Figure No. 1 Banded massive sulphide from Frank Creek Discovery Trench. Sulphides in the rock consist mainly of pyrite, chalcopyrite and sphalerite.

1.0 SUMMARY

Work performed on Barker Minerals Ltd. mineral properties in 2008 was concentrated in three areas; the Frank Creek, Black Bear and GERIMI Properties.

On **Frank Creek Property**
Diamond drilling concentrated at the F9 Target Area. Eight holes were drilled in a grid pattern to test the Trend 3 soil anomaly and Cu-Pb-Zn mineralization discovered in trenches there in 2007. A 4.65 metre intercept of semi-massive to massive sulphide with 50% - 90% total metal content occurred in Hole FC08-34 at a depth of 16.55m - 21.20m. Within this section the highest Cu, Pb and Zn values were 2,090 ppm, 2,220 ppm, 8,500 ppm respectively, over 1.12m. Other holes also had significant intersections of Cu-Pb-Zn sulphide mineralization.

Five other holes targeted conductors from previous surveys and sought continuity and attitude information regarding mineralization encountered in previous drill programs. Except for local massive or syngenetic-style mineralization evident at Frank Creek's Discovery Trench of 2001, and several DDH holes to date, the most common character of mineralization on surface at Frank Creek is a footwall or stockwork style mineralization.

The overturned nature of the geologic strata in the area was affirmed, though this has been known from previous outcrop and drill hole data. Overturned strata suggest a possible massive sulphide may be intact below the footwall zone exposed on the surface. A recommendation is made to test a low resistivity anomaly (conductor) from the 2004 Titan-24 geophysical survey for a possible massive sulphide body below the footwall-style mineralization in the F9 Target Area.

On **Black Bear Property**
New roads and logging facilitated prospecting in a 2.0 km long area between the Providence adit northwestward to the area of the 'Trump' quartz-galena showings. Numerous new quartz vein outcrops and float were discovered in a 2 km x 1 km area. The new quartz-galena showings indicate a strong persistence of the of the quartz veining northwest of the Providence workings. The quartz-galena veins at the Providence area have been explored intermittently since at least 1926. Comprehensive surveys including trenching are recommended to isolate the most promising of the new vein structures for drill testing.

On **GERIMI Property**
Mineralization described for the Lynda showing in Minfile 093B 025 and previous explorers' assessment reports was confirmed by prospecting and cursory mapping. Copper mineralization was associated with bedding planes and contacts in limestone and siltstone. Historic geophysical work detected anomalous magnetic trends and soil sampling surveys had Cu anomalies, partly masked and limited by deep overburden. It is recommended that the historical anomalies and showings be followed up by new geochemical and geophysical surveys. In particular, enzyme leach analysis of soils should be done as this technique has elsewhere proven able to detect the most subtle deep-buried sources.

LIST of APPENDICES

2.0 INTRODUCTION

This report describes the geological, geochemical, geophysical, mapping, trenching and diamond drilling work performed on Barker Minerals Ltd. mineral properties between April 2008 and October 2008. The properties are located near Likely, British Columbia.

On Frank Creek Property geochemical and geophysical targets were tested by 13 diamond drill holes (2,375 m). 4.65 m of semi to massive sulphides were intersected in one hole; other holes had significant intersections of Cu-Pb-Zn sulphide mineralization.

On the Black Bear Property where recently built logging roads improved access, new galena-bearing quartz veins in float and outcrops were found, demonstrating good continuity of quartz veining over a 2 km strike distance between the historical Providence developed prospect and the historical Trump prospect.

On the Gerimi Property the historical Lynda showing was sampled and assessed.

In this report chemical abbreviations are used for the elements discussed. The elements and abbreviations are:

Ag	Silver	Cr	Chromium	Pb	Lead
As	Arsenic	Cu	Copper	Sb	Antimony
Au	Gold	Eu	Europium	Se	Selenium
Ba	Barium	Hg	Mercury	Ti	Titanium
Bi	Bismuth	Mn	Manganese	Zn	Zinc
Cd	Cadmium	Mo	Molybdenum		
Co	Cobalt	Ni	Nickel		

3.0 PROPERTY DESCRIPTION and LOCATION

The Property consists of contiguous claims listed in Appendix B – Barker Minerals Ltd. Mineral Claim Details. The Property is outlined in Figure No. 3 – Barker Minerals Ltd. Mineral Claims. Mineral claims comprising the Property are located generally in the area between Quesnel and Cariboo Lakes of the Cariboo Mining Division in British Columbia and are 100% owned by Barker Minerals Ltd. of Prince George, B.C.

The Property is approximately 10 km north of the settlement of Likely and 90 km northeast the City of Williams Lake. The City of Prince George is 155 km to the north.

The geographic coordinates of the Property are:
52.71° North Latitude and 121.63° West Longitude or
593000 E and 5842000 N UTM coordinates (NAD 83).
The relevant maps are:
N.T.S. Map No. 93A/11, 93A/12, 93A/13, 93A/14, 93B/16.

Details about the mineral claims are provided in Appendix B – Barker Minerals Ltd. Mineral Claim Details.

5.0 PHYSIOGRAPHY and ACCESSIBILITY

The following description in *italics*, is after McKinley, 2004:
The property is situated in the central part of the Quesnel Highland between the eastern edge of the Interior Plateau and the western foothills of the Columbia Mountains. This area contains rounded mountains that are transitional between the rolling plateaus to the west and the rugged Cariboo Mountains to the east. Pleistocene and Recent ice sheets flowed away from the high mountains to the east over these plateaus and down to the southwest (Cariboo River), west (Little River) and northeast (Quesnel Lake), carving U-shaped valleys. The elevation ranges from 700-1650 m. Precipitation in the region is heavy, as rain in the summer and snow in the winter. Drainage is to the west via the Cariboo, Little and Quesnel Rivers to the Fraser River. Quesnel Lake, the main scenic and topographic feature in the region, is a deep, long, forked, glacier-carved lake with an outlet at 725 m elevation. Vegetation is old-growth spruce, fir, pine, hemlock and cedar forest in all but the alpine regions of the higher mountains (mainly above 1400 m elevation). Weldwood has been actively logging fir, spruce and pine in the area.

Access to the Frank Creek and Black Bear areas is via gravel logging roads bearing northeast from Likely. Access to the Gerimi project is mainly via gravel logging roads southeast from Quesnel.

6.0 HISTORY

6.1 Frank Creek Property

Old placer workings on the lower portion of Frank Creek suggest placer mining was conducted perhaps since the turn of the 20th century and possibly earlier.

6.1.1 Work done in 1980.

The relevant reports are Assessment Reports 9669 and 9677 by M.G. Larsen.
Work was done in 1980 by May G. Larsen on the Darcy claims and Alan claims, each consisting of 2 claim units. The Darcy claims straddled the Cariboo Lake Road, on the southeast side of Cariboo Lake approximately 2.5 km northeast of the south end of the lake. The Alan claims straddled Wilby (Pearson) Creek, 5.0 km east of the south end on Cariboo Lake. Prospecting and conventional panning for gold was done. A field chemical test kit and a fluorescent lamp were used to detect various elements and minerals. Nothing of interest was found.

6.1.2 Work done in 1981.

The relevant report is Assessment Report 10252 by T.A. Jones.
Work was done in 1981 for Canadian Nickel Mining Limited on the BT claims, consisting of 103 claim units covering Browntop Mountain and the head waters of Frank Creek, north of Seller Creek and Badger Peak. Geological mapping was done and rock and stream sediment samples were collected. Samples of quartz veins had geochemical results of up to 250 ppb Au. The quartz veins occurred in a drainage area of a stream where a silt sample had 330 ppb Au. Quartz veins up to 1 metre thick

were stated to be abundant near the common corner of the BT 5, 6, 7, 8 claims, this on a hill approximately 2.0 km southwest of Goose Peak. Follow up work was recommended.

6.1.3 Work done in 1981.

The relevant report is Assessment Report 10264 by J.S. Christie et al.
Work was done in 1981 for E & B Explorations Inc. on the Boomerang Property consisting of 104 claim units in the head waters of Seller Creek and covering Badger Peak on the south side of Canadian Nickel's BT claims. Reconnaissance stream sediment and soil sampling was done to follow up government geochem data indicating a 750 ppm As anomaly in a stream. The stream and soil samples returned values up to 345 ppm As and up to 1,500 ppm Pb. Gold values obtained were low. Areas of very rusty soil and outcrop occurred in the anomalous drainage and quartz vein float containing galena, tetrahedrite and sphalerite were found. Follow up work was recommended.

6.1.4 Work done in 1983.

The relevant report is Assessment Report 11620 by Beaton, R.H.
Work was done in 1983 for Silver Standard Mines Limited on the Thunder Property consisting of 36 claim units roughly along the southeast side of Cariboo Lake, extending from Frank Creek southwest toward Wilby Creek. Initial prospecting in early 1983 discovered pyrite-chalcopyrite mineralization on the 'D' logging road on the west side of Frank Creek. Subsequent follow up included 419 soil samples collected over a grid consisting of 22.4 km cut line over a 1.2 km x 2.0 km area. Soils anomalous in copper, zinc or silver were followed up by limited mechanical trenching at 3 locations along roads. Minor sulphide mineralization was found and was deemed to be probably related to lenses of intrusive rock and to a lesser degree quartz veining. No follow up work was recommended.

6.1.5 Work done in 1983.

The relevant report is Assessment Report 13154 by Mar, J.
Work was done in 1983 for Esso Minerals Canada on the NB claims consisting of 40 claim units covering Wilby Creek drainage and southward toward Seller Creek. Work consisted of geological mapping over the claims area and stream sediment and soil sampling concentrated close to the banks of Wilby Creek. Stream sampling included heavy mineral concentrates and conventional stream sediments. 13 rock, 8 heavy mineral and 124 soil samples were collected. Rocks mapped were considered to be metamorphosed volcanic and sedimentary rocks belonging to the Harveys [Ridge] Succession and granitic gneiss, possibly a sill, belonging to the Quesnel Lake Gneiss. Rusty carbonate-sericite altered rock appeared to occur widespread on the north side of Wilby Creek. Minor pyrite, chalcopyrite, galena and sphalerite occurred with quartz and altered rock.

Several rock samples were anomalous in Au and in pathfinder elements; the highest Au value was 445 ppb. The Assessment Report text states that stream sediments indicated an enhanced background for As and Sb but modest Au values. Heavy mineral concentrate Sample No. H331 had 3,600 ppb Au however and a conventional stream sample at the same location on Wilby Creek had 130 ppb Au. The Assessment Report text states that the soils gave 'best responses' or anomalies in As, Co, Cu and Pb. No Co, Cu or Pb results in soils are provided in the report however. Though a suite of anomalous metals were acknowledged the soil results were considered sporadic with no well-defined trends. No follow up work was recommended.

6.1.6 Work done in 1984 to 1986.

Work on [Frank Creek] *was done from 1984 to 1986 by the Rasmussen Brothers, who re-entered and re-explored the old Apostle placer drift on the west bank of the creek and dug a 48 foot (14.6 metre) shaft higher on the creek. When large massive sulphide boulders were found at the base of placer*

gravels on the east side of the creek, a hard rock claim, the Home Run (9 units) was staked, but little or no exploration was done and the claim lapsed in 1987. (Guinet, 1988).

6.1.7 Work done in 1986.

The relevant reports are Assessment Reports 15420 and 15804 by Schmidt, U.
Work was done in 1986 for Casmiro Resource Corp. on the C1, Conch1 and C3 claim groups totalling 56 claim units. The C1 and Conch1 claims were located approximately 2.0 km south of the south end of Cariboo Lake, on the west side of Esso's NB claims. The C3 claim was located on the east side of Esso's claims and in the headwaters area of Wilby Creek and south tributary of Frank Creek.

The purpose of the work was to locate areas of precious metals mineralization. Approximately 179 soil and 8 silt samples were collected and analysed. Geological mapping was also done in the C3 claim area. Metamorphosed sedimentary and intrusive rocks were observed. The report states no significant gold values occur on the C3 soil grid and that geochemical anomalies in other elements on the Conch 1 and C3 grids indicated off-property sources. An anomaly on C1 grid was considered to reflect lithological boundaries. It was recommended that the soil grids be extended.

6.1.8 Work done in 1987.

The relevant report is Assessment Report 17696 by Guinet, G.
Work was done in 1987 for Golden Eye Minerals Ltd. on the MASS claim consisting of 9 claim units covering the lower portion of Goose (Frank) Creek just above the Cariboo Lake Road, on the southeast side of Cariboo Lake.

The occurrence of numerous boulders of massive sulphides, up to just over 1.0 m in size, in the lower portion of Goose (Frank) Creek prompted prospecting and stream sampling to be done on the MASS claim area. 20 stream sediment samples were collected along a 1,300 m length of Goose (Frank) Creek. The source of the massive sulphide boulders was not found and the stream sampling had no interesting results. Further work was recommended to be done on the north side of the property, to include geochemical and geophysical (EM) surveys.

6.1.9 Work done in 1988-1989.

The relevant report is Assessment Report 19345 by Martin, L.S.
Work was done in 1988-1989 for Formosa Resources Corp. and Golden Eye Minerals Ltd. on the MASS Property totalling 100 claims covering the main parts of the drainages of Frank Creek and Wilby Creek.

Work consisted of geological mapping, soil sampling, VLF-EM and magnetic geophysical surveys and mechanical trenching. Approximately 1,400 soils and 166 rock samples were collected on a cut grid over approximately 2.0 km x 2.5 km in area. A suite of 30 elements was analysed. This work was concentrated on the west side of the lower part of Frank Creek.

Geological mapping outlined volcanic and sedimentary rock units of the Harveys Ridge Division and intrusive rocks of the Quesnel Lake Gneiss.

Three representative massive sulphide boulders from Frank Creek had assay results of:

Sample No.	Cu %	Pb %	Zn %	Ag oz/T	Au oz/T	Ba %
Q5351	0.45	3.91	3.48	3.50	0.001	0.75
Q5352	0.07	3.81	5.44	4.24	0.001	3.08
Q5353	1.38	2.13	2.24	1.96	0.005	0.32

Soil sampling results indicated a coincident Cu, Pb, Zn soil anomaly occurring in the vicinity of D logging road where Barker Minerals would in 1999 uncover massive sulphide mineralization in bedrock in their 'Discovery' trench (later named Frank Creek showing). Barium was conspicuously not anomalous in this area. This anomalous area had weak coincident VLF-EM anomalies. A significant magnetic anomaly occurring approximately 500 m to the west could not be explained.

The southern part of the MASS Property grid had anomalies in Cu, Pb, Zn and Ba in an area of weak local magnetic anomalies and a fairly consistent VLF-EM anomaly oriented NW-SE. These geophysical anomalies were thought to related to geological contacts between volcanic and sedimentary rocks and the Quesnel Lake Gneiss intrusive.

The trenching work did little more than indicate the presence of a thick blanket of till and that some of the soil anomalies may be transported. Further work was recommended to include soil sampling, trenching and eventually a drilling program.

6.1.10 Work done in 1991.

The relevant report is Assessment Report 21930 by McClintock, J.A.
Work was done in 1991 for Formosa Resources Corp. and Annex Exploration Corp. on the MASS and ANNEX Options totalling 245 claim units. These claims covered almost all of the southeast side of Cariboo Lake and extended from Wilby Creek in the south to Little River in the north.

Work consisted of prospecting, geological mapping, stream silt and soil sampling and 388 line km of helicopter borne EM, magnetometer and radiometric surveying. 56 stream silt, 21 soil and 5 rock samples were collected. The objective was to find the bedrock source of numerous massive sulphide boulders known to occur near the mouth of Frank Creek.

The helicopter-borne EM survey found 7 areas of conductors; all of the conductors were deemed possibly caused by sulphides. Most of the conductors occurred in rocks mapped as Harveys Ridge Group. Black argillaceous schists were noted; these varied from non-graphitic to graphitic.

Magnetic anomalies were interpreted as possibly associated with intermediate and mafic volcanic rocks. All conductive anomalies occurred on the southwest side of Frank Creek except for the minor Area H located northeast of Frank Creek. Most of the conductive responses occurred as parallel multiple horizons. Conductors at Anomaly E were considered a priority for follow-up.

Further southwest, toward Wilby Creek, a much larger conductive complex was evident. Graphitic schist known to occur in some parts of the survey area was assumed a probable cause of most of the conductor anomalies there. Notwithstanding the considered occurrence of graphitic schists, the geophysical interpreter determined 7 areas of conductors worthy of follow up for base and precious metals mineralization.

The radiometric survey determined elevated potassium counts got were possibly associated with sediments having thin overburden cover at higher elevations on the property. The radiometric results did not appear to be mapping any specific lithology.

Further work was recommended to include prospecting, soil sampling and detailed mapping and a Max-Min EM geophysical survey. 610 m of diamond drilling was also recommended.

6.1.11 Work done in 1992.

The relevant report is Assessment Report 22599 by Donaldson, W.S.
Work was done in 1992 for Formosa Resources Corp. and Annex Exploration Corp. on the MASS Property totalling 176 claim units covering the area between Frank Creek and Wilby Creek to the southwest.

Work consisted of prospecting, geological mapping, VLF-EM and HLEM ground electromagnetic surveys, rock, soil and stream silt sampling and mechanical trenching. The electromagnetic and soil sampling surveys were done over 7 small widely separated grids established over locations where the previous year's helicopter-borne EM survey defined conductors not explained by rock outcroppings. 308 soil samples were collected over these grids. The geophysical and geochemical surveys were successful in detecting conductors and numerous Pb and Zn soil anomalies in a 30-element suite analyzed. Six trenches were mapped and sampled over locations of HLEM and soil anomalies. Bedrock in the trenches consisted of metamorphosed sedimentary rocks, frequently graphitic.

It was deemed all the geophysical anomalies from the various EM surveys done in 1991 and 1992 were due to conductive graphitic argillite and schist. High Pb and Zn values in rocks, soils and streams were deemed due to high background values in the metasedimentary rocks and quartz veins and faults and shears resulting in remobilization of minerals. It was concluded the geological environment remained compatible with the massive sulphide mineralization observed in boulders in Frank Creek. It was considered the source for these boulders was not found because it may be located up ice (and off the property) or is too small to be detectable by the work done [over the 7 scattered grids]. Further work was not recommended.

6.1.12 Work done in 1992.

The relevant report is Assessment Report 22642 by Donaldson, W.S.
Work was done in 1992 for Rio Algom Exploration Inc. on the CCH Property consisting of 38 claim units between the lower portions of Wilby Creek and Seller Creek. Rio Algom was also the operator of the work done for Formosa Resources and Annex Exploration on the MASS Property, adjacent to the northeast.

Work consisted of geological mapping and collection of 4 stream silt, 120 soil and 9 rock samples. A suite of 30 elements was analysed. The objective was to find the bedrock source of the numerous massive sulphide boulders known to occur near the mouth of Frank Creek on the MASS Property.

Some rock samples were anomalous in Au in quartz veins. Some soils were anomalous in Pb, Zn or Au, considered due to high background values in metasedimentary rocks. As on the MASS Property, the conclusion was that the source of the massive sulphide boulders in Frank Creek probably came from up ice, off the property, or was too small to be detectable by the work done. Further work was not recommended. [In this author’s opinion the work was too limited to find the massive sulphide source.]

6.1.13 Work done in 1996.
The relevant report is Assessment Report 24662 by Yorston, R.
Work was done for in 1996 by R. Yorston on the MASS claims, a 20-unit property staked by himself over the lower portion of Frank Creek, a part of the area of Formosa Resources' and Annex Exploration's lapsed MASS Property.

Work consisted of 60.9 m of percussion drilling in 2 holes. These holes were done on the branch D logging road at a hairpin turn just below where Barker Minerals Ltd. would later discover massive sulphides in boulders and bedrock in their Discovery trench in 1999. Both Yorston's percussion drill holes returned highly anomalous Cu, Pb and Zn results (1,766 ppm, 746 ppm, 2,969 ppm respectively). Follow up work was recommended but not done, the MASS claims lapsed in 1999 and Barker Minerals Ltd. staked the Frank claim over this area the same year.

6.1.14 Work done in 1998.
The relevant report is Assessment Report 25752 by Doyle, L.E.
Work was done in 1998 for Barker Minerals Ltd. on the Frank Creek Property (Jess 1-3 claims) in the middle part of Wilby Creek.

Work consisted of prospecting. Stream sediment and rock samples were collected and analysed for a suite of 32 elements. Several rock samples were highly anomalous, with Pb up to 9.06% and Ag up to 6.65 oz/T.

From 1998 onward all work on the Frank Creek Property was done for Barker Minerals Ltd. under the overall supervision and strategic guidance by Louis E. Doyle, President.

6.1.15 Work done in 1999.
The relevant report is Assessment Report 26003 by Payne, J.G.
Work was done in 1999 for Barker Minerals Ltd. on the Frank Creek Property, at the time consisting of Jess 1-4 and Frank claims totalling 92 claim units covering the lower half of Frank Creek and extending west to include the Wilby Creek area. The Frank Creek Property was a portion of a 80 km x 30 km claim block including 2,590 claim units staked in 1996 by Barker Minerals. This large group of claims is henceforth termed the 'Peripheral' claim block.

The 1999 prospecting by L.E. Doyle on the Frank Creek Property discovered massive sulphide boulders containing pyrite, galena, sphalerite and chalcopyrite on the D logging road, approximately 2.5 km up from the main 8400 (Cariboo Lake) Road. Grab samples from the boulders returned high values in base metals and pathfinder elements. Sample No. 99-F1 for example had 0.62% Cu, 11.1% Pb, 3.13% Zn, 14.0 oz/T Ag. The (Discovery) trench subsequently dug at this location exposed a stratiform, massive sulphide layer at least 1.2m thick over a strike length of 10 m (Wild, 2002a).

Mapping discovered pillow structures in mafic volcanic rocks on the Frank Creek Property indicating a seafloor environment. Mapping and lithogeochemical results by this time were indicating a bimodal (mafic-felsic) volcanic system favourable for hosting volcanogenic massive sulphide deposits. The orientation of the pillow structures indicated that, at least in the local area of Frank Creek, strata were overturned and younging of strata was toward the northeast, with mafic volcanics including pillow lavas stratigraphically overlain by felsic tuffs having a probable genetic relationship with the newly discovered massive sulphide zone.

Prospecting at Wilby Creek (Big Gulp showing) on the south side of the Frank Creek Property had encouraging results but no specific follow up was recommended. Soil and geophysical surveys were recommended at Seller Creek and other areas of the 'Peripheral' claim block.

Extensive follow up work recommended a detailed EM/magnetometer survey, grid soil sampling, a petrographic study, trenching and drilling to be done on the Frank Creek Property.

6.1.16 Work done in 2000.

The relevant report is Assessment Report 26504 by Payne, J.G.
Work was done in 2000 for Barker Minerals Ltd. on the Frank Creek, Ace, SCR and other areas of the 'Peripheral' and 'Quesnel Platinum' claim blocks totalling 3,842 claim units.

A Max-Min HLEM and magnetometer geophysical survey was done at Frank Creek and SCR. The resulting magnetic patterns outlined bedrock geological boundaries. The HLEM survey defined 11 conductors on the Frank Creek Grid and 3 conductors on the Sellers Grid at SCR. The geophysical report (Walcott, 2001) describes the 'Sellers Grid' as having been done on the 'Sellers Creek Property'. This is actually at the SCR prospect (Minfile No. 093A 203) and not to be confused with the Sellers Creek showing (Minfile No. 093A 131), approximately 7 km to the southeast.

The conductors at Frank Creek were thought attributable to sulphide mineralization and/or graphitic horizons. Most of the conductors were shallow and dipped steeply. Conductor A at Frank Creek was considered possibly related to Cu-rich sulphide stringers in outcrops located east and stratigraphically above the Frank Creek Discovery massive sulphide showing. The presence of stacked massive sulphide bodies was suggested and Conductor A an excellent target for follow up. The conductors at SCR were associated with magnetic anomalies. The most prominent conductor was associated with higher magnetics and having good correlation with Pb, Zn and Cu in soils taken in a 1986 survey. Others conductors were associated with the Big Gulp showing at Wilby Creek or altered volcanic rocks or soil anomalies. (Payne, 2001, pp. 17-18).

A reconnaissance VLF-EM traverse was done along a road at Big Gulp. The data indicated a significant conductor ('Big Gulp' C-Road) but no interpretation was provided (see Payne, 2001).

Petrographic analysis was done on several rocks from the Frank Creek and other areas of the 'Peripheral' claim block.

Follow up work was recommended for the Frank Creek Property and at the Ace, SCR, Quesnel Platinum and other prospects within the 'Peripheral' claim block. The recommendation for Frank Creek included further geological mapping and Max-Min geophysics along with a gravity survey and trenching and drilling.

6.1.17 Work done in 2001.

The relevant report is Assessment Report 26805 by Walcott, P.E.
Work was done in 2001 for Barker Minerals Ltd. on the Frank Creek, Ace and SCR Properties and other locations on the 'Peripheral' claim block.

Work done on Frank Creek Property consisted of Max-Min HLEM, magnetometer, dipole-pole induced polarization and gravity geophysical surveys and mechanical trenching. This work was concentrated at small areas near the F1 target (Discovery Trench-Frank Creek Showing) and up to

2.0 km away toward the west and southwest. HLEM and magnetometer work was also done at SCR and Big Gulp and gravity work was done at Big Gulp.

The HLEM survey extended previously known conductors on Frank Creek Property but the massive sulphide showing at the Discovery Trench was unresponsive to either the electromagnetic or induced polarization techniques. However anomalous chargeability values were observed just east of the showing. Gravity profiling over the showing area and previously located EM conductors failed to show any excess mass associated with them. The 1:20,000 scale TRIM maps used for terrain corrections in the gravity survey were deemed unsatisfactorily coarse for the purpose and the geophysical contractor recommended a new effort to be made with more accurate control for terrain corrections.

At SCR the prominent conductor and magnetic anomaly of the previous year was further defined. The geophysical report (Walcott, 2002a) describes the Sellers Grid at 'Sellers Creek' as having been extended eastward. This is at the SCR prospect (Minfile No. 093A 203) and not to be confused with the Sellers Creek showing (Minfile No. 093A 131), approximately 7 km to the southeast.

A gravity anomaly at Big Gulp was somewhat coincident with a topographic high. Three moderate conductors were evident at Big Gulp. Additional geophysical work was recommended to detail the anomalies at Frank Creek, Big Gulp and SCR.

The trenching program, totalling 707 metres excavated in 9 trenches and 31 test pits in the areas of the Frank Creek Showing (Discovery Trench) and within several hundred metres to the northwest and northeast. Trenching near the beginning of the D Road did not reach bedrock. The source of massive and semi-massive mineralized boulders there remained unexplained. The Discovery Trench was also deepened. The several massive sulphide layers in the Trench were truncated by faults. The same metasedimentary and volcaniclastic rocks and mineralized horizon that host the massive sulphide mineralization of the Frank Creek Showing in the Discovery Trench were uncovered in Trench TR-BW-10, approximately 375 m northwest of the Discovery Trench, and in trench TR-BW-04, up to 50 m southeast of the Discovery Trench. The potentially mineralized NW-SE trend was considered to now be over 425 metres along and open in both strike directions and to depth (Wild, 2002a and Perry, 2002). Frank Creek's massive sulphide occurrence was considered to resemble the Besshi-type Goldstream Mine Cu-Zn massive sulphide deposit, 230 km to the southeast. Other trenches and test holes generally targeted geophysical conductors. Trench TR-BW-03, 50 m south of the Frank Creek Showing, uncovered pyritic rocks but did not locate the target mineralized horizon. Other trenches hit graphitic faults or did not encounter obviously conductive rock.

Further work was recommended to include soil sampling ,mechanical trenching and 7,500 feet (2,286 m) of diamond drilling.

6.1.18 Work done in 2002.

The relevant report is Assessment Report 27125 Doyle, L.E.
Work was done in 2002 for Barker Minerals Ltd. on the Frank Creek, Ace, SCR Properties and other locations on the 'Peripheral' claim block totalling 4,092 claim units.

Work done on Frank Creek Property included 813 m of diamond drilling in 6 holes and 289 m of mechanical trenching in 5 trenches in and adjacent to the F1 Target area. Electromagnetic (Max-Min and VLF-EM), gravity, and induced polarization (IP) surveys were also done at Frank Creek .

Targets of this work were the northwest extension of the Frank Creek Showing toward the previous year's Trench TR-BW-10 and magnetic highs, conductors and chargeability anomalies from previous geophysical surveys. Drill holes FC02-05, 06 and 01 intersected disseminated, semi-massive and relatively narrow massive pyrite-rich mineralization along the mineralized trend between the Frank Creek Showing and Trench TR-BW-10. Besides pyrite, chalcopyrite, sphalerite and galena occurred in relatively minor amounts. The mineralized horizon was determined to be hosted by siliceous, sericitic, weakly chloritic phyllites and quartz-eye grits.

The geophysical surveys on the Frank Creek Property were done in the F1 Target area (Frank Creek Showing) and the F7 Target area (on the lower portion of D Road). Elevation control in the gravity survey was to 6 centimetre accuracy using a Sokkia total station and prism reflector. This was an improvement over the elevation control used in the 2001 gravity survey. As in a previous survey the Frank Creek Showing showed little response to IP or VLF-EM suggesting this showing does not have significant strike length or size. A new gravity traverse was not done over the Frank Creek Showing at the F1 Target. The conductor at F7 Target area was extended 100 m but the ensuing gravity traverse failed to detect an associated excess mass. The limited IP survey at Frank Creek confirmed the location of 2 previously located conductors but no further work was done on these.

Recommended follow up work included stratigraphic and lithogeochemical studies to define the paleotectonic setting of the mineralization, the most favourable host lithologies and the distribution of hydrothermal alteration to provide an exploration model for the area. Other recommended work included HLEM, VLF-EM and gravity geophysical surveys to trace continuations of known anomalies. Further drilling, trenching and soil sampling toward the northwest and southeast to follow the mineralized strike was also recommended.

6.1.19 Work done in 2003-2004.

The relevant reports are Assessment Reports 27655 and 28248 by Doyle, L.E.
Work was done in 2003-2004 for Barker Minerals Ltd. on the Frank Creek, Ace, SCR Properties and other locations on the 'Peripheral' claim block totalling 4,401 claim units.

A study (Barrett & MacLean, 2003) was done of the lithological and lithogeochemical features of approximately 503 rock and drill core samples from Frank Creek, Ace and the 'Peripheral' Properties, approximately 175 of these were from Frank Creek. Analyses were of rock-forming oxides and trace elements. The study included a petrographic examination of selected rock types. A review of possible analogs to Frank Creek and Ace was provided; these included places in Canada, Japan, Namibia and ocean ridges. The objective was to provide an interpretation of the host stratigraphy of the Frank Creek and Ace Properties and discussion of possible sea floor settings for the sulphide mineralization.

Conclusions by Barrett & MacLean relevant to Frank Creek were:
- The Frank Creek host rocks in the [Discovery] trench and nearby drill holes represent a sequence of distal continental shelf clastic sediments, with no evidence for felsic volcanic input.
- The lithological sequences at Frank Creek (and Ace) show features of both Besshi-type and Sullivan-type deposits. The Frank Creek setting suggested a continental marine shelf undergoing rifting.
- Evidence of graded bedding in the 2002 drill holes and outcrops of basaltic pillow lavas approximately 1.5 km southwest of the Discovery Trench indicated younging of strata toward the northeast and that the mafic extrusives would be the stratigraphic footwall of the sulphide beds in the Discovery Trench.

- The interpreted occurrence of mafic magmatism on a faulted continental shelf bodes well for the development of hydrothermal systems and the formation of massive sulphide beds, as does the generally reduced nature of bottom waters as indicated by the presence of graphitic argillites.
- Such a setting would be favourable for the development of hydrothermal systems, and the formation of sediment hosted massive sulphide deposits in sub-basins containing reduced bottom waters (now black shales and Mn-rich sediments).
- Much more drilling is required to explore the large tracts of favourable geology in the Cariboo Lake area that could host massive sulphide deposits (specific locations at Frank Creek and Ace Properties were recommended).

A Titan-24 geophysical survey included DC resistivity, induced polarization and deep-penetrating tensor-magnetotelluric surveys over 15.8 line km in a 1.5 x 2.4 km area on Frank Creek Property. The purpose was to identify drill targets characterized by high chargeability or low resistivity. 90 separate anomalies of varying significance were identified; 18 were considered major low resistivity features. Barker Minerals' F1, F3, F7 and F8 Target areas 'all hosted pronounced chargeability high and resistivity low anomalies consistent with massive sulphides or graphite' (Donohue et al., 2004, pp. i,ii).

The 90 anomalies of the Titan-24 survey were grouped into 3 major geophysical Trends A, B and C (Barker Minerals, Company News, Aug 26, 2004):

Trend A – a large broad conductive and variably polarizable zone, present on the western portions of survey lines 5100, 5300 and 5500. Locally, strong Cu, Pb and Zn soil anomalies from previous surveys correlated with the geophysical Trend on lines 5300 and 5500. Trend A remained open to the west and south.

Trend B – a flat lying conductive and polarizable zone extending from line 5100 in the south to line 6100 in the north, the trend becoming thicker and stronger toward the north and remaining open to the north. The high chargeability anomaly reached surface in narrow sections near the F1 Target area (Frank Creek Showing). Locally, strong Cu, Pb and Zn soil anomalies correlated with the geophysical Trend on line 5700.

Trend C – a steeply dipping conductive and polarizable zone on the eastern ends of lines 5100 to line 5900. Locally, Trend C is coincident with strong soil anomalies and a broad magnetic trend.

[Three geophysical Trends A ,B, C were identified in 2004 and are shown in Figure No. 4, next page.]

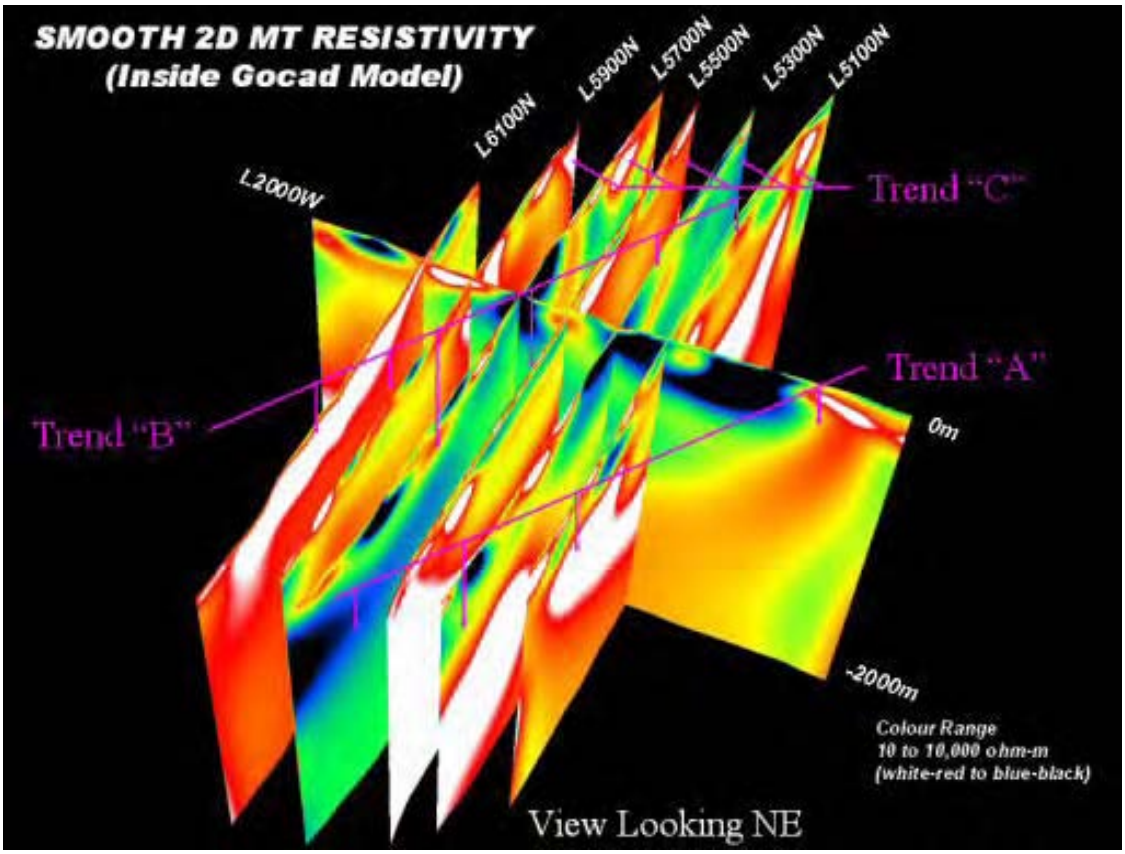

Figure No. 4 Frank Creek Property Geophysical Trends A, B, C resulting from the 2004, Quantec Geoscience Ltd. Titan 24 Distributed Array Survey. This Figure is from Barker Minerals Ltd. website, Company News, Aug. 24, 2004. See Doyle, 2005, Assessment Report 28248, Appendix II for the relevant Quantec Geoscience Ltd. report.

The Titan-24 geophysical survey is discussed in detail in Section 12.1 in this report.

In 2003 109 m of trenching in 2 trenches was completed at SCR. The targets were coincident geochemical soil and geophysical anomalies. Boulders with Cu, Pb and Zn mineralization were found in fairly deep till.

Trenching in 2004 focused on the Trend B anomaly of the Titan-24 geophysical survey. In the F7 Target area mineralized sub-outcrop contained stringer and semi massive mineralization containing pyrite, sphalerite and chalcopyrite. Usually the trenching was not able to reach bedrock due to thick glacial overburden.

Diamond drilling in 2004 included 7 holes (1,880 metres total). The holes were all located in the F7 Target area, low on the D Road, between approximately 400 m and 900 m west northwest of the Frank Creek Showing. The holes targeted geological features and geophysical anomalies. Zones up to 70 m wide of alteration (mainly sericite and chlorite) were reported and disseminated, stringer, semi-massive and narrow massive sulphides were described in the core logs for 6 of the 7 holes. One hole ended short at 41.8 m. Hole FC04-07 between 122.9 m and 307.9 m (185 m) had 4 (30 cm to 90 cm) zones of sulphides with aggregate Cu/Pb/Zn geochemical results of at least 10,000 ppm.

Hole FC04-13 between 257.6 m and 433.0 m (175.4 m) had 12 (10 cm to 60 cm) zones of sulphides with aggregate Cu/Pb/Zn geochemical results of at least 10,000 ppm. These results were sub-economic but indicated an extensive mineralizing hydrothermal system.

Recommendations for further work included:
- continue trenching geophysical and geochemical targets using a larger backhoe.
- the Titan-24 geophysical anomalies to be tested by systematic drilling, and geophysical surveying, particularly EM, to be made down the boreholes.
- soil sampling over strike extensions of known mineralized trends and over specific target areas.
- a 3D geoscientific model to be built from the extensive existing data set in order to refine interpretations.

6.1.20 Work done in 2005-2006.
The relevant report is Assessment Report 28978 by Doyle, L.E.
Work was done in 2005-2006 for Barker Minerals Ltd. on the Frank Creek Property.

Work done on Frank Creek Property included 1,566 m of diamond drilling in 4 holes in 2005, and 2,037 m in 5 holes in 2006. The 9 holes mainly targeted geophysical anomalies from the 2004 Titan-24 geophysical survey. Zones of sericite, chlorite, silica and iron carbonate alteration were encountered. Base metal sulphide mineralization occurred in stringers and narrow semi-massive and massive zones. The results were sub-economic but indicated the presence of an extensive mineralizing hydrothermal system consistent with a massive sulphide environment. Two further drill holes were completed in December 2006. These holes are described below together with work done in 2007.

Recommendations for further work included:
- continued systematic testing of geophysical targets defined by the Titan-24 survey of 2004. The work to consist of soil sampling, trenching and drilling.
- a reconnaissance exploration program to examine the largely unexplored part of Barker Minerals' properties between the Frank Creek and Ace massive sulphide prospects, and other areas of the large 'Peripheral' claim block.

6.1.21 Work done in 2006-2007.
The relevant report is Assessment Report 29740 by Turna, R. and Doyle, L.E.
Work was done in 2006-2007 for Barker Minerals Ltd. on the Frank Creek, Kangaroo and MAG Properties and other locations on the 'Peripheral' claim block. By this time the 'Peripheral' contiguous block of claims was 115,217 hectares in size under the Mineral Titles Online staking system and extended approximately 80 km x 30 km east-west and north-south.

On Frank Creek Property two drill holes (705.0 m) were done in December 2006 to test EM geophysical targets from the 2004 Titan-24 geophysical survey. Narrow zones of Zn and Pb-rich mineralization were encountered in zones of sericite, chlorite, silica or carbonate alteration.

889 soil samples were collected over the survey grid cut in 2004 for the Titan-24 geophysical survey. Seven anomalous multi-element patterns or Trends were recognized.

Trend 1, a NW-SE trending soil anomaly near the Frank Creek Showing included anomalous Cu, Pb, Zn and pathfinder elements. Trench FC07-3 and test pits were dug over this anomaly. This trench contained a stockwork of pyritic stringers containing chalcopyrite, sphalerite and galena. Trend 3, a

NW-SE trending soil anomaly 750 m southwest from the trench dug over Trend 1, also included anomalous Cu, Pb, Zn and pathfinder elements. Trenches FC07-1,2,4,5 and test holes were dug over this anomaly. These trenches (F-9 Target area) all contained small lenses and pods of massive sulphide mineralization. Sulphides in these trenches contained mainly pyrite and galena with less chalcopyrite than the Trench FC07-3 over Trend 1. Trench FC07-5 contained a 2m x 5m pod of semi massive sulphide.

A petrographic study of representative rocks from the 2007 trenches indicated the mineral host rocks were rhyolitic volcaniclastics.

6.2 Black Bear Property

Placer mining for gold was conducted on Black Bear Creek in the early 1900's and earlier.

Some of the information below is from the Energy, Mines & Petroleum Resources (EMPR) Annual Reports for 1902, 1926, 1947, 1948, 1949 and Exploration in BC for 1976, 1977, 1980.

6.2.1 Work Done in 1926-1951

The Annual Report for 1926 for the Black Bear 1-4 claims states that 'many quartz showings', some of 'impressive size' were being handpicked of galena for the silver content. A quartz vein 'at least 50 feet wide' was identified at a falls in Black Bear Creek; from it a picked grab sample assayed 0.02 oz/T Au, 43 oz/T Ag, 40% Pb. Another wide vein was exposed in an open cut at 3,300 foot elevation on the north side of Black Bear Creek about 2 miles up from the mouth. 10 to 15 tons of ore were taken from here in 1926; a picked grab sample assayed 0.06 oz/t Au, 144 oz/T Ag, 76% Pb. Two adits were begun in 1926; by 1947 they totaled 190 feet of crosscuts and drifts exploring 3 vein structures; the property name was Providence by this time. In 1948 5 tons of ore sent to the Trail smelter yielded 319 oz. Ag, 3,294 lb. Pb, 12 lb. Zn. Exploration in 1976 to 1980 by successive owners included 200 soil samples, 5 diamond drill holes (355m) mainly targeting 3 quartz veins, and geological mapping.

6.2.2 Work Done in 1951-1968

R.B. Stokes (1972) states that in 1951 7 tons of handpicked ore from the main vein yielded 1 oz. Au, 683 oz. Ag, 6,401 lb. Pb and 15 lb. Zn. In 1967-68 825 feet of tunnels were driven to explore the 3 main Ag-Pb-bearing quartz veins. Eleven underground diamond drill holes (2,217 feet) were done.

6.2.3 Work Done in 1972

The relevant report is Assessment Report 3944 by R.B. Stokes.
Work was done on the B.G. claims by D.G. Leighton on the quartz and galena showings on the north side of Blackbear Creek as had been worked since 1926. In the 1972 program 410 soil samples were collected over 3 grids. Strongly anomalous values (up to 7,500 ppm Pb and 66 ppm Ag) occurred over an extension of the main zone where the most prominent vein was traceable for 600 feet. Further soil sampling and geological mapping were recommended, to be followed up by hand and mechanical trenching.

6.2.4 Work Done in 1976

The relevant report is Assessment Report 6048 by R. Buckley.
Work was done on the old showings in the adit area on the Like claims by DeKalb Mining Corp. Some trenching was done and samples collected from these. Five diamond drill holes (355m) were

done. The holes did not encounter significant veins. Further diamond drilling was recommended to test the known veins.

6.2.5 Work Done in 1980

The relevant report is Assessment Report 8291 by J.G. Payne.
Trenching by hand and backhoe and geological mapping were done on the Like claims by Anglo Canadian Mining Corp. in the area of the old showings and adits. It was concluded that chip samples taken across the mineralized veins would not be representative due to the erratic occurrence of high grade pockets of argentiferous galena. Thus average values of veins are not a significant factor, whereas the presence of veins with some galena are significant. It was determined that the mineralized quartz veins are controlled along northwest trending zones and that exploration should be along these zones from the known showings.

6.2.6 Work Done in 1981

The relevant report is Assessment Reports 8318 by D.G. Mark.
A seismic refraction survey was done for Mr. G. Smith on a placer lease at the mouth of Spanish Creek at Cariboo River. The purpose was to discover buried river channels which could contain concentrations of placer gold. Several possible channels in bedrock were outlined.

6.2.7 Work Done in 1981

The relevant report is Assessment Report 9916 by J.W. MacLeod.
Prospecting was done for Mr. W. Greyson on the NOV 1,2,3 claims in the vicinity of 2 old adits and a dam associated with placer operations, on the west side of Spanish Creek opposite the mouth of Black Bear Creek. The exploration was for a porphyry gold type deposit. A number of quartz veins were sampled; 9 rock samples were collected. A recommendation was made for a soil sampling survey to be done.

6.2.8 Work Done in 1981

The relevant report is Assessment Report 10251 by T.A. Jones.
Canadian Nickel Company Ltd. did prospecting and reconnaissance stream sampling on the BB claim group along Spanish and Black Bear Creeks. The exploration was for gold. Ten rock, 23 stream and 7 heavy mineral stream samples were collected. Two small streams draining the north side of Blackbear Creek in the vicinity of the Providence adit had 100 ppb and 200 ppb Au. These were recommended for follow-up. Stronger Au anomalies on Spanish and Black Bear Creeks were got from areas of historic placer workings and no recommendation was made regarding these.

6.2.9 Work Done in 1982

The relevant report is Assessment Report 10812 by J.L. Deleen.
A single diamond drill hole (71 m) was done by W. Grayson on the NOV 1,2,3 claims on the west bank of Spanish Creek near where it is joined by its tributary, Black Bear Creek. The purpose was to test the value of several quartz veins above a nearby old adit. The core contained small quartz veins, up to 20 cm. Core samples were anomalous in precious and base metals but were not considered economic. It was suggested further soil sampling would be useful but no specific work was recommended.

6.2.10 Work Done in 1983

The relevant report is Assessment Report 11773 by J.L. Deleen.
Apex Energy Corp. did soil sampling on the NOV 1,2,3 claims. The exploration interest was due to small quartz veins in outcrops and a long history of small placer Au workings on Spanish and Black

Bear Creeks. The soil sampling was concentrated on the west bank of Spanish Creek opposite from the confluence of Black Bear Creek from the east. 1,610 soils were collected. Six areas, variably anomalous in Au, Ag, Cu or As were identified. A percussion drilling program was recommended on 4 of these.

6.2.11 Work Done in 1983

The relevant report is Assessment Report 12566 by B. Woodsworth.
Prospecting traverses were done over the Big 2 and 3 claims by Clearbrook Mining Ltd. to assess the general geology and the prospects for quartz vein-related Au mineralization. These claims covered the upper part of Black Bear Creek east of the Providence area. 4 rock samples were collected. A program of prospecting, mapping and soil sampling was recommended, to be possibly followed up by 600 m of percussion drilling in 10 holes.

6.2.12 Work Done in 1984

The relevant report is Assessment Report 13285 by G.N. Cooper.
Homestake Mineral Development Company did geochemical sampling and geological mapping on the Trump claim group. Work was concentrated on the west flank of China Mountain between Black Bear Creek and Collins Creek, northwest of the Providence area. 163 soil, 12 stream silt and 41 rock samples were collected. The purpose was to determine the prospects for galena and silver-bearing quartz veins. Four quartz veins, some described as large, containing galena were discovered. The highest geochem results from selected grab samples were 24,953 ppm Pb and 458.4 ppm Ag. The highest results in the soils were 521 ppm Pb and 4.5 ppm Ag; these were adjacent to galena-bearing quartz veins. The highest Au in soil was 115 ppb but this could not be reproduced in a later sample from the site. Further work to determine the economic significance of the galena-bearing quartz veins was suggested but a work program was not specified.

6.2.13 Work Done in 1984

The relevant report is Assessment Report 13306 by E.R. Rockel.
Apex Energy Corp. did geophysical work at scattered locations on the NOV claim group. The work was concentrated on the west bank of Spanish Creek. 2.75 line km of IP were done, as well as 5.25 km of VLF-EM and 3.75 km of magnetics. IP, EM and magnetic anomalies were mainly attributed to various possible causes such as graphite, lithologic variations, depth of overburden and sulphide mineralization. The limited survey did not allow specific interpretations but drilling was suggested to test locations of coincident geophysical and previous geochemical anomalies. Mechanical trenching was recommended at several locations. Additional geophysical work was suggested to follow up any encouraging sub-surface exploration.

6.2.14 Work Done in 1984-1985

The relevant report is Assessment Report 13986 by G.A. Medford.
Ranald Resources Ltd. did soil sampling and a ground magnetic survey over approximately 24 line km on the LT1 claim on the north side of China Mountain approximately 3 km northeast of the Pioneer area on Black Bear Creek. Approximately 650 soil samples were collected. A strong magnetic anomaly trending 600 m north-northeasterly and open to the south, coincided with a gossanous area. Three other magnetic anomalies coincided with Pb, Zn and Ag soil anomalies. A three-phase work program was recommended. It included staking additional ground to the south, mapping, geophysics, rock and soil sampling, trenching and drilling.

6.2.15 Work Done in 1987

The relevant report is Assessment Report 17103 by S.A.S. Croft.
Malcom Resources Ltd. did geochemical and geophysical work on the east part NOV claim group. Work was concentrated on the east side of Spanish Creek and north and east sides of Black Bear Creek, and at 'Spanish Canyon' in Spanish Creek, just west of the mouth of Black Bear Creek. The VLF-EM survey did not detect any conductors that coincided with anomalous geochemistry. Several weak conductor anomalies were thought to probably related to lithologic variations. The soil sampling survey included 574 soil samples collected. 13 soil lines were done between Black Bear Creek to the west and the low road to the east used in 2008 to access the Providence area. Four anomalies were identified including Au pathfinder elements, Ag, Pb and Zn which supported a southeastward extension of an auriferous quartz vein structure from exposures in Spanish Canyon. Grab rock samples of quartz veins from trenches at Spanish Canyon had up to 0.818 oz/t Au, 4.43 oz/t Ag and 2.8% Pb; these values were translated from ICP analysis results. Economic gold values in quartz veins were strongly associated with argentiferous galena and pyrite in calc-silicate selvages. The geological setting of the NOV claimgroup was considered to be similar to the Frasergold deposit 65 km to the southeast. It was suggested that exploration should be continued but no specific recommendations were made.

6.2.16 Work Done in 1988

The relevant report is Assessment Report 17751 by M. Matherly.
Prospecting was done by Mr. Matherly in the area of the headwaters of Black Bear Creek. 47 grab rock samples were collected. A sample of quartz with galena had 2,240 ppm Pb, 152.8 ppm Ag and 50 ppb Au.

6.2.17 Work Done in 1989

The relevant report is Assessment Report 20062 by D.A. Thompson.
Work on the Otto claims by Priority Ventures Ltd. included diamond drilling of 6 holes (294 m). The property covered most of the area between Black Bear Creek and Collins Creek to the north. The drilling tested a quartz vein at least 7.6 m wide in a surface exposure. Grab samples from the vein had up to 66.5% Pb, 73.79 oz/t Ag and 0.023 oz/t Au. Soil samples taken the previous year over the vein had values up to 4,000 ppm Pb and 14.4 ppm Ag in an area described as a major Ag-Pb anomaly. The vein had a strike of 157^{o} and could be followed for 254 m. The drill holes intersected quartz-carbonate veins in up to 12 feet widths and had frequent and extensive intersections of quartz-carbonate flooding in up to 40-foot widths. Zones with galena returned significant Ag and Pb values but no significant Au or Zn. Trenching, VLF EM and prospecting were recommended to outline the extensions of quartz veins and to determine drill hole targets.

6.3 Gerimi Property

6.3.1 Work Done in 1964

The relevant report is Assessment Report 639 by W.R. Bacon.
Soil sampling, prospecting, geological mapping and limited vertical loop EM and ground magnetics were done on Mastodon-Highland Bell Mines' Ltd. Gerimi and Sam claim groups located between Gerimi Creek to the southeast and Cantin Creek, 6km distant, to the northwest. Limestone outcrops were observed at several locations, locally cut by volcanic or granitic dikes. The limestone was well fractured and locally mineralized with pyrite, chalcopyrite, tetrahedrite and bornite. The soil survey got 'strong positive indications' over areas of limestone, though only where bedrock was exposed or near the surface and where at least a little Cu mineralization was evident. It was considered that

dispersion of Cu through the soil was limited, thus masking the geochemical response. Weak conductive zones were assumed to be associated with mineralized shear zones. It was concluded that the sporadic Cu mineralization observed warranted further work.

6.3.2 Work Done in 1964

The relevant report is Assessment Report 629 by D.L. Hings.
A ground magnetometer survey was done by Coast Silver Mines on their B-1 group of Claims over 75,825 feet (23.1km) on 21 cut lines on the north and south sides of the westward-flowing Gerimi Creek. Linear magnetic anomalies were associated with a 'substantial' magnetite formation, a mineralized limestone contact and a possible mineralized shear. A mineralized outcropping between anomalies A-1 and A-3, approximately 1,500m apart, was not covered by the survey. It was concluded the magnetic survey should be extended westward over this outcropping.

6.3.3 Work Done in 1965

The relevant report is Assessment Report 628 by D.L. Hings.
Coast Silver Mines' previous year's ground magnetometer survey was extended with 37,517 feet (11.4km) on 16 cut lines. Several linear magnetic anomalies were evident, in part associated with a limestone contact. Geological mapping was recommended.

6.3.4 Work Done in 1982-1983

The relevant report is Assessment Report 11458 by J.A. Turner.
Work was done on Phantom 1 claim by Newmont Exploration of Canada Ltd. on the part of Gerimi Creek explored by Coast Silver Mines in the 1960's. Geologic mapping was done and 33 rock and 322 soil samples were collected over the property in follow-up of a government airborne survey which indicated a magnetic anomaly on Gerimi Creek. A dolomitic limestone was considered the most mineralized unit, hosting the Lynda showing, where disseminated tetrahedrite and chalcocite occurred along bedding planes. Figure No. 2 of the report indicated the Lynda Showing to be along the road near the northeast corner of the Phantom 1 claim. At this showing a 1 metre chip sample had 2,445 ppm Cu, 3,600 ppb Hg, 3.4 ppm Ag and 15 ppb Au. An outcrop in Gerimi Creek had chalcopyrite and a 15cm chip sample on a vein had 1,250 ppm Cu, 65ppb Au; another sample on the same vein had 105 ppb Au. Soil sampling results were generally low; high values up to 570 ppm Cu at the Lynda showing were not considered important and other scattered anomalous values were thought to be erratics. Fourteen soils were anomalous in Au, with 4 samples having at least 100 ppb Au. One soil had 720 ppb Au; a re-sample of this site had only 10 ppb Au. Locally thick overburden was thought to be partly masking any geochemical response in the soils. Though reverse circulation drilling was recommended to test the southeast part of the claim where the 720 ppb soil occurred, no further work was done in the Gerimi Creek area.

6.3.5 Work Done in 2000-2007

The following description, *in italics*, is after McKinley (2004).
During 2000, Barker Minerals staked several areas of coincident airborne magnetic anomalies, chromium/nickel/cobalt/gold stream sediment anomalies and mafic to ultra-mafic rocks. The areas staked are near reported occurrences of PGMs in placer concentrates as known from previous unpublished studies and assay results from samples collected from local placer miners during 2000. Barker Minerals collected and assayed 97 rock samples to confirm the presence of the favourable mafic to ultra-mafic rock types, which are host to PGM deposits in other areas of the world (Payne, 2001; BC Assessment Report). Prospecting by Barker Minerals' personnel resulted in the discovery of a Cu-anomaly in the Geremi Creek area.

Reconnaissance geological mapping and sampling were conducted over portions of these claims in order to identify and confirm the occurrences of mafic and ultramafic rocks. Thin-section petrographic examinations were made on six samples. Geological mapping and rock geochemistry confirmed and characterized the presence of mafic and ultramafic rocks in the property. Several samples collected from hematite-altered amygdaloidal mafic flow rocks are anomalous in Cu, Ag and Hg (Payne, 2001; BC Assessment Report).

During 2000, several reconnaissance ground magnetometer and VLF-EM surveys were conducted by Barker staff along roads, in order to confirm and locate more accurately the anomalies identified in previous airborne surveys. These geophysical survey traverses were conducted near the locations of stream samples that contained anomalous concentrations of PGE's per Rublee (1986). Several ground magnetic anomalies confirmed the results of the airborne survey. Several VLF-EM survey traverses show significant crossovers that should be followed up with more detailed geological and geophysical studies controlled by conventional cut grids. In several of the traverse profiles, magnetic anomalies coincide with VLF-EM crossovers.

During the period 2001 - 2002, the Company conducted GPS surveying of claim post locations in order to more accurately define mineral claims in this project area and to obtain required assessment work credits (Walcott, 2001).

In 2007 Barker Minerals Ltd. did VLF-EM, magnetic and IP geophysical surveys on their MAG Property, 5 km southeast of Gerimi Creek. The relevant report is Assessment Report 29740 by Turna, R. and Doyle, L.E.

7.0 EXPLORATION PROGRAM 2008

7.1 Economic Targets and Work Done

Frank Creek Property

The economic target at Frank Creek is volcanogenic massive sulphide. Some have favoured the massive sulphide prospect at Frank Creek to be Besshi-type. Christopher Wild, former Chief Geologist of Goldstream Mine, 230 km to the southeast, stated the geological setting, mineralization and host rocks here are similar to the Goldstream Mine mineral deposit, a Besshi-type massive sulphide, which produced more than 2 million tonnes of ore at a grade in excess of 4.0% copper and 2.2% zinc (Wild, 2002a). Schiarizza and Ferri (2002) were of the same opinion. Others consider the Frank Creek prospect to be probably Kuroko-type (Turna, 2008). Disagreement is likely to continue.

A diamond drilling program was done on the Frank Creek property to test the 2007 survey's Trend 3 Cu-Pb-Zn soil anomaly where significant Cu, Pb and Zn mineralization was discovered in Trenches FC070TR4 and TR5 in 2007, to test certain HLEM conductors from the 2000 geophysical survey and to improve understanding of the geology at certain locations. Most of the drilling at the Trend 3 anomaly was done in a grid pattern. The economic target was Kuroko-style volcanogenic massive sulphides. Core size used was NQ2 or HQ stepping down to NQ2 when the hole became tight. Drilling began July 11, 2008 and finished August 25, 2008. 2,375 metres were drilled in 13 holes; 817 core samples were analysed. Sixteen soil samples, collected the previous year, were analyzed in 2008 using an enzyme leach lab analysis method. The soils' grid coordinates and results are provided in Appendix E Analytical Data - Frank Creek 2008 Soil Sampling, but are not drawn on a map in this report or otherwise discussed as the few samples are not important at this time.

Black Bear Property

The economic target at Black Bear is high grade Ag ± Au in quartz-galena veins in sedimentary rocks. Though analyses for gold in quartz grab samples have given values around 0.818 oz/T Au (Assessment Report 17103), Black Bear has been explored mainly for silver to date. Placer gold operations have occurred on Black Bear and Spanish Creeks over several decades. Black Bear and Spanish Mountain are in the same mineral deposit class according to the BCGS Minfile No. 093A 003 (Providence, Black Bear) and Minfile No. 093A 043 (Spanish Mountain). Black Bear is located 5.0 km northeast of the Spanish Mountain gold deposit which hosts both high-grade structurally controlled mineralization and lower grade stratigraphically controlled mineralization. A NI 43-101 compliant resource estimate for a portion of the Main Zone at Spanish Mountain contains 1.75 million ounces of gold in the Measured and Indicated categories with 67.06 million tonnes averaging 0.81 g/t Au (Skygold Ventures Ltd. website, January 30, 2009).

Work on Black Bear in 2008 consisted of prospecting and rock sampling of numerous new quartz vein outcrops and float discovered early in the year. 14 rock and 6 soil samples were collected. New roads built for logging activities made more accessible a 2.0 km long area between the Providence adit to the southeast and the area of the 'Trump' quartz-galena showings to the northwest. Galena with less pyrite occurred in many of the veins and quartz breccia. Some quartz boulders were up to 1 m x 2 m in size. At a location 750 m northwest of the Providence adit was an approximately 2 m x 20 m exposure of quartz in outcrop. The new quartz-galena showings in the 2 km x 1 km area indicate a strong persistence of the of the quartz veining northwest of the Providence workings.

Gerimi Property

The BCGS Minfile 093B 025 considers the Lynda showing at Gerimi to represent a sedimentary-hosted Cu type of deposit.

Work on this property consisted mainly of rock sampling along the road on either side of the Lynda showing and assessing the character of the mineralization. 7 rock and 4 soil samples were collected. Copper mineralization was associated with bedding planes and contacts in limestone and siltstone.

7.2 Sampling Method and Approach

Drill core was split with a table mounted diamond saw in the cutting trailer at camp. Half the core was returned to the core box while the other half was placed in a plastic bag, tied and stored prior to shipment to the analytical lab. Core recovery factors during drilling which could materially affect the accuracy of the results are described as core recovery percentages in the drill logs. Core recoveries were generally good, frequently close to 100%, though locally poor due to gouge or broken rock. Rock samples from surface sampling were bagged, tied and stored similar to core. Core and rocks were shipped in plastic rice bags to the analytical lab. Soil samples were allowed to air dry before being placed into a box for shipment. Samples were stored in the garage or cabin at the camp prior to shipment. After sampling the core boxes were neatly stacked in piles adjacent to the core cutting trailer.

Completed drill holes were marked in the field by wood plugs inserted in the holes. Soils were collected from the 'B' soil horizon, generally 300 gram weight, from about 30 cm depth. Rock samples were representative grabs or chips over a certain distance as described for each sample in Appendix C - Sample Descriptions.

7.3 Laboratory Methods

7.3.1 Sample Preparation and Analysis

All samples were sent to ActLabs Laboratories Ltd. of Ancaster, Ontario. ActLabs code 1C (exploration), 1H ('Au+48') and 7 (enzyme leach) analytical methods were used. Method 1C used fire assay-ICP/MS, 1H used variously, INNA (neutron activation) or ICP (inductively coupled plasma) and code 7 used ICP/MS analytical methods. ActLabs' analytical methods are described in Appendix D - Analytical Methods.

All lab results are in Appendix E - Analytical Data.

7.3.2 Verification of Accuracy

Check samples from WCM Minerals of Burnaby, BC with certified known metals content were sent at intervals in the 2008 work program to ActLabs for analysis. Actlabs' analyses of the check samples during the Frank Creek drill program are provided in the drill logs. ActLabs' results were comparable with the certified values. A more detailed study of ActLabs' reliability is not made in this report.

8.0 REGIONAL GEOLOGY

The geological descriptions below derive mainly from Struik (1988), Panteleyev et al. (1996) and Payne and Perry (2001).

During the mid-Jurassic the North American continental plate collided with a group of island arcs to the west. Regional deformation and metamorphism are related to these events.

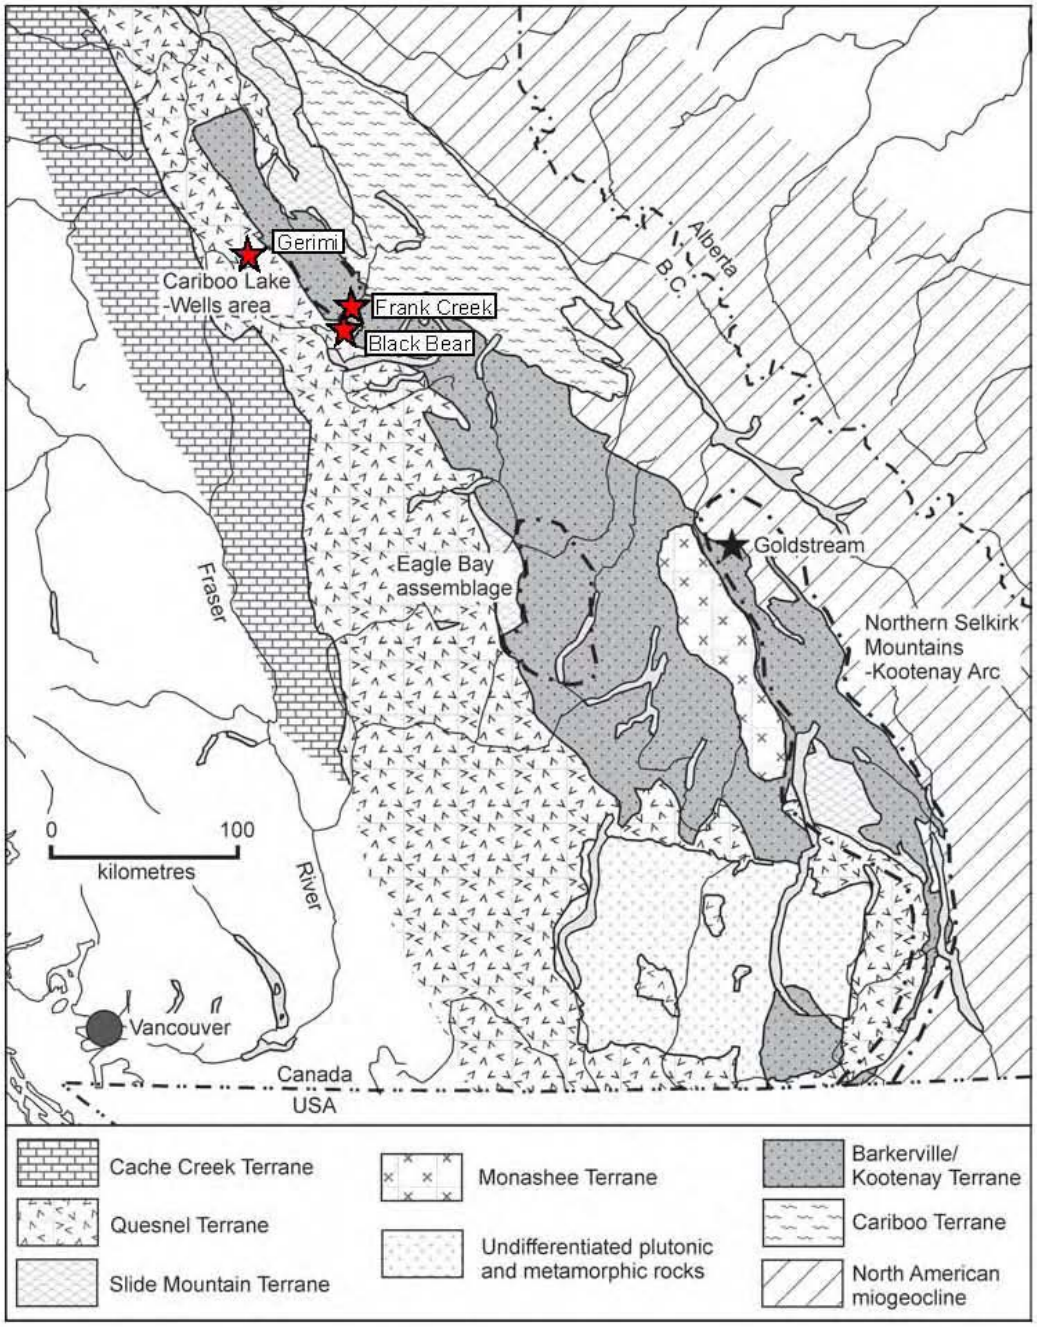

Figure No. 8 Terrane map of southern British Columbia. Barker Minerals' properties are indicated by red stars.

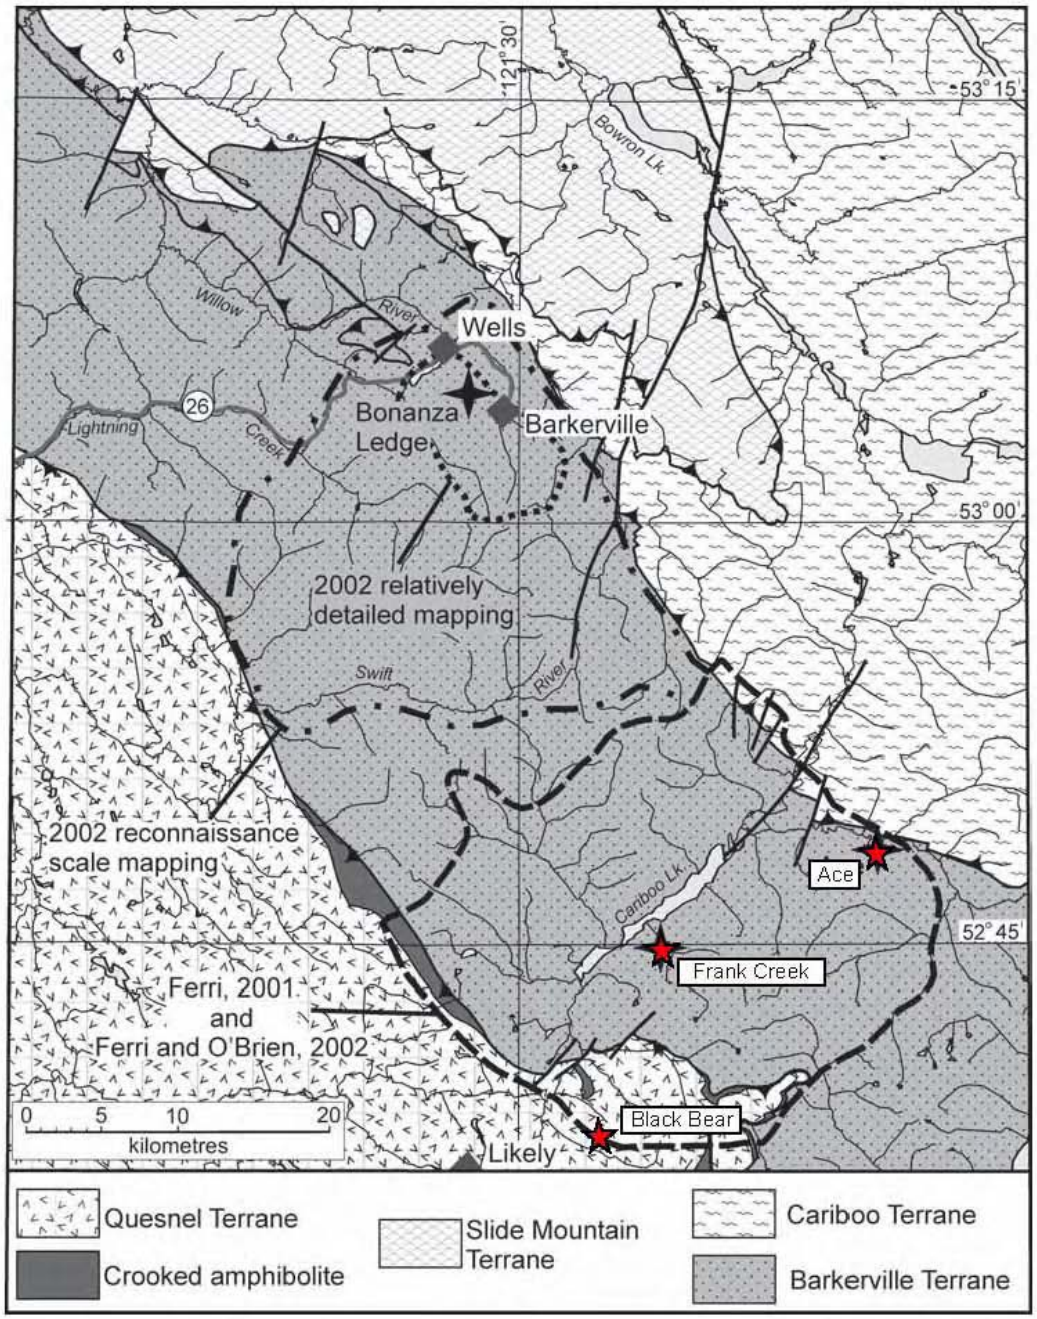

Figure No. 9 Terrane map of Cariboo Lake – Wells area showing areas mapped by BCGS in 2000 – 2002. Barker Minerals' properties are indicated by red stars.

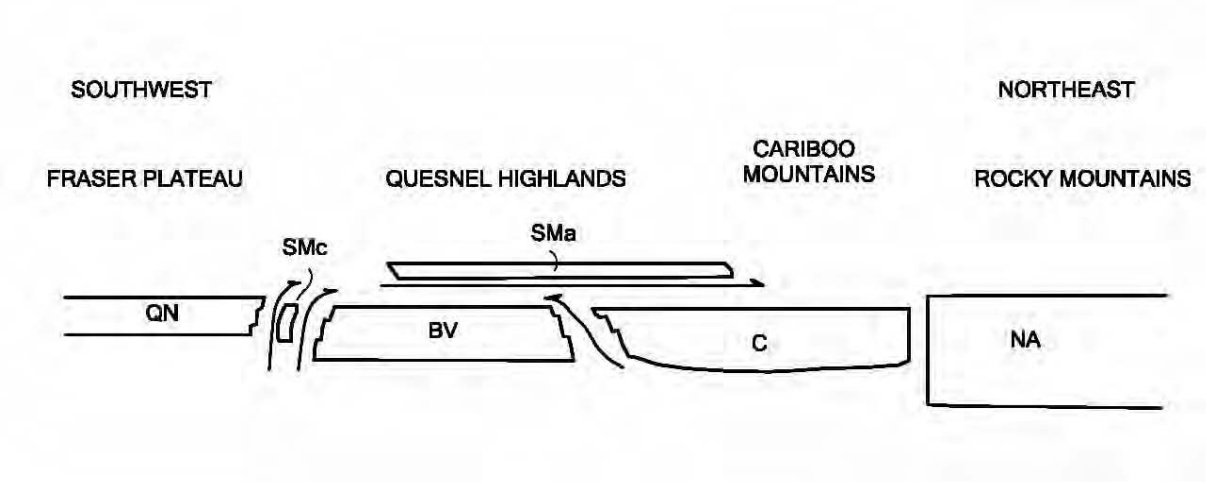

Figure No. 10 Schematic Regional structural Section from southwest to northeast across the four Terranes in Barker Minerals' claims area, showing the relative structural position of the Terranes. The Terrane symbols are BV-Barkerville, C-Cariboo, Sma-Slide Mountain (Antler Formation), SMc-Slide Mountain (Crooked amphibolite), QN-Quesnel and NA-North American. (after Struik, 1988).

Quesnel Terrane

The Late Triassic to Early Jurassic Quesnel terrane…was accreted to the North American continent, in part by subduction and in part by obduction. The Eureka thrust fault marks the boundary between the Quesnel and Barkerville terranes. The terrane is partly submarine and partly subaerial, consisting of volcanic and volcaniclastic rocks and co-magmatic intrusions, with minor carbonate lenses and related sedimentary rocks.

The principal assemblage in the Quesnel Terrane is the Triassic-Jurassic Nicola island arc – marginal basin sequence. The underlying rocks are the Crooked amphibolite, part of the Slide Mountain assemblage, a mylonitized mafic and ultramafic unit of oceanic marginal basin volcanic and sedimentary rocks. Rocks of Quesnel Terrane and Crooked amphibolite are structurally coupled and tectonically emplaced by the Eureka Thrust onto the Barkerville Terrane, to the east.

Two lithostratigraphic subdivisions of the Quesnel Terrane consists of: a basal Middle to Late Triassic metasedimentary unit of dominantly black phylitic rocks, approximately 7 km thick, and an overlying Late Triassic to Early Jurassic volcanic arc assemblage, approximately 9 km thick. The overlying volcanic rocks outline a northwesterly trending belt of subaqueous and subaerial volcanic rocks, deposited along a series of volcanic-intrusive centres that define the Quesnel island arc of predominantly alkalic basalts.

Within…the northern extension of the Quesnel Trough, the term…Takla Group has been applied to rocks identical to the Quesnel belt rocks…Equivalent rocks to the south…are generally referred to as Nicola Group…Baily (1978) pointed out the similarity of the Quesnel volcanic units with both the Nicola Group rocks to the south and the Takla Group rocks to the north…The term Takla leads to ambiguity because in northern British Columbia it has been used for rocks in both Quesnel and Stikine terranes…The usage for the Triassic-Jurassic volcanic arc and related rocks in Quesnellia currently preferred is Nicola Group. The term Takla Group possibly should be discarded…
(Panteleyev et al., (1996).

The Quesnel Trough is a well-mineralized region typical of other Late Triassic to Early Jurassic volcano-plutonic island arcs in the Cordillera. It hosts a wide variety of mineral deposits. The principal recent exploration and economic development targets in the central Quesnel belt are alkalic intrusion-related porphyry copper-gold deposits and gold-bearing propylitic alteration zones formed in volcanic rocks peripheral to some of the intrusions. Other important targets are auriferous quartz veins in the black phyllite metasedimentary succession. The veins in some black phyllite members have potential to be mined as large tonnage, low-grade deposits. Tertiary rocks are mineralized with copper and gold. Antimony-arsenic and mercury mineralization in some apparently low temperature quartz-calcite veins indicated the potential for epithermal deposits. Placer mining for gold, said to occur together with platinum, has been of major historical and economic importance.

Slide Mountain Terrane

Rocks of the Devonian to Late Triassic Slide Mountain Terrane were partly obducted, partly subducted during collision of an oceanic plate with the continent. Small slices of mainly mafic volcanic rocks and ultramafic rocks of the Slide Mountain Terrane occur in and parallel to the Eureka thrust. Minor lithologies include chert, meta-siltstone and argillite.

The Crooked amphibolite, considered likely a part of the Slide Mountain Terrane, includes three major constituent rock types: greenstone, metagabbro and meta-ultramafite. North of Quesnel Lake, the map units consist of mafic metavolcanics, amphibolite, chlorite schist, serpentinite, ultramafic rocks and pillow lavas. Chemical analyses indicate subalkaline tholeiitic compositions of basalts formed on the ocean floor. If the Crooked amphibolite is a sheared and metamorphosed equivalent of the Antler Formation and is part of the Slide Mountain Terrane, it is separated from the underlying Barkerville Terrane by the Eureka thrust, a wide zone of mylonitization. The Crooked amphibolite and the overlying rocks of Quesnel Terrane are structurally coupled and emplaced tectonically onto Barkerville Terrane.

Barkerville Terrane

The Barkerville Terrane is made up of the Snowshoe Group and Quesnel Lake gneiss. The Snowshoe rocks are Upper Proterozoic to Upper Devonian metasediments, considered correlative in age with Eagle Bay rocks of the Kootenay Terrane to the south. The Snowshoe rocks are dominated by varieties of grit, quartzite, pelite, limestone and volcaniclastic rocks. The stratigraphic sequence is not well understood. The region was deformed by intense, complex, in part isoclinal folding and overturning. Locally, strong shear deformation produced mylonitic textures. The Quesnel Lake gneiss is a Devonian to Mississippian intrusive unit varying in composition from diorite to granite to syenite. It is generally coarse grained, leucocratic, often with megacrysts of potassium feldspar. The main body of gneiss is 30 km long by 3 km wide and is elongated parallel to the eastern border of the Intermontane belt. Its contacts are in part concordant with, and in part perpendicular to, metamorphic layering.

The contact between the Barkerville Terrane and Cariboo Terrane to the east is the Pleasant Valley Thrust. The Barkerville and Cariboo Terranes were juxtaposed prior to emplacement of the Slide Mountain Terrane which was thrust over both of them. The northeastern third of the Barkerville Terrane is the main zone of economic interest in the Cariboo district. Struik described it as “gold-enriched”, because it contains the historic Wells and Barkerville mines and the Cariboo Hudson deposit, approximately 40 km and 20 km northwest of the project area, respectively.

Cariboo Terrane

The northeastern part of Barker Minerals' 'Peripheral' claim group is underlain by Precambrian to Permo-Triassic marine peri-cratonic sedimentary strata of the Cariboo terrane. The Cariboo Terrane consists mainly of limestone and dolomite with lesser siliceous, clastic, sedimentary rocks and argillite. Some geologists believe that the Cariboo Terrane is a shallow, near-shore facies and the Barkerville is a deeper, offshore facies of the same erosion-deposition system. No rifting is suspected between the Cariboo Terrane and the North American continent, in contrast to that between the Barkerville Terrane and the North American continent. Lithologies within the Cariboo Terrane correlate well with parts of the Cassiar Platform and Selwyn Basin of Yukon and northern British Columbia.

The Cariboo and Barkerville Terranes are separated by the regional Pleasant Valley thrust fault, which dips moderately to steeply northeast. Struik (1988) states the Cariboo block was thrust from the east over the Barkerville block along a strike length of over 100 km. The Cariboo Terrane was cut by the Jurassic-Cretaceous Little River stock, a medium-grained granodiorite grading to quartz monzonite. Some of the carbonate layers in the lowest part of the Cariboo terrane (or upper part of the Barkerville Terrane) are enriched in zinc and lead. Since the 1970's, preliminary exploration on stratiform Zn-Pb targets has been conducted in this area.

Glaciation and glacial deposits

The last glacial stage that affected the Quesnel Highland, the Fraser glaciation, began 30,000 years ago. Much of this ice had melted by 10,000 years ago, but small remnants are preserved high in the alpine areas of the Cariboo Mountains. At lower elevations, glaciers of this age scoured the debris left by preceding ice advances, almost completely destroying them, leaving a chaotic assemblage of unsorted till, moraine and drift, with lenses of gravel and sand that had been roughly sorted by melt water and rivers, leaving behind beds of silt and clay that were stratified by settlement in ice-dammed lakes. In the Cariboo area, the debris covers bedrock in valleys below 1,700 m, leaving typical glacial features such as U-shaped valleys, ice-sculpted drumlins, moraine terraces and glacier and river benches. On the Barker Minerals properties, glacial deposits range from one to a few tens of metres thick. Some glacial till deposits are overlain by well-bedded glaciolacustrine clay and silt deposits up to a few tens of metres thick.

In much of the Cariboo district, a layer of distinctive, hard, compact, semi-rigid blue clay sits either on or slightly above bedrock and acts as "false" bedrock. It was formed from glacial drift left behind by the last ice advance prior to the Fraser glaciation and was compacted by the weight of the Fraser stage ice. In the placer-gold areas of the Cariboo, large amounts of gold were recovered from gravel resting on this clay. In places the clay layer was penetrated by the placer miners to reach richer "pay streaks" on true bedrock below.

9.0 FRANK CREEK PROPERTY

9.1 Diamond Drilling

Several of the diamond drill holes describes below targeted geophysical conductors from previous work. These (HLEM conductors) are illustrated on Figure No. 11 below.

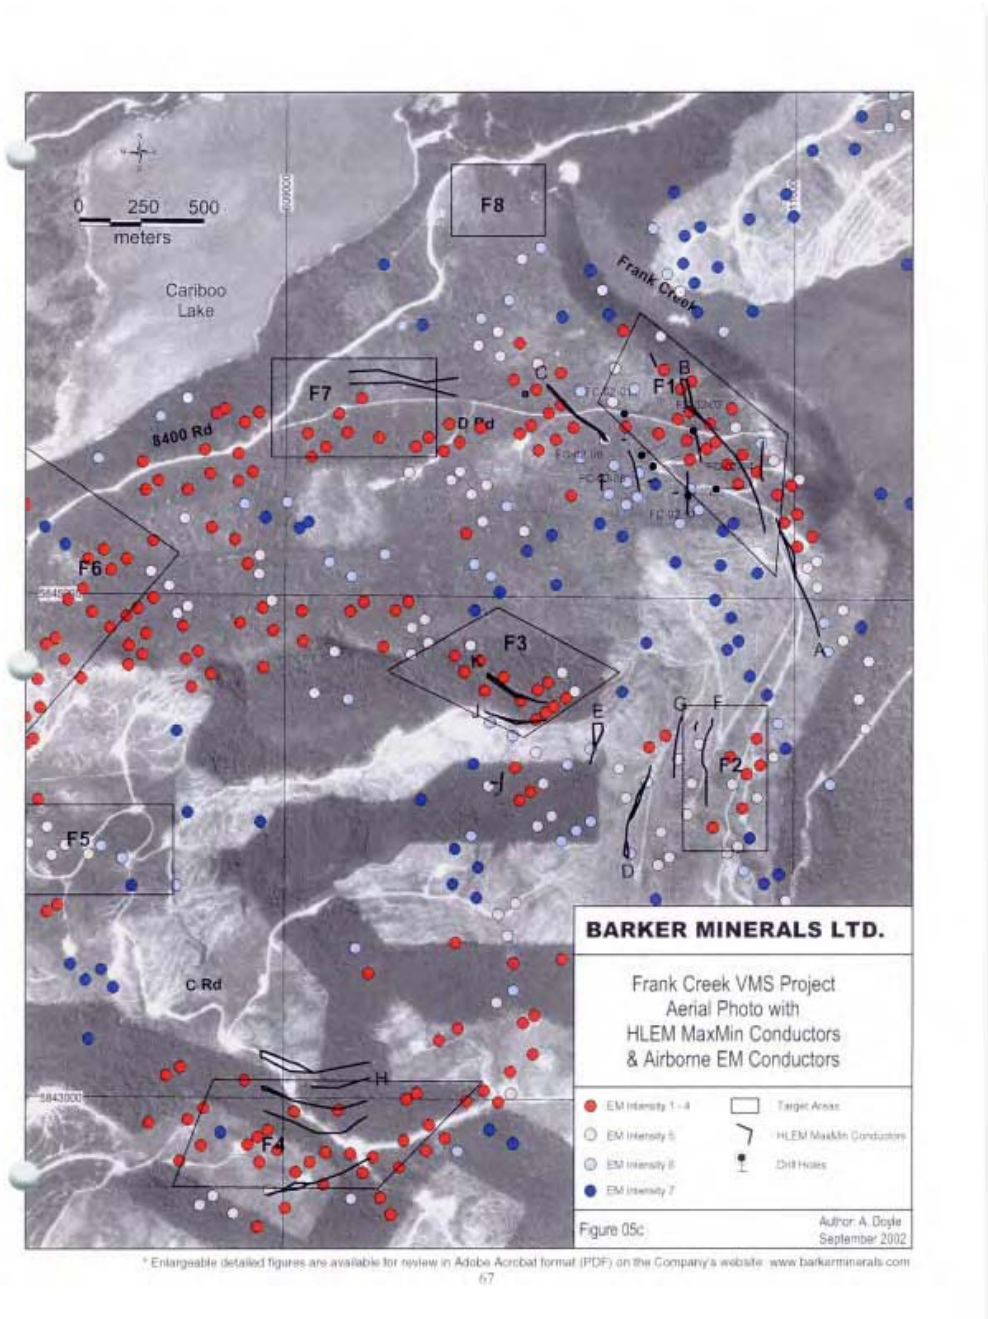

Figure No. 11 Frank Creek Property Geophysical Conductors, showing location of F1 Area targeted by several DDH holes in 2008. The drilling grid in the F9 Area, not indicated on this airphoto, is located between F1 and F3 Areas. (From Assessment Report 27125, Appendix 5, Figure 05c).

DDH FC08-25

The purpose of the hole was to intersect and determine orientations of mineralized zones in previous DDH's FC04-9,10,11,FC06-23 and test a geophysical conductor. This hole was terminated prematurely due to caving in of the fragile argillite rock encountered. Gouge at several locations in the hole suggested faults. The core was generally of graphitic argillite with minor sandy laminations disturbed by crumpling, dismemberment and slump brecciation apparently while the rock was a soft

sediment. Weak schistosity, parallel to bedding was crumple-folded. Quartz 'sweats' parallel to bedding/foliation were common. At 25 m depth clasts of light sandstone from higher in the hole occurred in a dark siltstone, suggesting the strata are overturned. Zn content averaged approximately 150 ppm, considered a high background. The highest geochem results were associated with a gouge zone at 19.0m. Though the geophysical target was not reached the graphitic argillites in the hole could make a good conductor.

DDH FC08-26

The purpose of the hole was to test a N-S oriented geophysical conductor. This hole was terminated prematurely due to caving in of the fragile rock encountered. Gouge at several locations in the hole suggested faults. The core was generally of volcaniclastics predominating higher in the hole, and graphitic argillite and siltstone predominating lower in the hole. Multilithic slump breccia was fairly commonly evident. As in Hole 25, bedding laminae, quartz veinlets and breccia clasts displayed a crumple-folding and dismemberment associated with low grade regional metamorphism and movement. The highest geochem values, at 38 m, were associated with quartz veins. Some sulphide bands, dismembered in graphitic argillite, seemed syngenetic. Though the geophysical target was not reached the graphitic argillites in the hole could make a good conductor.

DDH FC08-27

The purpose of the hole was to test the same geophysical conductor as Hole 26. Broken rock and gouge zones hampered drilling. Similar to Hole 26, the core was generally of volcaniclastics predominating higher in the hole, and increasingly siliceous graphitic argillite and siltstone predominating lower in the hole. Multilithic slump breccia occurred. Fine bedding laminations occurred locally, often rumpled and contorted as if by soft sediment slumping. It is uncertain whether the conductor targeted by Holes 26 and 27 can be explained by graphitic argillites present or by a conductive fault zone with a N-S orientation. No significant geochem results occurred in Hole 27. The Section (Figure No. 19) for Holes 26 and 27 suggest a semi-horizontal bedding contact for strata in the area.

DDH FC08-28

The purpose of the hole was to test a N-S oriented geophysical conductor, possibly a southward continuation of the N-S conductor targeted by Holes 26 and 27. The core was generally of felsic volcaniclastics, siliceous argillite, siltstone and sandstone. The argillite, usually black, was variably graphitic. Multilithic slump breccia, as usual, with light sandy clasts in a dark argillic matrix, occurred extensively in the hole. Gouge zones at approximately 110 m and 210 m may represent faults. The slump breccia and syngenetic sulphides in this hole are similar to those in the Frank Creek Discovery Trench of 2001 adjacent to the south. The highest Cu-Pb-Zn geochem results were associated with apparently syngenetic sulphide bands occurring in a slump breccia at approximately 44.8 m (see Figure No. 15).

Figure No. 15 Sulphide Bands in Hole FC08-28, occurring in slump breccia at 44.8m, second column from top. The sulphides are mostly chalcopyrite. Lighter rocks above and below are silicified and sericitized.

The conductor target here may be explained by the sulphide bands, graphitic argillite or possibly by gouge zones encountered in this hole. This is a complex area wherein N-S and NW-SE conductors co-incide, each with a possibly different cause.

DDH FC08-29

The purpose of the hole was to test a conductor between DDH Holes 13 and 17 and to determine orientations of mineralized zones in these older holes. The core consisted generally of siltstone, argillite and sandstone. Strong silicification and sericite alteration occurred extensively. Bedding laminations often appeared disturbed or rumpled, as if flowed when a soft sediment. A good example of graded bedding occurred at 29.7 m within finely laminated sand and siltstone where grain size got finer downward in the hole, indicating stratigraphic tops are overturned.

Figure No. 16 Graded Bedding in Hole FC08-29 with increasing fineness downward, evidence that rock strata are overturned.

Significant Cu-Pb-Zn mineralization occurred extensively between 91 m – 250 m, local concentrations were in bands, some appearing syngenetic, and with quartz veins and silicification and local sericite alteration. Quartz veins were locally important.

A mineralized altered zone, dipping moderately westward, extends through Hole FC08-27, between older holes FC04-13 and FC05-17. This represents approximately a 150m down dip extension. It should be noted that in Assessment Report 28978, Figure Section L57N Hole, Hole FC05-17 is incorrectly drawn at 19+50W. FC05-17 is actually located at 18+50W on Line 57N and Hole FC08-29 is at 19+40W, approximately halfway between Hole FC04-13 and FC05-17.

Figure No. 17 Sulphides in Hole FC08-29 occurring in apparently syngenetic bands near 232.3 m and associated with quartz veins at 236 m.

DDH FC08-30

The hole was part of the drilling grid in the F9 Target Area of Trenches FC07-TR4a,TR4b and TR5 of the previous year. This hole was drilled directly underneath 2007's Trench FC07-TR5 which contained significant sulphides occurring in stringers parallel to the rocks' foliation and in Cu-Pb-Zn lenses. The best sulphide zone, at 36.33 m - 39.55 m, corresponds with the a Cu-Pb-Zn showing on the underside of a 2 m x 5 m semi-massive sulphide lens described in Turna, R. and Doyle, L.E. (2008). The upper portion of the hole was characterized by extensively silicified and sericitized felsic volcaniclastics, commonly characterized by distinctive bluish quartz 'eyes'. There were several mafic dikes. The lower portion was a more chloritized volcaniclastic. Relatively minor argillite and siltstone displayed soft sediment flow or slump breccia textures. At approximately 12.7 m depth graded bedding suggested overturned strata. Sulphides occurred irregularly in sulphide wisps, apparently bedding-parallel, spotty blebs, in quartz veins and very finely disseminated. The bedding-parallel sulphide wisps were probably a sulphide stockwork aligned by regional foliation or shearing, and not necessarily syngenetic.

The Section (Figure No. 21) for Holes 30, 31, 32 and 37 suggest an almost horizontal bedding contact for strata in the area. Notwithstanding the seemingly syngenetic character of some of the sulphides in the core and 2007's trenches FC07-4 and FC07-5, the sulphides do not appear to be stratabound and may mainly be a stockwork type mineralization that occurs in the footwall of volcanogenic massive sulphide deposits.

DDH FC08-31

The purpose of this short hole was to test the sulphide mineralized zone between Trench FC07-TR5 and DDH Hole FC08-30. Strongly silicified and sericitized felsic volcaniclastics occurred throughout the hole; bluish quartz 'eyes' were evident. The upper 48 m of the hole was strongly mineralized with

sulphides in bedding-parallel wisps and seemingly syngenetic bands. Between 39 m – 45 m sulphides were 10%, occurring in wisps with little associated gangue.

DDH FC08-32

The hole was part of the drilling grid in the F9 Target Area. Similar to Hole 30, the upper portion of the hole was characterized by silicified and sericitized felsic volcaniclastics characterized by quartz 'eyes' or porphyroblasts, sometimes bluish. The lower portion was locally more chloritized volcaniclastic. Relatively minor graphitic argillite and siltstone occurred. Local concentrations of sulphides occurred near the top of the hole and in the lower half.

DDH FC08-33

The hole was part of the drilling grid in the F9 Target Area. This hole was drilled directly underneath 2007's Trench FC07-TR4a and 4b which contained significant sulphides occurring in stringers parallel to the rocks' foliation and in massive sulphide lenses. The core consisted generally of volcaniclastics, locally felsic, siltstone and argillite and minor mafic dikes. As usual in the F9 Target Area silicification and sericite alteration were predominant throughout the hole. The most important sulphide zone occurred at 14 m – 26 m in a volcaniclastic unit. The Section (Figure No. 22) for Holes 33 and 35 suggest a moderate westward dip to strata.

DDH FC08-34

The hole was part of the drilling grid in the F9 Target Area. The core consisted sheared argillite slump breccia in the upper part of the hole, in sharp contact with 'blue eyed' felsic volcaniclastics below, with increasing argillite content downward. The felsic volcaniclastic contained a 4.65 m section of 50% - 90% semi to massive sulphides with very little veining or gangue at 16.55 m to 21.20 m. Within this section the highest Cu, Pb and Zn values were 2,090 ppm, 2,220 ppm, 8,500 ppm respectively, over 1.12 m. At approximately 42 m – 50 m significant sulphides occurred in bedding-parallel wisps. This zone, from 16.55 m to approximately 50 m, dips shallowly west where it is encountered again in Hole FC08-36 (Figure No. 23).

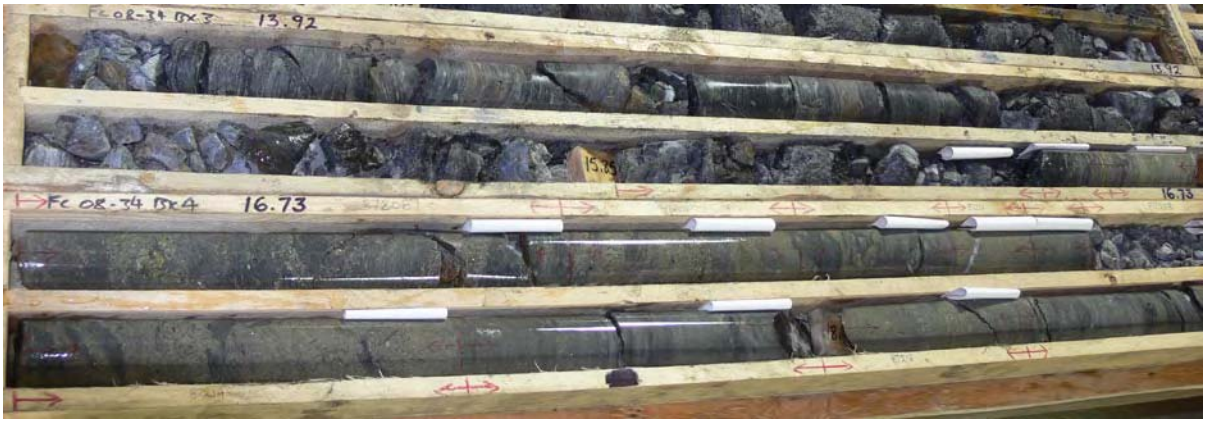

Figure No. 18 Semi to Massive Sulphide Zone in Hole FC08-34 showing sheared argillites above, contact at 16.55 m and the upper part of sulphide zone to approximately 19.6 m.

DDH FC08-35

The hole was part of the drilling grid in the F9 Target Area. Similar to Hole 33, the core consisted generally of volcaniclastics, locally felsic with blue 'eyes', siltstone and argillite and minor mafic dikes. The argillites locally displayed slump breccia texture and disturbed rumpled bedding. Silicic and sericite alteration predominated but variable chloritic alteration occurred extensively. A significant

sulphide zone occurred between 46 m – 88 m. Here sulphide wisps associated with little gangue were semi-parallel with bedding, seem possibly syngenetic. These bands or wisps are overprinted by a stockwork of pyritic stringers. This sulphide zone is apparently the down dip extension of the mineralization in Trench FC07-TR4a and Hole FC08-33, a down dip extension of at least 120 m so far, apparently getting wider down dip. It is unclear whether the sulphide zone is stratabound.

DDH FC08-36

The hole was part of the drilling grid in the F9 Target Area. The upper part of the hole consisted mainly of siltstone and argillite, locally graphitic, and volcaniclastics. This and a layer of 'blue eyed' felsic volcaniclastics below had zones of semi to massive sulphides. The upper, better sulphide zone occurred in volcaniclastic breccia and seemed to correlate with the 4.65 m sulphide section in Hole FC08-34. If this correlation is correct the mineralization does not appear stratabound.

DDH FC08-37

The hole was part of a drilling grid in the F9 Target Area. The sequence of lithologies encountered was similar to that in Holes 30 and 32. At approximately 109m-122.5m quartz veins are abundant. The Section (Figure No. 21) for Holes 30, 31, 32 and 37 suggest an almost horizontal bedding contact for strata in the area. Cu, Pb and Zn values are highest in a zone from approximately 82 m - 90 m in Hole 37, and this appears to correspond with the sulphide zones in Holes 30 and 31 and in Trench FC07-TR5.

Drawn by: RT	Fig.No. 23

10.0 CONCLUSIONS

10.1 Frank Creek Property

The results of DDH Holes FC08-25 to 28 were inconclusive. Holes 25 and 26 did not reach the geophysical conductor targets due to squeezing in the holes caused by broken rock. The conductive zone targeted by Hole FC08-27 may be explained by graphitic argillite encountered or possibly a fault-related gouge zone. The conductive zone targeted by Hole FC08-28 could be explained by the sulphide bands encountered or graphitic argillite or fault gouge. Hole FC08-29 affirmed the down-dip continuity of sulphide mineralization previously encountered in 2004 and 2005 in holes FC04-13 and FC05-17. Holes FC08-30 to 37 drilled in a grid pattern at F9 Target Area, affirmed the stockwork or footwall-type nature of the Cu-Pb-Zn sulphide mineralization in the area, notwithstanding occurrences of syngenetic-appearing sulphide bands. A good example of overturned graded bedding in Hole FC08-29 added to similar proof of overturned strata from DDH holes from past years (see historic assessment reports regarding drilling at Frank Creek) and overturned pillows in lava (Ferri, 2000, pg. 47 and Ferri, OF 2001-11, Map). The overturned geology implies, particularly at the F9 Target Area, the geology exposed at the surface is the footwall zone to possible massive sulphides, intact, at a deeper level. A semi-horizontal lie to shallow westward dip to geologic strata is indicated in the Drilling Sections (Figures 19, 21, 22 and 23). This accords with Ferri (OF 2001-11, Section B-B') for the Frank Creek area. This orientation on the intermediate scale does not preclude NW-SE fold structures and steeper dips on the smaller scale or larger regional scales.

10.2 Black Bear Property

New roads and logging facilitated prospecting in a 2.0 km long area where numerous new quartz vein outcrops and float were discovered. The new quartz-galena showings in the 2 km x 1 km area indicate a strong persistence of the of the quartz veining northwest of the old Providence workings.

10.3 Gerimi Property

Mineralization described for the Lynda showing in Minfile 093B 025 and previous explorers' assessment reports was confirmed by prospecting and cursory mapping. Copper mineralization was associated with bedding planes and contacts in limestone and siltstone. Historic geophysical work detected anomalous magnetic trends and soil sampling surveys had Cu anomalies partly masked and limited by deep overburden. Results were encouraging enough to recommend follow-up work which was also recommended in the historical assessment reports but not done.

11.0 RECOMMENDATIONS

11.1 Frank Creek Property

The Titan-24 IP geophysical survey of 2004 detected a strong low resistivity (conductor) anomaly underlying the F9 Target Area. This anomaly should be tested by diamond drilling in a grid pattern. The conductor target not reached by Hole FC08-26 should be targeted by a DDH hole set up closer to the conductor. Methodical trenching of the numerous geochemical and geophysical targets on the property should be done.

The Cariboo Lake and Frank Creek area of Barkerville Terrain remain undiminished as an under-explored possible massive sulphide district. Comprehensive exploration for volcanogenic massive sulphides should be extended outward from the present Frank Creek exploration area, in particular toward Barker Minerals' Big Gulp showing (Minfile 093A 143), 2.5 km SW, Unlikely showing (Minfile 093A 163), 4.5 km WSW, SCR prospect (Minfile 093A 203), 7.5 km SW, and Ace prospect (Minfile 093A142), 15 km NE for Frank Creek. These Minfiles describe the showings as having massive sulphide characteristics and are classed variously as volcanogenic, syngenetic, stratiform.

11.2 Black Bear Property

Thorough mapping of the newly discovered quartz veins in their 1 km x 2 km area should be done concurrent with magnetometer and VLF EM surveys to locate veins and favourable structures. A soil sampling survey should be done over the same area. Trenching of the new quartz exposures and geochemical and geophysical targets should be done prior to choosing drill targets.

11.3 Gerimi Property

Magnetometer and VLF EM surveys should be done to re-locate magnetic anomalies and structures detected by previous explorers. Geologic mapping should locate limestone bodies and favourable contact zones. Soil sampling should be done with enhanced detail at geophysical targets, the Cu mineral showings at the Lynda and on Gerimi Creek and at geochemical anomalies not followed up sufficiently by previous explorers. Enzyme leach lab analysis method should be used on the soils as this can detect the most subtle buried sources.

APPENDIX A

Glossary of Technical Terms and Abbreviations

Glossary of Technical Terms and Abbreviations

Anomalous	Chemical and mineralogical changes and higher than typical background values in elements in a rock resulting from reaction with hydrothermal fluids or increase in pressure or temperature.
Anomaly	The geographical area corresponding to anomalous geochemical or geophysical values.
Argentiferous	Containing silver.
Background	The typical concentration of an element or geophysical response in an area, generally referring to values below some threshold level, above which values are designated as anomalous.
BCGS	British Columbia Geological Survey.
B.C. MEMPR	British Columbia Ministry of energy Mines and Petroleum Resources.
cm	Centimetre.
Cratonic	Pertaining to a craton, an old part of the continental crust, generally making up the interior portion of a continent such as North America.
DCIP	An electrical method which uses the injection of current and the measurement of voltage and its rate of decay to determine the subsurface resistivity and chargeability.
DDH	Diamond drill hole
EM	Electromagnetic.
Float	Loose rocks or boulders; the location of the bedrock source is not known.
Grab sample	A sample of a single rock or selected rock chips collected from within a restricted area of interest.
g/t	Grams per tonne (metric tonne). 34.29 g/t (metric tonnes) = 1.00 oz/T (short tons)
Ha	Hectare - an area totalling 10,000 square metres, e.g., an area 100 metres by 100 metres.
HLEM	Horizontal loop electromagnetic.
ICP	Inductively coupled plasma.
IP	Induced polarization.
km	Kilometre.

lb.	Pound.
Leucocratic	Light-coloured.
Max-min	An HLEM technique to test for resistivity and conductivity of rocks.
MT	Magnetotelluric. A electrical method that uses natural variations in the Earth's magnetic field to induce electric current in the ground to determine the subsurface resistivity.
NNW-SSE	North northwest – South southeast
NW-SE	Northwest - southeast.
N-S	North-South
oz.	Ounce.
oz/T	ounces per ton (Imperial measurement). 34.29 g/t (metric tonnes) = 1.00 oz/T (short tons)
oz/st	ounces per short ton (Imperial measurement, same as oz/T). 34.29 g/t (metric tonnes) = 1.00 oz/st (short tons)
ppb	Parts per billion.
ppm	Parts per million (1 ppm = 1,000 ppb = 1 g/t)
Protolith	The original rock before it was metamorphosed.
TDEM	Time Domain EM.
Tholeiitic	A type of basalt. The most common volcanic rocks on Earth, produced by submarine volcanism at mid-ocean ridges and make up much of the ocean crust. Chemically, these basalts have been described as subalkaline, that is, they contain less (Na_2O plus K_2O) at similar SiO_2 than alkali basalt.
TRIM	Terrain Resource Information Management
VLF	Very low frequency
VMS	Volcanic-related massive sulphide.

APPENDIX C

SAMPLE DESCRIPTIONS

Black Bear Property

Gerimi Property

Ace Property

SAMPLE DESCRIPTIONS

(Black Bear Property)

Sample No.	ActLabs Certificate	Location (NAD83) Easting	Northing	Sample Type

86068 A08-7318 605600 5833285 Rock
Float. 15 cm across quartz vein with galena and pyrite and attached sugary limestone and shale.

86068C A08-7318 605576 5833321? Soil
Orange brown soil, representative of this quarry area.

86105 A08-7318 605255 5833703 Rock
15 cm across mineralized part of quartz vein, locally brecciated with galena in breccia matrix.

86106 A08-7318 605255 5833703 Rock
25 cm across quartz-siderite vein. Galena occurs siderite in fractures in quartz. Three main quartz veins here, parallel.

86107 A08-7318 605255 5833703 Rock
1.40 m across rusty rotten country rock. Phyllitic siltstone with rotted out cubes.

86108 A08-7318 605255 5833703 Rock
Grab of 'barren' quartz. Has grey zones and minor pyrite cubes in cracks.

86109 A08-7318 605255 5833703 Soil
Orange brown soil, representative of this quarry area.

86110 A08-7318 605200 5834103 Rock
Grab of quartz vein float, contains galena. Abundant quartz float here, some with galena in fractures.

86111 A08-7318 605320 5833693 Rock
40 cm across quartz sub-outcrop, contains galena. Abundant quartz float here appears to be sub-outcrop.

86112 A08-7318 605282 5833666 Rock
35 cm across quartz with galena in outcrop. Abundant quartz float here, several 1m x 2m boulders.

86113 A08-7318 605282 5833666 Soil
Orange brown soil, representative of this area.

86114 A08-7318 605746 5833229 Soil
Orange brown soil, representative of this area. Much orange soil here and some quartz float.

86115 A08-7318 605196 5834055 Rock
30cm chip. Small sandstone outcrop. No fizzing. Phyllitic. Includes small quartz veinlets. Vitreous, clear. Rock seems silicified or a quartzite. Bedding strikes 123^{o} dips 43^{o} NE.

86116 A08-7318 605200 5834103 Rock
Same location as 86110. 30cm chip in apex of outcrop-scale fold. Phyllitic quartzite. Very minor rust. Includes small quartz veinlets. Similar to above. No vein material included in sample.

86116C A08-7318 605200 5834103 Soil
Same location as 86110.

Sample No.	ActLabs Certificate	Location (NAD83) Easting	Northing	Sample Type

86117 A08-7318 605255 5833703 Rock
Same location as 86105-86109. 40cm chip of rusty phyllite with small pyrite cubes in bedding planes on upper side of middle quartz vein. No quartz included.

86118 A08-7318 605255 5833703 Rock
35cm chip of same as above. More yellowy colour. Fissile rock. No quartz included. On underside of upper vein.

86118C A08-7318 605255 5833703 Soil
Reddish hematitic soil on underside of upper vein.

86119 A08-7318 605010 5834254 Rock
Grab from layered phyllite boulder is 30% vitreous quartz vein parallel to foliation. Very slight rust and hematite.

86120 A08-7318 605010 5834254 Rock
Grab from green gabbro boulder. Contains fuchsite. Two very large boulders here are green due to fuchsite. Fairly strongly magnetic. No sulphides. Massive, homogenous, rounded.

(Gerimi Property)

Sample No.	ActLabs Certificate	Location (NAD83) Easting	Northing	Sample Type

86301 A08-7513 556665 5860722 Rock
Grab. Limestone with malachite and azurite stains associated with a stockwork of calcite veins.

86302 A08-7513 556665 5860722 Soil
Brown soil from atop bank.

86303 A08-7513 556756 5860632 Soil
Maroon soil.

86318 A08-7513 557290 5860179 Rock
Outcrop on floor of quarry. 75cm chip. Greenish maroon amygdaloidal basalt with malachite stains.

86319 A08-7513 557290 5860179 Rock
Outcrop on floor of quarry. 95cm chip. Amygdaloidal basalt with malachite stains. Grey (chalcocite?) spots.

86320 A08-7513 557290 5860179 Soil
Maroon soil from same spot as 86319.

86321 A08-7513 557454 5860058 Rock
50cm chip of greenish intrusive (dike?) with malachite stains.

86322 A08-7513 557454 5860058 Soil
Maroon soil from same spot as 86321.

86323 A08-7513 556663 5855831 Rock
Grab. Gabbro. Magnetic.

Sample No.	ActLabs Certificate	Location (NAD83) Easting	Northing	Sample Type
86324	A08-7513	556663	5855831	Rock

Grab. Felsic intrusive. Not magnetic? Younger than the above gabbro?

86325	A08-7513	556663	5855831	Rock

Grab. Black hornblendite hornfelsic rock. Strongly magnetic.

(Ace Property)

Sample No.	ActLabs Certificate	Location (NAD83) Easting	Northing	Sample Type
86121	A08-7318	624871	5852375	Rock

On Ace Property. At site of DDH 02-03. Grab from Trench 97-1B. Pyritic quartz vein attached to very pyritic schist.

86122	A08-7318	627103	5852249	Rock

On Ace Property. At site of DDH 98-1. Grab. Composite grab of pyritic quartz veins in outcrop in ditch.

APPENDIX D

Analytical Methods

Code 1C-Exploration

A 30 g sample is weighed, mixed with fire assay fluxes and fused at 1050°C for 1 hour. After cooling the lead button is separated from the slag and cupelled at 1000°C to recover the Ag (doré bead) + Au, Pt, Pd. The Ag doré bead is digested in hot (95°C) HNO_3 + HCl. After cooling for 2 hours the sample solution is analyzed for Au, Pt, Pd by ICP-OES. Smaller sample splits are used for high chromite or sulphide samples to ensure proper fluxing and metal recoveries.

Note: If values exceed upper limits, reanalysis by fire assay Au, Pt, Pd (Code 8) is recommended.

Code 1C-Exploration Elements and Detection Limits (ppb)

Element	Detection Limit	Upper Limit
Au	2	10,000
Pt	5	10,000
Pd	4	10,000

Code 1H – Au + 48

INAA Portion

An approximately 30 g aliquot, if available, is encapsulated and weighed in a polyethylene vial and irradiated with flux wires and an internal standard (1 for 11 samples) at a thermal neutron flux of 7 x 10^{12} n cm^{-2} s^{-1}. After a seven day decay to allow Na-24 to decay the samples are counted on a high purity Ge detector with a resolution of better than 1.7 KeV for the 1332 KeV Co-60. Using the flux wires the decay corrected activities are compared to a calibration developed from multiple certified international reference materials. The standard present is only a check on accuracy of the analysis and is not used for calibration purposes. From 10-30% of samples are rechecked by re-measurement.

Further details are available on isotopes and gamma-ray energies used in Hoffman, E.L., 1992. Instrumental Neutron Activation in Geoanalysis. Journal of Geochemical Exploration, volume 44, pp. 297-319.

Total Digestion - ICP Portion

A 0.25 g sample is digested at 260°C with four acids beginning with hydrofluoric, followed by a mixture of nitric and perchloric acids, heated using precise programmer controlled heating in several ramping and holding cycles which takes the samples to dryness. After dryness is attained, samples are brought back into solution using aqua regia. With this digestion certain phases may be only partially solubilized. This leach is partial for magnetite, chromite, barite, spinels, zircon and massive sulphides. The solutions are analyzed using either a Varian VISTA PRO, Varian 735-ES or Perkin Elmer OPTIMA 3000 Radial ICP.

Notes: * Element may only be partially extracted.

† Element reported by multiple techniques if one or more techniques may not be total.

Assays are recommended for values which exceed the upper limits.

Code 7 Enzyme Leach[SM]

A 1 g sample of -60 mesh B soil horizon material is leached in a glucose oxidaze solution which contains an enzyme. The enzyme reacts with amorphous MnO_2 dissolving it. The metals are complexed with the gluconic acid present. The solutions are analyzed on a Perkin Elmer ELAN 6100 or 9000 ICP/MS. The analytical package consists of a suite of 60 elements at sub-ppb to ppm levels. Selected anomalous samples are checked by repeating the process. Duplicate samples are run one for every 15 samples.

Code 7 MAJ add-on is available for obtaining data on major elements and S in the leach solution.

APPENDIX F

FRANK CREEK PROPERTY
DIAMOND DRILL HOLE LOGS for
FC08-25 to FC08=37

PROPERTY: FRANK CREEK

BARKER MINERALS LTD.

DRILL HOLE NO. FC08 - 25

Dip & Azimuth Tests			DDH FC08-25	**Easting (NAD 83):** 609777	**Core Size:** NQ2	**Started:** July 11, 2008
Depth	**Dip**	**Azmth**	**Other tests**	**Northing (NAD 83):** 5845786	**Hole Azimuth**: 70°	**Finished:** July 14, 2008
14.33	-80.5°	46.9°		**Grid Location:** 58+70N/21+30W	**Hole Angle:** -80°	**Logged by:** R.Turna
No lower dip test done due to risk of losing instrument in tight hole.				**Elevation:** 990 m	**Total Depth:** 60.05 m	**Analysis by:** ActLabs
						Drilling by: G & O Drilling

Note: Azmths above are underestimated by approx. 20°.
Tests done using Reflex EZ-Shot.

								Alteration Scale: 1 - 5 v. weak/weak/moderate/strong/v.strong						
Depth (m)				**%**	**%**	**%**	**%**	**Cr**	**Seri-**	**2nd**	**2nd**	**2nd**		
From	**To**		**Description**	**Py**	**Cpy**	**Sph**	**Gal**	**Mica**	**cite**	**Carb**	**Sil**	**Chl**		**Reactions to Magnet and Acid.**
			Purpose of the hole is to intersect and determine orientations of mineralized zones in DDH's FC04-9,10,11,FC06-23 and test a geophysical conductor.											
0.00	7.62		Casing. No core recovery											
7.62	8.20		Siltstone. Light to dark grey layers. Mostly brecciated, appears a slump breccia, some clasts not rotated much away from another. Some clasts appear weakly strung out, evidently weakly sheared or foliated. Pyrite blebs and cubes up to 9mm. No veining	2								1		Some dark layers or zones pull a magnet very weakly, probably due to pyrrhotite. Local weak fizzing.
8.20	8.23		Gouge. Very crumbly.	5										
8.23	8.40		Rubble. Brecciated siltstone in upper half. Greenish grey sandstone in lower half. Local blebby and coarse crystalline pyrite.	5								tr		
8.40	10.30		Sandstone or volcaniclastic. Light to medium greenish grey. Generally fairly well sorted with local minor darker silty layers. Locally fairly highly fractured with narrow crumbly gouge. Pyrite is disseminated with less in stringers and blebs. A few quartz veinlets. Pervasive sericite.	5					3					Local weak magnetism. No fizzing.
10.30	10.40		Gouge. Very crumbly.	5										

Depth (m) From	Depth (m) To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
10.40	11.28		Siltstone. Light to dark grey disturbed laminations. Similar to that at 8.0 m. Locally high fracture intensity parallel to bedding, 15 deg to core axis (CA). Minor disturbed quartz veinlets 70 deg and 55 deg to CA. Pyrite is disseminated and parallel to bedding in stringers. Local coarse blebs At 11.18 m a thin blackish layer is dismembered, due to slumping?	5										Local very weak magnetism. No fizzing.
11.28	11.40		Rubble.											
11.40	18.00		Argillite. Dark grey to black. Generally well laminated. Light grey laminations are mm scale, crenulated, slightly strung out or boudinaged. Laminations are generally 10 deg to CA. At 13.2 m is a 30 cm zone of intense fracturing and crumbly rock. Local minor crumbly fractured zones occur above and below. Rock is soft, usually graphitic, writes on paper. Minor veinlets are disturbed, discontinuous. Pyrite is blebby, cubes to 5mm, finely disseminated. Trace bits of chalcopyrite in veinlets. The bottom 2 m is somewhat a breccia, locally black clasts occur in a light sandy matrix, locally the other way around. The 'breccia' might be a soft sediment slumping. Good sedimentary contact at 11.28 m is 50 deg to CA.	5	tr									No magnetism. No fizzing.

Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
18.00	25.00		Sandstone or volcaniclastic. Light to medium greenish grey. Not well sorted and has local minor darker silty layers. Same as at 8.4-10.3m. May be a felsic volcaniclastic. Very weak schistosity is ubiquitous, evident as micro boudinage about 80 deg to CA. Top 1.3 m is a strongly pyritic micro breccia, about 20% pyritic. The pyrite in this sub-zone occurs in weakly schistose stockwork and bedding-parallel layers and blebs. Locally the pyritic stockwork coalesces to a thin (5 mm) layer of sandy pyrite, appearing as a very thin 'massive' sandy pyrite layer. At 19.0m a 4cm gouge zone. Below this sub-zone pyrite is mainly disseminated and blebby, no stockwork, thus 10% pyritic on average. Rare specks of chalcopyrite. Pervasive sericite throughout. Local weak pervasive silicification. Natural sedimentary contact at 25 m is irregular, clasts of the lighter rock of above occur in black siltstone of below, suggesting the rock below is younger.	10	tr				3		1			Rare local weak magnetism appears related to pyrrhotite. No fizzing.
25.00	29.80		Argillite. Dark grey to black. Soft. Graphitic, writes on paper. Graphite is greater below 27.57m, and core is rather massive, not laminated.. Locally somewhat laminated. Dismembered laminations, very weak schistosity and minor bedding parallel quartz veinlets suggest bedding is 40-80 deg to CA, usually 40 deg. Very weak spotty pervasive carbonate and silica alteration if any. Minor disturbed quartz veinlets. Carbonate veinlets are more rare. Pyrite is disseminated, blebby and cubes to 8mm. Bottom contact is at a 2 cm quartz vein 80 deg to CA.	5						tr	tr			Local weak magnetism. Weak local fizzing is uncommon, sometimes related to carbonate veinlets.

Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
29.80	41.76		Argillite. Dark grey to black, with 10% sandy laminations. Generally graphitic, more or less. The laminations are usually disturbed, crenulated, boudinaged. At 35.8m-38.3m has slump breccia texture. Very weak wavy schistosity is parallel to bedding, generally 70 deg to CA. At 30.8m has 8cm of shattered rock and gouge, possible minor fault at 45 deg to CA. Very weak spotty pervasive carbonate and silica alteration if any. Quartz veining is more significant, 5%. A 30cm qtz vn, 45 deg to CA at 31.3m, an irregular 30cm qtz vn at 32.3m, these contain pyrite blebs, not significantly more than wall rocks. Pyrite is disseminated and in bedding parallel blebs. Coarser pyrite tends to located in the minor sandy laminations. Scattered specks of chalcopyrite or tarnished pyrite. Bottom 1m is a slump breccia, very soft, crumbly toward bottom.	5	tr					tr	tr			Local weak magnetism is common, due to magnetite or pyrrhotite. Rare weak fizzing due to carbonate veinlets.
41.76	46.80		Rubble, crumbly zones, intensely shattered argillite. Graphitic as above. Dark grey to black. No significant veining. Pyrite is disseminated. Drilling is very difficult.	5										
46.80	63.05		Argillite. Dark grey to black, with 10% sandy laminations. Generally graphitic, more or less. Same as at 30m -41m. Good laminations at 48.5m-60m are 70 deg to CA. Soft weak more graphitic zones alternate with harder zones that seem very slightly silicified. Quartz 'sweats' parallel to bedding/foliation are common. 54m-55m and 57.5m-58m has shattered rubble. Hole continually caving in from above, stopped prematurely due to impossible to make any further progress. Very sandy black effluent water. 0.7m of black sand below EOH marker is from cave in.	5							tr			Rare weak pull on magnet, cause uncertain. Very rare weak fizzing at veinlets.
			End of Hole at 63.05 m.											

Lithology: DDH FC08 - 25

			EOH										
			Summary: Siltstone and sandstone high in hole. Graphitic argillite lower down.										
			Weak spotty magnetism is common, likely due to pyrrhotite.

No lower dip test done. Bottom core tubes (70 ft) lost in tight hole.				**Elevation:** 1,099 m	**Total Depth:** 111.86m	**Analysis by:** ActLabs
						Drilling by: G & O Drilling

Note: Azmths above are underestimated by approx. 20°.
Tests done using Reflex EZ-Shot.

Depth (m)								**Alteration Scale: 1 - 5** v. weak/weak/moderate/strong/v.strong						
From	**To**		**Description**	**% Py**	**% Cpy**	**% Sph**	**% Gal**	**Cr Mica**	**Seri-cite**	**2nd Carb**	**2nd Sil**	**2nd Chl**		**Reactions to Magnet and Acid.**
			Purpose of hole is to test geophysical conductor north of Discovery Trench.											
0.00	6.10		Casing. No recovery.											
6.10	26.60		Volcaniclastic. Upper 30 cm is rusty on fractures, below which is a 20 cm quartz vein. Medium green. Variably but usually intensely fractured. Pyrite occurs irregularly disseminated, in blebs and as 5mm cubes. Grey sulphides seem evident in local silicified spots but cannot be identified. Secondary chlorite is pervasive and in fine stringers and along fracture surfaces. Patchy pervasive sericite and silica. Emerald green Cr mica is evident in fractures and as green clasts in local breccia (see at 11.3m). Quartz veins are minor, irregular and intensely fractured. Between 21.7m-23.4m has more qtz veining. At 15.m-16m is very dark rubble and gouge. Slump breccia is evident at 18.5m-20.0m, and intermittently below approximately 22m; lighter coloured volcanic clasts in a dark silty matrix. Locally the rock has fine laminae, 75 degrees to core axis (CA) at 21m. Lower contact (75 deg to CA) is sharp, erosional, where a 1cm qtz vein in the rock below is abruptly cut off, indicating the lower rock at this local scale is older.	1		tr?	tr?	1	2	1	1	3		No noticeable magnetism. No noticeable fizzing.

Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
26.60	29.05		Volcaniclastic. Medium yellowish green. Somewhat uniform texture, weakly foliated. Strong pervasive alteration is yellow-green sericite. Abundant fairly dark grey wavy wisps and patches appear to be quartz-sulphide veins. These have soft pervasive edges, not sharp. Perhaps hydrothermals injected into soft sediment or rock not fully lithified? The grey sulphide is too fine to identify, but is apparently abundant. Locally heavy-feeling core has abundant grey sulphide with grey quartz. **Box 6 is to be stored in core library at Likely camp.**	10		1?	1?	2	4	1	3			No noticeable magnetism. No noticeable fizzing.
29.05	33.25		Black rubble and gouge. The upper 50cm is mostly contorted irregular qtz vein. The rock is apparently a breccia. Local dismembered laminae. Lower contact is 30 deg to CA.	5										No noticeable magnetism. No noticeable fizzing.
33.25	47.65		Volcaniclastic as at 26m-29m. Strong pervasive alteration as before, medium yellowish green. Grey wisps are more abundant, consists mainly of grey quartz, generally parallel foliation at 40 deg to CA. At 37.3m relatively coarse galena and sphalerite with some chalcopyrite occur in quartz veins.	5	tr	0.1	1?	1	4		4			No noticeable magnetism. Rare weak fizzing at carbonate veins.
47.65	55.60		Black chloritic sheared breccia. Pyrite cubes up to 15mm.	5							2	5		Rare weak magnetism. No noticeable fizzing.

Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
55.60	76.50		Volcaniclastic as at 34m-47m. Minor small porphyritic andesite dikes occur within but are not significant. Fuchsite sometimes visible on fracture surfaces. 57.5m-60m is mostly irregular quartz vein with lesser carbonate; the carbonate does not fizz well, likely white Fe carb. Pyrite appears mainly disseminated, Grey wisps persist, seem mainly grey quartz. At 68.3m-69.1m is mostly shattered rock and local gouge. At 76 m a 30 cm qtz-carb (no fizzing) vein is not associated with significantly more sulphides, this seems generally the case with most veins, though sometimes coarser sulphides present are identifiable. Lower contact is 80 deg to CA, sharp.	2		tr		tr	4	1	3			Rare weak magnetism, cause is unclear. Rare weak fizzing at carbonate veins.
76.50	81.70		Slump breccia. Dark grey to black. Graphitic. Medium grey clasts appear silicified volcaniclastic. The breccia is fragile, most of the interval is shattered or rubbly, with local gouge. At 81.3m-81.7m is black gouge. Quartz veins are irregular, not significantly sulphidic.	0.5							tr			No noticeable magnetism. No noticeable fizzing.
81.70	82.40		Basalt dike at 40 deg to CA. Very dark marroon grey. Uniform, fresh texture. Small white feldspar phenocrysts obvious against dark matrix.	0.1										No noticeable magnetism. No noticeable fizzing.
82.40	97.40		Argillite. Generally black. Generally very graphitic but variably. Small qtz veins occur. Pyrite is disseminated, mostly in irregular blebs and cubes up to 10mm. At 91.80 m a 1 cm band of silty textured syngenetic pyrite is somewhat folded and dismembered. At 86.1m-93.1m the rock is hard, competent, pervasively silicified. Outside of this sub-zone silicification is much less and the rock quality is poor. Local minor gouge and shattered rock. The lower 4 m is rather fragile and broken. The lower 3 m has somewhat more irregular qtz veining..	5	tr						2			No noticeable magnetism. No noticeable fizzing.

								Alteration Scale: 1 - 5 v. weak/weak/moderate/strong/v.strong						
Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
97.40	102.60		Siltstone. Mostly crumbly with common gouge. At 99.67m-99.95m a qtz vein. Small qtz veins occur.	2							1			No noticeable magnetism. No noticeable fizzing.
102.60	111.86		Interbedded 80% volcaniclastic and 20% siltstone. Mostly crumbly, fragile, strongly pervasively altered. At 111.30m-111.55m is crumbly gouge. At this depth several drill rods got irretrievably stuck. Hole ended prematurely. Conductor at hairpin turn in road not reached.	2					4		3			No noticeable magnetism. No noticeable fizzing.
			End of Hole at 111.86 m.											

Lithology: DDH FC08 - 26

66.14	-59.3°	33.2°	Mag = 5715 Temp = 15	**Elevation:** 1,109 m	**Total Depth:** 117.96m	**Analysis by:** ActLabs
117.96	-59.2°	34.3°	Mag = 5716			**Drilling by:** G & O Drilling

Note: Azmths above are underestimated by approx. 20°.
Tests done using Reflex EZ-Shot.

Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
			Purpose of hole is to test geophysical conductor north of Discovery Trench.											
0.00	9.14		Casing. No recovery.											
9.14	17.37		Andesitic volcaniclastic. Has a significant component of lithic clasts, perhaps an epiclastic. A mix of tuff and sandstone? Light greenish grey. Soft locally crumbly rock. Alteration is pervasive, strong. Crumbly gouge at 14.20 m and 14.35 m. Local high fracture intensity. Minor quartz veining. Pyrite is disseminated and less in thin stringers. Lower contact is approximate, occurs in rubble, merely acknowledges more altered rock above, more laminated rock below.	3					4		2			No magnetism detected. No fizzing.
17.37	21.80		Same volcaniclastic-sandstone mix as above. Locally more greyish, locally more greenish. Local fine bedding laminations tend to be 70 degrees to core axis (CA), somewhat disrupted. Inconsistent mixed texture. Alteration weakens slowly downward. Locally crumbly but getting more competent overall. Pyrite is disseminated but also increasingly blebby, and in cubes to 1 cm. Lower contact is approximate, location uncertain as rock textures vary, but seems essentially a conformable bedding contact.	3					2		1			No magnetism detected. No fizzing.

Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
21.80	45.20		Slump breccia. Dominantly lithic volcaniclastic with minor grey siltstone and sandstone. Variable texture and composition. 40.0m-42.0m is more greenish and less brecciated. Pervasive sericite is locally strong and sometimes masks breccia texture. Obvious slump breccia texture is at 31.0m-35.5m and 44.5m-45.2m. Local high fracturing. Veins are not very significant, some larger (10-20cm) are irregular. Pyrite is disseminated, blebby, cubic, as above. Lower contact occurs at a grey 5 cm qtz vein. Samples 86758, 86759, 86760, 86761 are of more heavily qtz veined sections, 86759 is light yellow green due to sericite.	3				tr	3	1	2			No magnetism detected. No fizzing.
45.20	52.70		Volcaniclastic, fairly felsic (or silicified?). Medium grey. Local lithic clasts. Middle half of zone is shattered, crumbly, more sericitic. Pyrite is as above. Veins always few and generally not significant. Lower contact is sharp, wavy, appears erosional or disconformable.	3					3		2			No magnetism detected. No fizzing.
52.70	60.00		Crystal lithic tuff. Very dark grey, locally greenish or greyish due to wispy sericite. Dark siliceous very fine grained matrix with light grey feldspar phenocrysts to 3mm. Locally strongly fractured. Seems interbedded with the coarser volcaniclastic of above as this occurs intermittently in narrow sub-zones below as well. Lower contact is sharp, 70 deg to CA, crumbly gouge below.	1					1		3			No magnetism detected. No fizzing.
60.00	62.60		Rubble, crumble, gouge. Greenish grey. Sericitized volcaniclastic with some qtz vein fragments. Cave in occurred. Rods got pulled. Same lithology continues below.	0.5					4		1			No magnetism detected. No fizzing.
62.50	69.20		Lithic volcaniclastic and minor interlayers of very fine porphyritic crystal lithic tuff as at 53m-60m. Variable texture as before. Veins are minor. Pyrite occurs as above.	3					3		2			No magnetism detected. No fizzing.

Depth (m) From	Depth (m) To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
69.20	88.65		Lithic volcaniclastic and minor interlayers of very fine porphyritic crystal lithic tuff as above; the upper portion of this interval has fine bedding laminations 70 deg to CA. Laminations are common throughout, otherwise not significantly different from above interval. Fuchsite occurs in some fractures and preferentially within some lighter coarser laminations in the upper half of this zone.	3				1	3		2			No magnetism detected. No fizzing.
88.65	91.70		Very fine grained siliceous argillite. Very dark grey to blackish. Fine light grey (bedding) laminations are not necessarily characteristic but occur locally. These are usually rather swirly and contorted, rumpled, (possibly while a soft sediment?). Generally very competent though fractured. Pyrite occurs irregularly mainly as blebs and cubes. Lower contact occurs at a 10 cm qtz vein.	1					tr		1			No magnetism detected. No fizzing.
91.70	110.60		Mostly slump breccia, consisting mainly of lithic volcaniclastic typical of this hole. Texture quite variable as usual. Minor porphyritic (crystal tuff) sections. Lower contact is sharp, apparently 70 deg to CA, unclear in broken rock.	1					3		1			No magnetism detected. No fizzing.
110.60	117.96		Argillite. Very dark grey to black. Very fine grained, hard, siliceous. Appears graphitic though silicification makes the rock hard, doesn't write well. Uncommon light grey laminations are somewhat contorted, rumpled as in similar rock at 89m-91m; may be a soft sediment deformation as this is quite contrary to the consistent 70 deg to CA attitude typified at 70.5m-72.0m. Pyrite is very finely disseminated but most occurs in small blebs. Rare galena in qtz veins.	0.5			tr				3			No magnetism detected. No fizzing.
			End of Hole at 117.96 m.

DRILL HOLE NO. FC08 - 28

Dip & Azimuth Tests			DDH FC08-28	**Easting (NAD 83):** 610516	**Core Size:** HQ, NQ2	**Started:** July 19, 2008
Depth	**Dip**	**Azmth**	**Other tests**	**Northing (NAD 83):** 5845456	**Hole Azimuth**: 90°	**Finished:** July 23, 2008
				Grid Location: Line 55N	**Hole Angle:** -60°	**Logged by:** R.Turna
166	-62.3°	70.5°	Mag = 5710 Temp = 14.4	**Elevation:** 1,132 m	**Total Depth:** 249.02m	**Analysis by:** ActLabs
249.02	-60.9°	70.3°	Mag = 5707 Temp = 14.1			**Drilling by:** G & O Drilling

Note: Azmths above are underestimated by approx. 20°.
Tests done using Reflex EZ-Shot.

Depth (m)								**Alteration Scale: 1 - 5** v. weak/weak/moderate/strong/v.strong						
From	**To**		**Description**	**% Py**	**% Cpy**	**% Sph**	**% Gal**	**Cr Mica**	**Seri-cite**	**2nd Carb**	**2nd Sil**	**2nd Chl**		**Reactions to Magnet and Acid.**
			Purpose of hole is to test a conductor on north side of the Discovery Trench.											
0.00	4.57		Casing. No core recovery.											
4.57	19.70		Volcaniclastic. Some dark lithic clasts. Top 1 m is weakly rusty on fractures. Fairly uniform sandy texture except where modified by local breccia, veining or alteration. Light greenish grey grading to medium grey downward as alteration weakens. At 13m-15m has compositional layering (bedding laminae) 40 degrees to core axis (CA). A ubiquitous phyllitic foliation exists. Greenish colour and alteration intensity are stronger at 4.57m-10.5m and 15.8m-19.7m where quartz veining is also stronger. Sericite is pervasive, fairly strong in the upper veined section, wispy and weaker in the lower veined section. There are 2 types of qtz veins, equally abundant and occurring usually together; older deformed grey veins with somewhat blended edges and younger white veins with sharp edges. Veins make up about 10% of the rock in this zone. The white veins often contain soft black inclusions that appear to be graphite. Pyrite occurs mainly in blebs and cubes to 8mm size.	2					3	1	3			No noticeable magnetism. No noticeable fizzing (Fe carbonate in pervasive alteration and veins do not fizz).

Depth (m) From	Depth (m) To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
19.70	21.90		Argillite slump breccia. Dark grey to black. Primarily silicic. Possibly graphitic. Shattered rock and local gouge is common. At 21.0m-21.25m is crumbly black gouge. Upper contact is gradational and ripped up or disturbed. Lower contact is unclear in broken rock. No significant veining. Pyrite is blebby.	2							1			No noticeable magnetism. No noticeable fizzing.
21.90	43.90		Felsic volcaniclastic. Small qtz eyes are common. Bedding laminae are 70 deg to CA, usually are not prominent, especially in altered rock. Same sandy uniform texture as in top zone and inconsistent sericitic and Fe carbonate alteration, pervasive but variable in intensity. Grey and white qtz veins as before but only about 3% of the rock. Pyrite as before, though less. Stronger grey quartz veining occurs at 27.70m-28.75m, 38.80m-39.50m. Bottom contact is lost between stones, no evidence of gouge here. **Boxes 14-17 to be stored in core library at Likely camp**.	1					3	2	1			No noticeable magnetism. No noticeable fizzing.

Depth (m) From	Depth (m) To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
43.90	61.57		Slump breccia. Medium grey sandstone with minor dark siltstone laminae. Locally light greyish green due to locally stronger pervasive sericite. Breccia clasts are often not much rotated away from neighbouring clasts, are usually stretched somewhat due to regional shearing. The breccia clasts lie parallel to each other (is this due to regional shearing or to original deposition if the slumping was not very violent?). Laminations (often sulphide-rich) and bedding-parallel breccia clasts are 80 deg to CA. **Several silty (syngenetic?) sulphide bands** with chalcopyrite occur at 44.56m-45.10m; the thicker chalcopyrite bands are 4cm, 4cm, 9cm wide; this 60 cm section is approximately 40% sulphide, mostly chalcopyrite. Other less massive bands occur at 51.20m-51.30m, 55.86m-55.96m and 58.57m-58.93m. 1-4 mm thick sulphide bands parallel to bedding and foliation are common in the entire zone though decreasing imperceptibly downward. The above narrow massive sulphide bands and laminations are all fairly parallel and appear mainly syngenetic.	10	3				1		2	1		No noticeable magnetism. No noticeable fizzing.
61.57	64.40		Rubble. Black graphitic argillite with qtz vein pebbles.	2										No noticeable magnetism. No noticeable fizzing.
64.40	65.40		Argillite. Graphitic. Very dark grey to black. Bedding laminae are swirly and rumpled (a soft-sediment slump?), some are sulphide-rich (syngenetic?). At 64.65 m a 10 cm section of crumbly gouge. Lower contact occurs at a qtz vein.	5							1			No noticeable magnetism. No noticeable fizzing.
65.40	67.67		Slump breccia. Medium grey sandstone with minor dark siltstone laminae same as at 44m-61m. Contains fragmented 3mm-10mm sandy sulphide bands.	5							2			No noticeable magnetism. No noticeable fizzing.

Depth (m) From	Depth (m) To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
67.67	76.25		70% graphitic argillite, 30% sandstone and siltstone. Commonly, though not usually, slump breccia texture is evident. The coarser beds are more sulphidic. Pyrite is disseminated and cubic, more in the argillite, more in laminations in the silt and sandstone. Lower contact at 60 deg to CA, grades into siltstone below.	2							1			No noticeable magnetism. No noticeable fizzing.
76.25	94.95		Sandstone. Light to medium grey. Pyrite is cubic and blebby, spotty. No significant sulphide laminations. Lower contact is irregular.	2					1	1	1			No noticeable magnetism. No noticeable fizzing.
94.95	98.50		Slump breccia. Mostly sandstone clasts.	1										No magnetism or fizzing.
98.50	108.80		Slump breccia. Pervasive sericite alteration increasing downward rapidly. Medium grey to light greenish grey downward. Breccia clasts tend to be disguised somewhat by alteration. Locally the rock is crumbly. At 105.30m-105.52m a silty massive pyrite band is 90 deg to CA. Carbonate occurrences appear to be Fe type, not fizzy in acid. Other, very narrow pyritic laminations occur above and below, between 104.24m-106.50m.	5	tr				4	3	1			No noticeable magnetism. No noticeable fizzing.
108.80	110.34		Crumbly rubble, dry gouge.	0.5					5					No magnetism or fizzing.
110.34	130.25		Slump breccia. Mostly sandstone clasts are usually disguised by patchy but generally strong pervasive sericite. Pyrite occurs irregularly. **At 118.56 m core size was stepped down from HQ to NQ2**. Lower contact occurs at a crumbly shattered Fe carbonate vein. At 128.65m-129.85m a light greenish felsic tuff.	1					4	1	2			No noticeable magnetism. No noticeable fizzing.

Depth (m) From	Depth (m) To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
130.25	161.28		70% sandstone, 20% dark argillite, 10% slump breccia. Variable grain sizes and textures. Sericite alteration is more spotty and weaker overall. Below approximately 130m a 'spotted' texture is increasingly obvious. The 'spots' are not phenocrysts but flower-like growths of mineral clusters (sericite?) related to weak alteration. The spots often overprint bedding laminae, sometimes line up along dark fractures. At 133.20 m is a 60 cm wide section of white sericitic and clayey gouge. At 143m-146m rock is crumbly with strong sericite alteration. Pyrite is mostly cubic and blebby. Lower contact is lost between broken rocks.	1					3	1	1			No noticeable magnetism. No noticeable fizzing.
161.28	164.10		Felsic volcaniclastic, as at 22m-43m. Small qtz eyes. Bedding laminae are 70 deg to CA, usually are not prominent, especially in altered rock. Same sandy uniform. Pyrite is cubic and blebby. Lower contact is gradational, conformable.	1					4	1	1			No noticeable magnetism. No noticeable fizzing.
164.10	205.62		Spotted, 60% siltstone, light to medium grey, and 40% argillite, dark grey to blackish. Repeatedly interfingering. Bedding laminations are common, generally 60-80 deg to CA, locally somewhat swirled or flowed (when a soft sediment). Very common 2-5mm sericitic flower-like ('spots') mineral growths related to a weak alteration. Pyrite is blebby and cubic to 12mm. Sample Nos. 86828-86832 are in areas of locally greater qtz veining. Sample No. 86833 is of locally stronger sericite alteration. At approximately 200m-206m are small reddish hematite spots. Lower contact is irregular, approximately 35 deg to CA.	2					2	1	1			No noticeable magnetism. Very rare, very weak fizzing apparently related to veinlets.
205.62	207.65		Mafic dike. Medium yellowish green. Hard, fresh looking. Massive, fine grained. Pervasive sericite. Lower contact is lost in gouge. **Library sample taken at 206.70 m for thin section**.	tr					3					No noticeable magnetism. Spotty fizzing.

Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
207.65	211.00		Crumble, gouge, shattered rock. Rock appears to be sandstone or siltstone. Dark grey.	0.5					5	2				No noticeable magnetism. Spotty weak fizzing.
211.00	213.60		Andesite dike. Medium yellowish green. Hard, fresh looking. Massive, fine grained. Pervasive sericite. Same rock as at 207m-208m.	tr					3					No noticeable magnetism. Spotty fizzing.
213.60	214.40		Black gouge. Appears to be all graphite.											No magnetism or fizzing.
214.40	227.00		Laminated argillite. Dark grey to blackish. Originally siliceous. Hard rock, not necessarily graphitic. Laminae are lighter, siltstone, approximately 70 deg to CA, regular, suggesting a quiescent period (no slumping). Pyrite is blebby and cubic.	1							1			No noticeable magnetism. No noticeable fizzing.
227.00	232.70		Siltstone. Finely laminated approximately 70-80 deg to CA, regular, suggesting a quiescent period (no slumping). Has some darker argillic laminae. Irregular quartz veins occur. Pyrite is blebby and cubic. Lower contact against vein is 30 deg to CA.	1					1					No noticeable magnetism. No noticeable fizzing.
232.70	233.40		90% quartz veins. Irregular, disturbed, white. Wall rock in vein breccia is siltstone. Lower contact is lost in vein breccia.											No noticeable magnetism. No noticeable fizzing.
233.40	243.85		Laminated argillite. Dark grey to blackish. Originally siliceous. Hard rock, not necessarily very graphitic. Similar to that at 215m-227m. Pyrite is blebby and cubic. Lower contact is unclear in rock disturbed by veins.	1							1			No noticeable magnetism. No noticeable fizzing.
243.85	249.02		Argillite similar to that above but strongly altered by sericite and silica. May be graphitic. Crumbly incompetent rock. 5% disturbed qtz veins. Sample Nos. 86834-86839 are in areas of locally greater qtz veining. Though the hole reached target depth, several HQ rods and shoe were stuck, had to be cut, shoe and some rods left in hole.	1					4		3			No noticeable magnetism. No noticeable fizzing.
			End of Hole at 249.02 m.

DRILL HOLE NO. FC08 - 29

Dip & Azimuth Tests			DDH FC08-29	**Easting (NAD 83):** 609967	**Core Size:** HQ, NQ2	**Started:** July 24, 2008
Depth	**Dip**	**Azmth**	**Other tests**	**Northing (NAD 83):** 5845629	**Hole Azimuth**: 90°	**Finished:** July 27, 2008
15.85	-70.0°	75.6°	Mag = 5696 Temp = 15	**Grid Location:** 57N 1940W	**Hole Angle:** -70°	**Logged by:** R.Turna
114.91	-69.6°	72.4°	Mag = 5700 Temp = 14	**Elevation:** 1,032 m	**Total Depth:** 304.5m	**Analysis by:** ActLabs
						Drilling by: G & O Drilling

Note: Azmths above are underestimated by approx. 20°.
Tests done using Reflex EZ-Shot.

Depth (m)								**Alteration Scale: 1 - 5** v. weak/weak/moderate/strong/v.strong						
From	**To**		**Description**	**% Py**	**% Cpy**	**% Sph**	**% Gal**	**Cr Mica**	**Seri-cite**	**2nd Carb**	**2nd Sil**	**2nd Chl**		**Reactions to Magnet and Acid.**
			Purpose of hole is to test conductor between DDH Holes 13 and 17 and to determine orientations of mineralized zones in these older holes..											
0.00	6.10		Casing. No core recovery.											
6.10	52.85		90% sandstone interbedded with 10% siltstone. The sandstone is generally well sorted but individual beds vary from somewhat coarse to fairly fine grained. Bedding laminations, 65 degrees to core axis (CA), are prominent in minor siltstone interbeds. Medium green, fairly uniform colour. The colour is mainly due to weak pervasive chlorite. Sericite is also pervasive, with yellowy green patches. White Fe carbonate seems present, not fizzing. Fairly massive, homogenous. At 24.70m is a very good example of **graded bedding** in sandstone within finely laminated sand and siltstone. Grain size gets finer down hole here, indicating stratigraphic tops are down, **overturned**. Some quartz veining, not significant, Low fracture intensity overall. Pyrite is mainly disseminated, some cubes to 8mm occur in finer, darker rocks. At 15.8m-18.3m the rock is dark green due to locally strong pervasive chlorite. At 18.3m-19.3m is crumbly rock with bad crumble between 18.7m-18.9m. Below 33.6m local sections are chloritic and minor breccia. Lower contact is sharp, 45 deg to CA. Sample 86842 is a quartz vein.	0.5					2	1		2		No noticeable magnetism. No noticeable fizzing.
			Box 10 showing graded bedding at 24.70 m is to be stored in core library at Likely camp.											

Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
52.85	55.80		Mafic dike. Medium grained, massive, homogenous. Medium yellowish green. Small emerald green clasts are occasionally evident (fuschite). Pyrite is disseminated. **Library example taken at 54.10 m for thin section.** Lower contact is 40 deg to CA.	tr				1	2		1			No noticeable magnetism. No noticeable fizzing.
55.80	87.43		90% sandstone interbedded with 10% siltstone, similar to that at 6-52 m. Usually somewhat coarse grained, massive, uniformly textured. Occasional graded bedding indicate tops are overturned. Siltstone layers tend to be finely laminated and locally chloritic. Veining is greater in lower part of section. 35 cm quartz-calcite vein at 75.4 m has quartz and calcite crystals in vugs. Pyrite is in fractures and disseminated. Library example taken at 58.20m for thin section, shows rounded blue (opalescent?) quartz detrital grains to 3mm in coarse sandstone. **Library example taken at 58.20 m for thin section. At 63.09 m core size stepped down from HQ to NQ2.** Lower contact is sharp but irregular, approximately 80 deg to CA, grading into mainly finer rock below.	0.5					1			2		No noticeable magnetism. Weak rare fizzing at quartz carbonate veins.

Depth (m) From	Depth (m) To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
87.43	137.35		Argillite. Dark grey to blackish. Locally finely laminated. Generally disturbed by veins, and slump textures such as breccia and rumpled or flowed bedding laminations. 90% of the quartz veins are grey, older generation and quite irregular and disturbed. 10% of the veins are white, not significantly disturbed, mostly quartz with some Fe carbonate that does not fizz in acid. Locally graphitic, generally originally siliceous, locally silicified. 97.4m-99.37m is crumbly gouge. 126m-130m is more graphitic, crumbly, shattered. Upper part of section is more veined. Pyrite occurs irregularly in blebs. Lower contact is sharp, 65 deg to CA.	1						1	3	1		No noticeable magnetism. No noticeable fizzing.
			The following samples were taken between 87m-137m mainly based on variations in quartz vein content: Sample Nos. 86848 & 86849 - 10% veins, 86850 - 5% veins, 86851-10%veins, 86852-505 veins, 86853-40% veins, 86854-crumbly gouge with 20% veins, 86855-between veins, 86856-30% veins,86857-40% veins, 86858-30% veins, 86859-20% veins, 86860-10% veins, 86861-between veins, 86862 5% veins, 86863 & 86864-between veins. Vein counts are inadequate at indicating the relatively large volume of quartz veining between approximately 94m-110m. See Sample Intervals for sample locations.											
137.35	139.95		Hydrothermal breccia. Light to medium grey. Breccia clasts appear to be silicified siltstone. Strong pervasive silica alteration varies in intensity. Whitish alteration patches may be albite. Pyrite is patchy, occurring irregularly in blebs and dismembered (bedding?) laminae.	0.5							4			No noticeable magnetism. No noticeable fizzing.

Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
139.95	142.95		90% siltstone and 10% argillite. Bedding laminations are common, usually disturbed. Medium greenish grey, finer layers are dark grey. Pyrrhotite, pyrite, chalcopyrite, sphalerite occur irregularly, mainly in bedding parallel laminations. Pyrrhotite laminae are magnetic. At 142.34m-142.95m is 20% silty sulphides, (apparently syngenetic?), parallel to bedding laminations.	5	0.5	0.1			3		3	1		Locally magnetic laminae. Pyrrhotite is approximately 3%. No noticeable fizzing.
142.95	144.20		Argillite as at 88m-137m. Not veined much. Lower contact is 75 deg to CA. Lower contact is typical conformable bedding.	1							2	1		Spotty weak magnetism is related to pyrrhotite. No noticeable fizzing.
144.20	153.00		90% siltstone and 10% argillite, as at 140m-143m. Bedding laminations are common, usually disturbed. Sulphides occur irregularly. Sericite and silica alteration are pervasive. At 150.95m-151.49m are 10% sulphides in a vein breccia.	3	tr	tr			2		3	1		Locally magnetic laminae. Pyrrhotite is approximately 3%. No noticeable fizzing.
153.00	158.95		Siltstone. Dark grey. Is darker and finer from 157.58, downward. Very fine grained. Fine laminations appear disturbed, flowed. Is originally siliceous. Not veined much. Lower contact is unclear in broken rock and disturbed laminae.	2							3			Locally magnetic due to spotty pyrrhotite. No noticeable fizzing.

Depth (m) From	Depth (m) To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
158.95	178.20		Siltstone. Medium grey. Very fine grained. Upper contact is indistinct, gradational, merely indicated increasing silicification and sulphide downward. Pyrrhotite, pyrite, chalcopyrite, sphalerite occur mainly in bedding parallel laminations. Disturbed bedding laminations are common. Pyrrhotite laminae are magnetic. At 161m occur several qtz-filled en-echelon tension gashes. At 171.70m-172.82m is a minor dark argillite zone. At 173.15m-173.40m is a quartz vein containing 30% sulphides, mostly chalcopyrite, and a 6 cm lower selvage of pyrrhotite and less chalcopyrite and pyrite. At 173.95m-174.40m 30% patchy sulphides are chalcopyrite, pyrrhotite and pyrite, roughly bedding parallel, too rugged to say the if mineralization is syngenetic. Sulphide content is generally high between the high grade sections, seemingly bedding parallel and perhaps syngenetic. This zone's lower contact is gradational into argillite below and indistinct. **Box 45 to be stored at core library in Likely camp.**	5	1	tr					4			Locally magnetic due to spotty pyrrhotite. No noticeable fizzing.
178.20	181.30		Argillite, as at 143m-144m. Lower contact is confused in vein breccia.	2							2			No noticeable magnetism. No noticeable fizzing.
181.30	205.70		Siltstone as at 159m-178m. Originally siliceous and patchily silicified in sections of greater quartz veining. Bedding laminae are somewhat disturbed, generally 90 deg to CA. Pyrite is spotty, occurring in patches, blebs. At194.0-197.4 m pervasive silicification is very strong, still patchy.	2							4			No noticeable magnetism. No noticeable fizzing.

Depth (m) From	Depth (m) To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
205.70	208.60		Argillite as at 178-181 m. Central part is darkest, colour getting lighter gradually toward upper and lower contacts. Like other occurrences of this rock type, contacts with the siltstones often tend to be gradational. Bedding laminae are somewhat rumpled, generally 90 deg to CA. Pyrite is mainly concentrated in relatively few cubes.	1							2			No noticeable magnetism. No noticeable fizzing.
208.60	230.35		Siltstone, as at 181m-205m. At 214m-217m good bedding laminae are parallel, not disturbed, 65 deg to CA. Light greenish. Generally uniform well sorted fine texture. Pyrite is spotty, often in 1cm 'beds', apparently syngenetic. Little veining. Pervasive weak sericite and silica alteration is ubiquitous. Lower contact is irregular at qtz vein.	0.5					1		2			Spotty weak magnetism due to pyrrhotite occurring with pyrite. No noticeable fizzing.
230.35	236.01		Siltstone with intermittent sulphide bands, apparently syngenetic. At 230.35m-230.73m is irregular quartz vein. Light greyish mainly. Bedding laminae are common, 90 deg to CA. At 231.90m-232.00m is 90% sulphide containing chalcopyrite. At 232.16m-232.58m is 40% sulphides parallel to bedding laminae. At 233.40m-233.80m are bands of 20% sulphides. At 235.25m-235.52m are 80% sulphides and local strong pervasive silicification, apparently a selvage to a quartz vein adjacent below. At 235.52m-235.87m is mainly quartz vein with 40% irregular sulphides. At 235.87m-236.01m is 90% sulphides apparently as selvage adjacent to qtz vein above. **Boxes 59, 60 to be stored in core library at Likely camp.**	10	0.1				2		3			No noticeable magnetism. No noticeable fizzing.
236.10	237.65		Argillite. Blackish. Bedding laminae are 80 deg to CA. Interbedded within the siltstone.	2							1			No noticeable magnetism. No noticeable fizzing.

								Alteration Scale: 1 - 5 v. weak/weak/moderate/strong/v.strong						
Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
237.65	268.85		Siltstone. Bedding laminations are common but tend to be 'washed out' by alteration. At 241.48m-241.70m is 10% sulphides, somewhat banded, with chalcopyrite. Minor chalcopyrite noted at approximately 244m, 245m 248m, 262.5m, 263m, 264m. Some darker mineral also, may be sphalerite. Strong pervasive sericite and silica alteration is ubiquitous, local patches are somewhat crumbly with strong sericite. No particularly important zones, chalcopyrite occurrences notwithstanding. Lower contact is gradational as alteration weakens, becomes darker, chlorite dominating. **Box 63 to be stored in core library at Likely camp.**	5	0.1	tr			4		4			No noticeable magnetism. No noticeable fizzing.
268.50	304.50		Siltstone and volcaniclastic mixed. Significantly less altered and veined than rocks above. At 278.30m-278.55m is a light yellow green mafic dike, not significant. At 280.9m is a tiny speck of galena in a small quartz vein, not significant. Mineralization, veining and alteration are weak in this zone. At 289.15m-192.2m is a minor argillite layer. **End of Hole at 304.5m.**	1			tr		2		1	2		No noticeable magnetism. No noticeable fizzing.

DRILL HOLE NO. FC08 - 30

Dip & Azimuth Tests			DDH FC08-30	Easting (NAD 83): 609756	Core Size: HQ,NQ2	Started: July 28, 2008
Depth	Dip	Azmth	Other tests	Northing (NAD 83): 5845070	Hole Azimuth: 30°	Finished: July 31, 2008
12.2	-60.8°	8.9°	Mag = 5698 Temp = 13.7	Grid Location:	Hole Angle: -60°	Logged by: R. Turna
124.05	-59.7°	15.2	Mag = 5720 Temp = 16.1	Elevation: 1,166 m	Total Depth: 249.02m	Analysis by: ActLabs
249.02	-58.6°	19.7	Mag = 5730 Temp = 14.9			Drilling by: G & O Drilling

Note: Azmths above are underestimated by approx. 20°.
Tests done using Reflex EZ-Shot.

Depth (m)								Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong)						
From	To		Description	% Py	% Cpy	% Sph	% Gal	Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
			Purpose of hole is to extend drilling grid in area of Trenches FC07-TR4a,TR4b and TR5.											
0.00	4.57		Casing. No core recovery.											
4.57	4.70		Different rounded stones. Slightly rusty. Likley from overburden.											
4.70	28.15		Felsic volcaniclastic. Medium grey. Variable sandy texture. At 11m-13m is a minor interbed of coarser, lithoclastic rock with dark lithic clasts in a felsic matrix containing oval quartz 'eyes', rarely bluish. This appears an epiclastic sandstone rather than an original volcanic rock (see 44.9m-45.5m below). Blue 'eyes' readily apparent at 17m. At 14.8m are slightly crumpled fine bedding lamellae at 60 degrees to core axis (CA). At 12.7m **graded bedding** gets finer downward, indicating overturned bedding. Extensive moderate pervasive alteration. 5% quartz veins. Sulphides occur irregularly, most in 5-10mm sulphide wisps, apparently bedding-parallel, apparently in sulphide stockwork, spotty blebs, in quartz veins and very finely disseminated, hard to see. High in section occur a couple of 6cm pyritic bands. **Box 2 showing 'eyes' and graded bedding to be stored in core library at Likley camp.**	5	tr	tr			3		3			No noticable magnetism. No noticable fizzing.

Depth (m) From	Depth (m) To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
28.15	31.70		Felsic volcaniclastic. Light green. Uniform colour and sandy texture due to stronger sericitic alteration. Pervasive sericite is strong, uniform. Veins and sulphides same as above. Alteration change at upper 'contact' is gradational, at lower contact abrupt at a narrow gougy fracture.	3					4		3			No noticable magnetism. No noticable fizzing.
			At 4.70-4.77m is 90% pyrite. Beginning of bedrock. Lower contact is 40 deg to CA. At approximately 6m occur four 1cm pyrite bands apparently associated with quartz. At 6.23-6.7m is a 2cm pyrite band, 10 deg to CA, in shattered rock. At approx. 7-7.5m is 10% pyrite in stockwork-like stringers. at approx. 7.75m is a 6cm band of 90% pyrite 85 deg to CA, seems syngenetic. At 7.76-9.35m 10% pyrite and 2% sphalerite occur in a hydrothermal breccia. At 9.35-9.55m 20% sulphide bands are 80 deg to CA, seem syngenetic. At 10.80-11.05m is 20% pyrite, trace sphalerite and chalcopyrite with a quartz vein. At approx. 16.5m and 23.7m are wisps of pyrite, less sphalerite and blebby pyrite , sphalerite in minor qtz vein gangue. At approx. 25-29m occur a stockwork of pyrite-sphalerite wisps. At approximately 36-38m occur several bedding-parallel stockwork wisps of pyrite and less sphalerite. At approx. 40m is 10% pyrite, trace sphalerite in a quartz vein.											

Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
31.70	42.68		Felsic volcaniclastic. Similar to that at 5m-28m. Medium greenish grey. Fairly uniform sandy texture, appears to coarsen imperceptibly downward, as sericite gets slightly stronger down. Fuschite specks sometimes visible. **Best sulphides are at 37.19m-38.09m** where 40% pyrite, trace sphalerite occur in bedding-parallel lamellae 65 deg to CA, possibly syngenetic but occur with locally stronger pervasive quartz gangue. Similar weaker mineralization occurs at 37.2m-37.8m with 10% pyrite in bedding parallel stockwork, with quartz gangue, disturbed by later white quartz vein. At 36.4m and 36.7m are bigger irregular patches of pyrite. Lower contact is conformable, interfingery, 70 deg to CA. **Core boxes 8 & 9 are to kept in Barker Minerals' core library at Likely camp.**	5		tr		tr	3		3			Rare weak magnetism appears due to pyrrhotite. No noticable fizzing.
42.68	44.90		Argillite slump breccia. Dark grey to blackish. Variable disturbed texture with breccia clasts. Weak 'spotted' alteration texture increases downward; these are 'flowers' of incipient sericite growth from myriad centres. Veined as rock above. Pyrite is spotty, blebby. At 42.08 m is 10cm of gougy breccia, 50 deg to CA. Lower contact is abrupt.	3					1		2			No noticable magnetism. No noticable fizzing.

Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
44.90	45.50		Lithoclastic epiclastic sandstone. Considered an eroded and redeposited quartz eye volcanic. Coarse grained. Upper contact is sharp, 80 deg to CA. Higher up coarse lithoclastic section has flame structures into a 20cm finer sandstone below, then an abrupt sedimentary contact with the lower coarse lithoclastic, 40 deg to CA. The coarse lithoclastic sandstone has quartz 'eyes' but no blue ones. Pyrite is mainly in the middle sandstone as irregular cubes and insignificant dissemination. Textures within this section seem decidedly sedimentary. Lower contact appears conformable.	0.1					1		1			No noticable magnetism. No noticable fizzing.
45.50	54.77		Felsic volcaniclastic. Similar to that at 32m-42m. Light green imperceptibly becoming greyer downward with weakening alteration. Fairly uniform sandy texture, appears to get finer imperceptibly downward, as sericite gets slightly weaker down. Upper coarser section has oval blue quartz eyes. Contains several blackish clasts (erratics), with highly rounded rounded to extremely irregular angular shapes. These erratics appear to have been dumped by an explosion? Spotted alteration texture becoming common. The spots here are altered phenocrysts, angular crystal shapes, not incipient flowery growths as discerned above. Spotty, blebby minor pyrite. Hardly any veins. **Best sulphides in this section occur at 45.50m-45.69m** where occurs a coarse blebby band of 70% pyrite and minor sphalerite. This appears the 2nd best sulphide occurrence in the hole to this depth. Lower contact is irregular at vein. **Core boxes 10, 11 showing sulphides and 'blue eye' volcaniclastic to be kept in core library at Likely camp.**	0.1		tr			4		2			No noticable magnetism. No noticable fizzing.

Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
54.77	55.50		Vuggy quartz-Fe carbonate vein, white, with no sulphides. Contains some wall rock clasts. Lower contact is sharp, 40 deg to CA.											No noticable magnetism. No noticable fizzing.
55.50	58.00		Argillite slump breccia. Dark grey to blackish. Exhibits slump breccia textures. Softish, somewhat graphitic. Pyrite is irregular, spotty, blebby, cubic.	1							1			No noticable magnetism. No noticable fizzing.
58.00	99.45		Felsic volcaniclastic. Sericitized phenocrysts spotted texture is common. Light to medium greenish grey. Grey and blue quartz eyes occur, these larger and more prominent at 79m-83m and exhibiting semi-rounded hexagonal cross sections. Variable textures, fine to coarser, minor interbedded fine and argillic layers. 3% quartz veins, somewhat evenly spaced, older grey ones and younger white ones. Pyrite is spotty, irregular, blebby, cubic. **At 71.45m HQ stepped down to NQ2**. At 92.85m are wisps of yellow-brown (sphalerite?). Lower contact is irregular.	0.5		tr			3		2			No noticable magnetism. No noticable fizzing.
99.45	110.62		Chloritized volcanic. Dark greenish black becoming lighter, less chloritic downward. Flowery spotted alteration texture is locally prominent. Rumpled flow textures occur. Spotty pyrite is blebby, cubic.	1								4		No noticable magnetism. No noticable fizzing.
110.62	130.63		Volcaniclastic. Chlorite and sericite alteration are variable, locally strong. Rock does not seem so felsic or silicified as above. Minor finer interbeds of apparent epiclastic occur. Pyrite is blebby cubic, irregular, spotty as before. Minor quartz veining. spotted alteration texture is common. This alteration is in phenocrysts and apparent 'flowers' as well. Minor yellow-green mafic dikes occur at 110.75m-111.31m, 114.42m-115.40m. At approx. 128m-130m has somewhat more grey qtz veins.	0.5					1			2		No noticable magnetism. No noticable fizzing.

Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
130.63	141.00		Siltstone and minor argillite. Medium to dark grey. Bedding laminae seem 85 deg to CA but are somewhat disturbed, strung out, breccia or flow textures exist but are not prominent. Spotted alteration texture is common. At 138.3m-140.2m is shattered rock with crumbly gouge. Lower contact is irregular.	0.1					1			1		No noticable magnetism. No noticable fizzing.
141.00	147.60		Strongly altered rock with 30% grey qtz veins. At 141.85m-142.34m is a minor yellow-green mafic dike.	1					4		4			No noticable magnetism. No noticable fizzing.
147.60	148.44		Mafic dike. Yellow green due to pervasive sericite but hard, not crumbly.	0.1				tr	3		3			No noticable magnetism. No noticable fizzing.
148.44	170.50		Chloritized volcanic rock. Strong pervasive chlorite is somewhat patchy but most of the section is dark greenish grey with original textures unclear. The chloritic rock has a somewhat flowed, sheared appearance, with perhaps a stronger foliation developed. Locally breccia is evident. Minor white qtz veining, not significant. Pyrite occurs irregularly, spotty, blebby, cubic. Yellow green mafic dikes occur at 151.57m-151.95m, 154.7m-156.2m, the latter's upper and lower contacts are 65 deg to CA. Mafic dikes are also at 165.37m-165.65m and 166.93m-167.04m.	0.5					2		1	4		No noticable magnetism. No noticable fizzing.
170.50	175.62		Mafic dike. Yellow green due to pervasive sericite, hard. Upper and lower contacts appear gradational in altered rock.	0.1					3		1			No noticable magnetism. No noticable fizzing.
175.62	181.90		Chloritized volcanic rock. Disturbed textures, not readily discerned in dark chloritic rock. Locally brecciated. Minor white qtz veins. Pyrite occurs irregularly, spotty, mainly cubes to 15mm. At 178.70m-179.3m is crumbly gouge.	0.5					1			4		No noticable magnetism. No noticable fizzing.
181.90	182.72		Quartz vein. Contains minor Fe carbonate. White. No sulphide content. Contains some wall rock clasts. Small vugs.											No noticable magnetism. No noticable fizzing.

								Alteration Scale: 1 - 5 v. weak/weak/moderate/strong/v.strong						
Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
182.72	190.35		Chloritized volcanic rock. Disturbed textures, not readily discerned in dark chloritic rock. Locally brecciated. Bedding lamellae are disturbed, few, 45 deg to 85 deg to CA, not reliable. Pyrite occurs irregularly, spotty, mainly cubes to 10mm.	0.5					1			4		No noticable magnetism. No noticable fizzing.
190.35	202.55		Mafic dike. Yellowish green. Typical uniform massive texture. At 194.70m a bleb of chalcopyrite in a minor isolated grey-white qtz vein with coarse cubic pyrite, insignificant. Upper and lower contacts are 70 deg and 80 deg to CA, respectively, seem gradational in altered rock, unclear.	0.1	tr			tr	3		1			No noticable magnetism. No noticable fizzing.
202.55	249.02		Altered volcanic rock. Less dominated by chlorite. Variable sericite and chlorite intensities. Few bedding lamellae are 45 deg to 85 deg to CA. May not be reliable. Pyrite occurs irregularly, spotty, mainly cubes to 10mm. Minor blebs chalcopyrite with qtz vein. Minor (sphalerite?) wisps. Minor quartz veining, except at 243m-246m where 60% veins are grey and later vuggy white. **End of Hole at 249.02 m.**	0.5	tr	tr				2		2		No noticable magnetism. No noticable fizzing.

14.33	-45.5°	7.5°	Mag = 5812 Temp = 15.6	**Grid Location:**	**Hole Angle:** -45°	**Logged by:** R.Turna
32.61	-45.5°	8.4°	Mag = 5714 Temp = 17.9	**Elevation:** 1,166 m	**Total Depth:** 60.05m	**Analysis by:** ActLabs
60.05	-45.0°	9.5°	Mag = 5710 Temp = 19.8			**Drilling by:** G & O Drilling

Note: Azmths above are underestimated by approx. 20°.
Tests done using Reflex EZ-Shot.

								Alteration Scale: 1 - 5 v. weak/weak/moderate/strong/v.strong						
Depth (m)				**%**	**%**	**%**	**%**	**Cr**	**Seri-**	**2nd**	**2nd**	**2nd**		
From	**To**		**Description**	**Py**	**Cpy**	**Sph**	**Gal**	**Mica**	**cite**	**Carb**	**Sil**	**Chl**		**Reactions to Magnet and Acid.**
			Purpose of hole is to test mineral showing between Trench FC07-TR5 and DDH Hole FC08-30.											
0.00	6.10		Casing. No recovery.											
6.10	6.40		Rounded stones, likely overburden.											
6.40	48.00		Felsic volcaniclastic. Light to medium grey. Fairly uniform 'sandy' texture. Variances in original texture are masked by medium to strong pervasive sericite and silica alteration. Sulphides are fairly abundant but occur irregularly and somewhat spotty, mainly in wisps, often seemingly bedding-parallel, with concentrations at vein selvages. Some of the sulphide bands may be syngenetic, but the impression is of a foliated sulphide stockwork pervading minor (syngenetic bands?). **At approximately 39m-45m sulphides are abundant,** 10%, in myriad wisps with little gangue. Sulphides seem to diminish suddenly below 48m though a change in lithology here is not evident in silicified rock. **Keep all 13 boxes of this hole in core library at Likely camp.**	5	tr	1	tr		3		4			No noticable magnetism. No noticable fizzing.
			At 17.69m-18.0m and 19.66m-19.82m are 10% sulphides, the latter with quartz gangue. At 19.97m-20.17m is 10% sulphides. At 24.59m-24.84m is 30% sulphides. At 28.36m-28.5m is 30% sulphides associated with quartz gangue. At 28.85m-28.96m is 90% sulphides. 38.96m-39.05m is 30% sulphides. At 40.76m-42.23m is 15% sulphides in stringers, with chalcopyrite bleb.											

Depth (m) From	Depth (m) To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
48.00	60.05		Felsic volcaniclastic, as above. Seems somewhat coarser. Light greenish grey. Sericite is stronger. Sulphides are less. Upper 'contact' is gradational, imperceptible change from dominantly silicified to more sericitized downward. White quartz veins are more common than in above section. Upper contact is an almost imperceptible gradational change in alteration. At 57.0m-60.0m is a relatively coarse crystal tuff with quartz 'eyes', some bluish. **End of Hole at 60.05 m.**	2					4		3			No noticable magnetism. No noticable fizzing.

Lithology: DDH FC08 - 31

Depth (metres)			Summary Description	%	%	%	%	Alteration Scale: 1 - 5					
From	To			Py	Cpy	Sph	Gal	Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl	
6.40	48.00		**Felsic volcaniclastic. More sulphides and silicification. <u>At approximately 39m-45m sulphides are abundant.</u>**	5	tr	1	tr		3		4		
48.00	60.05		**Felsic volcaniclastic. Less sulphides, more sericite and qtz veins.**	2					4		3		
			EOH										
			Summary: Felsic volcaniclastic. Stockwork and apparently syngenetic sulphides occur. Sulphide showing in Trench FC07-TR5 intercepted between 24.59m and 39.05 metres.

			Purpose of hole is to extend drilling grid.											
0.00	5.75		Casing. No core recovery.											
5.75	19.75		Felsic volcaniclastic. Light to medium grey. Quartz porphyroblasts very common. Rusty weathering along fractures, sometimes adjacent to quartz veins, penetrate to 16 m. Pervasive silica alteration is dominant, ubiquitous but not intense. Incipient sericite growths show flowers or spotted appearance along fractures (at 15.65 m), at phenocrysts and locally merging to pervasive style. Emerald green fuschite occurs in hairline stringers. Narrow stringers of sphalerite & galena mineralization are at 11.7 m, 15.3 m, 17.3 m with fuschite, and 19.15 m. 8cm bands of fairly massive sphalerite and galena with trace chalcopyrite occur at 18.51m-18.59 and 18.85m-18.93m with minor accompanying quartz and fuschite nearby.	0.5	tr	tr	0.1	tr	1		3	tr		No noticable magnetism. No noticable fizzing.
19.75	22.08		Crystal tuff. Light grey. Relatively coarse grained. Numerous quartz 'eyes' are sometimes blue ovals, sometimes hexagonal crystals. Contact with rock above is unclear, interfingering. Trace wisps of brownish sphalerite. Lower contact appears conformable, gradational, but not graded.	tr		tr			1		1			No noticable magnetism. No noticable fizzing.

Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
22.08	80.70		Felsic volcaniclastic as at 6m-19m. Light to medium grey. Quartz porphyroblasts very common. Uniform texture but with rare dark rounded clasts. Incipient sericite alteration is evident in 'spotted' texture, 'flowers' and altered plagioclase phenocrysts. Fushite not commonly seen, occurs in hairline stringers. Chlorite alteration is patchy. Veins overall are minor. At 30.17m-30.62m is a vuggy white quartz-Fe carbonate vein. At 66.75m-69.05m is crumbly gouge, mainly related to locally very strong sericite alteration.	0.5		tr	tr	tr	4		2	1		Uncommon spotty weak pulls on magnet due to pyrrhotite in some blebs and stringers. No noticable fizzing.
80.70	80.95		Argillite. Fine grained. Appears a fine grained unit interbedded with the volcaniclastic, preferentially chloritized. Soft, seems due more to chlorite, may not be very graphitic though sometimes it is possible to write with the core in a book. Spotted alteration texture.	0.1					1			2		No noticable magnetism. No noticable fizzing.
80.09	97.20		Felsic volcaniclastic as at 22m-80m. Light to medium grey. Spotted alteration texture. Uncommon local chloritic patches. Rare fuschite specks appear not significant. Uncommon brownish wisp appears to be sphalerite.	0.5		tr		tr	3		2	1		Uncommon spotty weak pulls on magnet due to pyrrhotite in some blebs and stringers. No noticable fizzing.
97.20	97.75		Clayey and crumbly gouge. Light to medium grey. Fault?	tr					5					No noticable magnetism. No noticable fizzing.
97.75	101.30		Felsic volcaniclastic as above. Pyrite is spotty as usual, occurring mainly in cubes and blebs. At 99.67m-99.95m is washed rounded rubble including quartz and volcaniclastic stones. Lower contact is sharp, 70 degrees to core axis (CA), seems a conformable sedimentary contact.	0.5					3		2	1		No noticable magnetism. No noticable fizzing.
101.30	111.77		Argillite. Dark grey to blackish. Irregularly graphitic. Soft rock, seems more due to strong pervasive chlorite, and graphite. Pyrite is as usual, spotty, cubic, blebby.	0.5								4		No noticable magnetism. No noticable fizzing.

Depth (m) From	Depth (m) To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
111.77	126.90		Interbedded volcaniclastic and less finer grained siltstone, sometimes finely laminated. This section is not a significantly different lithology from the volcaniclastic, merely reflecting typical interbedded nature of volcaniclastic and lesser fine sediments. At 117.70m is a 10 cm section of coarse cubic and blebby pyrite with minor sphalerite, typical of smaller occurrences of sulphide in the hole so far. At 119.30m-119.90m bedding laminae are 70 deg - 90 deg to CA. Pyrite is spotty, cubic, small blebs. Lower contact is gradational, 80 degrees to core axis (CA), seems a conformable sedimentary contact.	0.5		tr			2		1	2		No noticable magnetism. No noticable fizzing.
126.90	134.70		Volcaniclastic. More uniform texture. Overall weak to moderate pervasive sericite and patchy chlorite. As always so far in this hole veining is not important. Pyrite is spotty, erratic as usual, mainly cubes and blebs. Lower contact is sharp, 70 degrees to core axis (CA), seems a conformable sedimentary contact.	0.5					2		1	2		No noticable magnetism. No noticable fizzing.

								Alteration Scale: 1 - 5 v. weak/weak/moderate/strong/v.strong						
Depth (m)				%	%	%	%	Cr	Seri-	2nd	2nd	2nd		
From	**To**		**Description**	**Py**	**Cpy**	**Sph**	**Gal**	**Mica**	**cite**	**Carb**	**Sil**	**Chl**		**Reactions to Magnet and Acid.**
136.50	170.00		Volcaniclastic as before. Light to medium grey. Rather uniform texture. Pervasive silicification occurs extensively, sulphides are greater. Silicification is patchy, locally strong. Sulphides occur irregularly as usual, spotty in cubes, patches, wisps, aligned in fractures, vein selvages and wispy bands that are possibly bedding-parallel, syngenetic. Blebby chalcopyrite is in a qtz vein at 137.85 m and random other specks. At 140m-148m there occur occasional brownish wisps (sphalerite?). At 146.0m-146.25m is a zone of 60% sulphide including mostly coarse pyrite with sphalerite and very minor galena and chalcopyrite; seems a selvage to a small qtz vein. Such greater concentrations of sulphide, sometimes associated with relatively minor quartz gangue, also occur at several 5-10 cm zones between 167.90m-168.80m and 170.47m-171.90m. At 174.4m-175.5m is sand and rubble from hole cave-in. **Boxes 32, 33 to be stored in core library at Likely camp.**	3	tr	tr	tr		4		3	1		Weak local magnetism due to pyrrhotite in small patches and stringers. No noticable fizzing.
			At 148 m drilling was stopped two days to replace a broken driveshaft.											
170.00	188.06		Volcaniclastic as before. Light to medium grey. Upper contact is approximate and gradational, characterized by diminished sulphides in rock less chloritic. Small blebs of chalcopyrite occur in small qtz veins between approximately 170.0m-175.3m and 176.50m, 179.60m. Last 60 cm is siltstone. **End of Hole at 188.06 m.**	0.5	tr				4		3			Weak local magnetism due to pyrrhotite in small patches. No noticable fizzing.

			Purpose of hole is to test under Trenches FC07-TR4a, TR4b and to extend drilling fence.											
0.00	3.66		Casing. No core recovery.											
3.66	8.80		Volcaniclastic. Light greyish green. Fractured surfaces are rusty. Seems felsic but original composition and textures tend to be masked by alteration. Pyrite is spotty, mostly cubic, also blebby and along fractures. Lower 'contact' is gradational, marks a change in alteration and diminishing rust, rock looks fresher below.	3					3		1			No noticable magnetism. No noticable fizzing.

Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
8.80	32.61		Volcaniclastic, as above. Medium grey at upper and lower portions, middle quarter is light greenish with fairly strong pervasive sericite. At 23.57m-24.30m is an apparent fault gouge zone with upper and lower contacts 20 deg to CA, white clay gouge and quartzy shattered rock, with a later white quartz vein within at same orientation. Pyrite occurs as above but is somewhat less spotty, more uniformly distributed in this section. Sulphides occur mostly in discontinuous semi-parallel wisps, sandy textured, usually not associated with gangue, seem possibly syngenetic, but may also be a bedding-parallel stockwork. Best part is at approximately 14m-26m, **at 20.52m-21.07m sulphides are 50%** and at 20.92m-21.07m a 90% pyrite with minor chalcopyrite band occurs. Sulphide bands and relatively faded bedding lineations are approximately 70 degrees to core axis (CA). Minor sphalerite and galena occur with quartz veins at 14.3m and near 20m. Veins are not significant. Lower contact is approximate, representing an interfingering change in lithology and gradational change in alteration.	5	tr	tr	tr		3		1	1		No noticable magnetism. No noticable fizzing.
			Boxes 3,4,5,6 are to be stored at core library at Likely camp.											

Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
32.61	65.65		Siltstone & argillite. Characterized by contorted bedding laminations and generally fairly strong pervasive chlorite alteration. Yellowish green mafic dikes make a significant portion of this section, occurring at 38.97m-48.65m, 52.50m-57.00m and 62.55m-65.65m; only this last contact at the section end is fair at 70 deg to CA, the other dike contacts are irregular without useful orientations. The dikes are mainly sericitic, not chloritic. Some rare specks of fuschite in the dikes. The Siltstone bedding is too contorted or flowed to measure usefully. The siltstone is slightly more pyritic than the dikes, both are about 1%, pyrite mostly in cubes to 8mm, blebby mostly at white quartz vein selvages. The sulphides are spotty, erratic. At 42m-45m is mostly crumbly gouge and shattered rock, worst is at 43m-44m, with some late white quartz veins.	1				tr	1			4		No noticable magnetism. No noticable fizzing.
65.65	74.10		Felsic volcaniclastic. Medium grey. Lower contact is irregular, 90 deg to CA. Massive homogenous texture but for minor interbeds of laminated siltstone. Pervasive silicification. 'Spotted' texture due to incipient sericite alteration in small phenocrysts. Pyrite is spotty, mainly as cubes to 6mm. Lower contact is irregular but seems 90 deg to CA.	0.5					3		2	1		No noticable magnetism. No noticable fizzing.
74.10	78.03		Siltstone & argillite. Contorted bedding and fairly strong pervasive chlorite alteration. This section is mainly crumbly gouge in an apparent shear zone. Pyrite is spotty, mainly cubic. Lower contact is fairly sharp, appears a conformable sedimentary contact, 80 deg to CA.	0.5								4		No noticable magnetism. No noticable fizzing.

Depth (m) From	Depth (m) To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
78.03	86.60		Felsic volcaniclastic. Medium grey to light greenish due to variance in relative strengths of sericite and chlorite alteration. Massive homogenous texture as above. Pervasive alteration tends to mask original composition and textures. Pyrite is spotty, mainly cubic. Most of this section consists of shattered rock and minor narrow crumbly gougy zones. Lower contact is unclear in broken rock.	0.1					3		2	1		No noticable magnetism. No noticable fizzing.
86.60	90.03		Siltstone & argillite. Somewhat contorted bedding and fairly strong pervasive chlorite alteration. Near 89m bedding laminations vary from 45 to 75 deg to CA. Pyrite is spotty, mainly cubic. Lower contact is sharp, against crumbled rock below, 80 deg to CA.	0.5								4		No noticable magnetism. No noticable fizzing.
90.03	108.15		Volcaniclastic. Medium grey. Fairly massive texture, disguised by alteration. Pyrite is spotty, mainly cubic. Occasional bedding planes have various orientations, 30 to 60 deg to CA. At 96.65m are rare brownish wisps (sphalerite). **Some core was lost at 100.58 m where core size was changed from HQ to NQ2.** At 103m-105m copper-coloured brass smear on core from rubbing with core tube. 'Spotted' sericite alteration is obvious in lower part of section. Lower contact at vein is irregular.	0.1		tr			3		2	1		No noticable magnetism. No noticable fizzing.
108.15	108.90		White quartz vein. Contains blackish pieces of chloritized wall rock. No significant sulphides within or at selvages. Lower contact is sharp, 45 deg to CA.											

Depth (m) From	Depth (m) To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
108.90	238.88		70% volcaniclastic as above, interbedded with 30% dark chloritized siltstone. Some white quartz veins contain blackish chloritized pieces of wall rock. Bedding laminations are fairly common, occur extensively, especially in siltstone. Clear, undeformed bedding laminations at 157.60 m are 55 deg to CA. Sericite alteration is ubiquitous. Dark areas of strong chlorite, usually associated with siltstone, occur at approximately 105m-121m, 126m-131m, 147m-150m, 185m-205m, 226m-236; these are chloritic zones, not necessarily lithologic boundaries. These stronger chlorite zone vary from 3 to 4 in Alteration Intensity. An important concentration of grey quartz veins occurs at 185.4m-197.5m (30% qtz). (Continued below).	0.1	tr				3		3	3		Locally magnetic. From approximately 185m to EOH pyrrhotite is increasingly common. Pyrrhotite occurs spottily as blebs, patches and ragged stringers. No noticable fizzing.
			(Continued from above). Pyrite occurs irregularly as cubes to 15 mm, blebs, patches, stringers and vein selvages. Pyrite concentrations are spotty, best associated with grey and white quartz veins. Small blebs of chalcopyrite noted at 135.0m, 138.1m, 142.05m, 164.72m, 176.30m, 176.50m, 209.00m, 232.50m, 232.90m; these occur with and without quartz gangue. Several higher 'grade' sulphide sections occur with quartz gangue, these are not significant by themselves. **End of Hole at 238.88m.**

DRILL HOLE NO. FC08 - 34

Dip & Azimuth Tests			DDH FC08-34	Easting (NAD 83): 609666	Core Size: HQ, NQ2	Started: August 10, 2008
Depth	Dip	Azmth	Other tests	Northing (NAD 83): 5845128	Hole Azimuth: 30°	Finished: August 12, 2008
28.04	-60.0°	14.1°	Mag = 5694 Temp = 14.7	Grid Location:	Hole Dip: -60°	Logged by: R.Turna
142.34	-58.9°	18.6°	Mag = 5717 Temp = 17.5	Elevation: 1,127 m	Total Depth: 142.34 m	Analysis by: ActLabs
						Drilling by: G & O Drilling

Note: Azmths above are underestimated by approx. 20°.
Tests done using Reflex EZ-Shot.

Depth (m) From	Depth (m) To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
			Purpose of hole is to test extension of mineralization in Trench FC08-TR4 and to extend drilling grid.											
0.00	5.49		Casing. No core recovery.											
5.49	6.71		Rubble, shattered rock, rusty. Mostly grey volcaniclastic, including some pieces with bluish quartz 'eyes'. May not be bedrock.											
6.71	16.55		Argillite slump breccia. Dark grey to blackish. Contains grey clasts and stretched bedding laminations of siltstone or volcaniclastic. The fine grey bedding laminations are ubiquitous but all dismembered and strongly sheared. Fairly strongly sheared 80 degrees to core axis (CA). Most of the section is highly fractured or shattered. At 9.75 m is 50 cm of crumbly gouge containing broken white quartz veins. At 11.90 m, 12.80 m, 13.30 m, 16.00 m occur narrower zones of crumbly gouge and intensely shattered rock. Black gouge at 9.80 m and 11.90 m appears graphitic, though the rest of the section does not appear very graphitic but is chloritic. Pyrite is mostly cubic to 8 mm. Lower contact seems a conformable sedimentary contact, though disturbed by shearing as is the argillite above it. This contact may be an important marker for the top of the sulphide zone below.	1					1		1	3		No apparent magnetism. No apparent fizzing.

Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	v. weak/weak/moderate/strong/v.strong Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
16.55	21.20		**Semi-massive sulphides**. This section is 50% sulphides overall. Scattered dark sulphide appears to be sphalerite. Scattered silvery cubes appear to be galena. The sulphides are coarse to fine grained, occur in irregular patches distributed fairly equally in the section, not much of the sulphide occurs in stringers or veins. The sulphides commonly exhibit a 0.5% porosity of holes to 2mm have been eroded by ground waters. Very little quartz veining or gangue exists. At 18.0m-18.2m is rounded rubble suggesting poor recovery here with sulphides washed away. At 18.55m the gradation from local massive sulphide above to (volcaniclastic?) below seems a conformable sedimentary contact, suggestive that the sulphides are syngenetic. The rock between the sulphides is too strongly altered to determine its original textures and makeup. It seems similar to the rock below. Green wisps in the upper 15 cm are fuschite. Alteration is pervasive, generally strong, but has a patchy occurrence where sericitic and silicified zones seem to overprint darker chloritic parts. (Continued below).	**50**	0.1	0.5	tr	tr	4		3	2		Patchy weak and moderate pulls on magnet indicate pyrrhotite is common, mixed with the pyrite, can't estimate the percentage. No apparent fizzing.
			(Continued from above). The lower contact is interfingery, irregular, seems approximately 45 deg to CA. **Boxes 3 to 16 are to be stored at core library at Likely camp.**											

Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	v. weak/weak/moderate/strong/v.strong Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
21.20	75.00		Felsic volcaniclastic. Medium grey. Fairly massive. Small quartz 'eyes' are very common. Ovoid blue 'eyes' are clearly visible at 35 m, 50.5 m, and are fairly common. Bedding laminae are fairly common, occur extensively though are not a dominant texture, oriented 60 deg to 90 deg to CA. Pyrite occurs irregularly, spotty, cubic, blebby, concentrated somewhat at fractures and vein selvages, and in bedding-parallel wisps (syngenetic?), a 2 cm example at 46.71 m.. Sphalerite and galena noted in small qtz veins at 40.75 m and 41.92 m respectively; not significant. At approximately 61.6m-67.6m pervasive quartz is very strong, pyritic stringers are somewhat more abundant. At approximately 69m sericite alteration weakens downward in a darker grey rock. 'Spotted' sericitic texture becomes prominent. Pervasive chlorite getting stronger as rock grain size getting finer. Lower contact is approximate, interfingering, lithology and alteration change.	2	tr	tr	tr		3		3	1		Patchy weak and moderate pulls on magnet indicate pyrrhotite, mixed with the pyrite, can't estimate the percentage. No apparent fizzing.
75.00	78.94		Argillite. Dark grey to blackish. Bedding laminae are common, tend to be contorted, dismembered. Not quite looking a slump breccia though. **At 78.94 m core size was stepped down to from HQ to NQ2** due to squeezing in the hole, apparently by caving from near the top. Lower contact is lost with some core at the step down to NQ2.	0.1					1			2		No apparent magnetism. No apparent fizzing.
78.94	97.05		Felsic volcaniclastic as above. Quartz 'eyes' common and obvious. Pyrite and sphalerite seem are associated with quartz vein selvages. Light greenish grey. Spotted sericite alteration texture is prominent in phenocrysts. Bedding laminations are occasionally apparent. Grain size varies from fine to fairly coarse.	0.1		tr			3		2			Patchy weak and moderate pulls on magnet indicate pyrrhotite, mixed with the pyrite, can't estimate the percentage. No apparent fizzing.

Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	v. weak/weak/moderate/strong/v.strong Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
97.05	142.34		70% felsic volcaniclastic, 30% argillite, alternating, interfingering sharp irregular contacts. Monotonously weak in sulphides, pyrite occurs irregularly as usual, spotty, sometimes apparently with very minor sphalerite. Despite local slight concentration at veins or minor patches or wisps, overall pyrite is spotty and minor. Spotted sericite alteration texture is usually obvious, occurs extensively though seems to weaken imperceptibly downward. **End of hole at 142.34 m.**	0.1		tr?			2		1	3		Patchy weak and moderate pulls on magnet indicate pyrrhotite, mixed with the pyrite, can't estimate the percentage. No apparent fizzing.

Dip & Azimuth Tests			DDH FC08-35	Easting (NAD 83): 609679	Core Size: HQ, NQ2	Started: August 13, 2008
Depth	Dip	Azmth	Other tests	Northing (NAD 83): 5845053	Hole Azimuth: 30°	Finished: August 19, 2008
47.85	-59.9°	13.0°	Mag = 5766 Temp = 17.6	Grid Location:	Hole Dip: -60°	Logged by: R.Turna
130.15	-59.2°	16.6°	Mag = 5724 Temp = 20.1	Elevation: 1,158 m	Total Depth: 284.38 m	Analysis by: ActLabs
282.55	-57.5°	22.1°	Mag = 5697 Temp = 18.3			Drilling by: G & O Drilling

Note: Azmths above are underestimated by approx. 20°.
Tests done using Reflex EZ-Shot.

Depth (m) From	Depth (m) To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
			Purpose of hole is to extend drilling grid.											
0.00	10.36		Casing. No core recovery.											
10.36	19.10		Siltstone. Rusty. Rather fine grained and siliceous. Medium grey. Locally feldspar phenocrysts appear evident; this may be a minor dike. Contacts and textures are obscured by pervasive silicification. Quite rusty, especially along fractures. Pyrite occurs in cubes, blebs, patches. At 14.5 m rounded stones suggest lost gouge or core. At 15.25 is a minor gouge zone. Lower contact seems conformable, unclear in rusty rock.	1					2		3			No noticable magnetism. No noticable fizzing.
19.10	32.60		Slump breccia; 40% argillite, 30% siltstone, 30% volcaniclastic. The different rock types interfinger rather than being homogenously blended. Medium to dark greenish grey to blackish. Breccia clasts are common. Bedding laminations are common, they appear crumpled, disturbed, generally 65-85 degrees to core axis (CA). The rock is fairly strongly sheared parallel to CA. At 23.75m-26.0m is graphitic argillite crumble and gouge with much gouge washed away. At 26.8m-27m is shattered argillite and crumble. At 27m-27.5m is light greenish clay, sericite and late veins, probably a significant fault, lower contact is 45 deg to CA. Lower contact is sharp, 85 deg to CA.	1					1		1	1		Spotty magnetism due to pyrrhotite. At 27.1m weak fizzing at veins. Spotty fizzing between 27m-30.5m.

Depth (m) From	Depth (m) To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
32.60	40.28		Volcaniclastic with minor thin interbedded argillite. Generally a fairly massive texture. Medium greenish grey, green due to chlorite. Spotted weak sericite alteration. **At 36.27 m step down in core size** was due to squeezing at upper part of hole in gouge section. Lower contact is approximate, representing change in dominant alteration from chloritic to sericitic below and petering out of minor argillite layers.	0.5					1			1		Spotty magnetism due to pyrrhotite. No noticable fizzing.
40.28	46.35		Felsic volcaniclastic. At 43.2m-45.2m is massively textured but otherwise not significantly different. Lower contact is approximate, gradual, indistinct, mainly marking increased occurrence of sulphides in rock below.	2					3					No noticable magnetism. No noticable fizzing.

Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
46.35	88.83		Felsic volcaniclastic with significant sulphides. At 51.35m-61.65m pyrite is approximately 10%, occurring in wisps with little associated gangue. The wisps seem semi-parallel apparently with bedding, 60-90 deg to CA, and may be syngenetic. Pyritic stringers with no gangue also occur at various orientations, these seem a stockwork overprinting the fatter sulphide bands. At **51.35m-51.57m is a 30% pyrite** section bounded atop and below by 1cm white quartz veins. **At 52.50m-52.65m is a 50% pyrite zone**, upper and lower contacts are gradational, approximately 70 deg to CA, appears parallel the local bedding orientation, no associated gangue, appears syngenetic. At approximately 52m-54m bluish quartz 'eyes' are evident. **At 58.24m-58.64m is 40% pyrite** in wisps with very minor gangue. **Best sulphide zone occurs at 87.99m-88.83m; the upper and lower 14cm and 21cm are 70% sulphides with 30% sulphides between**. Alteration is variable, patchy, pervasive silicification is locally important. **Boxes 12 to 22 to be stored in core library at Likely camp.**	5	tr	tr	tr		3		4	2		The high sulphide concentrations contain a high pyrrhotite component and are locally fairly strongly magnetic. No noticable fizzing.
88.83	117.40		Felsic volcaniclastic. Light greyish green. Massive texture, locally lithoclastic. Pervasive sericite is generally strong and is ubiquitous. Chlorite increases near bottom of this section. Sulphides are very minor.	0.1					4		3	1		Spotty magnetism due to pyrrhotite. No noticable fizzing.

Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
117.40	145.65		60% blackish argillite, 30% yellow green mafic dikes, 10% grey green volcaniclastics. At 135.35m-137.84m a mafic dike is yellow green, its lower contact is 75 deg to CA. Most pyrite occurs as cubes to 15mm in the argillites. The argillites usually display slump breccia clasts and rumpled disturbed bedding laminations, generally seem approximately 60-90 deg to CA. Spotted sericite alteration, though not always prominent, occurs extensively. Lower contact is approximate in interfingering argillite and volcaniclastic, may be conformable at 65 deg to CA.	1					2		1	2		Spotty magnetism due to pyrrhotite. No noticable fizzing.
145.65	156.80		Volcaniclastics and minor argillite. Not significantly different from above but for proportions of lithologies and alterations. Lower contact occurs at a quartz vein.	0.5					3		1	1		No noticable magnetism. No noticable fizzing.
156.80	161.00		Argillite. Typical characteristics. Disturbed bedding laminations 70 deg to CA. lower contact with dike is irregular.	1					1		1	2		No noticable magnetism. No noticable fizzing.
161.00	169.97		Mafic dike. Light yellowish green. Lower contact is sharp, 70 deg to CA.	0.5					4		1			No noticable magnetism. No noticable fizzing.
169.97	176.42		Argillite. Typical characteristics. Disturbed bedding laminations 75 deg to CA. At 170.90m-173.40m is crumbly. Lower contact with dike is irregular.											No noticable magnetism. No noticable fizzing.
176.42	226.14		Volcaniclastic. Generally medium greenish grey. Alteration type and intensity varies, generally sericitic more or chloritic more, local silicification. Pyrite is spotty, blebby. Very minor small blebs of chalcopyrite occur with larger concentrations of pyrite. Lower contact is approximate, where sericite and silica alteration increases gradually. Lower contact zone is characterized by abundant white quartz veining.	1	tr				3		2	3		Weak to moderate spotty magnetism due to pyrrhotite. No noticable fizzing.

Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
226.14	255.12		Volcaniclastic. Blue 'eyes' sometimes evident (obvious at 250m). Greenish grey. Pervasive silicification is more extensive and stronger. Grey and white quartz veins are locally more abundant than usual. At 225.85m-226.14m is pyritic crumbly gouge. Pyrite getting more abundant, occurs in wisps and stringers, but is spotty, occurring irregularly. Local pyrrhotite. Small blebs of chalcopyrite visible at 241.70m, 242.77m. Greenish brownish wisps occur, (sphalerite? probably sericite wisps). Pyrite and chlorite are stronger between these locations. At 247.6m-247.95m is crumbly gouge. At 252.90m-253.24m is a zone of 90% graphite, very black and lightweight, with some pyrite, disseminated and a narrow stringer. The origin of this graphite is unclear (perhaps a fault mylonite?), its upper and lower contacts are sharp, 75 deg to CA. No argillite or graphitic unit is near, above or below; the volcaniclastic above is the same as that below.	2	tr	tr?			3		4	2		Weak to moderate spotty magnetism due to pyrrhotite. No noticable fizzing.
255.12	255.30		Clay gouge, possible fault.											
255.30	273.40		Volcaniclastic, as at 226m-255m. Grey and white quartz veins are locally fairly abundant. Lower contact is approximate, gradational, indicates a change from predominantly sericitic and silicic alteration to predominantly chloritic.	1					3		4	2		Weak to moderate spotty magnetism due to pyrrhotite. No noticable fizzing.
273.40	284.38		Volcaniclastic, as above. More massive homogenous texture. Medium to dark greenish. Some grey quartz veins occur. Pyrite seems to be weakening. **End of Hole at 284.38 m.**	0.5					1		1	3		No noticable magnetism. No noticable fizzing.

63.09	-57.2°	12.2°	Mag = 5758 Temp = 12.2	**Elevation:** 1,140 m	**Total Depth:** 119.79 m	**Analysis by:** ActLabs
117.96	-56.8°	14.3°	Mag = 5729 Temp = 15.8			**Drilling by:** G & O Drilling

Note: Azmths above are underestimated by approx. 20°.
Tests done using Reflex EZ-Shot.

Depth (m)								**Alteration Scale: 1 - 5** v. weak/weak/moderate/strong/v.strong						
From	**To**		**Description**	**% Py**	**% Cpy**	**% Sph**	**% Gal**	**Cr Mica**	**Seri-cite**	**2nd Carb**	**2nd Sil**	**2nd Chl**		**Reactions to Magnet and Acid.**
			Purpose of hole is to extend drilling grid.											
0.00	9.75		Casing. 1 m of rock recovered. Rounded stones in first 40 cm, may not be bedrock. Remaining 60 cm is half argillite, half volcaniclastic. Minor rust at pyrite cubes and fractures. Rocks are similar to those below.											
9.75	21.35		Siltstone interbedded with argillite, and lesser volcaniclastic. Contacts seem conformable. Light to dark grey, argillite is usually blackish. Bedding laminae are common, slightly rumpled, generally 70-90- degrees to core axis (CA). Dismembered laminae or breccia clasts are stretched parallel to bedding. This section may be in part a slump breccia. 'Spotted' sericite alteration is locally evident, mostly at phenocrysts in the minor volcaniclastics. Pyrite is spotty, occurs mostly as cubes to 1 cm, some shapeless blebs. At 17.9m-20.8m rock is shattered with rust on most natural fractures. At 18.0 m is 20 cm of crumbly gouge. At 20.7m-21.1m is crumbly gouge. Lower contact, 75 deg to CA, appears conformable.	0.5					1		1	1		Weak spotty magnetism between 15.85m and 17.98m, slightly weak magnetism at approx. 18.8m mark. No reaction to acid

Depth (m) From	Depth (m) To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
21.35	34.00		Volcaniclastic with 'spotted' sericite texture, alteration mostly at phenocrysts. Light to medium grey. Very minor siltstone and argillite layers have laminations 80 deg to CA. Pyrite occurrence is as above. At 30m-32m some narrow coppery brown stringers may be sphalerite, appear to be metamorphogenic 'sweats'. Lower contact appears conformable, 75 deg to CA.	0.5		tr?			2		1			Spotty weak magnetism at the 28.09m mark. No reaction to acid
34.00	48.64		Argillite and siltstone, finely laminated, strongly foliated generally 65-80 deg to CA, seems a shear zone. Stretched breccia clasts are fairly common. Argillite is dark, locally graphitic. Pyrite occurs spottily, blebby, cubic. At 39m-40m rock is very broken, the latter half shattered. Lower contact is sharp, appears conformable, 45 deg to CA.	0.5					1		1	1		Spotty magnetism throughout box 14 (45.60m-48.44m). No reaction to acid
48.64	52.34		Volcaniclastic breccia. Light greenish grey, fine grained. Appears a siltstone but 'spotty' sericite alteration is present (uncommon), this usually associated with volcanics. Also, some 'spots' have phenocryst shapes. As above, seems a shear zone, stretched breccia clasts are fairly common. Pyrite occurs as 'sandy' stringers, blebs and in fractures. Lower 'contact' is 70 deg to CA, merely marks increasing pyrite in same rock.	3					3		1			Spotty weak magnetism at approx. the 49.30 m mark. No reaction to acid

Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
52.34	53.00		**Semi to massive sulphides** in volcaniclastic breccia. Alteration and original textures indistinct due to sulphides. **At 52.53m-52.68m is 90% sulphide**, mostly pyrite, some sphalerite, also has pyrrhotite. This best sulphide zone correlates with the best sulphide zone in Hole FC08-34. **At 53m core size changed from HQ to NQ2**, approximately 0.5 m of core (possibly sulphide?) appears lost here. Contact with rock below appears lost in rounded argillite rubble here, probably fallen from higher in hole. **Box 16 is to be stored at core library at Likely camp.**	**50**		0.5			4		3			Massive sulphide portion has weak spotty magnetism.
53.00	64.00		Interbedded siltstone, argillite and volcaniclastic in weakly sheared rock. Fairly massive texture. Pyrite as usual is spotty. Lower contact is marked by 8 cm qtz vein, 85 deg to CA.	0.5					2		1			Wisp of pyrrhotite at 53.3m. Spotty magnetism from about 54.51m-55.00m . No reaction to acid
64.00	113.17		Volcaniclastic. Felsic. Fairly uniform, homogenous massive texture and colour. Medium greenish grey. At approximately 105m-106m blue quartz 'eyes' are obvious in a coarser section, rock appears rhyolitic here. Sericite and silica alteration is pervasive, sericite also occurs in greenish wisps. Sulphides are spotty, occur as blebs, and wisps, locally somewhat more concentrated than 1%. At 65.25m a small bleb of chalcopyrite in a 7 mm qtz vein. At approximately 96m-98m sulphide wisps are somewhat more common. Lower contact is sharp but indistinct, 85 deg to CA, appears conformable.	1	tr			tr	3		3			Spotty weak magnetism due to pyrrhotite wisps. No reaction to acid
113.17	119.79		Siltstone. Dark grey. Bedding laminations are not prominent, generally 85 deg to CA. White quartz veins are more common. Pyrite is blebby at veins, and cubic. **End of Hole at 119.79 m.**	0.1					1		1	2		No noticable magnetism. No noticable fizzing.

Lithology: DDH FC08 - 36

Depth (metres) From	To		Summary Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl

			Purpose of hole is to extend the drilling grid.											
0.00	11.89		Casing. No core recovery.											
11.89	21.95		Argillite or siltstone. Highly fractured, very rusty, limonitic at fractures. Bottom 15 cm is clayey gouge.	0.1					1		2			No noticable magnetism. No noticable fizzing.
21.95	36.78		Argillite. Top 25 cm is black clayey gouge. Dark grey to blackish. Minor light grey siltstone laminae are strung out by foliation, seems a shear zone. Laminae are 70-90 degrees to core axis. (CA). Pyrite is spotty, blebby, cubic. Lower contact is conformable, somewhat gradational, interfingery, 85 deg to CA.	0.5							1	1		No noticable magnetism. No noticable fizzing.
36.78	94.45		Volcaniclastic, with some siltstone and argillite higher in the section. Volcaniclastics are massive, somewhat fine grained, contains small feldspar phenocrysts, difficult to distinguish from siltstone mainly due to alteration. **At 60.66 m core size changed from HQ to NQ2**. At 77.7m-78.0m are small patches of pyrite, pyrrhotite with some chalcopyrite and sphalerite. At 82.6 m a coarse raggedy patch of pyrite, chalcopyrite and sphalerite occurs. (Continued below).	1	tr	tr	tr	2	3		1	1		Weak spotty magnetism noted at approx 50 m, 78 m, 84.3m. No acid reaction

Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
			(Continued from above). **At 84.70m-85.40m is the best sulphide occurrence;** the lower 18 cm is 50% pyritic with sphalerite, very weakly magnetic, its location suggests it as the down dip extension of the mineral zones in Trench FC07-TR5 and DDH holes FC08-30 and 31. At 85m-86m and other locations fuschite is evident. At 86.5 m and 86.9 m brownish sphalerite occurs in fractures and adjacent to a quartz vein. At 88.2 m a bleb of chalcopyrite occurs apparently in a fracture. At 90.0m a coarse patch of brownish sphalerite, chalcopyrite with some galena occur with minor quartz gangue. This mineralization is possibly remobilized, not necessarily syngenetic or stockwork. The lower 3 m is characterized by 'spotted' sericite alteration. **Box 22 is to be stored in the core library at the Likely office.**											
94.45	96.62		The contact with the rock above represents a gradational change in alteration. Volcaniclastic as above, somewhat finer grained, more chloritic. Dark greenish. At 95.3 m is a 50 cm white vuggy quartz vein with dark chloritized wall rock inclusions. This chloritic zone appears obviously related to this quartz vein. The lower contact marks the end of the chlorite zone with lithology the same.	0.5					2			4		No noticable magnetism. No noticable fizzing.
96.62	108.69		Volcaniclastic as above. Light to medium grey. Massive. The upper contact is characterized by 'spotted' sericite alteration. Phenocrysts are more apparent here. Pyrite is spotty, very minor, seems mainly disseminated. Lower contact is sharp, seems conformable, 70 deg to CA.	0.1					2		1			No noticable magnetism. No noticable fizzing.

Depth (m) From	Depth (m) To		Description	% Py	% Cpy	% Sph	% Gal	Alteration Scale: 1 - 5 (v. weak/weak/moderate/strong/v.strong) Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
108.69	165.93		Felsic volcaniclastic. Light greenish. Generally somewhat coarse grained. Finer grained portions occur, apparently interbedded with minor siltstone. Locally lithic clasts occur. Quartz 'eyes' are common, occur extensively, locally these are bluish. Blue 'eyes' are prominent at 116.5m, 123.6m, 129.35m, 160.1m. Most quartz veins are the white vuggy kind, overall veining is not much, though are fairly abundant at 109-122.5m. Rather poor in sulphides, no significant stringers or wisps. Sulphides occur spottily with white quartz veins and insignificant isolated blebs. Brown (sphalerite?) exists along some fractures. Fuschite alteration seems to occur extensively though not strong. Fushite is locally strong at 133.39m-133.47m. Pervasive sericite is ubiquitous. Lower contact is sharp, 75 deg to CA, seems conformable.	0.1	tr	tr		2	4		1			No noticable magnetism. No noticable fizzing.
165.93	212.80		Siltstone. Light to medium grey. Bedding laminations appear locally flowed, generally 60-90 deg to CA. 'Spotted' sericite alteration occurs locally throughout. At 188.35m-190.0m is a light green sericitic mafic dike with a 2 cm vuggy white quartz vein parallel to CA in the upper half of the dike. The upper and lower contacts of the dike are 90 deg and 45 deg to CA, respectively. White quartz veins are prominent for approximately 1 m above and below the dike. Pyrite is very spotty, occurs mainly blebby appears to increase slightly in lower part of section. Lower contact against gouge below is sharp, 85 deg to CA, has slight concentration of fuschite.	0.5				tr	1			1		No noticable magnetism. No noticable fizzing.

								Alteration Scale: 1 - 5 v. weak/weak/moderate/strong/v.strong						
Depth (m) From	To		Description	% Py	% Cpy	% Sph	% Gal	Cr Mica	Seri-cite	2nd Carb	2nd Sil	2nd Chl		Reactions to Magnet and Acid.
212.80	249.02		First 35 cm is clayey gouge. Volcaniclastic. Medium grey, light to dark greenish grey. Fine to medium grained, varies. Alterations are spotty, occurring irregularly, locally fairly strong, locally weak. Quartz veins occur with pyrite on selvages. Pyrite is spotty, blebby and cubic. Notwithstanding spotty occurrence, sulphides are very minor overall. At approximately 220m-237m grey and vuggy white quartz veins are somewhat more common. At 237.35m-239.70m is very strong pervasive silicification and an isolated concentration with chalcopyrite and sphalerite at 238.1 m. **End of Hole at 249.02 m**.	0.5	tr	tr			3		3	1		Very minor weak magnetism noted at about 238 m. No noticable fizzing.

Vein Counts: DDH FC08 - 37

Veins counts per average metre within intervals

Veins are greater or equal to 1mm in width.

APPENDIX H

STATEMENT OF EXPENDITURES

Barker Minerals Ltd.

Work was completed on the following claims:
504419, 504439, 514364,514525

Work was completed between October 31, 2008 and October 31, 2009

Geological - Drilling

Louis Doyle - Planning, supervising and report preparation		
21 days @ $350.00/day wages	$	7,350.00
21 days @ $125.00/day room & board	$	2,625.00
21 days @ $125.00/day vehicle & gas	$	2,625.00
Geocon Exploration Management Ltd. - VP of Exploration	$	30,000.00
Planning, supervising and report preparation from June 15th to Oct. 31		
46 days @ $125.00/day room & board	$	5,750.00
46 days @ $125.00/day vehicle & gas	$	5,750.00
Nimmi Dhada - Geological Assistant		
15 days @ $185.00/day wages	$	2,775.00
15 days @ $125.00/day room & board	$	1,875.00
15 days @ $125.00/day vehicle & gas	$	1,875.00
Ben Hall - Core splitter		
24 days @ $200.00/day wages	$	4,800.00
24 days @ $125.00/day room & board	$	3,000.00
Matthew Kenny - Core splitter		
22 days @ $200.00/day wages	$	4,400.00
22 days @ $125.00/day room & board	$	2,750.00
Karen Hall - Core teching		
10 days @ $200.00/day wages	$	2,000.00
10 days @ $125.00/day room & board	$	1,250.00
Seth Beauchesne - Camp expiditor		
23 days @ $300.00/day wages	$	6,900.00
23 days @ $125.00/day room & board	$	2,875.00
23 days @ $125.00/day vehicle & gas	$	2,875.00
Harold Oxley - Camp expiditor		
15 days @ $300.00/day wages	$	4,500.00
15 days @ $125.00/day room & board	$	1,875.00

15 days @ $125.00/day vehicle & gas		$	1,875.00
Brian Hall - Camp expiditor			
15 days @ $300.00/day wages		$	4,500.00
15 days @ $125.00/day room & board		$	1,875.00
15 days @ $125.00/day vehicle & gas		$	1,875.00
ACD Contracting - Drill pad and road construction		$	74,971.25
46 days @ $125.00/day room & board		$	5,750.00
G & O Diamond Drilling		$	386,424.13
230 days @ $125.00/day room & board		$	28,750.00
	Geological drilling	$	603,870.38
Miscallaneous Drilling Expenditures			
Phil's core boxes		$	10,794.69
Imperial Oil		$	30,247.35
Bri-Mel Lowbedding & Piloting		$	1,056.00
Greyhound Courier		$	5,390.14
Quad rental			
46 days @ $100.00/day		$	4,600.00
Satelite phone			
46 days @ $25.00/day		$	1,150.00
	Misc. drilling expenditures	$	53,238.18
Geochemical			
Assays		$	39,733.27
	Total geochemical	$	39,733.27
Total Geological Expenditures		**$**	**657,108.56**
Total Geochemical Expenditures		**$**	**39,733.27**
Total Expenditures		**$**	**696,841.83**
Claimed on previous report		**$**	**158,234.89**
Claimed on second report		**$**	**538,606.94**

APPENDIX I

STATEMENTS OF QUALIFICATIONS

I, Rein Turna, of the City of West Vancouver, British Columbia, hereby certify that:

1. I am a graduate of the University of British Columbia with a B.Sc. in Geological Sciences granted in 1975.
2. I am a registered member of the Professional Engineers and Geoscientists of British Columbia.
3. I have worked as a geologist in British Columbia, Saskatchewan, Ontario, Yukon and Northwest Territories in Canada since 1975.
4. I carried out or supervised work described in this report.

R. Turna, P.Geo.
February 10, 2009
