse drainage and in Tackle Creek (AR's 18,159 and 20,202). Their work consisted of geologic mapping, soil and rock geochemistry, ground geophysics and diamond drilling. INCO, Mercury Explorations Ltd., National Gold Ltd. and Chapleau Resources Ltd. have done small programs on the Jacleg portion of the Rockies block claims. Ruby red Resources Inc. has been working on parts of the Rockies block of claims since 2002; this work has included surface geologic mapping, rock and soil geochemistry and ground geophysics (eg AR's 26,985, 28,643, 29,808). Ruby Red has recognized a potential for porphyry style mineralization within the claim block. Cretaceous quartz monzonite intrusions exist in the upper Lusier River drainage, at the top of the Wild Horse River drainage, in the East Wild Horse river tributary and immediately east of

Figure 2 Jacleg Property Area

Claim Map Showing Location of Soil Geochem Grid

the Estella mine site. Anomalous copper, gold, molybdenum, lead, silver, zinc, arsenic and bismuth are present on the claim block in the vicinity of some of the intrusions and this geochemical signature is compatible with a porphyry style of mineralization.

1.50 Purpose of Exploration Program

In 2007, a small soil geochemistry grid was completed within part of Lewis Creek canyon to evaluate known copper mineralization and the survey detected local anomalous gold, copper and cobalt mineralization (Klewchuk, 2008; AR 29,808). Additional soil geochemistry was completed in 2008 to further evaluate the areas of anomalous soils.

2.00 GEOLOGY

The eastern portion of the Rockies claim block where exploration activity was undertaken in 2008 is underlain by Mesoproterozoic Purcell Supergroup rocks of the Fort Steele and Aldridge Formations. These rocks are described by Hoy (1993):

Purcell Supergroup rocks in Fernie west-half are exposed in the Purcell Mountains and the Hughes, Lizard and Galton ranges east of the trench. Throughout the Purcell Mountains, formations are generally thick, contacts between them are gradational and lateral facies or thickness changes are gradual. However in the northern Hughes Range the lower part of the Purcell Supergroup is markedly different, with predominantly fluvial, alluvial fan and deltaic deposits at the base, overlain by a relatively thin and heterogeneous Aldridge succession. Facies and thickness changes within the Aldridge Formation are pronounced here indicating influence of syndepositional faults or growth faults. A thick succession of turbidites, interlayered with gabbro sills, was deposited to the south and west. The transition between these contrasting facies marks the edge of the Purcell basin in early Purcell time. The tectonic disturbance recorded in these rocks continued intermittently near the basin edge during deposition of younger, generally shallow-water sediments.

The Fort Steele Formation is exposed along the western edge of the Rockies claim block in the Jacleg and Loose leg areas and is described by Hoy as:

The Fort Steele Formation comprises predominantly cross-bedded and massive quartz arenite, quartz and feldspathic wacke and siltstone, interpreted to be primarily deposits of a braided fluvial system. The formation is characterized by thick sections of massive and crossbedded quartz arenite and a number of large fining-upward cycles, termed megacycles, that are several hundred meters thick. Fine-grained siltstone and argillite facies are not abundant, comprising less than 10 per cent of the total exposed succession. These are interpreted to be alluvial fan and fan-delta deposits.

The Aldridge Formation conformably overlies the Fort Steele Formation on the Loose Leg and Jacleg portions of the Rockies claim block. The lower part of the Aldridge Formation is divided by Hoy (1993) into six distinctive units, A1a to A1f. These units are further described by Hoy:

The basal member of unit A1 (A1a) ... consists of medium to dark grey to black, finely laminated argillite and siltstone. Flaser and lenticular bedding occur occasionally and graded siltstone-argillite couplets up to 3 centimeters thick may define bedding. Its basal part is generally coarser grained and may include minor quartz wacke, siltstone and wacke with dolomite cement.

A1b is a conspicuous unit, from 20 to more than 100 meters thick, characterized by abundant carbonate and referred to as the "carbonate marker unit". It consists primarily of interlayered silty or argillaceous dolomite, dolomitic argillite or siltstone interbedded on a 2 to 3 meter scale. Dolomitic layers are brown weathering, commonly finely laminated and may contain isolated mound-shaped stromatolites or cryptal algal mat deposits. Lenticular beds, crossbeds, scours and ripple marks are common within siltstone or dolomitic siltstone. Grey limestone, interbedded with dolomite, is prominent near the top of Unit A1b just north of Wasa Creek; thinly interbedded chert and dolomite, and pods of brown-weathering dolomite in siltstone are occasionally present.

Unit A1b grades upward into A1c, a succession of interbedded argillite and siltstone. South of Lewis Creek, A1c can be subdivided into three subunits. These include a massive to faintly laminated black graphitic argillite, overlain by a lighter colored grey, greenish grey or tan, finely laminated siltstone or silty argillite and, finally, a medium to dark grey, rusty weathering, massive to faintly laminated argillite. Rusty weathering dolomite pods, minor calcareous argillite and rare, thin silty quartzite layers occur locally within the two upper subunits.

Unit A1d is a distinctive unit south of Lewis Creek that hosts both the Kootenay King and Estella lead-zinc deposits. It consists largely of buff-weathering dolomitic siltstone interlayered with buff to grey, finely laminated argillite. Sedimentary structures, including lenticular bedding, flaser bedding, tangential crossbedding and graded siltstone-argillite couplets, commonly with flame or load casts at their base, are conspicuous. To the south, the unit becomes a coarser grained tan siltstone or wacke with only minor argillite or dolomitic siltstone. To the north it changes to a dark, finely laminated argillite with only minor interbedded siltstone. Contacts with underlying argillite of Unit A1c and overlying, generally dolomite-free siltstone and argillite of unit A1f are gradational across many tens of meters.

Unit A1f comprises siltstone and argillite with minor dolomitic siltstone and occasional wacke and quartz arenite beds. Graded bedding is common and ripple crosslaminations, lenticular bedding and mud-chip breccias occur in the middle and upper parts of the unit. The contact with the overlying middle Aldridge is placed at the base of the first, prominent, thick-bedded quartz wacke turbidite sequence.

A number of thick, massive to faintly laminated quartz arenite or quartz wacke beds (referred to as 'quartzites' and mapped as unit A1e) occur within A1d and less commonly within A1c.

Structure

The structure of the Jacleg and Loose Leg areas is dominated by a large, open, recumbent anticline that developed from eastward thrusting. The axial plane of the anticline dips to the west; bedding along the western part of the structure dips shallowly to steeply east; further to the east, in the vicinity of the upper portion of Lewis Creek, bedding dips steeply west and is overturned. Regional cleavage is developed parallel to the axial plane of the fold.

3.00 SOIL GEOCHEMISTRY

Small extensions to the 2007 Jacleg soil grid were completed in 2008. Location of the soil grid is shown in Figure 2. Sample locations were established using a hand-held GPS receiver; lines were run using a compass and sample spacing was determined using a hip chain; sufficient GPS readings were taken to provide confidence in locating sample sites on a map. Soil samples were collected from the 'B' horizon at a depth of approximately 15 cm and placed in Kraft paper bags, dried and shipped to Acme Analytical Laboratories Ltd. at 1020 Cordova Street East, Vancouver, B.C. where they were analyzed for a 30 element ICP package and geochemical gold by standard analytical procedures. Location of soil samples on the grid is shown in Figures 3, 4 and 5; complete soil sample geochemical analyses are in Appendix 1.

Four east-west oriented lines (L6150N, L67N, L68N and L69N; see Figs. 3 to 5) were sampled with a total of 184 soils collected. These soils were intended to help evaluate anomalous gold, copper and cobalt values detected in 2007; coincident and associated gold-copper anomalies were detected in 2007 near the eastern end of L66N and near the western end of L61N. The 2007 soil results are shown with the 2008 soil results in Figures 3 to 5.

Results

The extension of the 2007 gold anomaly near 6450E – 6475E on L66N was not identified by the 2008 soil sampling on lines 67N, 68N and 69N. The 2007 gold anomaly near the west end of L61N (Fig. 3) correlates with a 32 ppb Au value on L6150N at 5200E and this may be part of a subtle NE trend of anomalous gold that is evident on Lines 65N to 69N (eg 132 ppb Au at 5975E on L67N and 76 ppb Au at 6300E on L69N).

Elevated copper values (Fig. 4) occur locally but tend not to be coincident with gold. The highest copper value detected in 2008 is 227 ppm at 6200E on L68N. A high copper value of 169 ppm Cu at 5600E on L6150N is part of a NE trend of elevated copper values extending from L61N to L63N.

Higher cobalt values (Fig. 5) tend to be associated more with higher copper values than with higher gold values.

4.00 CONCLUSIONS

1. The 2008 soil grid on the Jacleg property detected locally elevated gold and copper values; higher gold values tend to occur near higher copper values but they tend not to be coincident.
2. There is a general NE trend to both higher gold and higher copper values, suggesting structural control.
3. Higher cobalt values tend to occur with higher copper values.

7.00 AUTHOR'S QUALIFICATIONS

As author of this report I, Peter Klewchuk, certify that:

1. I am an independent consulting geologist with offices at 1 – 200 Norton Avenue, Kimberley, B.C.
2. I am a graduate geologist with a B. Sc. degree (1969) from the University of British Columbia and an M. Sc. degree (1972) from the University of Calgary.
3. I am a Fellow of the Geological Association of Canada and a member of the Association of Professional Engineers and Geoscientists of British Columbia.
4. I have been actively involved in mining and exploration geology, primarily in the province of British Columbia, for the past 33 years.
5. I have been employed by major mining companies and provincial government geological departments.

Dated at Kimberley, British Columbia this 25th day of March, 2009.

Peter Klewchuk, P. Eng.
