1.0 SUMMARY

The Golden Eagle property covers 82 km^2 within the northern Coast Mountains of British Columbia, just south of the British Columbia/Yukon border. Seven of the 26 mineral claims are owned by TroyMet Exploration Corp. who is earning a 100% interest in the remainder of the property by making annual cash payments under an option agreement with Ron McMillan.

The property lies along the eastern margin of the Late Cretaceous-Tertiary intrusives of the Coast Belt within arc volcanic and arc-derived sedimentary rocks of the Intermontane Belt. The regionally significant, northwest-trending Llewellyn fault zone cuts through the property and has a strong correlation with the majority of BC Minfile occurrences in the region.

The exploration history of the property dates back to the 1890’s when prospectors traveling to the Klondike explored the area. Several small adits that are present were probably driven in the early part of the 20th century but no documentation of the work is known. The current Golden Eagle property can be split into three portions (Northwest, Central and Southeast), each of which underwent extensive and parallel exploration campaigns from the early 1980’s to the present. The northwest portion of the property contains anomalous multi-element stream geochemistry and notable gold intersections from trenches and drill core as skarn-type mineralization in meta-volcanic rocks bordering Cretaceous intrusions. The central portion of the property contains gold bearing quartz-sulphide veins documented on North Mountain, Middle Ridge and South Mountain and was the focus of the 2008 exploration program. The southeast portion of the property includes an area of quartz-carbonate stockwork veining variably mineralized with gold, copper and zinc in mafic volcanics.

The arsenopyrite-rich quartz veins of the Tannis Zone on Middle Ridge were first drilled in 2005 by Marksmen Resources Ltd., a predecessor of Troymet, with intercepts of 2.9 m @ 14.39 g/t Au and 5.5 m @ 10.73 g/t Au and 104.2 g/t Ag. Further drilling on the Tannis Zone in 2006 was limited to one hole due to winter weather conditions; intersecting two quartz-arsenopyrite veins with lower grades, but indicating their continuity to depth.

The 2008 exploration program consisted of diamond drilling on the Tannis Zone and geologic mapping and prospecting on North Mountain, Middle Ridge and South Mountain. Mapping and prospecting further defined the distribution of rock units and quartz-sulphide veining along a northwest trend nearly 5 km in length and resulted in the collection of 124 rock samples. Twelve diamond drill holes totalling 2306 metres were completed based on recommendations from drilling in 2005 and 2006. Drill intersections from 2008 indicate the highly variable nature of the quartz-sulphide veins both in terms of metal content and continuity along strike and at depth. The best intersections returned 5.09 m @ 7.93 g/t Au and 23.8 g/t Ag and 4.3 m @ 2.05 g/t Au and 43.8 g/t Ag.

Observations from mapping and drill core indicate that the quartz-sulphide veins are synchronous with late-stage cooling of the Late Cretaceous granite pluton and the slightly later rhyolite intrusion. An intrusion-related gold model of mineralization is supported by the presence of a large felsic intrusion, a geochemical signature that includes As-Bi-Sb-Pb-W and relatively cryptic alteration associated with the veining.

Recommendations for future work on the property involve detailed analyses of geochemical and geophysical data to develop and prioritize drill targets on a property-wide scale. The geochemical compilation should be used to identify multi-element zonation patterns as a tool for exploration targeting. Existing geophysical data should be re-interpreted and possibly followed up with ground geophysical surveys with the goal of directing exploration efforts to intervening valleys with little to no outcrop but favourable positioning along the northwest trend of mineralized vein occurrences. The most viable drill target to come out of the surface program is on South Mountain within a cluster of 9 gold and silver bearing veins exposed over a ~100x100 metre area.

2.0 INTRODUCTION

Equity Exploration Consultants Ltd. (“Equity”) was contracted by TroyMet Exploration Corp. (“TroyMet”) to carry out a diamond drilling program on their Golden Eagle property during the summer of

2008. This program was carried out under the senior author's direction and Equity was requested by TroyMet to compile and interpret the results. The literature used in compiling this report consisted of assessment reports filed with the British Columbia Ministry of Energy and Mines and government reports and maps. Information on property ownership was supplied by TroyMet.

3.0 RELIANCE ON OTHER EXPERTS

The authors have not relied on a report, opinion or statement of an expert for information concerning legal, environmental, political or other issues.

4.0 PROPERTY DESCRIPTION AND LOCATION

The Golden Eagle property is located within the northern Coast Mountains of British Columbia, just south of the BC/Yukon border. It lies within the Atlin Mining Division, centred at 59^o 52' north latitude and 134^o 50' west longitude (Figure 1).

The Golden Eagle property consists of 26 contiguous mineral claims covering 82 km^2, as summarized in Table 1 (Figure 2). A predecessor company of TroyMet purchased seven claims and holds them outright; there is no underlying royalty. TroyMet is earning 100% interest in the remainder of the property from Ron McMillan by making annual cash payments. The McMillan option is subject to a 1% net smelter royalty, of which 0.5% can be purchased for $500,000 prior to October 1, 2009 and to a 2.5 km area of influence.

Location Map

EQUITY	Date: NOV 2008	Scale: 1:7,000,000	Figure	1
	U.T.M. Zone UTM 8 - NAD83	Mining District ATLIN		
	N.T.S. 104M/	State/Province BC		

Surface rights over the Golden Eagle property are owned by the Province of British Columbia. No significant surface disturbance nor any major environmental liabilities were noted during the authors' field visits. Exploration permits must be obtained from the British Columbia Department of Mines prior to carrying out further exploration on the property.

5.0 ACCESSIBILITY, CLIMATE, LOCAL RESOURCES, INFRASTRUCTURE, PHYSIOGRAPHY

The Golden Eagle property lies approximately 35 kilometres south of Carcross (Yukon) and 50 kilometres northeast of Skagway (Alaska). The paved South Klondike Highway runs through the centre of the property, with cat and ATV roads extending away from it (Figure 1). Helicopter access is necessary to reach most of the property and all of the 2008 drilling was helicopter-supported, although an ATV road extends to the eastern edge of the Tannis Zone drilling on Middle Ridge.

The property is located in the Boundary Ranges of the northern Coast Mountains, trending northwesterly for 23 kilometres from southeast of Tutshi Lake to Bennett Lake. The property is rugged and largely above tree-line. Elevations range from 700 metres on Tutshi Lake to over 1,500 metres on Middle Ridge, between Tutshi and Bennett Lakes and 2,100 metres on the peaks southeast of Tutshi Lake. Lower elevations are covered by balsam and lodgepole pine, with willow and alder in avalanche chutes. Alpine vegetation is present above treeline, which lies at about 1,400 metres elevation. The area is subject to a northern climate and, depending on elevation, can be worked from June until October.

6.0 HISTORY

Table 2 summarizes all reported exploration work carried out on the ground currently comprising the Golden Eagle property.

The mineral exploration history of the Bennett Lake area dates back to the 1890's, when prospectors traveling over the Chilkoot trail and down Bennett Lake to the Klondike goldfields first started exploring the area. In 1915-16, Fred Storey drove a 180 metre adit (the "Ruby Silver Adit") in granodiorite above Bennett Lake, without intersecting significant mineralization (BCDM, 1913-16). Four adits on Middle Ridge (the "Tannis Zone"), three more adits about 2.5 kilometres north of the Ruby Silver Adit and one on North Ridge were also likely driven near the start of the 20th century, although documentation is lacking.

The current Golden Eagle property can be split into three portions, each of which underwent extensive and parallel exploration campaigns from the early 1980's to the present.

6.1 Northwest Portion of Property (Plateau, Stibnite, LQ, Skarn, Cowboy Zones)

Premier Mining flew an airborne magnetics survey in 1970 over their claims along Bennett Lake at the extreme northwestern corner of the current Golden Eagle property (ELC, 1970).

In May 1981, Du Pont carried out reconnaissance stream sediment geochemistry over the Tagish-Bennett area and carried out initial exploration on claims staked to cover anomalous streams, including their Tuts (immediately east of the south end of Tutshi Lake), Gaug (Bennett Plateau) and Shui (immediately west of the current Golden Eagle property on the north side of Paddy Pass Creek) claims. The initial anomalous levels of Zn and Cu in stream sediments were confirmed for the Tuts, but no significant mineralization was found and Du Pont let their claims lapse (Neelands and Holmgren, 1982a). On their Gaug claims, anomalous Au, Ag, Cu and Mo values were confirmed and quartz-arsenopyrite-pyrite veins with up to 1.34 g/tonne Au were discovered (Neelands and Holmgren, 1982b). In 1982, Du Pont mapped their Gaug property, reporting a 4-m wide Cu-bearing shear zone and quartz-arsenopyrite(-stibnite-galena-sphalerite) veins with up to 27.6 g/tonne Au. Their grid-based soil survey returned elevated Au-Ag-Pb-Zn values, particularly in the vicinity of the main creek gorge, with peak values of 1150 ppb Au and 44.0 ppm Ag (Copland, 1982).

In 1983, Texaco Canada carried out geophysical and geochemical surveys on their Ben claims, located immediately south of the Gaug claims. Lhotka and Olsen (1983) reported 17 Au- or Ag-bearing occurrences, with up to 22.7 g/tonne Au and up to 2136 g/tonne Ag, mainly from <1 m quartz-sulphide veins.

Du Pont's Gaug claims lapsed in 1986. They were re-staked as the Pavey property and optioned to Lodestar, who re-mapped and sampled the property in 1987 (Davidson, 1987). In 1988, Lodestar optioned Texaco's Ben claims as well and carried out a property examination (Davidson, 1988). The following year,

Claim Location Map

EQUITY	Date NOV 2008	Scale 1:100,000	Figure 2
	U.T.M. Zone UTM 8 - NAD83	Mining District ATLIN	
	N.T.S. 104M/15	State/Province BC	

Lodestar constructed a cat road into the Pavey property from the Klondyke Highway and did limited prospecting (Lueck, 1989). In 1990, Lodestar carried out extensive excavator trenching and re-established road access into their property. Two new showings were discovered during the course of this work: visible gold in quartz-calcite stringers within chlorite-actinolite skarn (the “Skarn Zone”) and fracture-controlled arsenopyrite-stibnite-pyrite within silicified Boundary Ranges metamorphic rocks (the “Cowboy Zone”). Lodestar drilled 11 short holes from 4 drill sites on the Skarn and Cowboy Zones, with the best intersections grading 4.0 m @ 7.4 g/tonne Au and 8.0 m @ 3.4 g/tonne Au, both from the Skarn Zone. (Blanchflower, 1990).

In 1993, Hemlo Gold optioned Lodestar’s Pavey property and carried out a short geochemical program, concluding that “silicification and mineralization….was observed in a northwest trending belt 2.5 km long by 300 m wide” (Duke, 1993). In 1994, Hemlo Gold did limited mapping and soil geochemistry on the Skarn and Plateau zones (Bidwell, 1994).

The Pavey and Ben claims were allowed to lapse in 1995 and 1996 and were re-staked by Westmin Resources as their Bennett property. In 1996, Westmin conducted mapping and geophysical surveying, focused on the till-covered plateau above Bennett Lake, and identified a northerly-trending 700 x 200 metre overburden-covered chargeable zone (Rowins, 1997). Westmin drilled 11 holes on the Skarn Zone and their Plateau chargeability anomaly. Very graphitic argillite was determined to be the source of the chargeability high. On the Skarn Zone, Westmin’s best intersection graded 7.63 g/tonne Au across 3.45 metres core-length (Terry and Bradford, 1998).

6.2 Central Portion of Property (North Mountain, Middle Ridge, South Mountain)

In 1986, Hugh Copland staked his Catfish claim to the southeast of Texaco’s Ben claims on North Mountain, reporting an old 15 m adit on a <1 m wide quartz-pyrite-stibnite-arsenopyrite-galena vein with up to 23.3 g/tonne Au and 147 g/tonne Ag (Copland, 1987).

Frame Mining acquired their Catfish claims over North and South Mountains and Middle Ridge in 1988. Morris (1988) mapped the Catfish property, re-discovered three old adits on Middle Ridge and described a zone of quartz-arsenopyrite veining (now termed the “Tannis Zone”) with up to 47.3 g/tonne Au, which could be “traced for 2.5 kilometres”. Frame’s 1989 program focused on Middle Ridge, with trenching confirming the Au-bearing nature of the Tannis Zone quartz-arsenopyrite veins (Davis, 1989). An induced polarization (IP) survey showed moderate to strong chargeability anomalies over the known veins and a large, complex zone of unexplained moderate to strong chargeability on the south slopes of Paddy Pass Creek, in an area of little outcrop (Walcott, 1990).

The Catfish claims lapsed, were restaked as the Tutshi Lake property and a short VLF-EM survey was run in 1997 over Paddy Pass Creek, between Middle Ridge and North Mountain, without any significant results (Mark, 1997).

6.3 Southeast Portion of Property (Jessie, Carbonate, Camp)

In 1929, Joe Bussinger described two showings: Jessie (Minfile 104M-027, Tenure 516870) and Big Thing (Minfile 104M-071, Tenure 367761). Both of these were described as Au- and Ag-bearing chalcopyrite-pyrrhotite-galena-sphalerite shear zones (BCDM Annual Report, 1929).

As a follow-up to their May 1981 reconnaissance stream sediment geochemistry over the Tagish-Bennett area, Du Pont carried out initial exploration on their Tuts claims, staked to cover anomalous drainages immediately east of the south end of Tutshi Lake and apparently downstream of the Jessie showing. The initial anomalous levels of Zn and Cu in stream sediments were confirmed for the Tuts, but no significant mineralization was found and Du Pont let their claims lapse (Neelands and Holmgren, 1982a).

In 1986, Noranda staked their Tuts claims over a large carbonate-altered zone and several Au-bearing float samples, later expanding it to cover all of the current Golden Eagle property southeast of Tutshi Lake. Mackay and Reid (1987) reported the Carbonate Zone to be up to 300 metres wide and five kilometres long, with <5% stringers and disseminations of pyrite and chalcopyrite and rock samples grading up to 6.4 g/tonne Au and 4% Cu. Noranda reported a grade of 4.13 g/tonne Au across 4.0 metres for the Jessie Zone.

In 1987, Noranda carried out detailed soil geochemistry, mapping, some trenching and an airborne EM/magnetics survey over their Tuts claims; this was not filed for assessment credit. However, the airborne survey indicated an 800 m long conductor aligned with the Carbonate Zone. It was ground-truthed with HLEM and drilled in 1988, showing it to be due to graphitic sediments (Duke, 1988). Two more drill holes tested a linear, 800 m long, NW-trending soil geochemical anomaly in the Camp Zone, located two kilometres southeast of the Jessie Zone. They intersected a wide zone of <1 g/tonne Au results, including 64.5 m @ 146 ppb Au (Duke, 1989).

The Noranda claims started to lapse and R. H. McMillan staked his Tutshi #1 claim over the Jessie showing in 1994. He took silt samples that year which confirmed the previous results (McMillan, 1995), but his claim eventually lapsed.

As more of Noranda's Tuts claims lapsed, R. H. McMillan re-staked them as the Golden Eagle claims. In 1999, Prism Resources acquired them and the data from the 1987 Noranda airborne geophysical survey. Walcott (2000) reprocessed the data and suggested an Eskay Creek VMS model within the Boundary Ranges metamorphic rocks, a model which he felt could be neither supported nor disproved by the airborne survey, since EM conductors are not present either at Eskay Creek nor within the Boundary Ranges rocks on the Golden Eagle property.

6.4 Marksmen/Signet/Troymet

In 2001, Marksmen Resources Ltd. examined and optioned R. H. McMillan's Golden Eagle property southeast of Tutshi Lake (McMillan, 2001) and staked claims over Middle Ridge. In 2003, Marksmen surveyed 10 lines with IP and magnetics over the Carbonate and Camp Zones and 3 more in the Tannis Zone area on Middle Ridge, identifying interesting chargeability anomalies in each area (Dzuiba, 2002).

In 2003, Marksmen purchased the Bennett property from Westmin; these claims are not covered by the McMillan option agreement. Their 2003 program consisted of mapping and geochemical sampling in the vicinity of old showings across the property; they also re-sampled Frame's Tannis Zone trenching (Casselman, 2003).

In 2004, Marksmen commissioned a helicopter-borne magnetic/EM/radiometric survey over the entire Golden Eagle property (McPhar, 2004), with limited follow-up groundwork designed to investigate anomalies. A northerly-trending magnetic high, associated with a number of <500 metre strike-length quadrature lows, was identified in the Camp Zone/Carbonate Zone area; volcanogenic massive sulphide mineralization was suggested as a possible source. Similar magnetic/EM signatures, although not as well defined, were noted also east of the Skarn Zone and west of the Plateau Zone; rhyolite-hosted quartz-arsenopyrite veining in the Tannis Zone did not show any significant magnetic or electromagnetic signature (Casselman, 2005).

Marksmen carried out ground geophysical surveys in 2005 and drilled 7 core holes on the Skarn, Tannis and Camp zones. These included the first three holes drilled on the Tannis Zone, which returned intercepts of 2.9m @ 14.39 g/tonne Au and 5.5m @ 10.73 g/tonne Au and 104.2 g/tonne Ag (Casselman, 2007). In October 2005, Marksmen's mineral properties were transferred to Signet Minerals Inc.

In 2006, Signet built an ATV road up to the Tannis Zone on Middle Ridge and carried out detailed mapping there. Signet drilled one hole on the Skarn Zone, to test a chargeability high and intersected 1-3% pyrrhotite without significant gold grades. A hole testing a chargeability high on the Plateau Zone intersected graphitic mudstone and shale, with no significant precious metals. Three holes on chargeability anomalies at the Carbonate Zone intersected carbonate alteration with disseminated pyrite and pyrrhotite; the best intersection graded 2.64 g/tonne Au across 3.1 metres core-length. Four drill sites were prepared in the Tannis Zone, but only one could be drilled due to winter weather conditions. It intersected two quartz-arsenopyrite veins with lower grades (3.1 m @ 1.58 g/tonne Au and 2.0 m @ 0.58 g/tonne Au), but indicating their continuity to depth (Casselman, 2007). In August 2007, Signet's mineral properties were transferred to Troymet Exploration Corp.

6.5 2008 Exploration Program

Exploration in 2008 comprised a surface program of geological mapping, prospecting and diamond drilling on the central portion of the property (North Mountain, Middle Ridge, and South Mountain). Field crews were based out of Spirit Lake Wilderness Resort, eight kilometres north of Carcross, Yukon. Fieldwork was helicopter and ATV supported from a staging area on the west side of the South Klondike Highway close to the project site. Equity Exploration Consultants Ltd. of Vancouver, BC was contracted to manage and execute the surface exploration program and has been retained to report on the results as described herein.

A total of 124 rock samples were collected between August 7th and September 12th, 2007. Rock samples were marked in the field by a combination of pink and blue flagging plus a small aluminum tag on which has been inscribed the sample number, the type of sample, the initials of the sampler, and the date the sample was taken. All rock samples were located using a hand-held GPS. Characteristics of the rock sample were recorded on a sample form and the data from these forms has been included in Appendix C.

2306 m of NQ-sized diamond drilling in 12 holes was completed during the 2008 program by Apex Diamond Drilling of Smithers, BC (see Section 9.0 for details). All drill core was processed at a tent-covered wood frame core shack at the 2005/06 camp location in the northwest portion of the property. Recovery and rock quality designation (RQD) were measured and recorded for each drill run. A KT-10 magnetic susceptibility metre was used to measure magnetic susceptibility for each drill run. An average value for each run was determined by collecting 3-5 individual measurements. Mineralized and altered sections of drill core were sawn by gasoline powered core saws, with one half submitted for analysis and one half retained on site. Sample intervals are marked by laboratory sample tags stapled into core boxes. All drill core was stacked on site near the core shack.

Samples were transported from the project site to Whitehorse in rice sacks sealed with individually numbered security tags. The rice sacks were transferred to Byers Transportation in Whitehorse and delivered to the ALS Chemex Laboratories preparation facility in Terrace, BC. All rock and drill core samples were analyzed for gold by 30 g fire assay-atomic absorption spectroscopy and a multi-element analysis package that utilized an aqua regia digestion and ICP-AES techniques. Pulp assays were carried out for high geochemical values of Au and Ag by fire assay followed by a gravimetric finish. Pulp assays were also carried out for high geochemical values of As, Cu, Pb, or Zn by atomic absorption spectroscopy. Samples with >10 ppm Au had the reject material analyzed by 1,000 g screen fire assay. These assays were used for plotting and calculations. The procedures, results and conclusions of the sampling QA/QC program are summarized in Appendix F. Certificates of analysis are presented in Appendices G and H.

Upon completion of the field program, eight samples were selected from the drill core and surface samples and prepared as polished thin sections by Vancouver Petrographics Ltd. The thin sections, including offcuts and hand samples were submitted to Minerals Services Canada Inc. in North Vancouver for petrographic and SEM analyses; the report is included in Appendix E.

A magnetic declination of 22.5° E was used for all compass measurements. Structural measurements are all reported utilizing the right-hand rule. All maps and UTM coordinates are referenced to the 1983 North American Datum (NAD-83; Zone 8).

7.0 REGIONAL GEOLOGY

The regional geology of the project area is summarized from Mihalynuk (1999). The Golden Eagle property straddles a Cordilleran scale boundary between the mainly Late Cretaceous-Tertiary intrusives of the Coast Belt and mainly Mesozoic arc volcanic and arc-derived sedimentary rocks of the Intermontane Belt. In the project area, the Intermontane Belt is composed of the regionally metamorphosed Boundary Ranges Metamorphic Suite to the west and the Whitehorse Trough Assemblage to the east. Separating these two major divisions is the Llewellyn fault zone, a crustal scale structure with high regional gold-arsenic and antimony geochemistry (Figure 3).

The Boundary Ranges Metamorphic Suite consists of greenschist to amphibolite facies arc-related metamorphic rocks bounded on the east by the Llewellyn fault and on the west by intrusives of the Coast

Belt. This group of rocks is assigned to the Nisling Terrane or Nisling Assemblage, considered to be part of the pericratonic Yukon-Tanana Terrane. Protoliths include a diverse range of sedimentary, volcanic and intrusive rocks. A possible correlation with the Stikine Assemblage based on similar timing of magmatic activity suggests that protoliths of the Boundary Ranges are Devonian to Triassic in age. Metamorphic assemblages in the Tutshi Lake area are generally of low grade, dominated by chlorite-actinolite schists, compared to higher metamorphic grades to the southeast.

The Whitehorse Trough Assemblage is a term proposed by Mihalynuk (1999) to describe the Laberge Group and Stuhini Group strata in this area that together represent an overlap assemblage. The majority of the assemblage occurs within but is not confined to a northwest trending belt defined by the Llewellyn fault to the west and the Nahlin fault to the east.

The Stuhini Group forms a northwest trending belt that is continuous at least as far south as Tulsequah with correlative strata in the Yukon called the Lewes River Group. Lithologies in the Stuhini Group are diverse, including basic to intermediate subalkaline volcanic flows, pyroclastics and related arc sediments. Contacts between the Stuhini Group and the Boundary Ranges Metamorphic Suite are not well exposed in the region and it is possible that parts of the Boundary Ranges suite have Stuhini Group protoliths.

The Laberge Group is a succession of immature marine clastics preserved in a northwest-trending fold and thrust belt. Past workers have divided the Laberge Group into the Takwahoni and Inklin Formations with wide-ranging bases for classification which are not well suited to the project area. An informal definition that can be applied to the project area is that the Inklin Formation is an Early Jurassic mainly fine-grained clastic succession with locally abundant wackes and thin conglomeratic units while the Takwahoni Formation is Early-Middle Jurassic in age and composed of Stikinia derived conglomerate-rich clastic rocks. The rocks are regionally metamorphosed to prehnite-pumpellyite and epidote-albite facies and are hornfelsed to higher grades adjacent to plutons. Clearly defined contacts between the Laberge Group and older strata are limited but do occur near Tutshi Lake and within the Golden Eagle claim block with Laberge strata lying unconformably over Boundary Ranges metamorphic rocks.

As many as five separate young volcanic episodes represented by numerous widespread, isolated remnants occur in the region. In many instances, volcanism appears to have been focused along major structural breaks, such as the Nahlin and Llewellyn faults. Within the project area a package of intermediate pyroclastic and flow units of probable Lower to Middle Jurassic age occur northwest and southeast of Tutshi Lake. A variety of lithologies are present including a conglomeratic unit up to 250 m thick near the middle of the volcanic package most likely derived from the Laberge Group. Contact relations between the volcanics and Laberge Group are uncertain but it appears that the former paraconformably overly the Laberge Group strata.

Intrusive rocks of the Coast Plutonic Complex dominate the western portion of the regional map area (Figure 3), ranging in age from Jurassic to Early Tertiary. The Log Cabin Pluton is a sizable granite body U-Pb dated at 72+/-2 Ma that underlies part of the project area. The pluton straddles the assumed contact between Late Cretaceous intrusions comprising the uninterrupted crystalline Coast Belt west of the Boundary Ranges Metamorphic Suite.

The structural geology of the region involves multiple deformation events and crustal scale terrane bounding faults active over long time periods. In the Boundary Ranges Metamorphic Suite, five separate deformation events have been identified, with planar fabrics developed at least locally during each of the four oldest events. Sediments of the Laberge Group record a continuum of deformational events that began during deposition and peaked during contraction of the basin during terrane amalgamation with the resulting fold and thrust belt. Widespread folding of the Laberge Group does not occur in the underlying Stuhini Group and instead appears to have deformed as a series of semi-rigid east-dipping blocks. Late Cretaceous and younger intrusive rocks of the Coast Belt in the project area do not display pervasive structural fabrics; however, discreet zones of late brittle to semi-ductile deformation are common. Brittle deformation of intrusive bodies probably relates to uplift of the complex during the last 10 Ma.

The Llewellyn fault zone is a system of northwest striking, steeply northeast dipping to vertical strands that crosses through the project area with evidence of a protracted history of activity from the Late Triassic into the Tertiary. There is a strong correlation among the majority of the BC Minfile occurrences in the area and the Llewellyn fault zone. The fault zone is commonly one to three kilometres across and comprised of numerous elongate lenses of various, near vertical lithologies but locally consists of a discreet, near vertical structure only tens of metres across.

8.0 PROPERTY GEOLOGY AND MINERALIZATION

Mapping and prospecting in 2008 were limited to Middle Ridge (Tannis and Missing Link zones), North Mountain (Catfish Zone and Tim Vein) and South Mountain (South Mountain Zone), located in the middle of the Golden Eagle property, west of Tutshi Lake (Figure 4). The focus of mapping was the Tannis Zone, but lithologies present there extend into the other prospected areas.

8.1 Tannis Zone

8.1.1 Geology

The Tannis Zone consists of 6 lithologies of sedimentary, intrusive and metamorphic origin (Figure 6a). The oldest of these units is the Devonian-Triassic Boundary Ranges Metamorphic Suite (**Unit DTrBR**). This unit is seen on the east side of Middle Ridge (Photo 1) and has been strongly deformed with at least two phases of deformation. The rock type is a chlorite+biotite+/-silica+/-epidote schist composed of altered mafic volcanics and volcanic-derived sediments that have a strong S1 fabric, generally with a strike and dip of 340°/70°NE. Minor fluctuations in the S1 orientation are observed, such as F2 folding of the S1 foliation with the fold axis roughly plunging 60° toward the east. In addition to the schist, later intrusions were observed in the form of a plagioclase-phyric diorite with intense biotite+/-chlorite+/-epidote alteration and minor finely crystalline mafic dykes. Due to the scale of these intrusions they were not treated as a separate map unit.

The next oldest unit in the Tannis map area was the Laberge Group (**Unit lJLa**). This unit consists of volcanic-derived clastic sedimentary rocks in the form of argillites and conglomerates with an interval of limestone toward the base. This unit is exposed toward the west side of Middle Ridge and forms a thick package that dips moderately to the southwest. The limestone marker bed at the base of the unit may be the Sinwa Formation carbonate that defines the contact between the Upper Triassic Stuhini Group rocks and the Lower Jurassic Laberge Group rocks, or it may simply be a carbonate bed contained within the Inklin Formation of the lower Laberge Group. Given that both the Stuhini and Laberge Groups contain clastic sedimentary rocks, and the section exposed on Middle Ridge has been intruded by a later equigranular granite at the base, it is difficult to distinguish between the groups, and for the purposes of this report all the strata has been assigned to the Lower Jurassic Laberge Group.

In addition to the above mentioned metamorphic and clastic sedimentary rocks, there are also two later intrusions on Middle Ridge; equigranular biotite granite (**Unit LKg**) and finely crystalline rhyolite (**Unit LKr**). The granite is believed to be the eastern extent of the Late Cretaceous Log Cabin Pluton, part of the Coast Plutonic Complex (Figure 3). On the west side of Middle Ridge, the granite is observed to intrude the Laberge Group sedimentary rocks resulting in the hornfelsing of argillites nearest the intrusion. On the east side of the granite, the later, finely crystalline rhyolite that hosts majority of the mineralization in the area is seen to cross-cut the granite, Laberge Group rocks and the Boundary Range rocks. The rhyolite is observed as one main intrusion that has several small offshoots and near the top of Middle Ridge it engulfs a large slab of the Boundary Ranges. The margins of the rhyolite often show slight displacement from later, very minor movement, but where exposed flow banding is sometimes present suggesting fairly rapid cooling and possibly shallow emplacement.

The last and youngest lithology observed on Middle Ridge is the quartz-sulphide vein system. This vein system was the target of the 2008 drilling and surface program which focused on expanding the vein system along strike to the east and west and identifying new veins in the Middle Ridge, South Mountain and North Mountain locations. The veins of the Tannis Zone are variable in strike length, orientation, sulphide mineralogy and metal content. The most common suite of ore minerals includes arsenopyrite (with associated

scorodite alteration) +/-pyrrhotite+/-pyrite+/-galena+/-sphalerite while there are numerous gangue minerals as well in the form of quartz+/-chalcedony+/-chlorite+/-epidote+/-carbonate. In the Boundary Ranges rocks and the equigranular granite, there is often trace chalcopyrite present. The veins themselves range in thickness from 1-80 cm and strike-length from less than 1 metre to greater than 150 metres, and they "pinch and swell" along strike.

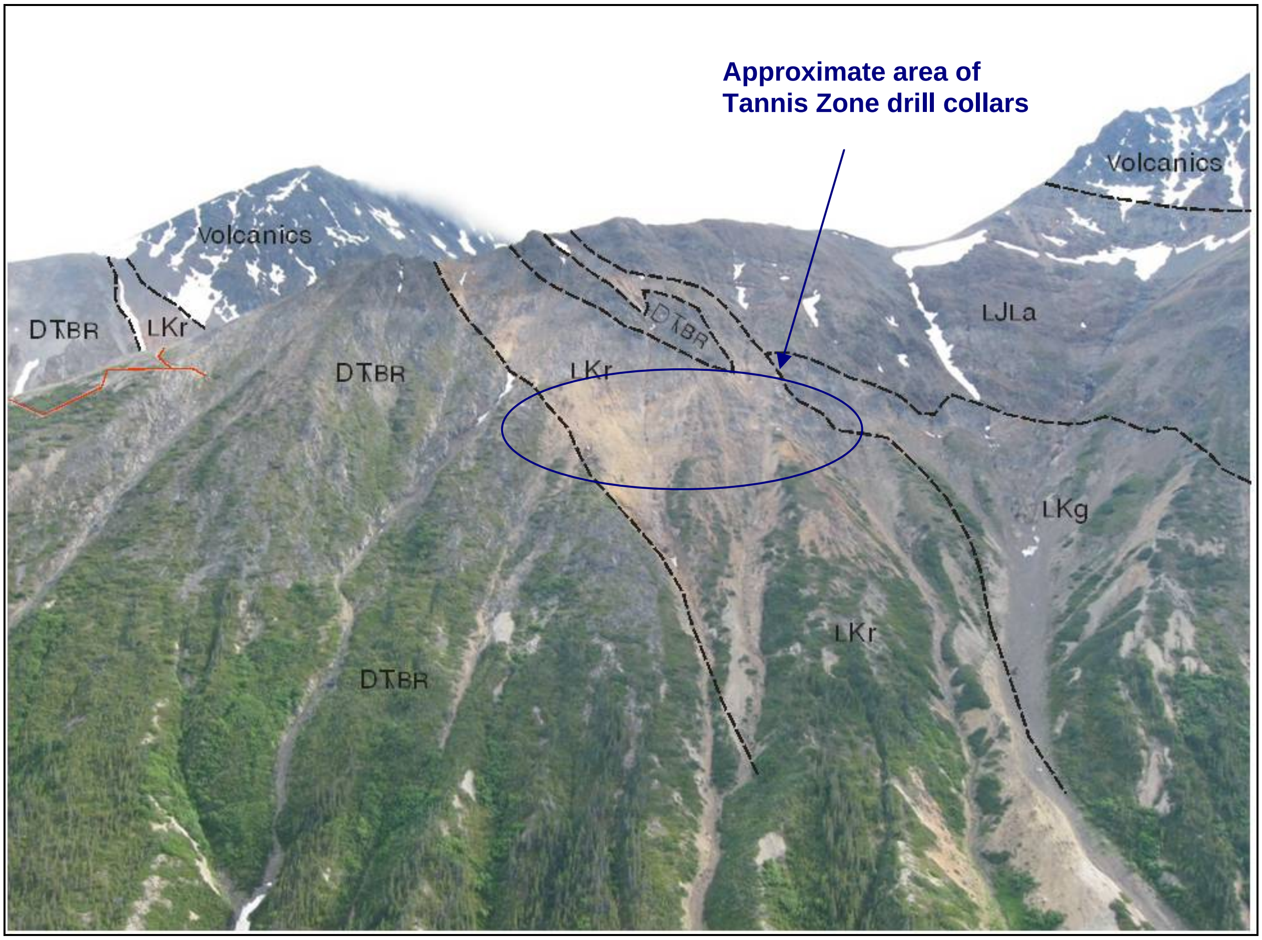

Photo 1: Looking south at Middle Ridge (foreground) and South Mountain (left background). The upper part of the ATV trail is shown in red. Refer to Figure 4 for lithology codes.

Detailed mapping of the vein system on Middle Ridge identified several orientations of veins; however the preferred orientation was undoubtedly 070°/85°S. This orientation is consistent with a pervasive fracture set that is present throughout the rhyolite unit at the Tannis Zone and at the South Mountain Zone. It is likely that the veins are simply filling pre-existing fractures in all lithologies, with the highest concentration occurring in the rhyolite due to its brittle rheology with respect to the surrounding sediments and granite. Several veins on the east end of the Tannis Zone occur in the Boundary Ranges rocks and appear to be massive arsenopyrite that has been remobilized into a fault plane.

8.1.2 Mineralization

On the very westerly extent of the Tannis Zone, the equigranular granite mentioned earlier is in contact with the Laberge Group sediments toward the base of the ridge. A total of four, relatively short (up to 5 metres), quartz-sulphide veins were sampled and contained high grade Au. These veins are initiated at the intrusive contact between the granite and the sediments and continue into the sediments before pinching out. The mineralogy of these three veins is practically identical to the vein system observed in the eastern part of the Tannis Zone. Table 3 shows the assay results for these samples in red.

There were a number of veins that were not sampled in any of the previous work completed on Middle Ridge, located in the granite to the west of the rhyolite intrusion. All samples from these veins contained significant Au and variable Ag and are shown in yellow in Table 3.

Sampling on the south side of Middle Ridge produced three samples with anomalous Au values and moderate to high Ag values. Some of these veins may have been sampled previously, as there were other samples in the vicinity. These samples are shown in blue in Table 3.

The quartz-sulphide veins sampled exhibit the same Au-As correlation that is observed in drill core from the Tannis Zone, with only two samples containing notable amounts of Ag (C287128 and C201120).

8.2 South Mountain Zone

8.2.1 Geology

The lithological units observed on South Mountain (Figure 6a) consist of the southern extension of the Tannis Zone rhyolite mentioned above, bounded on the east side by the Boundary Ranges Metamorphic Suite and on the west by an unnamed package of Jurassic(?) volcanic rocks. The rhyolite intrudes these two bounding units and proceeds to pinch out on the south side of South Mountain.

8.2.2 Mineralization

Nine separate quartz-arsenopyrite veins of varying lengths and thicknesses were mapped on South Mountain (Figure 6b). Mineralogy and orientation of these veins is similar to those on Middle Ridge. The longest of these veins is 110 metres and thickness ranges from 2 cm to 80 cm. A total of 15 samples were assayed with 13 returning significant Au+/-Ag+/-Pb values (Table 4).

In this zone alone there is significant variability between Au, Ag, As and Pb. For example, samples C287126 and C201146 are both high in Au, Ag and Pb and are from the same vein some 100 metres apart (strike distance) whereas in another adjacent, very minor vein, sample C202147 has much less Pb but higher Au (7.91 g/t) and Ag (1250 g/t). A thin section of the latter sample showed that the quartz vein material is mostly coarse-grained and internally deformed with localized clusters of small recrystallized grains. Chalcopyrite and galena occur sporadically as infill in cracks and cavities, and are typically pervasively replaced by a variety of secondary lead and copper ore minerals. SEM analysis indicates complex zoning of sulphides and oxides and that Ag occurs in lead-bearing secondary minerals, suggesting a primary argentiferous galena.

The presence of high-grade Ag+/-Pb with Au-As in many of the samples from South Mountain is distinct from other areas where these elements do not usually occur in significant quantities in the same sample. Other anomalous elements that occur in some of the samples are Bi, Cu and Sb (Figure 4).

In addition to these veins, on the south side of South Mountain is a small outcrop (approximately 50x50 metres) of the southernmost extent of the rhyolite intrusion, with two quartz-sulphide veins that were neither measured nor sampled due to helicopter issues with weather. This outcrop is separated from the main rhyolite intrusion on South Mountain by several hundred metres (laterally) of overburden, thus it is likely that the rhyolite extends in subcrop to at least that point.

8.3 Missing Link Zone

8.3.1 Geology

This zone extends west of the Tannis Zone (Figure 4) and is comprised of several lithologies. Perhaps the most significant is the prominent limestone marker bed in the Laberge Group sedimentary rocks which are well exposed and are discussed above in Section 8.1. The equigranular granite is also exposed and is observed to intrude the Laberge Group sedimentary rocks near tree line on Middle Ridge.

Two small dykes occur in this zone, both strikingly different from any of the lithologies observed elsewhere on Middle Ridge. The first is a chlorite-altered mafic dyke with a finely crystalline groundmass and large white weathering, plagioclase phenocrysts up to 10 mm in length throughout. The dyke cuts the Laberge Group and may be related to the volcanic rocks that cap the highest parts of Middle Ridge. Observations from a thin section concluded that most of the groundmass has been replaced by very fine-grained shreddy biotite that is commonly overprinted by chlorite. No primary mafic phase was observed, but granular anhedral titanite and anhedral poikilitic magnetite occur throughout, suggesting replacement of earlier mafic phases.

The second dyke is a medium-crystalline, equigranular tonalite dyke with little to no alteration. A thin section of the dyke identified a fine-grained, anhedral granular texture composed of K-feldspar and quartz, lesser plagioclase and muscovite with coarser-grained K-feldspar occurring throughout. Euhedral arsenopyrite is disseminated throughout the sample. A very low mafic mineral content and the presence of trace amounts of spessartine suggest the sample is an aplite with a linkage to the large granite body nearby.

8.3.2 Mineralization

Table 5: Missing Link Zone Significant Mineralization

Sample #	Au g/t	Ag g/t	As %	Pb %	Sample Type
C202118	0.109	140	0.189	3.69	Grab
C202135	0.057	10	0.107	1.13	Grab
C202136	0.104	17	0.141	1.77	Grab
C202144	1.05	3	19.7	0.002	Select

Fifty-one samples were collected in this zone, mostly of non-vein material mineralized with a suite of sulphide minerals consisting of arsenopyrite, pyrite, pyrrhotite, chalcopyrite, galena, sphalerite and molybdenite. The mineralization periodically occurs on either side of the above mentioned limestone bed, typically in a zone of fine-grained, argillaceous sediments. There is little mineralization in the limestone itself, which may be an artefact of tight porosity due to recrystallization. The mineralized envelope can be as wide as 20 metres on either side of the limestone bed or as narrow as a few centimetres. The grab samples from along the contact with the limestone averaged 1-3 g/t Ag with one sample (C202118) containing 140 g/t Ag (Table 5). An interesting aspect of this zone is the increased amount of Pb, with associated Cu, Sb and Zn anomalies. This may be attributed to the chemistry of the host rock that is not observed elsewhere or due to the disseminated style of mineralization as opposed to the quartz-sulphide veins predominant in the other zones.

The mineralization around the limestone bed in the Laberge Group sediments appears to be related to the equigranular granite. Given the moderate south-southwest dip of the Laberge Group sediments on Middle Ridge, it is likely that these sediments are truncated by the granite at depth, allowing for mineralizing fluids to percolate along bedding planes and deposit metals on route to the surface. Disseminated subhedral to euhedral arsenopyrite throughout the above mentioned mafic dyke, with corresponding biotite alteration and replacement magnetite are probably also related to the later granite intrusion.

A sample of semi-massive arsenopyrite from the aplite dyke (mapped as tonalite) assayed 1.05 g/t Au and 3 g/t Ag. The dyke is potentially a conduit for mineralizing fluids from the granite into the country rocks.

8.4 Catfish Zone

8.4.1 Geology

The Catfish Zone on North Mountain contains five mappable units (Figure 6a). These consist of the Boundary Ranges metamorphic rocks overlain by the Stuhini Group sedimentary rocks, as well as two distinct intrusive units, the equigranular granite (assumed to be the same as that on Middle Ridge based on mapping by Davis, 1989) and a series of small plagioclase porphyritic mafic dykes thought to be similar in origin as the dyke in the Missing Link Zone. The last unit is a series of quartz-sulphide veins with similar composition to those mapped in the Tannis and South Mountain Zones.

8.4.2 Mineralization

A total of 18 grab samples were collected from the Catfish Zone, the majority taken from a number of narrow veins up to several metres long hosted in both the granite intrusion (and associated dykes) and the Boundary Range metamorphic rocks to the east. Comparison of geochemical results of all 2008 rock samples clearly identifies a Bi-Mo-W anomaly in the Catfish Zone that is not present in any other zone.

Six samples with notable results can be divided into two groups. The first group contain anomalous values of Ag and Pb with associated Bi-Sb-Cu and are shown in blue in Table 6, while the second group is composed of Au+/-Ag with associated Bi-Mo-W and are shown in red. The Au bearing veins from the Catfish Zone are very different from other zones due to low As content, anomalous Ag, and generally low sulphide content overall as noted in hand samples with only trace amounts of arsenopyrite and chalcopyrite recorded.

8.5 Tim Vein

8.5.1 Geology

There are two lithologies present at this zone, which lies immediately west of the Golden Eagle property boundary (Figure 6a). The first is the equigranular granite that is also observed to the immediate east in the Catfish Zone and across the valley to the south in both the Missing Link and Tannis Zones. The second lithology is the 370 metre strike length quartz-sulphide vein that is hosted in the granite.

8.5.2 Mineralization

Table 7: Tim Vein Significant Mineralization

Sample #	Au g/t	Ag g/t	As %	Pb %	Sample Type
C201134	0.301	75	0.309	3.16	Grab
C287113	18.0	16	>30.0	0.015	Grab
C287114	3.64	<1	6.35	0.001	Chip
C287115	10.68	5	23.5	<0.001	Grab
C287116	4.11	3	7.76	0.001	Grab
C287117	3.45	2	>30.0	0.001	Grab

Sampling along the Tim Vein returned significant Au values (Table 7), increasing the western strike length of the vein system previously identified by the Catfish work in the late 1980's. The mineralogy of this vein is consistent with that of the known high grade vein system of the Tannis Zone, some 3.2 km to the southeast, with a shared metals association of Au-As (Figure 4).

Petrographic and SEM analyses of sample C287113 identified heavily fractured semi-massive arsenopyrite that is variably oxidized. Minor pyrite and chalcopyrite fill the arsenopyrite fractures and enargite and electrum form small inclusions in the arsenopyrite. Anhedral, fine-grained quartz commonly occurs interstitial to the sulphides.

This vein is thought to be associated with the granite intrusion that is found on both Middle Ridge and North Mountain. The vein is hosted in the granite and continues along strike to the west until it pinches out near the granite contact with a package of sedimentary rocks. This vein is outside the claim block; however it is very important as it indicates the extent of the system and that high grade Au mineralization exists this far from the Tannis Zone.

In contrast to the Au-As rich samples of quartz vein, sample C201134 is much different with 75 g/t Ag and 3.16% Pb. The sample was described as a sulphide-rich rock taken from within a zone of strong carbonate veining or alteration.

8.6 Property Geology and Mineralization Summary

There are a number of different units present on North Mountain, Middle Ridge and South Mountain; of particular importance are the quartz-sulphide vein system, rhyolite intrusion and the large equigranular granite and all may be directly related. The vein system is the youngest event, preceded by the rhyolite and then the granite. The attitude of the veins is controlled by pre-existing fractures that trend 070°-250° and primarily dip steeply to the south (65°-85°) but are also sometimes observed to dip to the north. Other conjugate(?) fracture sets were observed but are rarely associated with veins.

The quartz-sulphide vein system has been documented on North Mountain, Middle Ridge and South Mountain to be independent of lithology with variable concentrations of Au, Ag, Pb and other associated metals. This is a significantly sized area; the linear distance formed by the Tim Vein, Tannis and South Mountain Zones is nearly 5 km along a northwest-southeast trend with intervening glacial valleys that are covered by overburden and remain underexplored.

From a more regional standpoint, several localities around the granite contact were slightly metamorphosed and replaced by tremolite-actinolite, very similar to the system at the Skarn Zone on the north-western end of the property. It should also be mentioned that the “LQ Vein” in the northwest portion of the property displays strikingly similar characteristics as the North Mountain-Middle Ridge-South Mountain vein system. The LQ Vein occurs in close proximity to the Skarn Zone, both of which are only a few kilometres north of the Catfish zone and the Tim Vein.

Coincident anomalies shown in Figure 4 and discussed in this report are general trends only, derived from a limited amount of selective sampling. A more robust analysis would involve compilation of all previous work on the property and further sampling, however some trends are apparent and deserve attention. Quartz-sulphide veins from the Tannis Zone and the Tim Vein are geochemically related by Au-As anomalies, with limited Ag content. In contrast are the polymetallic veins from South Mountain and the Catfish Zone, although differences between these zones also exist. Samples of quartz-sulphide veins from a rhyolite host on South Mountain appear similar to the Tannis Zone, but include a much more diverse suite of metals of Au-Ag-As+/-Pb+/-Sb+/-Bi. The biggest differences at the Catfish Zone are low As values, and that the metal assemblages can be grouped into two suites: Au-Ag and Ag-Pb with associated anomalous elements that include prominent Bi-Mo-W with lesser Sb and Cu.

The mineralization observed at the Missing Link Zone is quite different than that of the vein systems elsewhere, which indicates a different mechanism of emplacement. Rather than the structural traps which allowed the deposition of quartz-sulphide veins elsewhere, chemical traps allowed emplacement of the same sulphide assemblage in the Missing Link Zone. As mentioned previously, the moderate dip of the Laberge Group rocks would likely intersect the granite intrusion at depth, allowing the limestone marker bed to act as a “chemical trap” leading to metal precipitation along its margins in the bedding planes of the argillites.

9.0 DRILLING

9.1 Overview

Diamond drilling for the 2008 program focused on the Tannis Zone with the completion of eleven holes from eight different setups. Table 8 contains the drill collar data and Figure 5 is a map of the drilling area. Apex Diamond Drilling of Smithers, BC completed 2306 m of drilling between July 30th and Aug. 26th. A total of 958 samples of drill core were collected, including the regular insertion of standards, blanks and duplicates as part of the QA/QC program (Appendix F). Sample lengths ranged from 30 cm to 1 m; selection was based on the presence of sulphide mineralization and veining, guided in part by results from previous drilling. Table 9 highlights significant intersections from the 2008 drill program.

9.2 Diamond Drill Hole Descriptions

TAN08-05

TAN08-05 was the first hole collared in the metavolcanics of the Boundary Ranges suite, 80 m along strike from quartz-sulphide veins intersected in the rhyolite intrusion in TAN05-03. Alternating lithologies of chlorite-biotite altered volcanics intruded by plagioclase-phyric diorite or granodiorite were encountered (Figure 7d). Veining and mineralization is limited throughout most of the hole with the exception of one zone immediately beneath 67 cm of fault gouge within a plagioclase-phyric intrusion (Photo 2). Arsenopyrite veinlets in the fault gouge indicate at least some of the mineralization post dates faulting.

The strongest mineralization occurs primarily as sulphide replacement of the host rock, consisting of 20% arsenopyrite with minor pyrite and chalcopyrite with an average grade of 1.61 g/t Au across 1.3 m. A thin section from this interval (sample C287261) consists of vaguely brecciated porphyritic rock that has been pervasively replaced by quartz, sericite and trace kaolinite. Former fine to medium-grained, tabular plagioclase and lesser, finer-grained K-feldspar phenocrysts are variably sericite altered. Sulphides consist of small subhedral to euhedral arsenopyrite crystals associated with quartz in vaguely defined ribbons suggesting quartz-arsenopyrite fracture infill after brecciation.

Photo 2: Mineralized zone from TAN08-05. Quartz-sericite-arsenopyrite replacement of a plagioclase-phyric intrusion in sample C287261 (bottom row) beneath a small interval of arsenopyrite rich fault gouge (top right).

TAN08-06

TAN08-06 was drilled to test the continuity of mineralization down dip of TAN08-05 (Figure 7d). This hole was abandoned at 109.4 m after the rods became stuck down the hole and attempts to resume drilling after retrieving the rods were unsuccessful. TAN08-07 is a re-drill of this hole.

TAN08-07

TAN08-07 drilled within similar lithologies as TAN08-05, however correlation among the diorite to granodiorite intrusions (dykes?) is not feasible (Figure 7d). The intrusions have likely been part of at least one of the two deformation events visible in the mafic volcanics, with a lack of tectonic fabric in the intrusions explained by the competency contrast between the diorite/granodiorite and the foliated volcanics. This hole contains only weakly anomalous samples with Au values up to 480 ppb from centimetre scale arsenopyrite veins and replacement mineralization. The mineralized fault encountered in TAN08-05 appears to correspond to a fault in this hole at 192 m that is only weakly mineralized, resulting in a sub-vertical orientation.

TAN08-08

This hole undercut TAN06-04 which intersected quartz-sulphide veins in the rhyolite intrusion (Figure 7b). TAN08-08 was the first hole to drill through the rhyolite into equigranular biotite granite observed on surface near the base of Middle Ridge and North Mountain and increasing in areal extent to the west. A sharp, undulatory contact divides the rhyolite and granite in the core, with no alteration or textural changes near the contact.

Three zones of quartz-arsenopyrite veining were intersected in TAN08-08 with variable gold values. True widths of mineralized zones are significantly less than the core lengths due to vein orientations that are typically at 20–30 degrees to the core axis. The uppermost vein section is nearly 4 m in core length but significant values are restricted to areas of increased arsenopyrite mineralization with 1.42 g/t Au and 11.9 g/t Ag across 1.44 m. Petrographic analysis of a sample of vein material (sample C287345) identified significant strain to the quartz with deformed and recrystallized grains present in similar amounts. Very fine grained arsenopyrite is disseminated or locally occurs as fracture infill with microcrystalline clusters and rims of possible scorodite (Photo 3).

Photo 3: Quartz-arsenopyrite vein from TAN08-08. Fine grained arsenopyrite disseminations and fracture infill in strained quartz; sample C287346.

The second zone is a 2 m interval of sheeted to massive quartz veins with minor arsenopyrite at 148 m that only returned one notable result of 756 ppb Au from a 62 cm sample. Scorodite was much more prominent than arsenopyrite in this sample. Oxidation at this depth is evident in the surrounding rocks by the amount of fracture controlled goethite and leaching of sulphides. A 40 cm sample of rhyolite breccia above the veined zone assayed 2.53 g/t Au and 38 g/t Ag. Here, quartz-arsenopyrite veins 1-2 cm wide both crosscut the breccia and are brecciated.

The third zone of quartz-arsenopyrite veining occurs within equigranular granite, averaging 3.07 g/t Au across 1.34 m where arsenopyrite+/-pyrite mineralization is strongest.

Consistent disseminated pyrrhotite and trace chalcopyrite mineralization within oxidized to relatively unaltered granite throughout the lower part of the hole produced a 26 m intersection averaging 0.103 g/t Au. An average grade for Ag cannot be calculated due to some samples assaying below the detection limit of 1 g/t but individual assays of 2-3 g/t Ag are common throughout the interval. Pyrrhotite occurs as blebs within the granite, apparently replacing primary biotite. This is the first occurrence of low grade gold mineralization over a significant core length on Middle Ridge.

TAN08-09

TAN08-09 drilled at a steeper angle from the same setup as TAN08-08 to test the continuity of quartz-sulphide veins in both the rhyolite and granite intrusions (Figure 7b). The contact between the rhyolite and granite is very sharp, similar to TAN08-08, but in this hole fragments <1 cm wide of what appear to be granite with diffuse boundaries are present in the rhyolite within 5 cm of the contact. Further down hole a 90 cm rhyolite dyke cross-cuts the granite. Both of these are indicators that the rhyolite post-dates the granite.

Only one sizable zone of quartz-sulphide veining was intersected in TAN08-09, which most likely correlates to the upper intersections in TAN08-08 and TAN06-04. Assay results from individual samples within the 5.09 m zone of quartz-sulphide veining in strongly silica-sericite altered rhyolite are highly variable, similar to the long vein intersections in other holes. Au values across the zone average 7.93 g/t but this is highly skewed as only two samples contain >1 g/t Au, one of which is a 57 cm sample that assayed 66.2 g/t Au and 145 g/t Ag (sample C287488). The combination of arsenopyrite-pyrite+/-chalcopyrite within this sample is notably different from arsenopyrite as the dominant sulphide throughout the rest of the zone and may be significant with respect to the high Au grade. Results from the screen fire assay of this sample show a large difference between Au content of the undersize and oversize fractions, indicating that there may be a substantial amount of coarse free gold. The opposite is noted from screen fire assays conducted on all other samples >10 g/t Au from the drill and surface program, where values from the undersize and oversize fractions are similar. Other anomalous metals contained within the quartz-sulphide veined section include Bi, Cu, Pb, and Sb.

As observed in other holes, sporadic narrow quartz-arsenopyrite-pyrite veins result in anomalous gold values. One sample of low angle quartz-arsenopyrite-pyrite-sphalerite veins in granite yielded 3.30 g/t Au, 57 g/t Ag, 0.32% Pb and 0.54% Zn. The lead and zinc values are the second highest and highest values respectively from the drill program. This sample lies within a large zone of low-grade Au mineralization present across the 80 m interval of granite that forms the lower part of the hole. Au grades are weaker than in TAN08-08 but for comparison a 34.36 m interval below the vein sample mentioned above averages 0.067 g/t Au. Sulphide mineralization consists of disseminated blebs of pyrrhotite with lesser pyrite, arsenopyrite and chalcopyrite with rare quartz-pyrite-arsenopyrite veinlets.

TAN08-10

TAN08-10 was located at the same site as TAN05-01 to test a greater depth and to step forward from previous drill holes on this section that were successful in intersecting quartz-sulphide veins. The dominant lithology was rhyolite, with sections of rhyolite breccia showing evidence of brecciation from hydrothermal veining and elsewhere due to later brittle faulting. A 3.8 m interval of granite near the bottom of the hole may be a xenolith entrained within the later rhyolite intrusion. The hole appears to have been stopped very close to the rhyolite-granite contact judging from the contacts observed in TAN08-08 and TAN08-09 (Figure 7b).

Many anomalous gold samples (>100 ppb) are present in this hole, often as standalone samples related to narrow (1-2 cm) quartz-arsenopyrite veins. Significant mineralization across larger intervals is restricted to the upper part of the drill hole. Between 32.77 and 36.57 m a fault(?) breccia of rhyolite and quartz-arsenopyrite vein fragments is high in arsenic (up to 6.2%) but gold values are in the 300 - 700 ppb range, not as high as might be expected based on the Au-As correlation observed in many other samples. Mineralized fragments indicate that mineralization pre-dates brecciation, which continues below, albeit to a weaker degree into a 4.3 m interval of quartz veining that averages 2.05 g/t Au and 43.8 g/t Ag with anomalous lead (up to 0.63%). A 1 m sample within this zone (G0672135) assayed 5.01 g/t Au and 108 g/t Ag, the second highest silver value from the 2008 drill program. A thin section of this sample included both quartz vein and brecciated wall rock (Photo 4). The quartz is fine to medium-grained, internally deformed and locally recrystallized to a much finer grain size. Subhedral to euhedral arsenopyrite, chalcopyrite and pyrite are disseminated along quartz grain boundaries and occur in partially filled vugs variably associated with sericite. Galena occurs interstitial to quartz and sulphides or intergrown with sulphides. Oxidation is marked by the presence of altered and corroded arsenopyrite, and more commonly by partially leached subhedral vugs and veinlets containing possible scorodite+/-covellite. The breccia hosting the quartz vein is clast supported and consists of small sub-angular clasts of quartz crystals, quartz vein fragments and sericitized and silicified fragments. The interclast matrix is essentially made up of cryptocrystalline material that is partially leached and locally associated with possible scorodite.

An isolated 30 cm sample at 67 m assayed 11.05 g/t Au due to a 3 cm wide quartz-arsenopyrite vein. This sample is highly anomalous in bismuth (970 ppm), one of the few samples anomalous in that element in the entire drill program.

Photo 4: Quartz vein breccia in TAN08-10. The lower portion of sample G0672135 (discussed below) is shown on the bottom row.

Five drill holes have been completed along this line of section with variable results, providing for multiple possibilities in correlating veins (Figure 7b). Mapping on surface has identified numerous veins in this area with multiple orientations (Figure 5). Most of the veins have a strike of approximately 70^{o} and dip 65^{o}-85^{o} towards the south; however at least one vein dips steeply to the east in the area. The most probable correlations identify two trends, with ~65^{o} and ~82^{o} dips respectively. These correlations are based on the alignment of veins in cross section, orientation measurements from drill hole intersections with respect to the core axis, and vein measurements made on surface.

TAN08-11

TAN08-11 was designed to test for the up dip continuation of arsenopyrite mineralization encountered in the Boundary Ranges suite in TAN08-05 and for possible strike length extension of quartz-sulphide veining intersected in the rhyolite intrusion in TAN05-02 (Figure 7d). The dominant lithology is chlorite-biotite altered mafic volcanics, locally with a well developed schistosity that has been folded by a second generation event. The volcanics have been intruded by diorite to granodiorite dykes. Both units are affected by later brittle faulting.

Two narrow arsenopyrite-rich samples separated by non-mineralized metavolcanics contain 1.96 g/t Au and 1.21 g/t Au each. The arsenopyrite is medium-grained, replacing the host rock and concentrated in bands 5-15 cm in true width. In cross-section (Figure 7d), this zone lines up with the replacement style of mineralization in TAN08-05 and the weakly mineralized fault gouge in TAN08-07. Some sort of fault would be expected within or beside the mineralization in this hole based on the other observations, but it is evident that arsenic-rich fluids were able to pass through the host rock, possibly linking up a series of small structures.

TAN08-12

TAN08-12 drilled at a different azimuth from the other 2008 holes to drill across a prominent gully 30 m to the southeast containing a quartz-arsenopyrite vein along the gully margin (Figure 7e). The entire drill hole was within chlorite-biotite altered volcanics of the Boundary Ranges Metamorphic Suite.

Semi-massive replacement of silica-flooded volcanics by pyrrhotite and lesser arsenopyrite across 20 cm of core length assayed 13.15 g/t Au, the second highest Au value for the 2008 drill program. This sample also contains the second highest Cu value at 941 ppm. Sulphide mineralization is very limited in samples immediately surrounding this narrow zone. 4 m down hole, fine grained sulphides in quartz boudins and pyrite-pyrrhotite stringers above a fault zone resulted in anomalous gold values up to 583 ppb. Within the strongly sericite altered fault zone, Au values averaging 1.70 g/t over 1.23 m are attributed to arsenopyrite veins, disseminations and matrix to the fault gouge.

TAN08-13

TAN08-13 drilled from the same location as TAN08-12 at a steeper dip. The highest gold assay in TAN08-13 is 3.93 g/t from a 40 cm fault zone with semi-massive arsenopyrite. Further down hole is a larger fault that is believed to correspond with the mineralized fault in TAN08-12, but with slightly lower gold grades encountered in this hole. Of note is the presence of a 10 cm fragment of quartz-arsenopyrite vein within the fault zone, similar to observations in the gully on surface that the disjunctive nature of the veining appears to be due to later faulting that aided the mobilization (remobilization?) of arsenic rich fluids. Plotting the data on a cross section indicates a fault dipping 81^{o} toward the northwest, with the 40 cm fault zone mentioned above a possible fault splay at a slightly shallower angle (Figure 7e).

TAN08-14

TAN08-14 undercut TAN08-07 and drilled entirely within variably deformed, chlorite+/-biotite altered volcanics of the Boundary Ranges Metamorphic Suite (Figure 7d). No significant arsenopyrite mineralization was encountered; however, variable pyrrhotite-pyrite disseminations and minor stringers occurred throughout locally with trace amounts of chalcopyrite. There are no anomalous samples in this hole; the highest Au value returned was 25 ppb.

TAN08-15

TAN08-15 is a 65 m undercut of TAN05-03 and TAN05-02, which were drilled within the rhyolite intrusion and intersected high-grade mineralization within quartz-arsenopyrite veins (Figure 7c). For example, individual assays in TAN05-02 were as high as 87.44 g/t Au and 279 g/t Ag while TAN05-03 had up to 34.28 g/t Au.

Only one interval of quartz-arsenopyrite veining was encountered in TAN08-15, near the bottom of the hole, with mineralization averaging 0.35 g/t Au and 5.9 g/t Ag across 6.23 m. The veins are at low angle to the core axis within sericite-silica altered rhyolite. Anomalous gold values up to 254 ppb occur in rhyolite with disseminated and fracture-controlled arsenopyrite for 18.6 m above the vein zone.

Correlating quartz-arsenopyrite veins among the three drill holes in this section is not straightforward due to widely varying assays and vein widths (Figure 7c). The Au and Ag rich interval in TAN05-02 may be part of a vein dipping at 45^{o} towards the south, an unfavourable orientation in terms of drill targeting due to topographic constraints. The apparent length of the quartz-sulphide veined zone (almost 8 m) can be attributed to the low angle of intersection to the core axis, with vein measurements noted in the drill logs ranging from sub-horizontal to 40^{o} to the core axis. The Au rich vein intersected in the upper part of TAN05-03 could also dip at a moderate angle to the south (between 30^{o}-45^{o}) providing an explanation for the fact that it was not intersected in the holes on either side. If the veins intersected in TAN05-03 followed the usual trend of steeply south-dipping then TAN08-15 should have intersected multiple zones instead of only one weakly mineralized zone near the bottom.

TAN08-16

TAN08-16 is a 60 m step out to the west along strike from all previous drill holes. Lithologies encountered include rhyolite, rhyolite breccia and biotite granite. The contact between the rhyolite breccia and the underlying granite is obscured by a large zone of weakly mineralized quartz-sulphide veining and alteration. Two other variably mineralized zones of quartz-sulphide veining were intersected within the rhyolite and granite; Au and Ag values are generally weak across these vein intersections. Numerous low-grade Au samples are present throughout the hole both as isolated samples and grouped intervals.

Quartz-sulphide veins in sericite-silica altered rhyolite were intersected between 13.89 and 18.08 m. Samples that returned the highest Au and Ag assays can be attributed to sulphide-rich portions of the veins, including one sample with pyrite as the dominant sulphide rather than arsenopyrite that assayed 1.75 g/t Au and 29 g/t Ag. This vein system is exposed on surface dipping steeply to the south (~85°) a short distance ahead of the drill collar but inaccuracies stemming from working with a handheld GPS at a small scale results in a poor representation of vein orientation on the cross section (Figure 7a). The vein set intersected in the upper part of this hole can be traced >60 m to the east, potentially forming the top intersection in each of TAN08-08, TAN08-09 and TAN06-04 (Figures 5 and 7b). Sporadic, narrow quartz-arsenopyrite veining (1-10 cm true width) and fracture-controlled arsenopyrite mineralization continues for 12 m beneath the zone of strongest veining with modest results except for one sample that assayed 2.04 g/t Au.

Within the granite is a 13 m zone of weak Au mineralization with anomalous Ag, Pb and Zn, including a 6 m interval of quartz veining with minor arsenopyrite. Results show little difference between Au values from samples of the largest quartz vein (3.5 m core length) and samples taken from granite containing veins <2 cm wide. Projection of a vein mapped on surface 20 m to the northeast that is dipping 85° towards the south onto the line of this cross section (Figure 7a), is in close agreement with the angle of the lower contact of the largest quartz vein. This implies that the lower, weakly mineralized zone of veining in TAN08-16 correlates to the high-grade Au and Ag rich intersections of TAN08-10 and TAN05-01 and potentially, the lower-grade intersection near the bottom of TAN08-08 (Figure 7b).

9.3 Drilling Summary

Drilling in 2008 expanded upon previous drill holes in the Tannis Zone that were directed solely at quartz-sulphide veins within rhyolite and rhyolite breccia to now include similar veins within equigranular biotite granite and the Boundary Ranges Metamorphic Suite. Previous workers recognized the probable link between the granite and rhyolite intrusions, including the possibility of the rhyolite representing a chilled contact (Morris, 1988). Observations from drill core indicate that the rhyolite is a later phase than the granite on Middle Ridge. Two of the three contacts observed in core (TAN08-08 and TAN08-09) were very sharp while the third contact, in TAN08-16, was obscured by a large section of weakly mineralized quartz-sulphide veining and alteration. Rhyolite dykes crosscut the granite, with the best example in TAN08-09 being a 90 cm dyke (core length) that caused strong chlorite alteration along the margins of the host granite. Other possible rhyolite dykes, especially in TAN08-16, have less clearly defined boundaries and at times look more like intense k-spar alteration obscuring the primary texture of the granite. However, alteration is so weak throughout most of the granite that it is more likely they are indeed dykes but may have been emplaced before the granite was fully cooled. The presence of a 3.8 m section of granite near the bottom of hole TAN08-10 could be attributed to a raft of host rock entrained within the rhyolite, also indicating the rhyolite is younger.

Chlorite-biotite alteration prominent in the Boundary Ranges is most likely related to regional deformation and metamorphism that resulted in the schistose texture of the metavolcanics and deformation of non-mineralized quartz and carbonate veins. All of the holes collared in the Boundary Ranges were within 20 m of the rhyolite contact without any apparent alteration or hornfels texture. The actual contact was not drilled due to constraints on drill pad construction with respect to the steep topography.

Gold values >1 g/t occurred in narrow intervals in all three rock units encountered in drill core. Accompanying many of the anomalous gold values are higher than background Ag values, however, only five samples from the entire drill program assayed >50 g/t Ag, all within holes TAN08-09 and TAN08-10. The fact that limited Ag was encountered in TAN08-08 which was drilled between these two holes highlights the variability among intersections.

In the rhyolite and granite intrusions the majority of anomalous gold values can be attributed to specific mineralized veins usually composed of quartz-arsenopyrite but locally including pyrite or pyrrhotite, and rarely chalcopyrite or sphalerite. Many gold assays from isolated, centimetre scale veins are comparable to or greater than gold values within the metre scale quartz-sulphide veins. In TAN08-10 for example, a 30 cm sample yielded 11.05 g/t Au due to the presence of a 3 cm wide quartz-arsenopyrite vein with minimal surrounding mineralization. The presence of weak background Au mineralization in the granite is very interesting and appears to be associated with the disseminated pyrrhotite rather than the quartz-arsenopyrite veinlets which cause localized ‘spikes’ of increased Au where they do occur. This large intrusion may be the source of mineralization of other rock units in this area. If this is the case then the mineralized fluids would be from a late cooling stage given that the rhyolite is a younger intrusive phase than the granite.

Four sub-parallel sections have been drilled across >200 metres of strike length, with spacing of 40-60 metres between holes on the same section. The fifth section at the eastern end was at a different azimuth (TAN08-12 and TAN08-13). Similar to observations from surface, the quartz-sulphide veins are discontinuous laterally and also at depth. No major structures are present in the area drilled but brittle faulting evident in the brecciated rhyolite and the Boundary Ranges suite indicates minor vein offsets should be expected. The best estimate of the maximum down dip extent of any vein drilled to date is >200 m from TAN08-10, TAN05-01 and TAN08-08 (Figure 7b).

Variable pyrrhotite-pyrite disseminations and veinlets are present within the Boundary Ranges Metamorphic Suite but the timing and cause of this ‘background’ mineralization is unknown, especially whether or not it pre-dates the granite intrusion. Gold bearing intervals in the Boundary Ranges drill holes are limited to fault and/or narrow replacement zones. Arsenopyrite is the dominant sulphide for samples that assayed >1 g/t Au, except for the highest assay in the Boundary Ranges of 13.15 g/t in TAN08-12 which contained semi-massive pyrrhotite with lesser arsenopyrite across 20 cm. Previous mapping has confirmed the presence of quartz-arsenopyrite veins in the Boundary Range, especially on the south side of Middle Ridge, but quartz veins in drill core were only noted in TAN08-13 as a 10 cm fragment within a mineralized fault zone.

10.0 DISCUSSION AND CONCLUSIONS

The 2008 program focused on the central portion of the Golden Eagle property and was successful in terms of further defining, as well as expanding, the area of Au-Ag mineralization related to quartz-sulphide veining in multiple rock types. Mapping and prospecting has identified the presence of quartz-sulphide veins that are often similar in appearance across a 5 km long belt. Taking into account similar occurrences in other parts of the property such as the LQ vein and the veins on the south side of South Mountain that were not sampled during the 2008 program, this length is extended to upwards of 8 km. The northwest trend of the quartz-sulphide vein occurrences mirror the trend of the Llewellyn fault zone, located a few kilometres to the east.

Drilling on the Tannis Zone in 2008 highlighted the inherent variability of gold-silver mineralization and discontinuity within veins but the system has been demonstrated to continue along a strike length of nearly 150 metres and greater than 200 metres down dip on at least one section in both the rhyolite and granite intrusions. Results from drill core also identified low-grade Au-Ag mineralization within the granite

Petrographic and SEM analyses of select surface and core samples highlighted a number of key features. The internal deformation and recrystallization of quartz within the vein samples indicate protracted periods of strain after initial vein formation. This conclusion draws attention to the importance of structures in the area, especially one as regionally significant as the Llewellyn fault zone which is known to have continued activity into the Tertiary. Thin section work also demonstrated the extent of oxidation to sulphide minerals, marked by the presence of oxides/hydroxides that are variably iron, lead, molybdenum, arsenic or antimony-bearing. Sulphide oxidation products are very fine-grained and commonly intermixed or occur in successive rims, precluding definitive identification without a comprehensive SEM-EDS analysis.

Based on observations from mapping and drill core in the Tannis Zone, it appears that the quartz-sulphide veins are synchronous with late-stage cooling of the Late Cretaceous granite pluton and the slightly later rhyolite intrusion, locally with multiple phases of sulphide minerals, predominantly arsenopyrite. Regional workers have noted the paucity of data to constrain the timing of mineralization of vein systems in northwestern British Columbia, but comparison with vein deposits immediately to the north in southwestern Yukon indicates that most mineralization is Late Cretaceous to Early Tertiary and related to intrusions of similar age (Mihalynuk, 1999).

In drill core from the Tannis Zone, mineralization was observed to occur both before and after brittle faulting. Deformation after quartz vein formation is supported by observations from thin sections of quartz veins such as in TAN08-10 where quartz vein fragments form clasts within the rhyolite breccia. In contrast is quartz-arsenopyrite infill after weak brecciation of the plagioclase porphyry in the Boundary Ranges suite in TAN08-05.

Despite the chlorite-biotite alteration and weak pyrrhotite-pyrite mineralization in the Boundary Ranges metavolcanics a porphyry model of mineralization is not supported due to the lack of pervasive hydrothermal alteration in the host rocks. Instead, intrusion-related gold is a possible exploration model. Evidence in favour of this model includes the presence of a large felsic intrusion, geochemical signature that includes As-Bi-Sb-Pb-W and relatively cryptic alteration associated with the veining. The role of the Llewellyn fault zone and associated higher order structures in this scenario is uncertain. As mentioned previously there is a strong correlation between the Llewellyn fault zone and the majority of BC Minfile occurrences in the region. This long-lived structure may have supplied metals to the felsic melt for the intrusion-related system.

Exploration in 2008 focused on a relatively small portion of an otherwise large property with numerous gold occurrences and prospects. Recommendations for portions of the Golden Eagle property not part of the 2008 exploration program should be drawn from previous reports, such as Casselman (2007). Recommendations for future work on the central portion of the property and related quartz-sulphide veins are described as follows.

Drilling in 2008 has proved that some of the smallest quartz-arsenopyrite veins (<2 cm) carry significant Au and that searching for areas of increased vein density regardless of vein widths may prove to be a worthwhile endeavour. Further work on the property will need to fully integrate recent data and conclusions into previous work in adjoining areas. The spatial variability in metal content should be explored to determine zonation patterns for use in exploration targeting. In the North Mountain-Middle Ridge-South Mountain area, exploration work has been concentrated near the areas of abundant outcrop which is dominantly alpine and subalpine leaving the intervening glacial valleys underexplored. The distribution of mineralization and veining observed to date indicates that the valley between Middle Ridge and South Mountain, and probably, the larger valley containing Paddy Pass are favourable exploration targets; airborne geophysical data should be re-interpreted in this light, and possibly followed up with ground geophysical surveys. Previous induced polarization (IP) surveys in the Middle Ridge area have concluded that chargeability anomalies do occur over the known veins and that unexplained chargeabilities of interest remain.

The Golden Eagle property on the whole contains many prospective areas for drilling and these should be prioritized once the recommendations described above have been undertaken. The most viable drill target to come out of the surface program is on South Mountain. A cluster of 9 veins is exposed over a ~100x100 metre area, all with approximately the same orientation and all containing significant gold-silver. In addition, there is potential for a “feeder zone” to occur at depth which would be responsible for the tightly clustered veins in this small area with surface samples containing up to 1250 g/t Ag and 7.9 g/t of Au. Initial drilling for this area could involve two holes (from the same setup), one at -45° and another at -60° with azimuth 160° to test the extent and grade of the veins at depth and the extent of the rhyolite at depth.

Respectfully submitted,

Jeremy Major & Justin MacDonald

Logged by: J. MacDonald	**Length (m):** 219.08
Drilled by: Apex	
Assayed by: ALS Chemex	
Core Size: NQ	
Date Started: 2008/07/30 **Date Completed:** 2008/08/02	
Dip Tests By: Reflex	
Objective Test the Boundary Range metamorphics for quartz-arsenopyrite veins along strike from TAN05-03.	

Summary Log:

Alternating lithologies of altered mafic volcanics and plagioclase-phyric intrusions ranging from diorite to granodiorite were encountered. Veining and mineralization is very limited throughout most of the hole with the exception of one zone of significant arsenopyrite replacement mineralization and lesser veining within and immediately below a 70 cm zone of fault gouge.

Project: Golden Eagle

Hole Number: TAN08-05

From **To** **Rocktype** **& Description**

Several very small flecks of Apy, hard to be certain.

148.69 155.88 DTrBR

Mafic volcanic with intense biotite and chlorite alteration throughout. Slight fabric seen in the form of biotite/chlorite banding.Contains several stringers of Po and some disseminated blebs as well. Selectivly sampled for assay.

« po 0.50%»

155.88 156.55 Zfzg

Fault gouge with mafic protolith. Fault gouge marks the start of the mineralized zone and contains Apy.

Mineralization: Disseminated Apy throughout fault gouge and it appears to have been post tectonic as there are small veinlets of Apy that are undisturbed relative to the gouge. Note that the mineralization does not cement the gouge and is fairly sparse. Unit contains 2 % Apy throughout. « as 2.00%»

156.55 158.49 DTrdi

Granodiorite intrusive with Apy mineralization throughout.

Mineralization: Coarse grained Apy is seen in 1-3 cm quartz veins as well as with a replacement texture in the unveined host rock. On the whole, the interval contains 15 % Apy however one interval contains 20 % (see range feature below) Apy and trace Py and Cpy. The is no scorodite present and only minor chlorite on fracture surfaces. Most of the mineralization is replacement rather than blebs or stringers in large quartz veins like the other holes displayed. The sulphides are most intense next to the fault gouge at the top of the mineralized zone and die out downhole.

Hole TAN08-06

Location: 6637037 m North
509375 m East

Logged by: J. MacDonald

Drilled by: Apex

Assayed by: ALS Chemex

Core Size: NQ

Date Started: 2008/08/02

Date Completed: 2008/08/03

Dip Tests By: Reflex

Objective

Test the continuity of mineralization down dip of TAN08-05 and for quartz-arsenopyrite veins along strike from TAN05-03.

Collar Elevation (m): 1269

Azimuth (º): 165

Dip (º): -55.0

Length (m): 109.42

Summary Log:

This hole was abandoned at 109.4 m after the rods became stuck down the hole and attempts to resume drilling after retrieving the rods were unsuccessful. TAN08-07 is a re-drill of this hole.

Downhole surveys:

Date Completed:	2008/08/05		
Dip Tests By:	Reflex		

Objective

Test the continuity of mineralization down dip of TAN08-05 and for quartz-arsenopyrite veins along strike from TAN05-03. This is the second attempt at the hole after TAN08-06 was lost at 109.4 m.

Summary Log:

Chlorite+/-biotite altered, foliated volcanics are intruded by plagioclase-phyric diorites to granodiorites. The mineralization encountered up dip in TAN08-05 is thought to be represented at depth by a narrow zone of disseminated mineralization rather than a competent vein system.

Downhole surveys:

Core Size: NQ	
Date Started: 2008/08/06 **Date Completed:** 2008/08/08	
Dip Tests By: Reflex	
Objective This hole was drilled as an undercut of TAN06-04 to test for quartz-arsenopyrite veins in the rhyolite intrusion.	

Summary Log:

Three zones of quartz-arsenopyrite veining were intersected, from 2-4 m in core length. The upper two intersections occurred within the rhyolite intrusion and the lower intersection lies within a coarse grained biotite granite. The granite is relatively fresh looking with 1-4% sulphide mineralization typically as blebby pyrrhotite with minor associated chalcopyrite.

From	To	Rocktype & Description
85.48	89.43	Qtz Vein

95% of the interval is composed of vein quartz with varying amounts of arsenopyrite; remaining 5% is quartz veined rhyolite or rhyolite fragments. Arsenopyrite shows strong fracture control within the quartz and where abundant results in a dark grey to black appearance to the core. Up to 50% arsenopyrite across 30 cm intervals. Only trace amounts of arsenopyrite across 50cm intervals in the upper part of the section. Rhyolite is pale yellow in colour and silica-sericite altered. Pale to vibrant green unknown mineral on fracture surfaces is typically soft and waxy - possibly scorodite. Also observed in a few places are small clusters of pale green, radiating fibrous crystals believed to be actinolite.

Contacts and an overall weak fabric to the rock are at low angles to the core axis.

Biotite Granite

Medium to coarse grained granite. Sharp contact with the rhyolite at 20-30 degrees to the core axis. Dominantly rusty orange oxidation pervasive throughout the core with lesser fresh looking, grey to pinkish grey colour. Consists of 25-30% quartz, 2-5 mm across; 40% feldspar, subhedral, 3-7 mm in length, partially sericitized (soft, pale green); and 5% biotite, mostly chloritized. Trace amounts of interstitial pyrrhotite and pyrite. Minor vuggy cavities 2-3 mm across possibly from leaching of sulphides.

« 179.53- 196.38 cl 1.00*»« ms 1.00%»« ge 2*»« po 0.10%»« py 0.10%»

From	To	Rocktype & Description

Vein quartz with strong fine-grained arsenopyrite mineralization, results in a dark grey to black colour within the quartz where strongest. May be a component of very fine grained pyrite that is contributing to this appearance. Pale to vibrant green, relatively soft mineral observed to form radiating, fibrous clusters - possibly actinolite.

199.16 225.25 LKg

« 199.16 - 202.44 ms 2.00*» « qz 1.00*»« ge 2.00*»« as 2.00%» « py 1.00%»
Similar mineralogy to the granite above the quartz vein. Contains quartz-chlorite-arsenopyrite-pyrite stringers and thin veins. Also arsenopyrite and pyrite blebs.

200.55m:
30 cm rhyolite dyke (?), fractured and mineralized similar to the surrounding core. Contacts poorly defined due to alteration and fracturing.

« 202.44- 225.25 cl 1.00%» « ms 1.00*» « ge 1.00*» « po 2.00%» « cp 0.20%»
Blebby chlorite up to 1 cm. Weak sericitization of feldspars. Sulphide mineralization occurs as pyrrhotite blebs (replacement of mafics?), with minor chalcopyrite, ranging from 1-4% total sulphide over m scale intervals. Pyrrhotite-chalcopyrite mineralization strongest downhole, in weakly oxidized to non-oxidized core. Rare pyrite and arsenopyrite

DRILL LOG

Project: Golden Eagle	**Collar Elevation (m):** 1283
Hole TAN08-09	**Azimuth (º):** 165
Location: 6637005 m North 509226 m East	**Dip (º):** -60.0
Logged by: J. Major	**Length (m):** 246.58
Drilled by: Apex	
Assayed by: ALS Chemex	
Core Size: NQ	
Date Started: 2008/08/08 **Date Completed:** 2008/08/10	
Dip Tests By: Reflex	
Objective TAN08-09 was drilled at a steeper angle from the same setup as TAN08-08 to test the continuity of quartz-arsenopyrite veins encountered in the rhyolite and granite intrusions.	

Summary Log:

Similar lithology to TAN08-08 with rhyolite in the upper part of the hole in sharp contact with equigranular biotite granite below. Only one notable zone of quartz-arsenopyrite veining was intersected, which may be correlated to the upper intersections in TAN08-08 and TAN06-04 indicating a vein system dipping approximately 85 degrees to the south. A deeper zone of quartz-arsenopyrite stringer and stockwork veining in this hole may be an expression of the larger veins drilled further up dip.

Downhole surveys:

Project: **Golden Eagle** **Hole Number:** **TAN08-09**

From **To** **Rocktype & Description**

quartz-arsenopyrite vein

166.70 **246.58** **LKg**

Sharp upper contact with the rhyolite at 15 degrees to the core axis. Diffuse fragments of what look like granite occur in the rhyolite within 5 cm of the contact. It appears that the rhyolite intrudes the granite.

< @ 166.70 uct 15.00° >

Coarse grained, equigranular quartz, feldspar and biotite. Pinkish grey to greenish grey in colour dependent on amount of iron oxide or chlorite alteration. Weak to moderate alteration of biotite and fracture coatings. Variable pale green sericitization of feldspars.

Disseminated blebs of sulphide occur throughout this unit, typically dominantly pyrrhotite, lesser pyrite, arsenopyrite and chalcopyrite. The sulphides are often present within cm size fine grained chlorite masses. More sporadic types of sulphide mineralization occur within thin quartz veins and stringers, or as fracture coatings.

« cl 2.00*» « ms 1.00*» « ge 0.50*» « po 2.00%» « py 0.50%»

178.29 - 179.11m:

Rhyolite dyke with blebby chlorite, pyrite and arsenopyrite. Pyrite-arsenopyrite fracture coatings. Sharp contacts at 45 and 30 degrees to the core axis with strong chlorite alteration in the granite.

« 180.53- 182.58 qz 1.00*» « as 1.00%» « py 2.00%»

Quartz stringers with pyrite-arsenopyrite 1-2 mm wide, chlorite selvages.

DRILL LOG

Project: Golden Eagle

Hole TAN08-10

Location: 6636928 m North
509241 m East

Logged by: J. MacDonald

Drilled by: Apex

Assayed by: ALS Chemex

Core Size: NQ

Date Started: 2008/08/11 **Date Completed:** 2008/08/13

Dip Tests By: Reflex

Objective

TAN08-10 was drilled from the same site as TAN05-01 to test a greater depth and to step forward from previous drill holes on this section.

Collar Elevation (m): 1333

Azimuth (º): 165

Dip (º): -45.0

Length (m): 237.44

Summary Log:

TAN08-10 intersected mineralization at many intervals, however, only two of these are considered to be significant in terms of the percentage of arsenopyrite observed. There are very few sections in this hole that did not have arsenopyrite, so the mineralization is indeed pervasive, but of low percentage overall. Two main zones of mineralization were intersected, the first was 3.87 m in core length and contained 3% disseminated arsenopyrite and associated scorodite, chalcedony and minor epidote alteration. This zone was hosted in fault breccia and evidence in the form of mineralized fragments/clasts was observed that indicated mineralization pre-dates faulting. Several metres down hole from this fault breccia, a competent 5 m (core length) quartz vein contained an interval with 1.1 m of 2% arsenopyrite. The second mineralized zone consisted of 10.2 m (core length) of 3% arsenopyrite hosted in a brecciated rhyolite. The quartz-arseopyrite veining cements the breccia and the arsenopyrite is finely crystalline to crypto-crystalline in some parts of the unit. Whether this breccia is caused by the vein system or by an earlier brittle fault is difficult to determine from the core.

From	To	Rocktype & Description

Apy possibly remobilized by fault fluids. Unit sampeled entirely.

Mineralization/Alteration:

In the form of finely crystalline Apy hosted in quartz veins and recemented by epidote and chalcedony veining. « as 3.00%» « py 0.01%» « cd 1.00*» « ep 2.00*» « sd 1.00*» « ms 1.00*» « qz 2.00*»

36.57 40.22 LKr Bx

Rhyolite breccia unit, clast supported and derived from brittle faulting. Clasts are up to 40 cm but average 2-4 cm and are angular. Fracture surfaces contain iron staining and minor epidote throughout. Large 3-5 cm epidote lined vugs in fault breccia and several clasts are weakly mineralized.

Mineralization/Alteration:

« ep 1.00*» « as 0.01%» « qz 1.00*»

40.22 45.27 Qtz Vein

Quartz vein with stringers of epidote, chalcedony and minor scorodite. Vein system dies out dh to rhyolite protolith with intense quartz veining. Vuggy porosity throughout and minor brecciation (vein breccia by later chalcedony/epidote veins up to 2 cm that cut qtz/Apy veins).

Mineralization/Alteration: Arseon is fine to meduim crystalline and almost cryptocrystalline in some quartz veins resulting in a dark grey color of the quartz. Chalcedony/epidote veins are narrow and planar to vug filling and blotchey.

Project: Golden Eagle **Hole Number:** TAN08-10

From	To	Rocktype & Description
96.18	98.89	Qtz Vein

Large quartz vein with smaller veinlets towards margins hosted in rhyolite. There is moderate epidote, chalcedony and scorodite alteration throughout and epidote is strongest. Some minor vein brecciation and up hole contact is at 20 deg to ca.

Mineralization/Alteration: Arseno occurs in the main part of the vein As cryptocrystalline to finely crystalline sulphide in the quartz veins resulting in a dark color. Arseno also occurs on the unit boundary (uphole) As vein hosted, coarse crystals up to 5 mm. Epidote fills/lines quartz vugs throughout and is very finely crystalline.

DRILL LOG

Project: Golden Eagle	**Collar Elevation (m):** 1285
Hole TAN08-11	**Azimuth (º):** 165
Location: 6637009 m North 509385 m East	**Dip (º):** -45.0
Logged by: J. MacDonald	**Length (m):** 182.51
Drilled by: Apex	
Assayed by: ALS Chemex	
Core Size: NQ	
Date Started: 2008/08/14 **Date Completed:** 2008/08/16	
Dip Tests By: Reflex	
Objective Test for the up dip continuation of mineralization encountered in the Boundary Range in TAN08-05, and for possible strike length extension of quartz-arsenopyrite veining intersected in the rhyolite in TAN05-02.	

Summary Log:

The dominant lithology is strongly deformed and chlorite+/-biotite altered mafic volcanics cut by non-deformed diorite to granodiorite dykes, with later brittle faulting. A narrow zone with strong patches of arsenopyrite replacment 10-30 cm wide may correspond to the mineralized intersection in TAN08-05.

Downhole surveys:

Overburden

6.71 18.47 DTrBR

Highly altered mafic volcanic. Medium grey/green in color due to intense chlortie and biotite alteration. Minor quartz/carbonate veining which is barren. Moderatly fractured and there is a strong foliation (S1) which is defined by chlorite and biotite +/- quartz but is ranodomly oriented due to secondary deformation folding it (S2).

Alteration:

« cl 3.00*» « bi 2.00*» « qz 1.00*» « ca 1.00*»

18.47 35.63 Zfzg

Large fault zone with breccia and gouge throughout. No orientation available in core. Intense chlorite alteration and moderate quartz/carbonate veining. Veins up to 15 cm contain chlorite/quartz but no sulphides.

Alteration:

« qz 1.00*» « cl 3.00*» « ca 1.00*»

35.63 133.32 DTrBR

Mafic volcanic with intense alteration. Color ranges from light brown (in biotite rich sections) to dark green (in chlorite rich sections) to brown/green stripes (both biotite and chlorite). Strong foliation defoined by the alteration minerals forming bands that define a S1 foliation that is folded by F2 open to tight folds. Fold axis vary throughout as do S1 orientations. Significant quartz veining throughout (5 % of unit overall) and are up to 20 cm

From **To** **Rocktype** **& Description**

133.32 135.00 Zfzg

Fault gouge/breccia with a protolith of both altered mafic volcanic and granodiorite. Appears as though the contact was faulted and the granodiorite may be in fault contact with the mafic volcanic rather than intruded.

Mineralization: Scattered arsenopyrite and pyrite/pyrrhotite stringers throughout the fault gouge/breccia. It forms competent veinlets indicating the mineralization was post faulting.

« as 2.00%» « ca 1.00*» « py 0.01%» « po 0.01%»

135.00 141.27 DTrdi

Medium crystalline plagioclase porphyritic diorite, light grey in color. Contains biotite crystals up to 4 mm. Highly fractured with moderate carbonate veinlets filling the fractures. Minor pyrite in calcite veinlets throughout.

Mineralization:< @ 136.80 as 0.01% >
« 135.00- 141.27 py 0.01%»

141.27 143.15 DTrBR

Mafic volcanic lens bounded by diorite on both sides. Strong chlorite alteration and minor biotite. Some calcite veining.

Project: Golden Eagle	**Collar Elevation (m):** 1303
Hole TAN08-12	**Azimuth (º):** 135
Location: 6636975 m North 509422 m East	**Dip (º):** -45.0
Logged by: J. Major	**Length (m):** 66.75
Drilled by: Apex	
Assayed by: ALS Chemex	
Core Size: NQ	
Date Started: 2008/08/17 **Date Completed:** 2008/08/18	
Dip Tests By: Reflex	
Objective Drill across the prominent gully 30 m to the southeast containing a quartz-arsenopyrite vein along the gully margin.	

Summary Log:

Persistently chlorite-silica-biotite altered volcanics occur throughout the hole with localized concentrations of pyrrhotite, pyrite and traces of chalcopyrite. There are two intersections containing significant arsenopyrite. The first intersection consists of 20 cm of semi-massive replacement by pyrrhotite-arsenopyrite. The second intersection is a 1.7 m fault zone containing fault gouge and altered volcanics with semi-massive arsenopyrite across 30 cm. Correlation with the gully on surface indicates a subvertical fault.

Downhole surveys:

			Overburden
1.52	38.54	DTrBR	

Chlorite-biotite+/-silica and sericite altered mafiv volcanics. Pervasive wavy foliation, locally defined by banded chlorite and biotite rich layers. Flood silica is often intergrown with the chlorite. Where foliation is weak to nonexistent the chlorite+/-silica looks like it is overprinting the brown biotite alteration. Plagioclase phenocrysts 1-2 mm are present across m scale zones with a weak foliation. Localized quartz boudins <2 cm wide and deformed quartz veins. Patchy muscovite/sericite alteration.

Variable mineralization across intervals less than 1m with localized concentrations of disseminated to blebby, magnetic pyrrhotite with occasional pyrite and traces of chalcopyrite. Rare patches of disseminated blebs of fine grained magnetite in the upper part of the hole. Sampled intermittently to test zones of increased mineralizaton.

« 1.52- 38.54 cl 2.00*» « si 2.00*» « bi 1.50*» « ms 1.50*» « qz 1.00*»

Dip Tests By: Reflex	
Objective Drilled from the same setup as TAN08-12 to test for quartz-arsenopyrite veins in the Boundary Range as mapped on surface and to test the continuity of the mineralized fault zone.	

Summary Log:

Chlorite-biotite-silica altered metavolcanics with minor pyrrhotite, pyrite and trace chalcopyrite similar to TAN08-12. There were two intersections with mineralized fault zones in this hole, 40 cm and 1.84 cm in core length. The lower intersection is believed to correspond to the fault intersected in TAN08-12.

Downhole surveys:

Overburden

1.52 43.29 DTrBR

Altered mafic volcanics. Dominantly intergrown silica-chlorite alteration that results in a dark greenish-grey overall appearance. Brown biotite alteration also present as alternating layers with chlorite in the foliation or as patchy alteration. Plagioclase-phyric layers 1-2 m wide occur in the upper part of the unit. Weakly to moderately foliated, inconsistent orientation due to later folding. Thin quartz veins mostly parallel to foliation and larger fragments and boudins.

Variable sulphide content, dominantly pyrrhotite wtih lesser pyrite and chalcopyrite disseminations, patchy replacement, and stringer veins.

DRILL LOG

Project: Golden Eagle	**Collar Elevation (m):** 1233
Hole TAN08-14	**Azimuth (º):** 165
Location: 6637074 m North 509361 m East	**Dip (º):** -60.0
Logged by: J. Major	**Length (m):** 179.53
Drilled by: Apex	
Assayed by: ALS Chemex	
Core Size: NQ	
Date Started: 2008/08/19 **Date Completed:** 2008/08/21	
Dip Tests By: Reflex	
Objective Test for near surface mineralization in the Boundary Range between this location and TAN08-07, as well as for the continuation of narrow replacement arsenopyrite intervals.	

Summary Log:

This hole was entirely in variably deformed, chlorite+/-biotite altered volcanics of the Boundary Range metamorphic suite. No significant arsenopyrite mineralization was encountered, however, variable pyrrhotite-pyrite-chalcopyrite disseminations and minor stringers occurred throughout the hole.

Downhole surveys:

Overburden

From	To	Rocktype & Description
1.52	68.86	DTrBR

Moderate to strongly biotite-chlorite altered mafic volcanics. Alternating biotite-chlorite layers where foliated, patchy intergrowth elsewhere. The foliation angle is inconsistent due to later open and tight folding. Localized silica flooding with chlorite lending the green colouration. Localized rounded cm-size patches of epidote-calcite alteration. Vein quartz present throughout, mostly non-planar with irregular boundaries, containing clasts of host rock, or fractured with chlorite infill - probably pre-dates second generation or later deformation events. Quartz boudinage well displayed locally. The quartz is not mineralized, but does rarely contain magnetite within chloritic fragments and selvages. Variable sulphide mineralization is generally weak overall but does include stronger intervals of pyrrhotite, pyrite and chalcopyrite.

« bi 2.00*» « cl 2.00*» « si 1.00*» « qz 1.00*» « ep 0.50*» « ca 1.00*» « po 0.50%»

DRILL LOG

Project: Golden Eagle	**Collar Elevation (m):** 1233
Hole TAN08-15	**Azimuth (º):** 165
Location: 6637063 m North 509287 m East	**Dip (º):** -55.0
Logged by: H. Awmack	**Length (m):** 258.78
Drilled by: Apex	
Assayed by: ALS Chemex	
Core Size: NQ	
Date Started: 2008/08/22 **Date Completed:** 2008/08/24	
Dip Tests By: Reflex	
Objective This hole was drilled to undercut TAN05-03 which intersected 3 gold bearing zones.	

Summary Log:

The entire hole was within the rhyolite intrusion and only intersected one mineralized zone with multiple quartz-arsenopyrite veins over 4.8 m core length, probably corresponding to the lowest intersection in TAN05-03. Minor disseminated and fracture-controlled arsenopyrite extends for 18.6 m core length above the vein zone.

Downhole surveys:

Overburden

From	To	Rocktype	& Description
1.52	223.60	LKr	

Rhyolite: pale blue-grey where unoxidized and cream-coloured where oxidized. 5% 0.5 mm muscovite clots, generally altered to pale green mica (sericitized?) and 2% 2mm euhedral quartz phenocrysts, in aphanitic silicious matrix. 2% unaltered to weakly chloritized biotite clots locally (e.g. 73.0-88.3m). Massive (no preferential alignment of phenocrysts) and unfoliated. Non-magnetic, non-calcareous. Oxidized and goethitic along fractures down to 151.05; pervasive goethitic patches extending away from fractures. Below 151.05, these fractures are unweathered, coated with a soft, pale yellow-green, waxy, transarent mineral (sericite?), black chlorite and pyrite cubes.

1.52-151.05: « ms 1.00*» pale green mica replacing muscovite clots

1.52-41.9: 1-2% 0.5-3mm dark grey planar quartz veinlets (2-5% from 19.9-35.9m) , generally at 40 degrees to core axis. Goethitic where oxidized, but only rare clusters of pyrite and no other sulphides.

< @ 225.15 lct -25.00°0° > 10 mm aspy

225.15 258.78 LKr

Rhyolite: Medium grey. Porphyritic with 2% pale green (sericitized) 1-3 mm muscovite clots, 1% 2-4 mm quartz phenocrysts, 0-2% (generally unaltered) 1-3 mm biotite clots and local pinkish 2-5 mm anhedral feldspar phenos in an aphanitic, fairly hard matrix. Non-magnetic, non-calcareous.

The rhyolite is commonly disrupted (brecciated locally); mm or cm-scale movement along fractures has created 5-15% voids. Some, but not many, of the voids containing yellow clay. It appears that the disruption occurred after the rhyolite had solidified (allowing brittle breakage) but still hot enough to weld together. This may be the rhyolite breccia in 2005 drill logs? The most developed sections are 228.3-229.9 and 237.2-243.5.

DRILL LOG

Project: Golden Eagle	**Collar Elevation (m):** 1297
Hole TAN08-16	**Azimuth (º):** 165
Location: 6636956 m North 509178 m East	**Dip (º):** -45.0
Logged by: J. Major	**Length (m):** 279.50
Drilled by: Apex	
Assayed by: ALS Chemex	
Core Size: NQ	
Date Started: 2008/08/24 **Date Completed:** 2008/08/26	
Dip Tests By: Reflex	
Objective Drill the quartz-arsenopyrite veins mapped on surface and test for the along strike continuation of veins intersected in the line of holes 60 m to the east.	

Summary Log:

Four mineralized intervals of quartz-arsenopyrite veins were intersected within both rhyolite and biotite granite, including at the contact between the two rock types. Two of the intersections correlate with veins that occur in holes to the east.

Downhole surveys:

Overburden

1.52 10.24 LKr

Rhyolite

2% quartz eyes <2 mm wide, 5-10% biotite and muscovite (sericitized?) phenocrysts. Pervasive orange goethite staining and fracture coatings. Trace disseminated arsenopyrite, locally altered to scorodite.

« ge 2.00*» « sr 0.5*»

< @ 8.68 fra > Pale green to yellowish green scorodite on fracture surface.

10.24 13.89 LKr

Quartz-veined Rhyolite

Non-minerazed planar quartz veins 1-10 mm in width, sub-parallel (sheeted?) at 30-50 degrees to the core axis. Veins have mm scale offsets along limonite cemented fractures. Trace amounts of blebby arsenopyrite along fractures.

« ge 2.00*» « qz 1.50*» « as 0.01%»

< @ 12.04 ven 25.00º 1.00-7.00mm >

Later arsenopyrite mineralization along a fracture at 25 degrees TCA that penetrates a 3-10 mm wide quartz vein at 30 degrees TCA.

13.89 18.08 Qtz Vein

Mixed quartz+/-arsenopyrite veins and altered rhyolite. Quartz comprises approximately 35% of the interval. Quartz-arsenopyrite veins range from 1 mm wide to 60 cm in core length. Also present are non-mineralized quartz veins <1 cm wide at moderate angles to the core axis (~50 degrees). Pale yellow-green pervasive sericite alteration of the rhyolite. Scorodite present along fractures and vein margins.

59.00 64.00 LKr Bx

< @ 59.00 uct 55° >
Sharp planar contact between the breccia and the overlying fractured rhyolite.

Textures range from:
1) jigsaw fit breccia of angular rhyolite clasts in a high density of cemented fractures and microfaults.
2) Fine grained granular texture with significant milling of rhyolite fragments resulting in a gradational size range of clasts to as small as 1 mm. Clasts are subrounded to rounded where there has been the greatest reduction in clast size.

Locally abundant vugs and void spaces. Matrix composed of silica and iron oxide (rusty orange goethite). Rare brecciated quartz veins observed.

Scorodite and blebby arsenopyrite both within clasts and matrix concentrated in the upper 40 cm, traces elsewhere.

Non-planar, sharp lower contact.

64.00 114.66 LKr

Rhyolite

Beige to pale greenish grey where not oxidized. Rusty orange goethite along fractures and locally pervasive through the core. Relatively fresh to chloritized biotite phenocrysts contrast with pale green sericite phenocrysts, possibly after primary muscovite. Pink to grey coloured 'banding' (surrounding microfractures?) and alteration envelopes to quartz veins at times appear like k-spar alteration but may instead be iron-oxide stained silica alteration. Minor quartz veining, mostly not mineralized. Localized arsenopyrite+/-pyrite blebs and stringer veins except where noted below. Submettalic grey manganese oxides blebs on fractures.

« 64.00- 114.66 ge 2.00*» « cl 0.50*» « ms 1.00*» « qz 0.50*» « as 0.10%» « py 0.01%»

« 78.33- 85.21 as 1.00-2.00%» « qz 2.00*»
Weak to moderate quartz-arsenopyrite veining. Veins are 1-10 mm wide, undulating and branching at low to moderate angles to the core axis. The most prominent veins are 0-30 degrees to the core axis, with smaller veins up to 50 degrees, resulting in cross-cutting relationships. Some veins have vuggy cavities with yellow-green scorodite. One of the larger veins has diffuse, non-planar boundaries and appears as if it was emplaced before the rhyolite was fully cooled and solidified.

Pink margins 5-10 mm wide to the larger veins look like possible k-spar alteration, as well as mm-scale pink 'stringers' throughout the core described previously.

Project: Golden Eagle **Hole Number:** TAN08-16

From	To	Rocktype	& Description
114.66	126.50	LKr Bx	

< @ 114.66 uct 35° >

Sharp upper contact between solid rhyolite above and brecciated rhyolite. Degree of brecciation varies from jigsaw fit to 1-2 m zones of subangular to subrounded mm size clasts in a vuggy, oxidized matrix. In some cases strong alteration by silica, sericite (+clay?), and iron oxides results in a brecciated appearance but it is uncertain as to what extent.

Aresnopyrite mineralization is concentrated in ~1 m intervals, along with scorodite. Faulted quartz-arsenopyrite vein fragments indicate mineralization pre-dates, or is synchronous with brecciation. One locality of dark grey arsenopyrite-pyrite matrix to angular rhyolite fragments is syn-brecciation or possibly late replacement.

« si 2.00*» « ge 2.50*» « ms 1.00*» « qz 1.50*» « as 1.00-2.00%» « py 0.50%»

The contact between the brecciated rhyolite and the underlying granite can not be pinpointed due to brecciation, alteration and mineralization. Small, altered rhyolite fragments (<5 mm) are difficult to distinguish from quartz phenocrysts in the granite. The lower contact is marked at a discrete fault above a zone of

« 188.74- 209.65 cy 2.00*» « cl 2.00*» « py 1.00%» « as 0.10%»
Vuggy cavities formed by weathering out of clay altered feldspar and chloritized biotite. Pyrrhotite present elsewhere in the granite has probably also been leached away. Fractured, rubbly core in places. Minor wavy to anastamosing dark grey stringers of very fine grained pyrite and trace arsenopyrite. Weak disseminated pyrite.

< @ 200.42 ven 30.00º 10.00-15.00mm >
Dark grey quartz-pyrite vein with lesser arsenopyrite. Pyritic stringers below.

« 209.65- 236.83 ms 0.50*» « cl 1.00*» « po 2.00%» « py 0.50%» « cp 0.01%»
Relatively fresh granite with disseminated blebs of pyrrhotite, lesser pyrite and chalcopyrite. At times it looks like the pyrrhotite is replacing the coarse biotite crystals.

« 226.06- 226.79 LKr »
Beige-pink rhyolite with quartz and feldspar phenocrysts and chlorite-pyrite blebs. Wavy, diffuse (fuzzy) boundary looks like the rhyolite may have intruded the granite before the granite was fully cooled. Lack of pyrrhotite mineralization in rhyolite compared to the surrounding granite may also support the rhyolite being later than the granite, however it could also be due to properties of the rhyolite (chemistry, porosity).

The granite 10 cm above and 50 cm below the rhyolite has a fine grained groundmass with quartz, feldpsar and biotite phenocrysts potentially representing a chilled margin which would suggest the rhyolite is a large xenolith.

From	To	Rocktype	& Description
236.83	247.49	LKg	

Biotite-Feldspar-Quartz Porphyry

Similar composition as the granite but texturally it is a biotite-feldspar-quartz porphyry in a grey silicious groundmass, possibly a separate stock from the granite. Contacts with the equigranular granite are broken and rubbly, but there is some evidence for a relatively sharp, well defined contact. The porphyry contains disseminated pyrrhotite and trace chalcopyrite similar to the granite.

« cl 1.00*» « po 1.00%» « cp 0.01%»

Beige-pink 'rhyolite' segments 5 - 70 cm wide are present in the upper part of this interval. They contain minor quartz and feldspar phenocrysts, with mm size chloritized biotite. Similar diffuse contacts as noted in the possible rhyolite dyke at 226 m. These intervals could be due to intense k-spar alteration rather than dyking, which is supported by 2-5 cm patches with a gradational change in colour and decreasing visible phenocrysts (Obscured by alteration?).

247.49	279.50	LKg	

Biotite Granite

Relatively unaltered, similar composition to previous granite. Minor chloritized fractures, white clay alteration of feldspars (kaolinite after plagioclase?), and weak calcite veining. Weak but consistent disseminated pyrite, trace chalcopyrite.

« cl 0.50*» « cy 0.50*» « ca 0.50*» « py 1.00%» « cp 0.01%»

CONDITIONS AND DISCLAIMER

This report is issued subject to the following conditions:

This report has been prepared on the basis of information as described in section 1 below. Other than as specifically noted in this report, Mineral Services Canada (MSC) has not conducted any work to verify the source, accuracy or completeness of information provided, and is not responsible for any shortcomings in these regards.

Discussions, conclusions and / or summaries are presented to assist the reader in highlighting key points; however they cannot be interpreted in isolation and must be considered with reference to and in the context of the body of the report.

Any reports, maps, graphs, logs or other information of a geological nature or otherwise, generated by MSC and contained in this report or submitted separately ("the information"), may be used for general information purposes only by the Client to whom the information is addressed. For other uses of the information, such as public disclosure, press releases, regulatory requirements, share exchange, financing and so forth, permission must first be obtained in writing from MSC.

Any quotations, excerpts and references from the report must be made in such a manner that their meaning and intent are not materially changed from the meaning and intent as contained in the report.

MSC will not be held liable for loss or damages resulting from work undertaken or reported in terms of this assignment, or decisions taken on the basis of such work and / or reporting.

PETROGRAPHY AND SEM ANALYSES OF EIGHT ROCK SAMPLES FROM THE GOLDEN EAGLE PROSPECT (B.C.)

1. INTRODUCTION

This report presents the results of petrographic and SEM analyses of eight samples received from Jeremy Major of Equity Exploration Consultants Ltd. Hand samples, polished thin sections and offcuts unstained for K-feldspar were submitted with brief descriptions of the samples.

The aim of the study was to characterize the mineralogy of the samples, focusing on lithology, alteration and mineralization. The SEM analyses were performed in agreement with the client to confirm the identity of uncommon mineral phases for which optical properties are not described in the literature.

2. METHODS

2.1 PETROGRAPHY

Petrographic descriptions were performed in the office of Mineral Services Canada Inc. using a Nikon eclipse E400 microscope equipped with transmitted and reflected light. Optical sample descriptions with representative photomicrographs are presented in Appendices 1 and 2. Hand sample and offcut descriptions are presented in Appendix 3. All modal abundance percentages are approximate.

2.2 SEM ANALYSES

Locations of interest were chosen by the author on four selected thin sections that were then coated using an Edwards 306A vacuum carbon coater to ensure good electrical conductivity and low background signal during SEM analyses.

SEM analyses were undertaken by the author using the scanning electron microscope at the Earth and Ocean Sciences Department of the University of British Columbia. The SEM is a Philips XL30 electron microscope with Princeton Gamma-Tech energy-dispersive X-ray spectrometer and image analysis systems. It is capable of processing various signals (secondary electrons, back scattered electrons) allowing for the examination and digital imaging of minerals and materials at both low and high magnifications, as well as qualitative and semi-quantitative energy-dispersive chemical analysis of minerals. The detection limit of the SEM-EDS semi-quantitative analyses is estimated to be 0.4-0.5 wt%.

3. VEIN SAMPLES

Five of the samples represent vein samples: samples C287345, G0672135, C202147 and C201124 are from quartz veins and sample C287113 is from a massive arsenopyrite (-quartz) vein.

3.1. Quartz vein samples

Quartz is typically fine- to medium-grained and strongly internally deformed as a result of dynamic recrystallization processes, displaying undulose extinction, subgrains and strongly lobate grain boundaries. Recrystallized quartz is variably present: it is rare in sample C202147 and occurs in similar amounts to deformed grains in sample C287345, forming common core-and-mantle textures. The wall rock of the vein is represented in one sample only (sample G0672135, Appendix A1.2) where it is interpreted as a volcanic breccia (possible rhyolite breccia).

Minor sulphides (<3 %) occur in the quartz vein samples. They consist predominantly of arsenopyrite, which in three samples (G0672135, C202147 and C201124, Appendices A1.2 to A1.4) is associated with minor galena, pyrite, chalcopyrite or molybdenite. Sulphides form small grains and clusters interstitial to quartz, locally lining quartz grain boundaries (Figure 2), or occur as very thin discontinuous veinlets associated with sericite.

Alteration is limited to the sporadic occurrence of disseminated sheaves of sericite (± epidote ± titanite ± carbonate) and to oxidation that is marked by: 1) a reddish stain on sericite and other gangue minerals and 2) the replacement of sulphides by various oxides, hydroxides and possible arsenates (scorodite). Sulphide oxidation products are very fine-grained and commonly intermixed or occur in successive rims (Figure 7). This precludes definitive identification, even with the semi-quantitative results of SEM-EDS analyses.

Alteration of arsenopyrite varies from the development of possible scorodite rims (+ jarosite in sample C287345) to the development of subhedral scorodite pseudomorphs and subhedral leached cavities preserving patchy possible scorodite ± covellite (Figure 4). Pyrite is variably rimmed by Fe-oxides/hydroxides. Chalcopyrite is locally rimmed by covellite or by various (Pb, Fe)-oxides when associated with galena and molybdenite, which are variably altered to (Pb, Mo)-oxides/hydroxides. Silver commonly occurs in (Pb, Mo)-oxides/hydroxides, suggesting galena is argentiferous (Figure 9).

Rare variably leached veinlets and cavities, containing dark reddish undetermined oxides/hydroxides associated with sporadic malachite, colourless carbonate or sericite, occur in most samples.

3.2. Arsenopyrite (-quartz) vein sample

Heavily fractured semi-massive arsenopyrite occurs with minor pyrite and chalcopyrite filling the arsenopyrite fractures (Appendix A1.5). Enargite and electrum (SEM-confirmed) form small inclusions in arsenopyrite. Electrum inclusions are typically less than 20 µm in size (Figures 12 and 13). Arsenopyrite is variably altered, locally forming corroded and oxidized masses (SEM confirmed). Elongated, fibrous-looking possible scorodite partially fills and lines cracks in arsenopyrite, commonly enclosing partially preserved arsenopyrite grains and masses of dark, partially leached unresolvable possible clay. Anhedral fine-grained quartz commonly occurs interstitial to sulphides.

4. IGNEOUS SAMPLES

4.1. Lithology

The igneous samples submitted are interpreted as brecciated feldspar porphyry (sample C287261, Appendix A2.1), K-feldspar phyric granite (sample G0672501, Appendix A2,2) and plagioclase porphyry (sample G0672502, Appendix A2.3).

Sample C287261 is the most altered of the igneous samples, only locally preserving partial plagioclase and less common, finer-grained K-feldspar phenocrysts in pervasively altered groundmass. The sample displays a vague possible clastic texture marked by the concentration of arsenopyrite and coarser-grained quartz in ribbons around porphyritic clusters (Figure 18).

The granitic sample G0672501 is characterized by a very low mafic mineral content and minor to trace biotite and spessartine. The fine-grained, anhedral granular texture is made up of quartz, K-feldspar, plagioclase and lesser muscovite with coarser-grained K-feldspar occurring throughout. The sample is therefore classified as K-feldspar phyric granite, but the low mafic mineral content and the presence of spessartine suggest the sample could be aplite. This requires confirmation with field observations.

Sample G0672502 consists of coarse-grained plagioclase phenocrysts in a fine-grained groundmass of quartz, tabular plagioclase and possible minor K-feldspar. No primary mafic phase was observed due to alteration but sub- to euhedral arsenopyrite is disseminated throughout. Alteration is too advanced to reliably identify other primary mineral phases for more specific lithology characterization (Figure 23).

4.2. Alteration

The type and degree of alteration varies throughout the samples.

Sample C287261 is pervasively altered by quartz, sericite and trace kaolinite with sericite itself locally overprinted by clay (Figure 18). A later calcite alteration phase is noted both by disseminated grains and subparallel veinlets cross-cutting the sample.

The granitic sample G0672501 is weakly altered. Alteration is marked by the local replacement of feldspars by secondary K-feldspar and / or sericite, by the local alteration of muscovite by sericite and by the presence of rare oxidation patches and oxidized cracks (Figures 19 and 21).

Sample G0672502 is selectively altered, with most of the groundmass replaced by very fine-grained shreddy biotite (commonly overprinted by chlorite). The primary porphyritic texture of the sample is well preserved. No primary mafic phase was observed, but granular anhedral titanite and anhedral poikilitic magnetite occurs throughout, suggesting replacement of earlier mafic phases (Figure 23).

4.3. Mineralization

Arsenopyrite is the only sulphide occurring in the samples.

In samples G0672501 and G0672502, arsenopyrite occurs disseminated (Figures 20 and 24) as euhedral (to subhedral in sample G0672502) grains that constitute approximately 5% of the intrusive rock in sample G0672502 and less than 1% in sample G0672501. Oxidized microveinlets and yellowish oxidation patches additionally occur in sample G0672501. SEM analyses show that these consist of arsenic- and / or antimony-bearing oxides / hydroxides. Neither scheelite nor powellite were observed in the samples.

Arsenopyrite is more common in sample C287261 (Figure 18). It makes up approximately 15 % of the sample and occurs as small sub- to euhedral crystals associated with quartz in vaguely defined ribbons, suggesting quartz-arsenopyrite fracture infill after brecciation.

5. SUMMARY AND CONCLUSION

- This report presents the results of petrographic and SEM analysis of eight samples from the Golden Eagle Project in British Columbia. The SEM analyses were performed to determine the identity and composition of certain optically unidentified mineral phases.
- The sample suite submitted consists of two sample sets: vein samples and igneous samples.
- Four of the samples are quartz vein samples (C287345, G0672135, C202147 and C201124) and one (C287113) is a massive arsenopyrite-quartz vein sample.
- Alteration in the quartz vein samples is limited to the sporadic occurrence of disseminated sheaves of sericite (± epidote ± titanite ± carbonate). Mineralization is weak and occurs in the form of small interstitial grains and clusters of arsenopyrite and minor associated pyrite, chalcopyrite, galena (possibly argentiferous) and molybdenite.
- Arsenopyrite in sample C287113 contains numerous small (< 20 microns) electrum inclusions. Enargite, pyrite and chalcopyrite also occur.
- Three of the samples are classified as igneous rocks: sample C287261 is classified as (brecciated) feldspar porphyry, sample G0672502 as plagioclase porphyry and sample G0672501 as K-feldspar phyric granite (possible aplite?). All samples are mineralized with arsenopyrite being the only sulphide.
- Oxidation of the sulphides is common in most samples and marked by the presence of oxides / hydroxides that are variably iron-, lead-, molybdenum-, arsenic- or antimony-bearing. Scorodite, wulfenite, mimetite and malachite were also observed throughout.
- Sulphide oxidation products are very fine-grained and commonly intermixed or occur in successive rims, precluding definitive identification. Comprehensive SEM-EDS analyses are recommended for more complete characterization of the oxides/hydroxides, arsenates and sulphides present in the samples.

Report reviewed by:
Tom Nowicki, Ph. D., P. Geo.

APPENDIX 1: DESCRIPTION OF VEIN SAMPLES

A1.1: **Thin section description, modal composition and photomicrographs of sample C287345**

LITHOLOGY:	Quartz vein
ALTERATION TYPE:	Sericite, oxidation

Thin section description:

This quartz vein sample consists of coarse-grained, internally deformed quartz and granular aggregates of finer-grained, recrystallized quartz grains. Deformed and recrystallized grains are present in similar amounts and locally display core-and-mantle structures. Alteration occurs as rare ribbons of sericite. Very fine-grained arsenopyrite is disseminated or locally occurs as fracture infill. It is variably sub- to euhedral and unaltered or forms small anhedral grains with coronas of possible scorodite that preserve the subhedral outlines of the original arsenopyrite. Clusters of subhedral grains of possible scorodite and jarosite (likely pseudomorphing arsenopyrite) also occur throughout defining thin veinlets .

MAJOR MINERALS

Mineral	**%**	**Distribution & Characteristics**
Quartz	90	Two types occur in similar proportions: 1) Fine- to medium-grained, anhedral to elongated, displaying subgrains, undulose extinction and irregular grain boundaries 2) Very fine-grained to microcrystalline, likely recrystallized from coarser-grained type 1 quartz

MINOR MINERALS

Mineral	**%**	**Distribution & Characteristics**
Scorodite	3	Disseminated microcrystalline clusters and rims around arsenopyrite, commonly with subhedral to euhedral outlines, variably associated with jarosite
Arsenopyrite	2	Disseminated or along cracks, occurs as small sub- to euhedral unaltered grains or as small anhedral partial grains rimmed by microcrystalline granular clusters of possible scorodite (± jarosite) that preserve the sub- to euhedral outline of the original arsenopyrite grains
Sericite	1	Rare clusters of sheaves throughout
Jarosite	tr	Disseminated granular clusters, commonly associated with possible scorodite

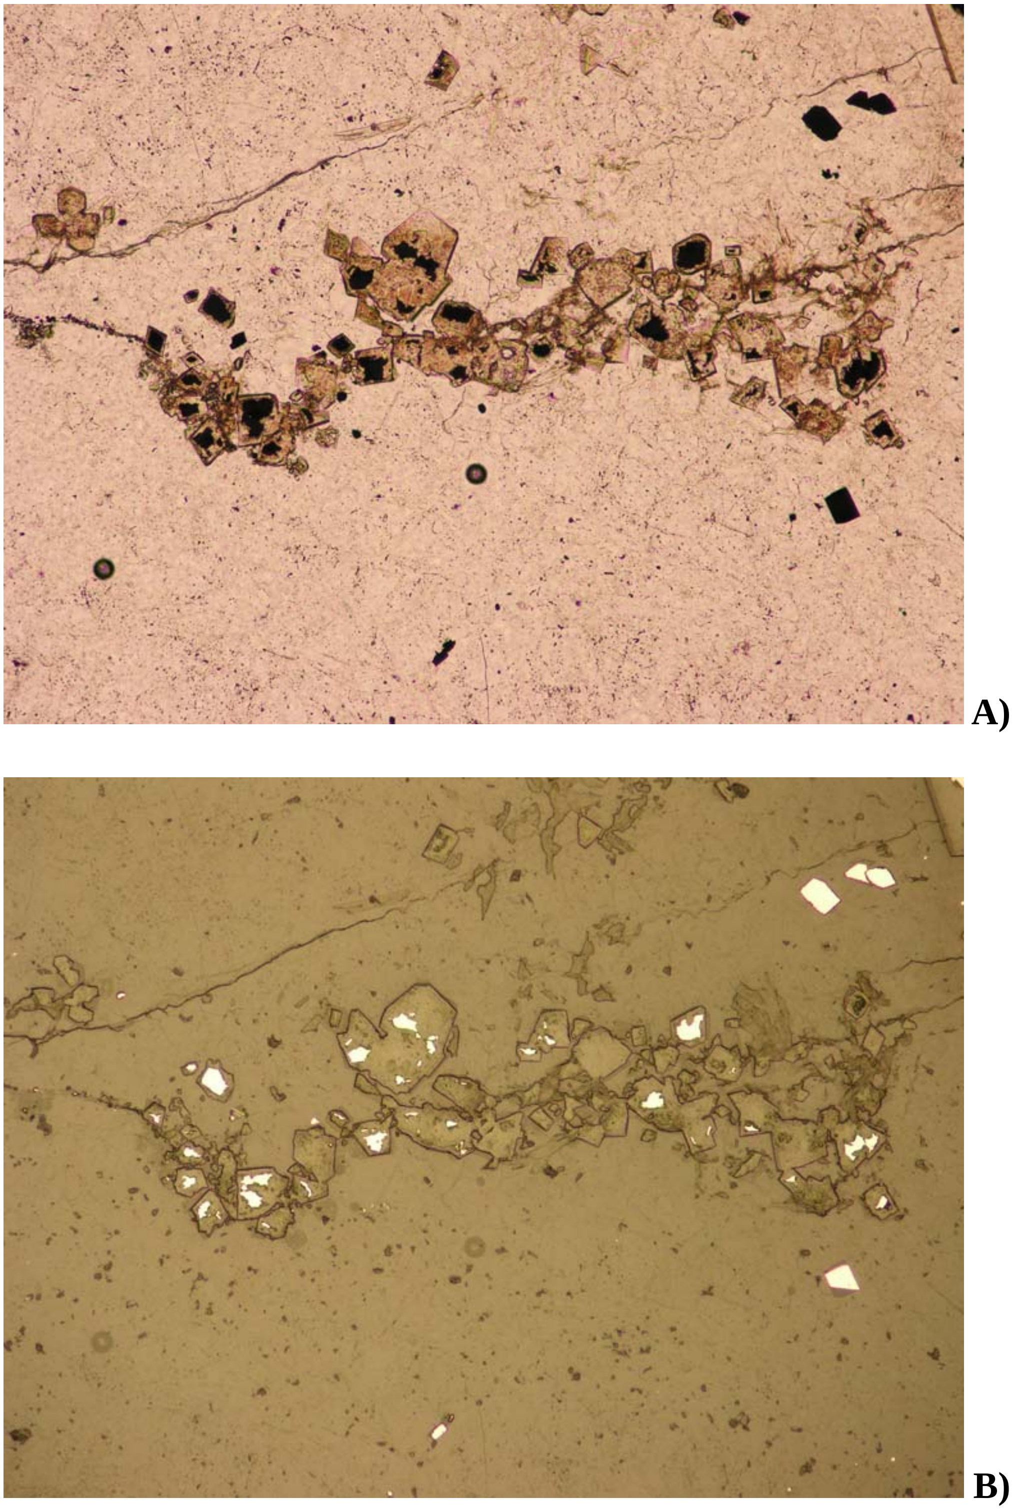

***Figure 1**: Photomicrograph of sample C287345 showing clusters of arsenopyrite lining very thin cracks in the quartz vein. Partially preserved arsenopyrite grains are rimmed by high relief, yellowish clusters of possible scorodite that preserve the subhedral outline of the original arsenopyrite grains. A) PPL, B) RL, = ~ 1.4 mm.*

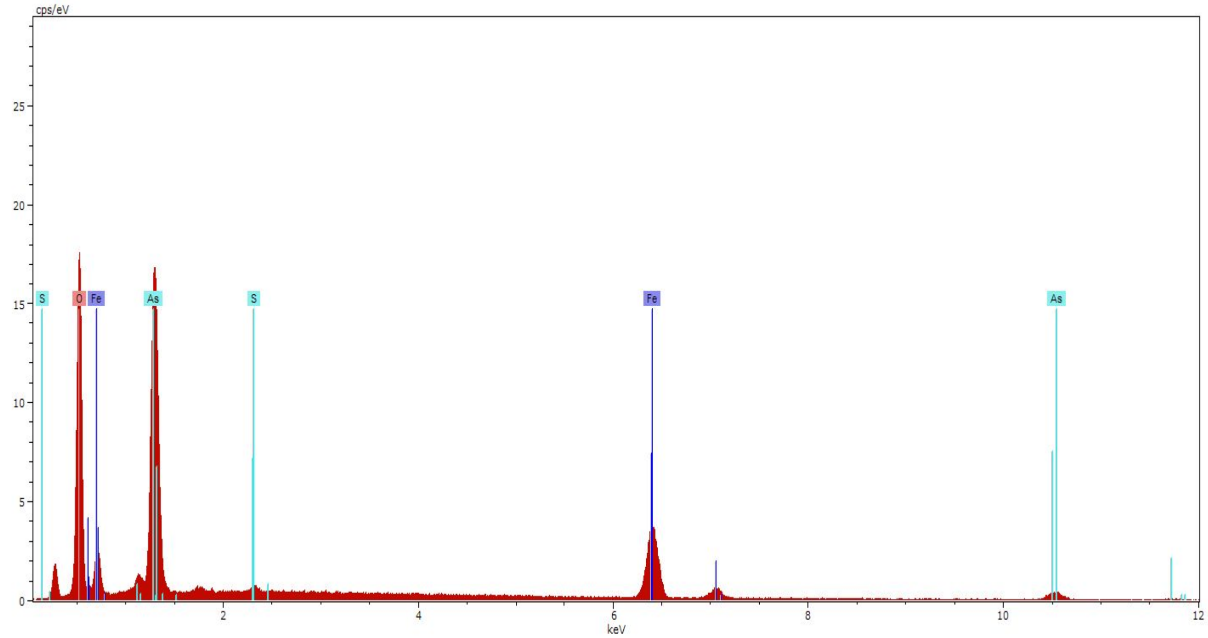

***Figure 2**: SEM-EDS spectrum obtained on a rim around arsenopyrite, showing it consists mostly of arsenic, iron and oxygen and is thus possible scorodite. Sulphur also occurs in small amounts.*

A1.2: **Thin section description, modal composition and photomicrographs of sample G0672135**

LITHOLOGY:	Quartz vein and volcanic breccia host rock
ALTERATION TYPE:	Sericite, oxidation

Thin section description:

The sample includes part of a wide quartz vein and its brecciated host rock.

Quartz in the vein is fine- to medium-grained, internally deformed and locally recrystallized to a much finer grain size. Sub- to euhedral arsenopyrite, chalcopyrite and pyrite are disseminated along quartz grain boundaries and occur in partially filled vugs variably associated with sericite. Galena occurs interstitial to quartz and sulphides or intergrown with sulphides. Oxidation is marked by the presence of altered and corroded arsenopyrite and more commonly by partially leached subhedral vugs and veinlets containing possible scorodite ± covellite.

The breccia hosting the quartz vein is clast-supported and consists of small sub-angular clasts made up of quartz crystals, quartz vein fragments and sericitized and silicified fragments. The interclast matrix is essentially made up of cryptocrystalline material (possible smectite/chlorite after devitrified volcanic glass) that is partially leached and locally associated with possible scorodite.

MAJOR MINERALS

Mineral	%	Distribution & Characteristics
Quartz	75	1) In the vein: fine- to medium-grained, anhedral to elongated with undulose extinction, subgrains and bulging grain boundaries; also as clusters of very small recrystallized grains 2) In the breccia host rock: fine-grained to microcrystalline, forming the groundmass of most clasts
Devitrified volcanic glass	10	Yellowish to brown, cryptocrystalline, forming interclast matrix in the host breccia, associated with sericite and possible scorodite
Sericite	5	Colourless to brown sheaves, occurring in vugs in the quartz vein and with clay in the interclast matrix of the host breccia

MINOR MINERALS

Mineral	%	Distribution & Characteristics
Arsenopyrite	2	Small to very small anhedral to euhedral corroded grains in the quartz vein occurring disseminated or in partially filled vugs
Scorodite	tr-1	Microcrystalline to very fine-grained subhedral and locally botryoidal patches and very small rosettes after arsenopyrite
Chalcopyrite	tr	Rare very small grains, occurring with covellite or galena
Pyrite	tr	Small grains, with inclusions of and associated with galena
Covellite	tr	Very small anhedral patches occurring with sericite and an undetermined (As, Fe, O)-phase in partially filled vugs, locally associated with chalcopyrite
Galena	tr	Small interstitial grains or intergrowths in sulphides

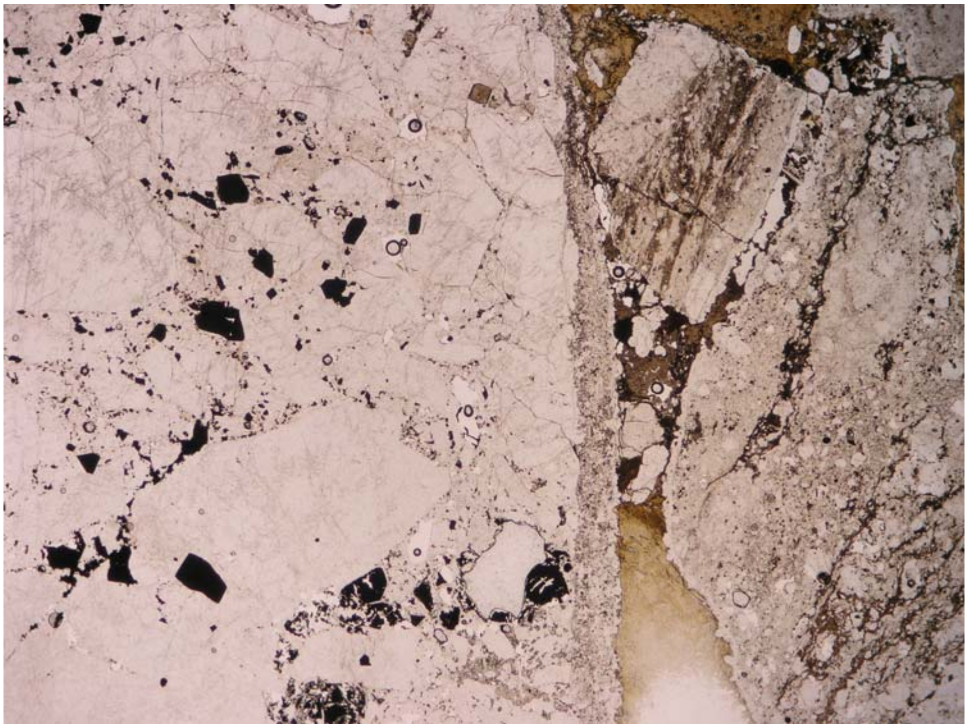

Figure 3: *Photomicrograph of sample G0672135 showing part of a quartz vein (left side) and its brecciated host rock (right side). Note the very fine-grained sulphides lining quartz grains in the vein. PPL, FOV= ~ 7 mm.*

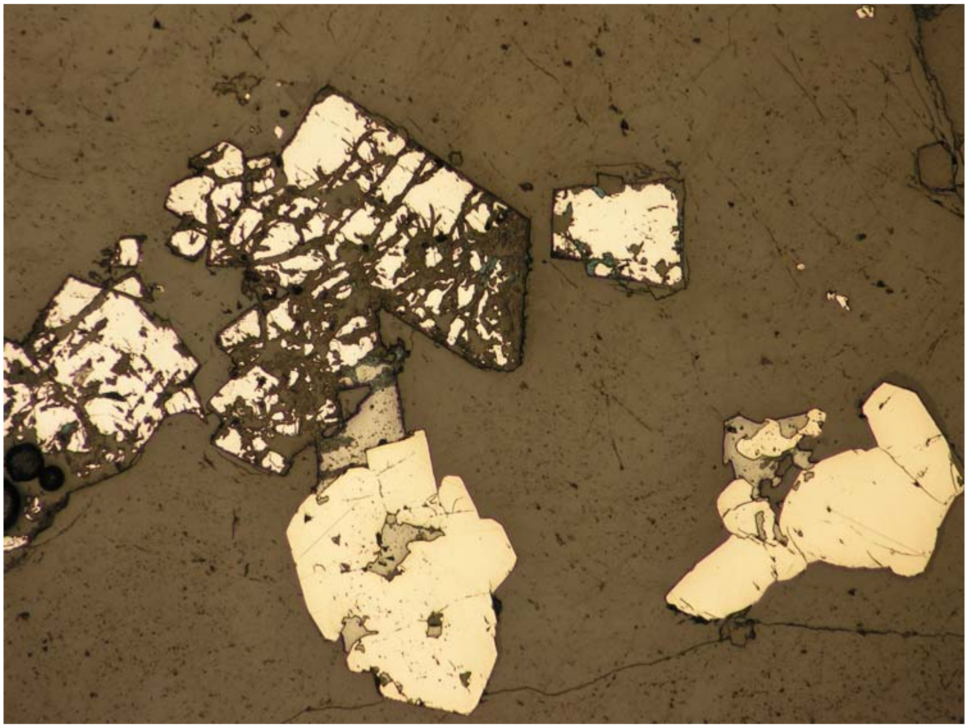

Figure 4: *Close-up of the sulphides in the quartz vein of sample G0672135. Sulphides consist of variably corroded whitish arsenopyrite grains associated with blue covellite (hardly visible at this scale) and a transparent (As, Fe, O)-phase that preserves the subhedral outlines of the original arsenopyrite. Anhedral yellowish pyrite associated with (possibly replaced by) grey galena is also present. RL, FOV = ~ 2.7 mm.*

A1.3: **Thin section description, modal composition and photomicrographs of sample C202147**

LITHOLOGY:	Quartz vein
ALTERATION TYPE:	Carbonate, oxidation

Thin section description:

This sample consists essentially of coarse-grained internally deformed quartz and localized patches in which quartz has recrystallized to a much finer grain size. Chalcopyrite and galena occur sporadically as infill in cracks and cavities, and are typically pervasively replaced by a variety of secondary lead and copper ore minerals, including malachite, mimetite and (Pb, Fe)-oxides, which are locally associated with colourless carbonate or epidote. SEM analyses additionally show that silver occurs in lead-bearing secondary minerals, suggesting a primary argentiferous galena.

MAJOR MINERALS

Mineral	**%**	**Distribution & Characteristics**
Quartz	95	Typically coarse-grained, anhedral to elongated (ratio up to 1:5), micro-cracked and displaying undulose extinction, subgrains and bulging grain boundaries Also locally as clusters of small recrystallized grains

MINOR MINERALS

Mineral	**%**	**Distribution & Characteristics**
(Pb, Fe)-oxides/ hydroxides	1	Opaque to deep red, occur as rims around sulphides and small anhedral masses lining cracks and cavities Also as pseudomorphs (after pyrite) with subhedral squared outlines in leached microveinlets
Malachite	tr-1	Green extremely fine-grained needles forming fan-like clusters and anhedral patches lining cracks, cavities and sulphides
Chalcopyrite	tr	Small masses, locally filling cracks and typically rimmed by (Pb, Fe)-oxides / hydroxides and malachite Also disseminated as extremely small grains (< 20 µm in size)
Carbonate	tr	Very fine-grained clusters in veins
Mimetite	tr	Small ribbons and masses associated with sulphides
Epidote	tr	Very small anhedral clusters in cracks and cavities
Galena	tr	Few small preserved grains in masses of oxides / hydroxides

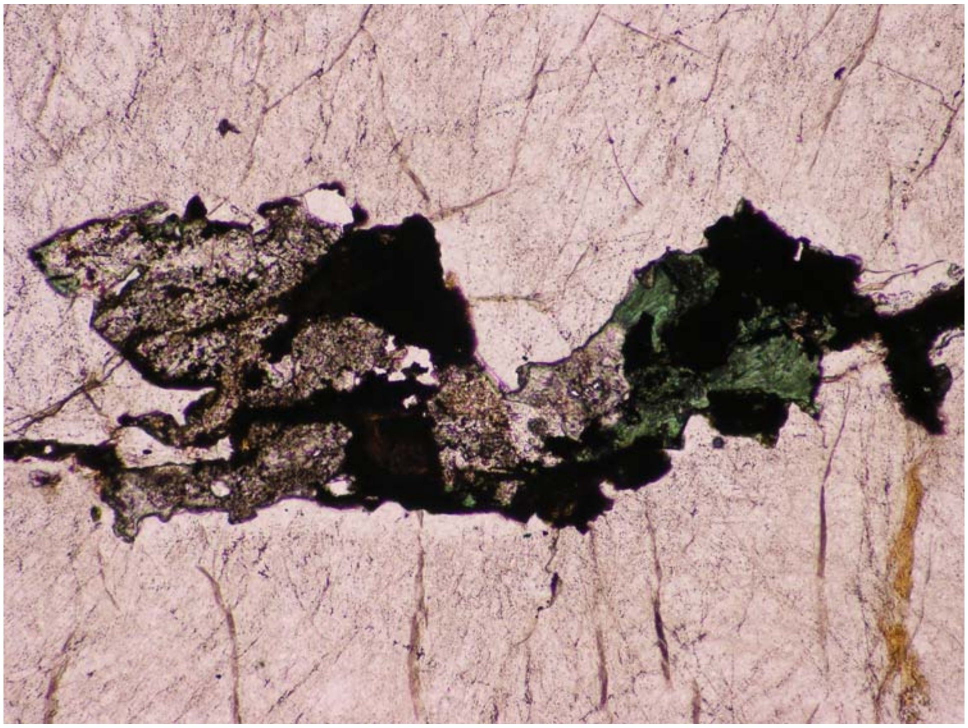

Figure 5: *Photomicrograph of sample C202147 showing an interstitial mass of malachite (green), light brown carbonate and opaque oxides between quartz grains. PPL, FOV = ~ 0.7 mm.*

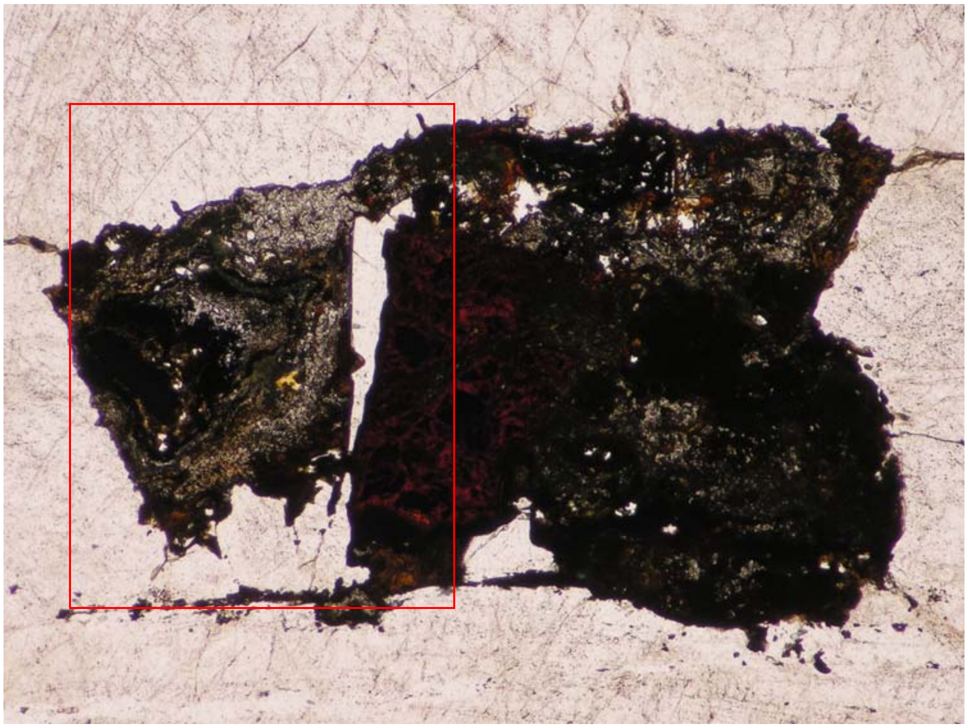

Figure 6*: Photomicrograph of a different interstitial mass of sulphides / oxides in sample C202147. This mass displays complex zoning. The rectangle indicates the location of Figure 7. PPL, FOV = ~ 0.4 mm.*

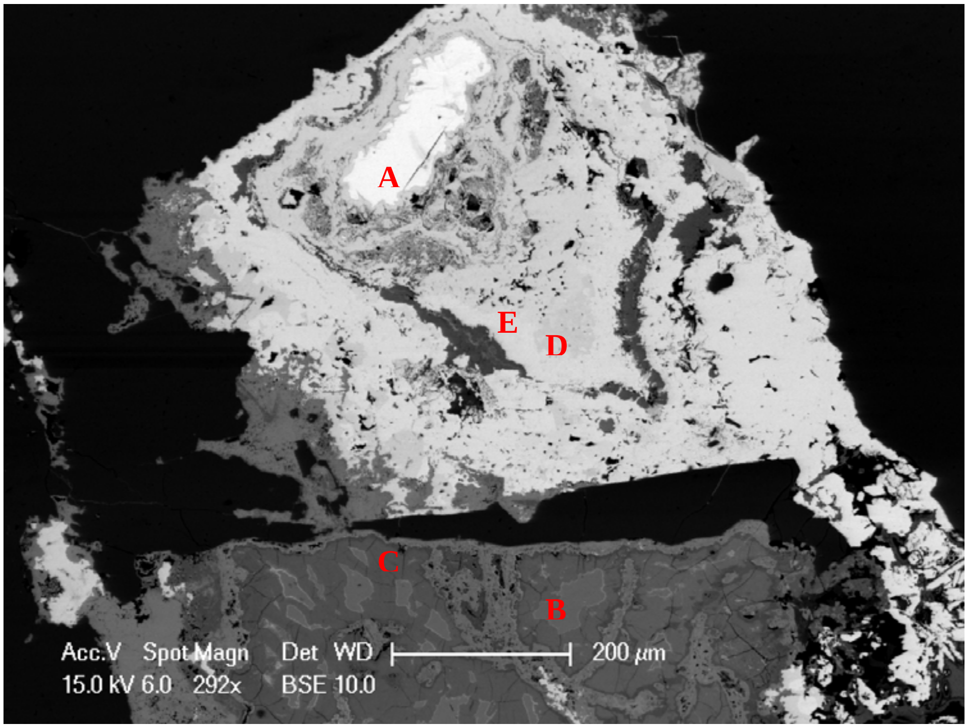

Figure 7: *SEM-BSE image of the location indicated by the rectangle in Figure 6 (rotated 90° counterclockwise) showing chemical zoning throughout. A is galena, B is chalcopyrite. SEM-EDS spectra of phases C, D and E are presented in Figure 8 and 9 below.*

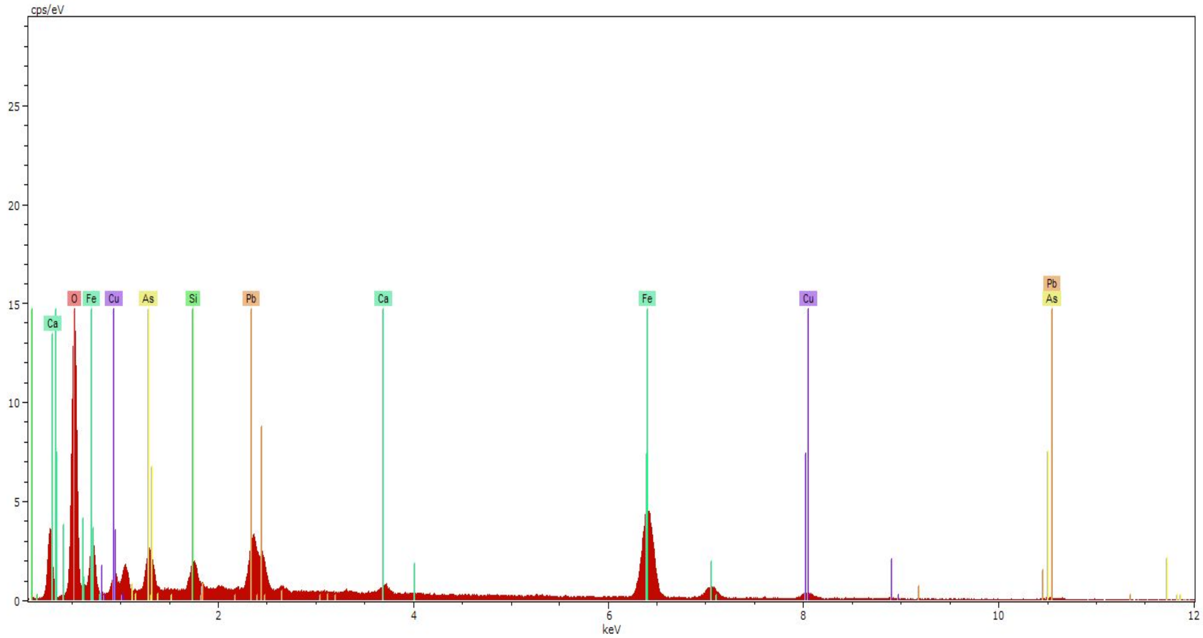

Figure 8: *SEM-EDS spectrum of phase C in Figure 7 showing it consists of a variety of elements dominated by oxygen, iron and lead. Based on the dominance of the oxygen peak, the phase is interpreted as possible (Pb, Fe)-oxide/hydroxide.*

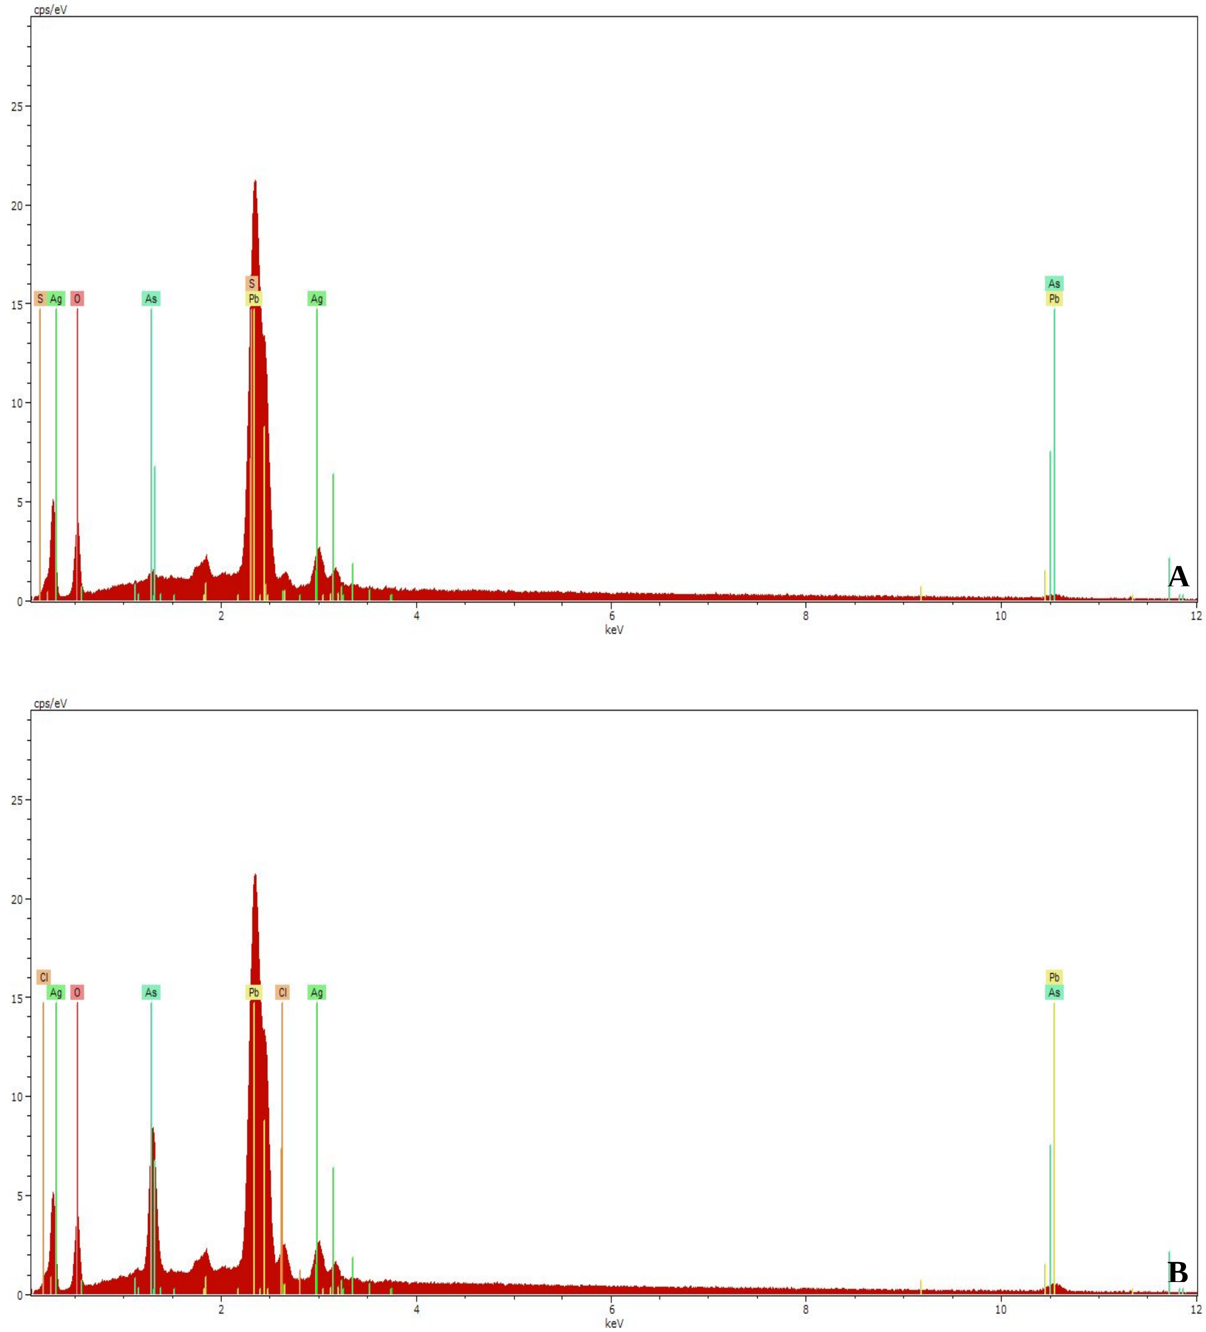

Figure 9: *SEM-EDS spectra of phases D and E in Figure 7.*

A) Phase D is dominated by lead and oxygen, with minor silver, arsenic and sulphur. It is interpreted as a possible lead oxide/hydroxide.

B) Phase E shows a strong arsenic contribution to the spectrum, in addition to lead and oxygen. Chlorine and silver are also present in minor amounts. The phase is interpreted as mimetite.

A1.4: **Thin section description, modal composition and photomicrographs of sample C201124**

LITHOLOGY:	Quartz vein
ALTERATION TYPE:	Carbonate, titanite, sericite, kaolinite, oxidation

Thin section description:

The sample consists mostly of medium- to coarse-grained, elongated massive quartz, locally associated with finer-grained recrystallized quartz aggregates. Alteration is marked by traces of fine-grained sericite and carbonate, disseminated along coarse-grained quartz grain boundaries or occurring in thin veinlets. Very fine-grained interstitial galena, molybdenite and chalcopyrite occur sporadically and are variably corroded by thin rims of undetermined oxides/hydroxides (possibly variably lead- and/or molybdenum-rich as in sample C202147) or associated with wulfenite (SEM confirmed).

MAJOR MINERALS

Mineral	%	Distribution & Characteristics
Quartz	95	Medium- to coarse-grained, strongly elongated (1:3 to 1:4) grains, cracked and displaying undulose extinction, subgrains and bulging grain boundaries Less commonly as finer-grained subhedral recrystallized grain aggregates

MINOR MINERALS

Mineral	%	Distribution & Characteristics
Carbonate	tr	Clusters of subhedral to euhedral grains lined by Fe-oxides/ hydroxides, filling cavities and cracks
Molybdenite	tr	One small strongly elongated mass associated with galena and wulfenite
Oxides / hydroxides	tr	Fine coating lining cavity- and crack-filling minerals
Sericite	tr	Clusters of small sheaves locally associated with carbonate and wulfenite
Wulfenite	tr	One botryoidal mass associated with galena and molybdenite and very small patches associated with sericite
Chalcopyrite	tr	One small grain associated with hematite, lined by Fe-oxides / hydroxides
Galena		One small irregular mass associated with molybdenite

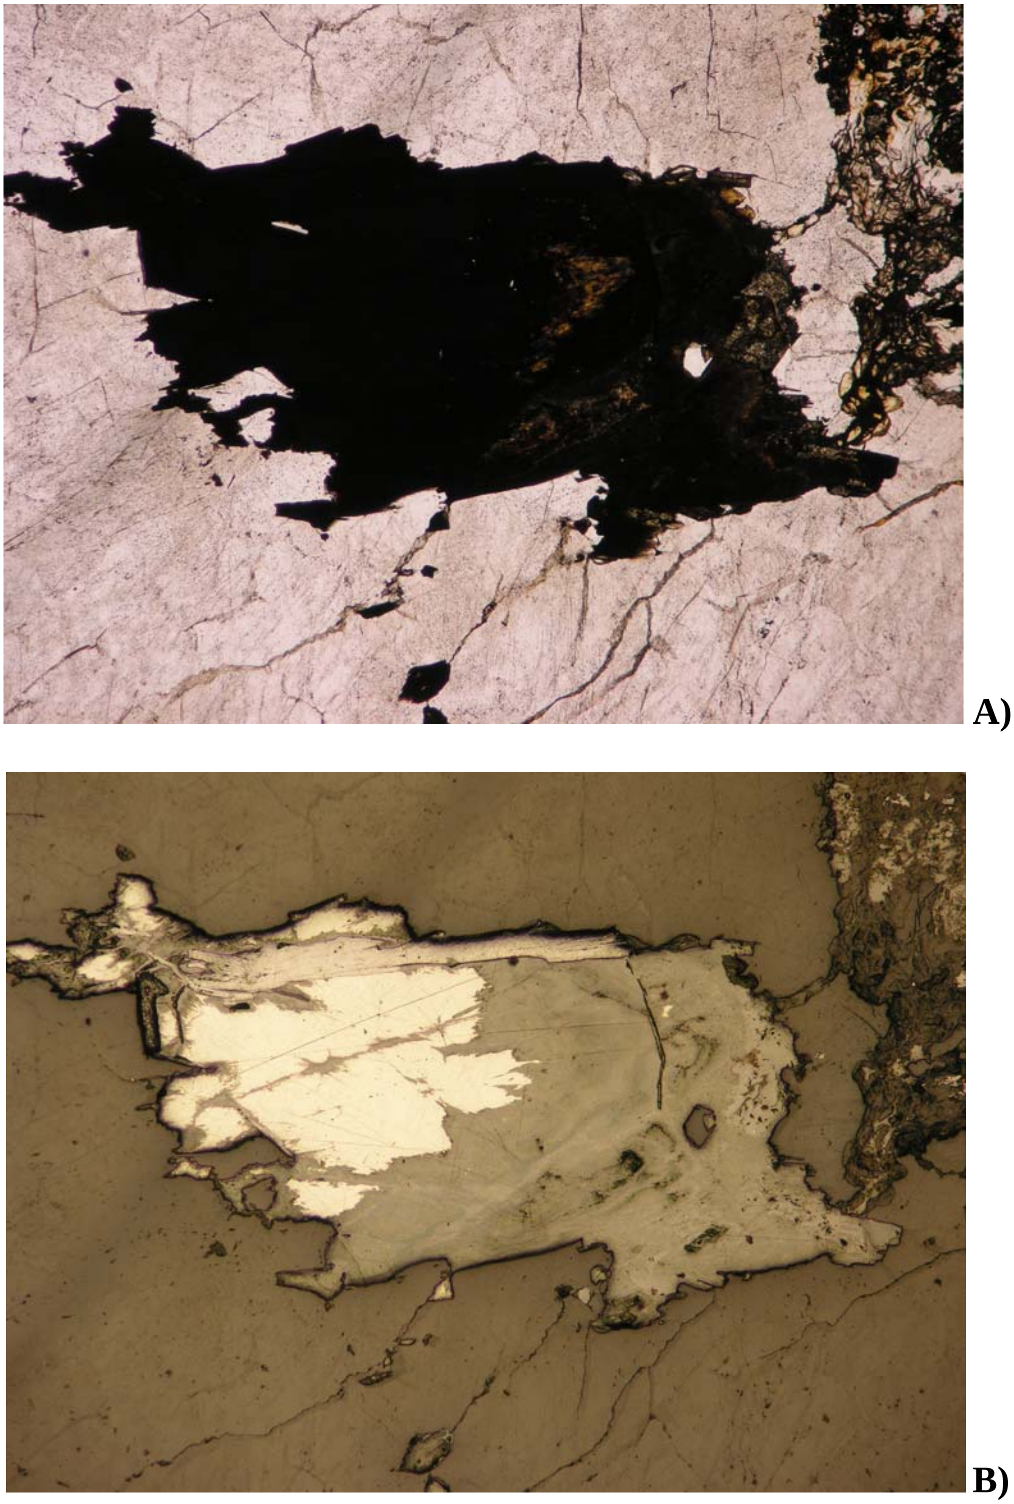

Figure 10: *Photomicrograph of sample C201124 showing an altered and oxidized mass of molybdenite (top) and galena (centre left) associated with wulfenite (centre right). The small grey masses associated with sericite in the top right hand corner are of similar composition. A) PPL, B) RL, FOV = ~ 2.7 mm.*

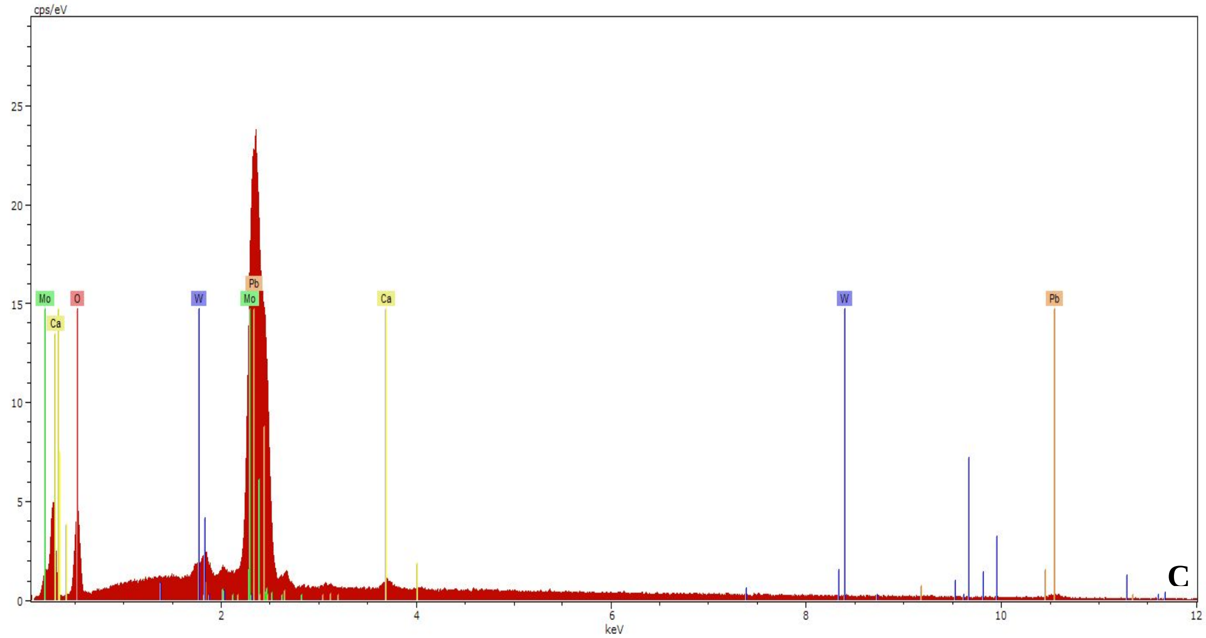

Figure 10 (continued): *C) Representative SEM-EDS spectrum obtained on the wulfenite in the mass depicted in Figure 10 A and B, showing that it essentially consists of lead, molybdenite and oxygen.*

A1.5: **Thin section description, modal composition and photomicrographs of sample C287113.**

LITHOLOGY:	Massive arsenopyrite (-quartz) vein
ALTERATION TYPE:	Oxidation

Thin section description:

The section consists mainly of heavily fractured semi-massive arsenopyrite with minor pyrite and chalcopyrite filling the arsenopyrite fractures. Enargite and electrum (SEM-confirmed) form small inclusions in arsenopyrite. Electrum inclusions are typically less than 20 µm in size. Arsenopyrite is variably altered, locally forming corroded and oxidized masses (SEM confirmed). Elongated, fibrous-looking possible scorodite partially fills and lines cracks in arsenopyrite, commonly enclosing partially preserved arsenopyrite grains and masses of dark, partially leached unresolvable possible clay.
Anhedral fine-grained quartz commonly occurs interstitial to sulphides.

MAJOR MINERALS

Mineral	**%**	**Distribution & Characteristics**
Arsenopyrite	75	1) Semi-massive, intensively cracked with fractures filled with quartz, clay and locally pyrite or chalcopyrite 2) Very small masses, partially preserved in pseudomorphs of possible scorodite
Quartz	10	Fine-grained, saccharoidal, locally with developed subgrains, highly fractured, forms most of the gangue between arsenopyrite
Oxidized arsenopyrite	5	Fine-grained, corroded masses variably pseudomorphing or replacing arsenopyrite and associated with clay
Scorodite	5	Very fine-grained, typically fibrous, lining microcracks in arsenopyrite

MINOR MINERALS

Mineral	**%**	**Distribution & Characteristics**
Clay	1	Microcrystalline, unresolvable patches throughout
Chalcopyrite	1	Small to very small anhedral grains disseminated and filling cracks in arsenopyrite
Pyrite	tr-1	Disseminated small anhedral masses locally intergrown with arsenopyrite, associated with marcasite or filling cracks in arsenopyrite
Enargite	tr-1	Very small anhedral inclusions in arsenopyrite
Electrum	tr	Extremely small (< 20 µm) inclusions in arsenopyrite

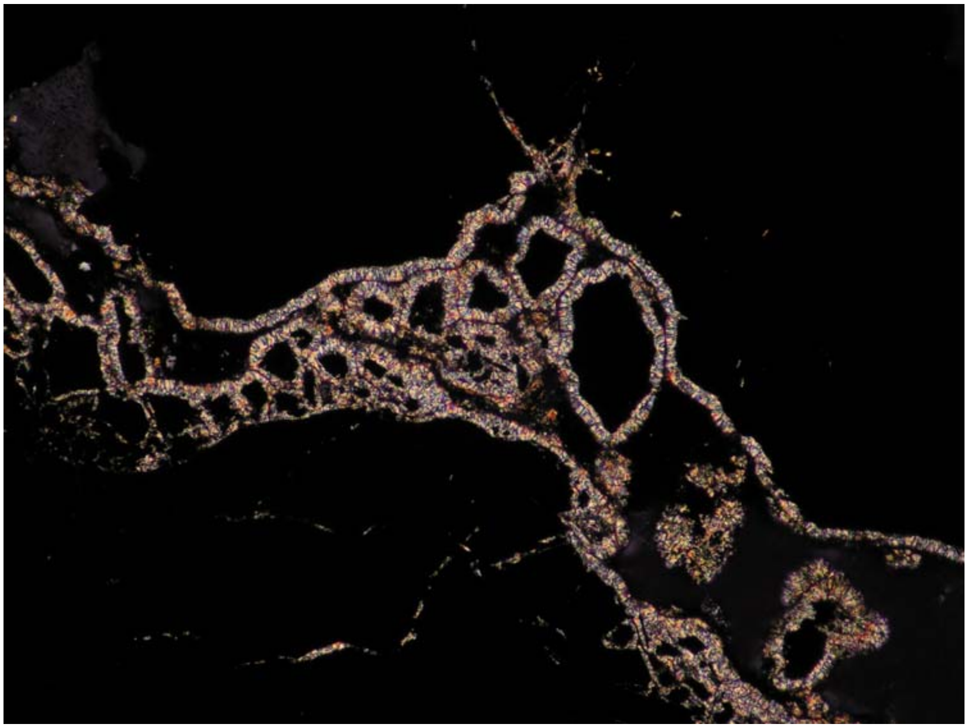

Figure 11*: Photomicrograph of sample C287113 showing very fine-grained fibrous masses of possible scorodite lining fractured massive arsenopyrite and rimming interstitial arsenopyrite in the fractures. XPL, FOV = ~ 7 mm*

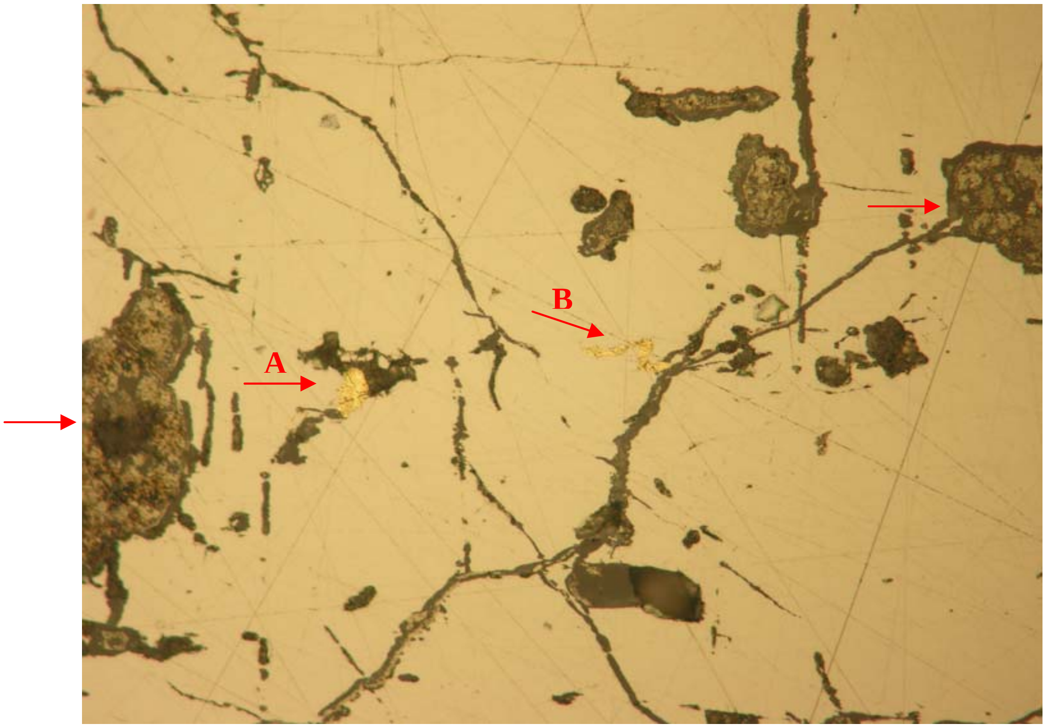

Figure 12*:Close-up of a fractured mass of arsenopyrite showing inclusions of electrum (particles A and B indicated by the arrows). The presence of electrum is confirmed by SEM analyses (Figure 14). Masses of altered arsenopyrite (indicated by arrows) also occur throughout. RL, FOV = ~ 0.28 mm.*

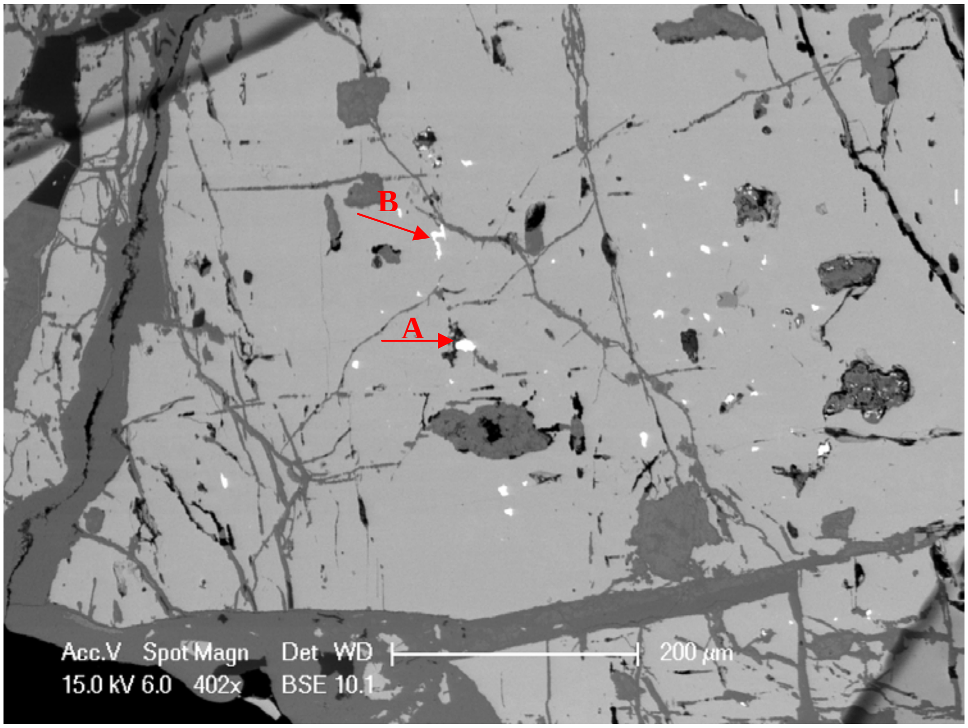

Figure 13*: SEM-BSE image of a larger area of the arsenopyrite containing electrum particles A & B shown in Figure 12. This image shows that many more smaller electrum inclusions are present.*

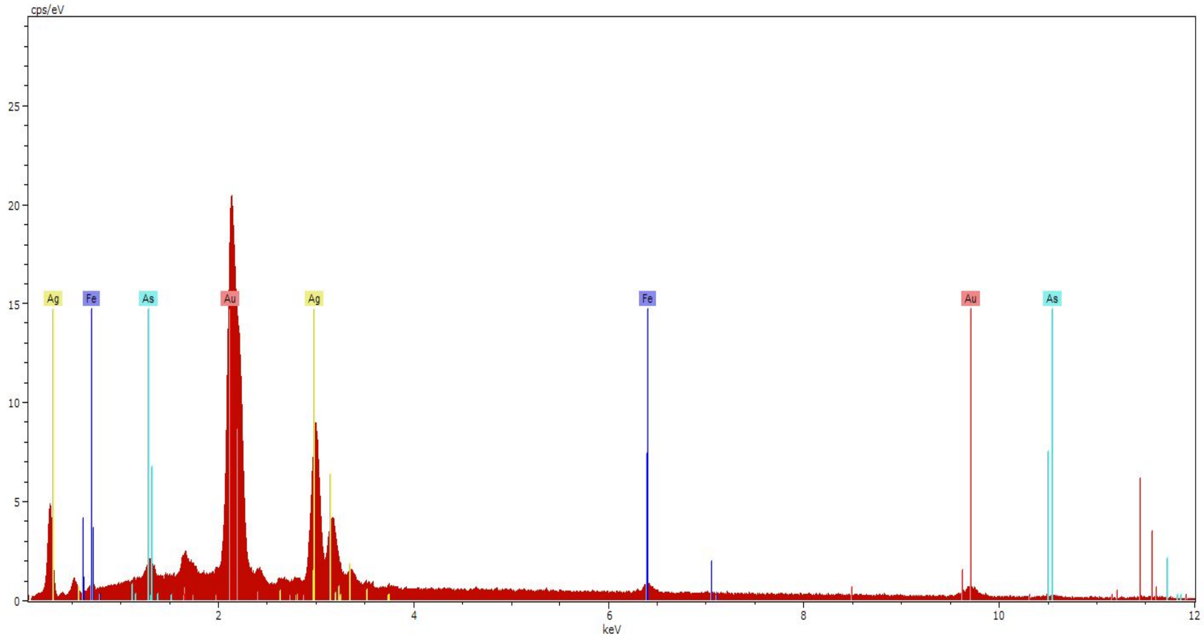

Figure 14*: Representative SEM-EDS spectrum obtained on electrum particles, showing dominant gold and silver peaks.*

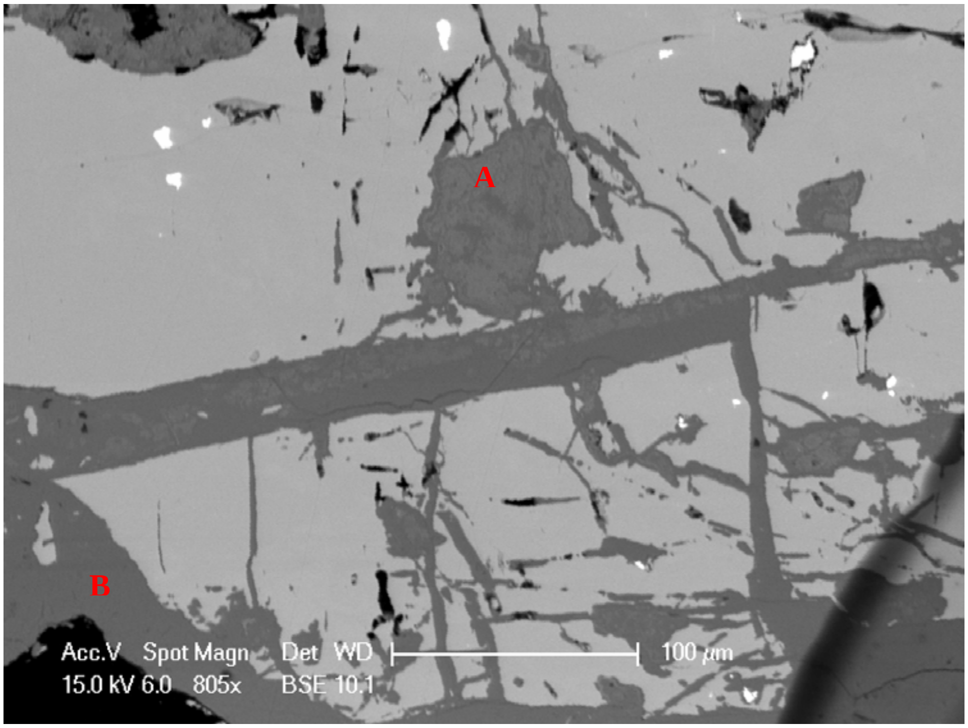

Figure 15*: SEM-BSE image showing masses and fractures in arsenopyrite, which are filled with two locally intergrown phases. Phase A is light grey, phase B is darker grey.*

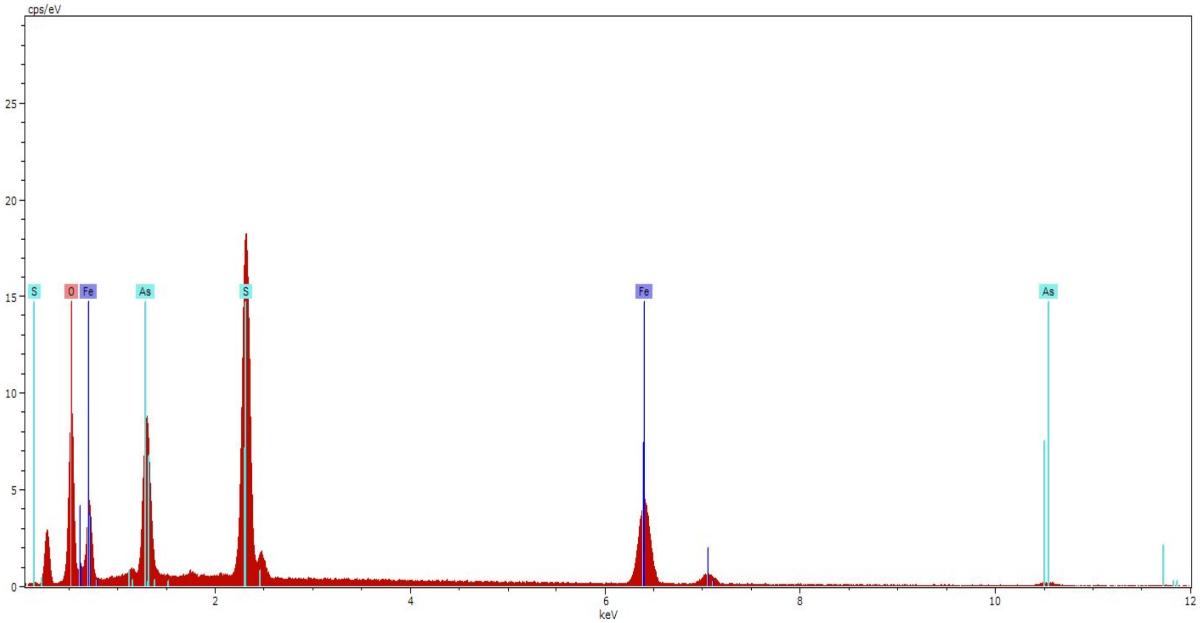

Figure 16*: SEM-EDS spectrum of phase A shown in Figure 15. Sulphur and oxygen are present with arsenic and iron, suggesting this phase is oxidized arsenopyrite.*

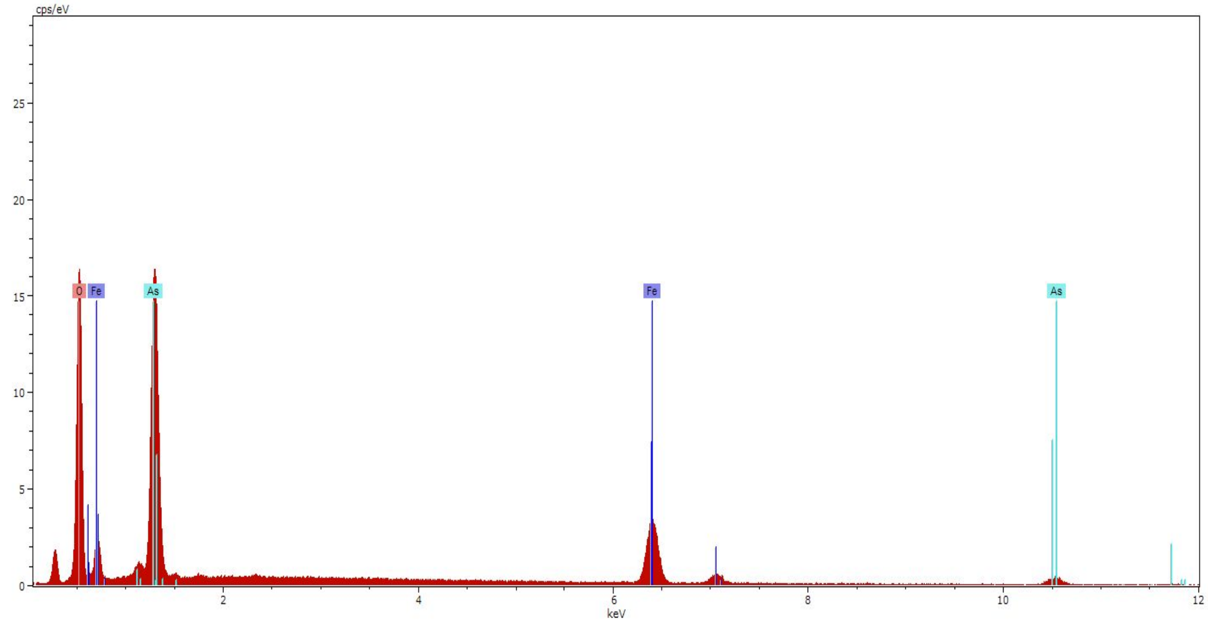

***Figure 17**: SEM-EDS spectrum of phase B shown in Figure 15. This phase lacks sulphur and contains only oxygen, iron and oxygen. It is interpreted as possible scorodite.*

APPENDIX 2: DESCRIPTION OF IGNEOUS SAMPLES

A2.1: **Thin section description, modal composition and photomicrographs of sample C287261**

LITHOLOGY:	Brecciated feldspar-porphyry
ALTERATION TYPE:	Sericite-quartz, kaolinite, clay

Thin section description:

The sample consists of a vaguely brecciated and porphyritic rock that has been pervasively replaced by quartz and sericite, which is itself locally replaced by clay. Former fine- to medium-grained, tabular plagioclase and lesser, finer-grained K-feldspar phenocrysts are variably preserved from sericite alteration. Former mafic phases and the groundmass are completely replaced by sericite sheaves and very fine-grained quartz, locally associated with kaolinite. Sulphides consist of fine- to medium-grained euhedral arsenopyrite, associated with medium-grained quartz to form aggregates that are not randomly distributed but appear to form a matrix around poorly-defined porphyritic clasts.

A later calcite alteration phase is noted both by disseminated grains and subparallel veinlets cross-cutting the sample.

The relative proportion of plagioclase and K-feldspar in the protolith could not be precisely determined due to pervasive alteration.

MAJOR MINERALS

Mineral	**%**	**Distribution & Characteristics**
Quartz	30	1) Fine- to medium-grained, anhedral with subgrains, undulose extinction and irregular grain boundaries 2) Extremely fine-grained occurring with sericite
Sericite	30	Small colourless to yellow-brown sheaves occurring as pervasive replacement throughout
Plagioclase	(15)	Fine- to medium-grained tabular twinned phenocrysts, variably preserved from sericite replacement
Arsenopyrite	10	Fine- to medium-sized sub- to euhedral grains, disseminated and in clusters
K-feldspar	(5)	Fine-grained tabular phenocrysts recognized by simple twinning, variably preserved from sericite replacement

MINOR MINERALS

Mineral	**%**	**Distribution & Characteristics**
Carbonate	3	Fine- to very fine-grained, commonly elongated in thin veinlets cutting the sample; rarely disseminated
Kaolinite	2	Disseminated extremely fine-grained clots
Clay	tr-1	Dark brown patchy alteration of sericite
Rutile	tr	Extremely fine-grained granular clusters and needles throughout

Modal abundance estimates (%) in parentheses indicate a high degree of uncertainty (see text for explanation)

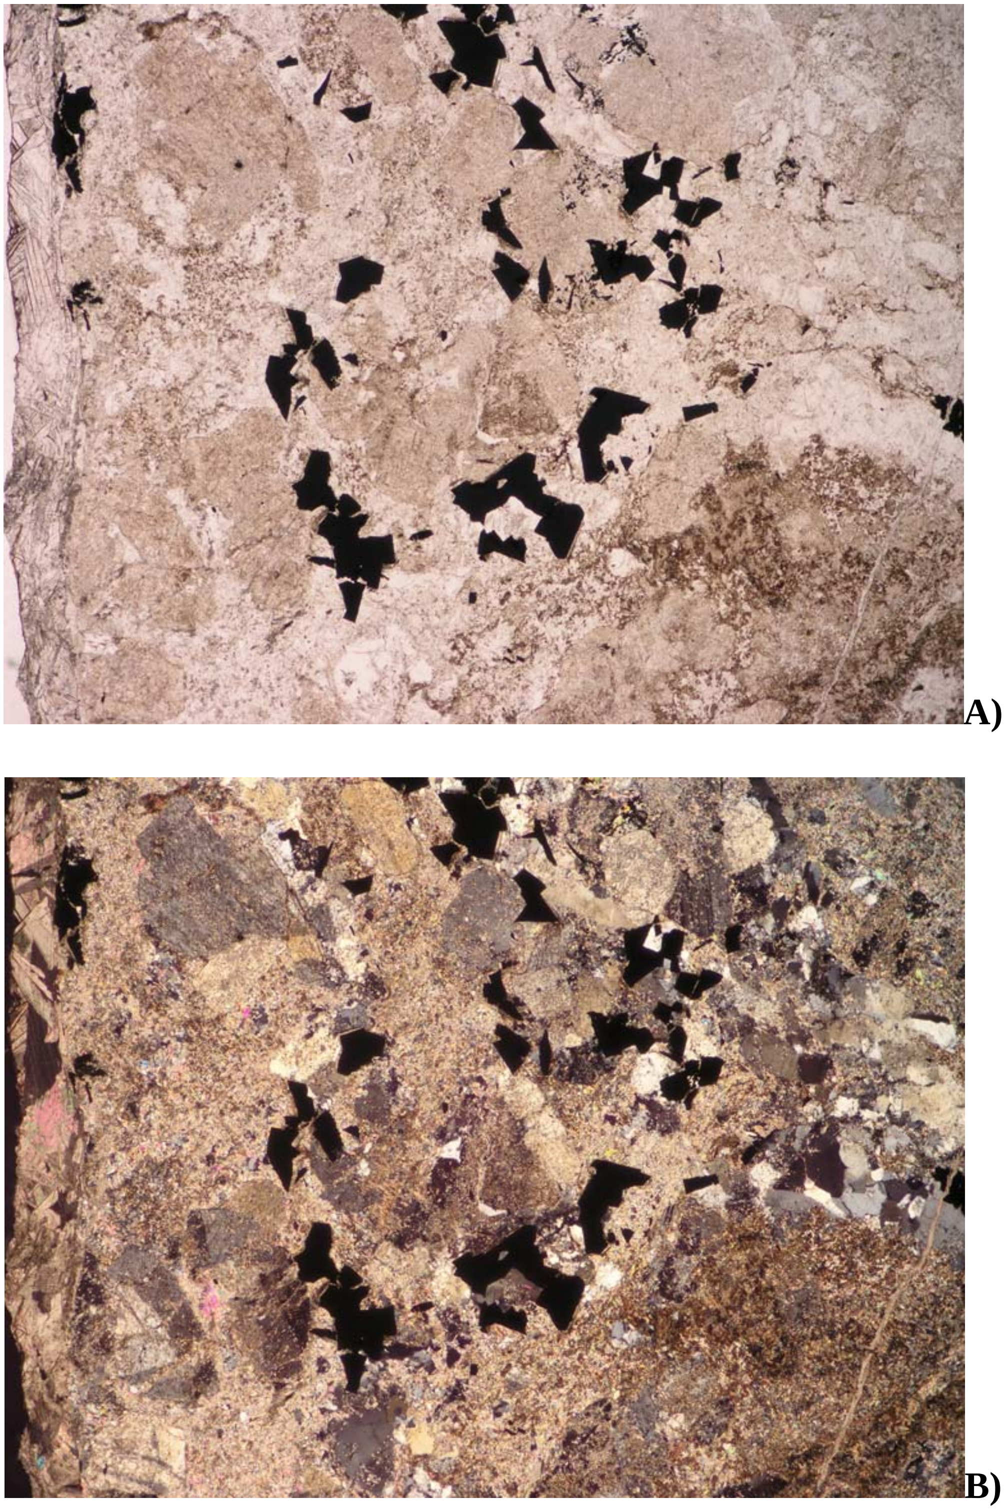

Figure 18: *Photomicrographs of sample C287261 showing medium-grained plagioclase phenocrysts (bottom right) in a finer-grained groundmass of felsic minerals pervasively altered by sericite. Note the roughly circular distribution of arsenopyrite that suggests vaguely defined porphyritic clasts. A) PPL, B) XPL, FOV = ~ 7mm.*

A2.2: **Thin section description, modal composition and photomicrographs of sample G0672501**

LITHOLOGY:	K-feldspar phyric granite
ALTERATION TYPE:	K-feldspar, sericite, oxidation

Thin section description:

This sample consists of granite as indicated by the dominant quartz-K-feldspar modal composition with minor plagioclase, muscovite and biotite components. K-feldspar locally reaches 7.5 mm in length while most phases are typically fine- to medium-grained, suggesting this is K-feldspar phyric granite.

Alteration is weak. It is marked by the local development of secondary K-feldspar after feldspars and fine-grained sericite after muscovite and feldspars. Rare euhedral arsenopyrite is disseminated throughout the sample. Sparse subhedral crystals of rutile and spessartine are also disseminated.

Oxidation is marked by the presence of small reddish patches of oxides/hydroxides disseminated and filling microcracks, indicated by SEM analyses to contain arsenic, antimony and iron.

MAJOR MINERALS

Mineral	**%**	**Distribution & Characteristics**
K-Feldspar	50	Fine- to coarse-grained, subhedral to euhedral, typically concentrically zoned and rarely twinned (simple twins suggest possible orthoclase composition); Contains local brownish alteration patches of possible secondary K-feldspar and displays irregular boundaries and non-uniform extinction
Quartz	35	Fine- to medium-sized anhedral grains, interstitial to feldspars
Plagioclase	5	Fine-grained, anhedral to subhedral, twinned with polysynthetic twins locally bent

MINOR MINERALS

Mineral	**%**	**Distribution & Characteristics**
Muscovite	2	Fine-to medium-grained, anhedral poikilitic sheaves
Sericite	2	Disseminated small sheaves and clusters after feldspars and micas
Arsenopyrite	tr-1	Disseminated fine-grained sub- to euhedral rhombs
Biotite	tr	Fine-to medium-grained, anhedral to subhedral brown sheaves
Zircon	tr	Disseminated small subhedral acicular grains
Rutile	tr	Disseminated small acicular grains
Spessartine	tr	Small granular clusters throughout
(Fe, As, Sb)-oxides/hydroxides	tr	Infill in microveinlets and yellowish patches throughout

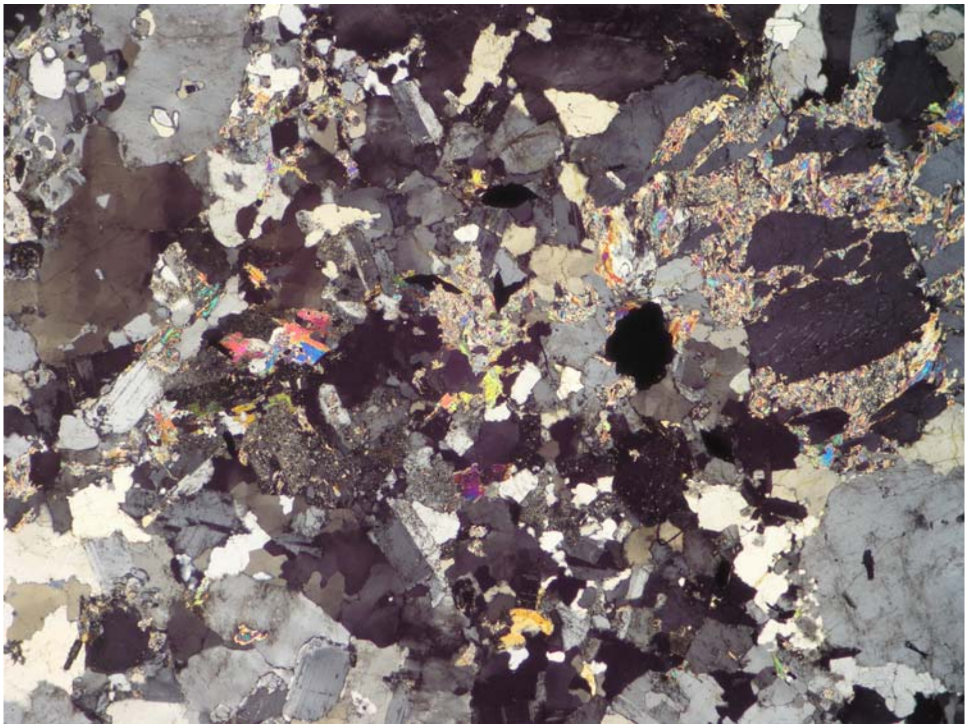

Figure 19: *Photomicrograph of sample G0672501, showing the granular assemblage of quartz, feldspar and colourful muscovite. PPL, FOV = ~ 7 mm.*

Figure 20: *Close-up of sample G0672501, showing the occurrence of arsenopyrite. RL, FOV = ~ 2.7 mm.*

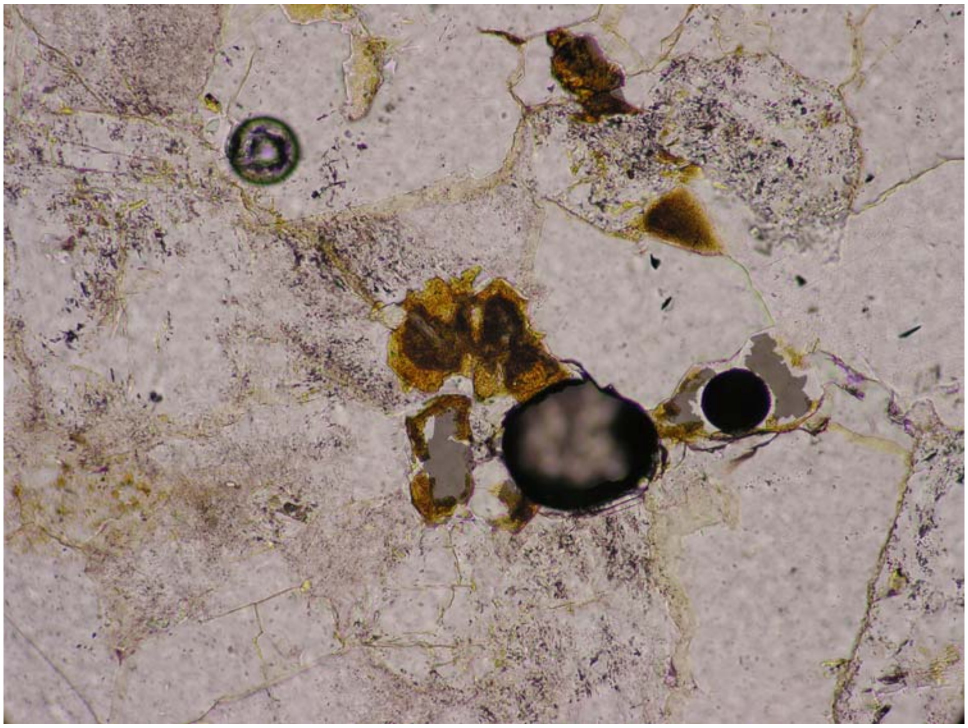

Figure 21: *Photomicrograph of sample G0672501, showing the occurrence of brownish masses interpreted as (Fe, Sb, As) oxides/hydroxides. PPL, FOV = ~ 1.4 mm.*

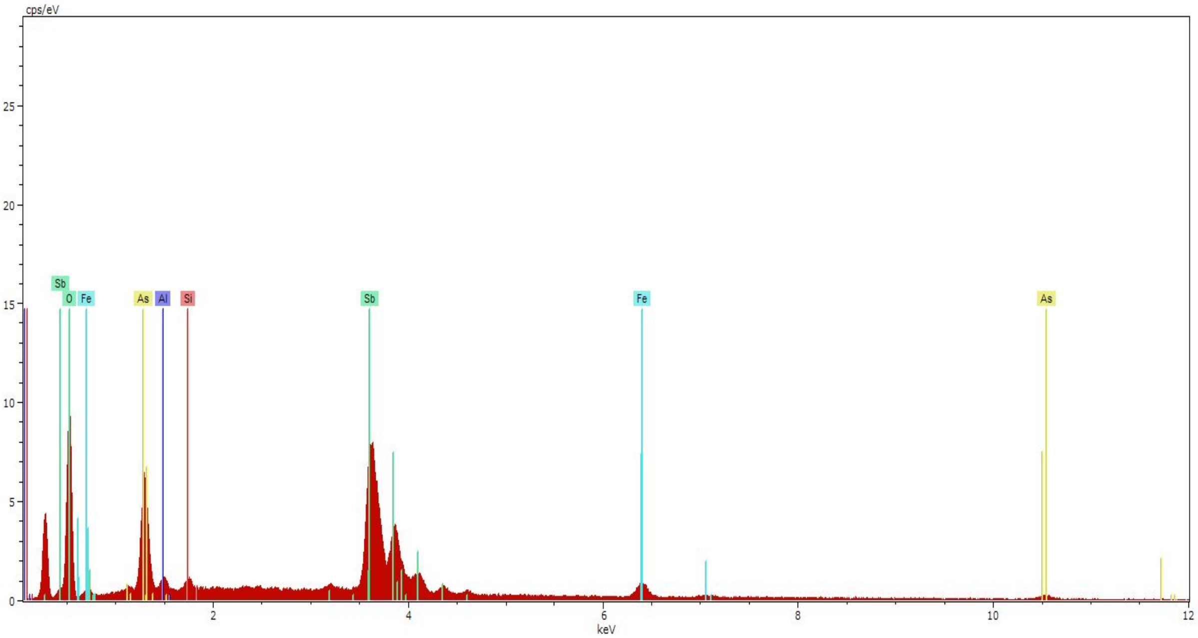

Figure 22: *Representative SEM-EDS spectrum of the oxides present in sample G0672501, showing they contain iron, antimony and arsenic. The silicon and aluminium peaks are probably due to substratum contamination.*

A2.3: **Thin section description, modal composition and photomicrographs of sample G0672502**

LITHOLOGY:	Plagioclase porphyry
ALTERATION TYPE:	Shreddy biotite, magnetite, titanite, chlorite

Thin section description:

This altered porphyritic rock consists of coarse-grained plagioclase phenocrysts in a fine-grained groundmass of quartz, tabular plagioclase and possible minor K-feldspar. Sub- to euhedral arsenopyrite is disseminated throughout. Shreddy biotite (itself commonly replaced by chlorite) is pervasive throughout the groundmass and commonly associated with titanite. The plagioclase phenocrysts are commonly replaced by shreddy biotite along cracks and cleavages. No primary mafic phase is observed (likely because replaced by titanite) but coarse poikilitic magnetite occurs throughout.

A poorly defined quartz vein (with alteration halo of chlorite at the expense of biotite) cuts the sample.

The relative proportions of plagioclase and K-feldspar could not be determined precisely since the off-cut was not stained for K-feldspar and because biotite alteration pervasively replaces plagioclase and K-feldspar grains.

MAJOR MINERALS

Mineral	**%**	**Distribution & Characteristics**
Quartz	30	Small anhedral grains forming part of the groundmass and occurring in a poorly defined vein
Plagioclase	(25)	Disseminated, fine- to medium-grained phenocrysts up to 10 mm in length and microphenocrysts in the groundmass, recognized by characteristic polysynthetic twins Pitted by microcrystalline shreddy biotite and locally zoned
Shreddy biotite	25	Very small sheaves in the groundmass around phenocrysts and pitting plagioclase (phenocrysts and groundmass)
Titanite	5	Disseminated small anhedral grains
Chlorite	5	Local replacement of shreddy biotite in the groundmass and in the alteration halo of a poorly defined quartz vein
K-feldspar	(5)	Small tabular grains enclosed in magnetite and as part of the groundmass, recognized by simple twinning

MINOR MINERALS

Mineral	**%**	**Distribution & Characteristics**
Magnetite	2	Disseminated medium-grained anhedral poikilitic phenocrysts and microphenocrysts, commonly enclosing titanite, quartz and K-feldspar
Arsenopyrite	1	Disseminated, fine- to medium-grained, subhedral to euhedral phenocrysts and microphenocrysts
Actinolite	tr	Small acicular grains throughout

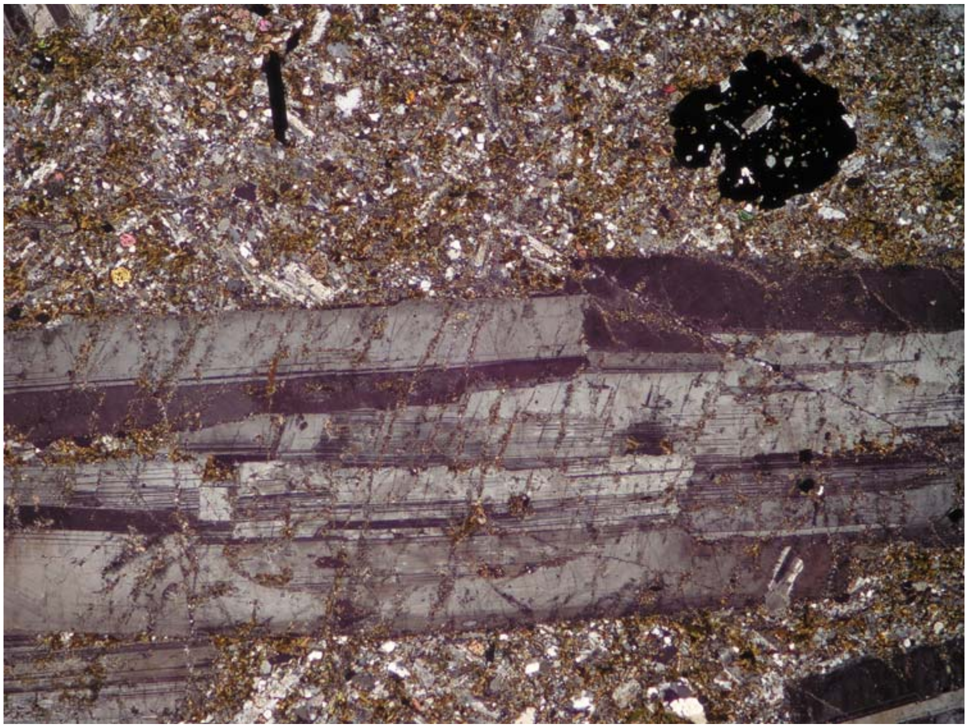

Figure 23: *Photomicrograph of sample G0672502, showing the plagioclase phyric texture of the rock and the pervasive alteration by very fine-grained brown biotite. PPL, FOV = ~ 7 mm.*

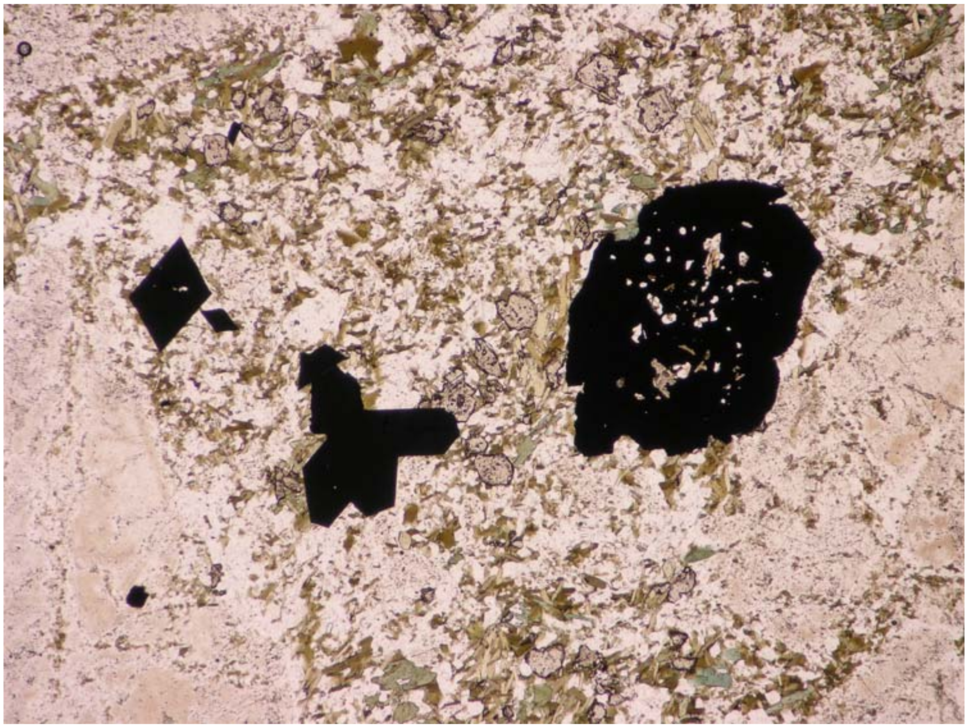

Figure 24: *Close-up of sample G0672502, showing opaque poikilitic magnetite (right), sub- to euhedral opaque arsenopyrite (left) and granular titanite (centre). PPL, FOV = ~ 2.7 mm.*

APPENDIX 3: HAND SAMPLE DESCRIPTIONS

A3.1: **Description of vein samples**

Sample C287345

The sample derives from a fractured translucent to dark grey, massive quartz vein. Quartz vein fragments are elongated, subangular and typically cemented by an extremely fine-grained black material that locally carries microcrystalline sulphides. Some yellowish to green patches and veinlets cross-cut the sample. The sample is not magnetic and does not react to cold dilute HCl.

Sample G0672135

The sample consists of part of a translucent to dark grey quartz vein and part of its breccia host rock. The quartz vein appears fine- to medium-grained and contains small disseminated sulphides as well as numerous small, anhedral to euhedral tabular vugs and thin veinlets that are commonly lined or filled by a greenish material.

The host rock breccia consists of subangular fragments (up to 2 mm in size) including possible quartz vein fragments and fragments of locally layered microcrystalline rock. The interclast matrix is aphanitic, pale green to orange-red in colour and may consist of altered volcanic glass.

The sample is not magnetic and does not react to cold dilute HCl.

Sample C287113

The sample is made up of massive, heavily fractured arsenopyrite containing disseminated masses of quartz and anhedral patches of yellowish to green material. The sample is not magnetic and does not react to cold dilute HCl.

Sample C202147

The sample derives from a fractured and oxidized, massive white and aphanitic quartz vein. Numerous cracks and vugs occur in the sample, typically containing sub- to euhedral quartz and lined by orange-red material. Very small patches of green malachite are recognized, disseminated in the quartz vein and associated with oxidized masses of sulphides. The sample is not magnetic and does not react to cold dilute HCl.

Sample C201124

The sample derives from a massive white and aphanitic quartz vein. Numerous cracks and vugs occur in the sample, typically containing sub- to euhedral quartz and locally lined by orange-red material. Small masses of sulphides including arsenopyrite and chalcopyrite are disseminated, sporadically associated with green malachite, but are not represented in the thin section. The sample is not magnetic and does not react to cold dilute HCl.

A3.2: **Description of igneous samples**

Sample C287261

This sample of brecciated feldspar porphyry consists of small tabular feldspar phenocrysts in a greenish to brown, translucent aphanitic groundmass. The nature of the feldspars (plagioclase and/or K-feldspar) is unknown (no K-feldspar stain performed). The brecciated rock is cemented by masses of quartz and arsenopyrite, and very thin calcite veinlets cross-cut the sample as indicated by strong reaction of the sample to cold dilute HCl. The sample is not magnetic.

Sample G0672501

This variably altered sample consists of a fine-grained (vaguely porphyritic) felsic igneous rock that appears to be made up essentially of quartz and feldspar. The nature of the feldspars (plagioclase and/or K-feldspar) is unknown (no K-feldspar stain performed). A brownish micaceous phase (likely biotite) occurs sporadically. Euhedral arsenopyrite is disseminated throughout. The sample is not magnetic and does not react to cold dilute HCl.

Sample G0672502

This greenish to black sample consists of a porphyritic rock. Dark grey elongated to tabular phenocrysts occur in a greenish to black aphanitic groundmass. Fine- to coarse-grained arsenopyrite is disseminated. The sample is strongly magnetic. It does not react to cold dilute HCl.

Appendix F: Quality Control / Quality Assurance

QUALITY CONTROL / QUALITY ASSURANCE

I Chain of Custody

All samples were packed in rice sacks and sealed with uniquely-numbered non-resealable security straps. Rice sacks were trucked to ALS Chemex Labs Ltd. preparation facility in Terrace and then transferred to the North Vancouver laboratory, an ISO 9001 registered laboratory. ALS Chemex reported that all bags were received in good condition, with all security straps intact, and with no evidence of tampering.

II Blanks

Blanks are samples which are known to be barren of mineralization and are inserted into the sample stream in the field to determine whether contamination has occurred after sample collection. Blank material for core samples consisted of commercially available fine silica sand.

a. Drill Core Blanks

A total of 24 blanks were inserted into the sample sequence in the field (approximately every 40th sample) and submitted for analysis. Reported values for Au and Ag from all blank samples were near or below the detection limits for these elements. Contamination appears to be an issue for other elements in a number of samples. One sample, C287400 contains anomalous values of Cr, Cu, Ni, Pb and Zn, while five other samples contain one or two anomalous values from a variety of elements. In conclusion, since Au and Ag are the only elements of economic interest the possible contamination indicated in the others is of no particular significance.

III Standards

Standards are mineralized reference samples of known value and are inserted into the sample stream in the field to determine if the reported values are within the acceptable limits of the laboratory. Standard material for core samples was obtained from WCM Minerals with the following reported values and standard deviations:

	Ag g/t	Au g/t	Cu %
Reference Value	**372**	**12.2**	**5.36**
Standard Deviation	**17.3**	**0.53**	**0.11**

a. Core Standards

A total of 25 standards were inserted into the sample sequence in the field (approximately every 40th sample). ALS Chemex analyzed the samples along with the core samples for Au and 34 element ICP. The Ag, Au and Cu values used in the following three figures are derived from fire assay with a gravimetric finish for Ag and Au, and from atomic absorption spectroscopy for Cu. Results were not received for all samples due to non-sufficient sample size required to perform all of the necessary analyses, however, enough data exists to identify trends and draw conclusions. Ag results are on average, 6.9% below the reference value but all samples do fall within three standard deviations of the reference value (Figure 1). Au values are scattered about the reference, with all samples except for one sample within two standard deviations, and the outlier within three standard deviations of the reference value (Figure 2). Scattered Cu values show a slight bias towards higher than reference values, but all sample are within two standard deviations (Figure 3).

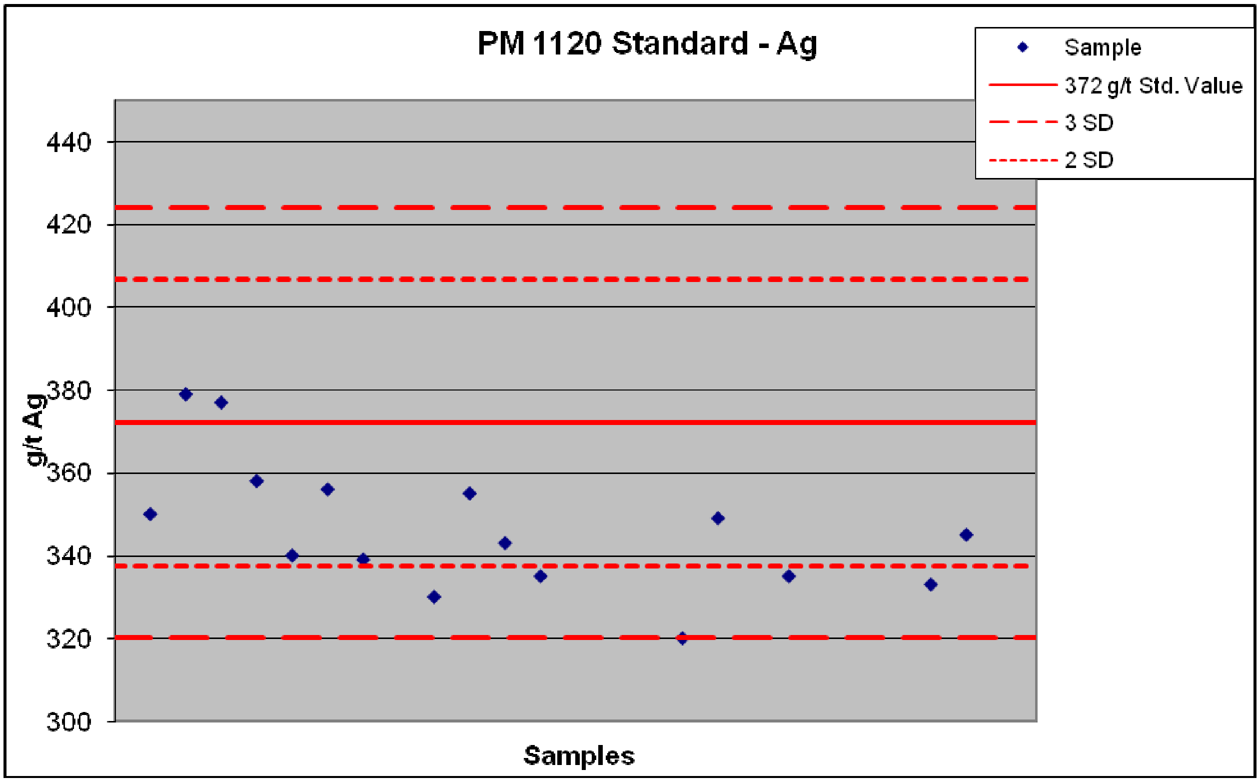

Figure 1: Comparison of Ag results from 16 standard PM 1120 samples inserted into the drill core sample stream. Horizontal lines show the known value of the standard, as well as 2 standard deviations and 3 standard deviations as reported from the laboratory supplying the sample material.

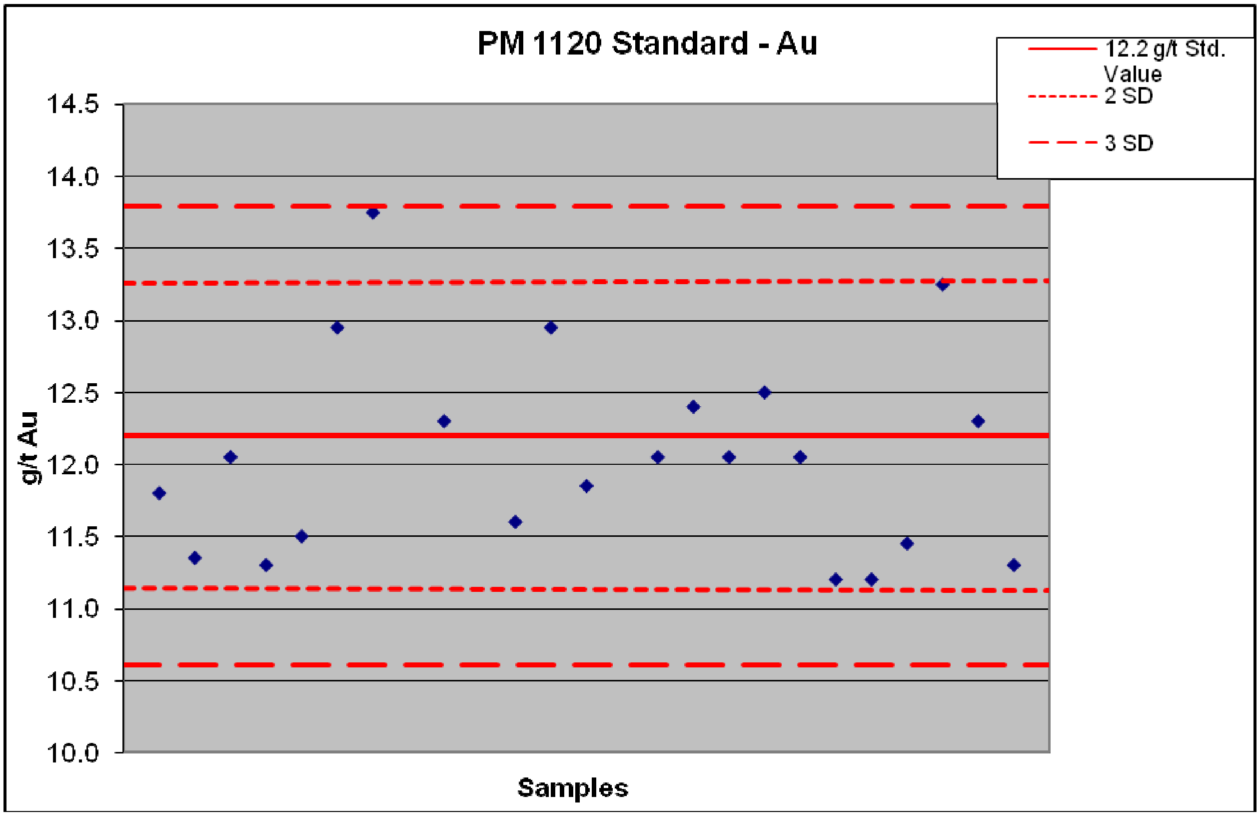

Figure 2: Comparison of Au results from 22 standard PM 1120 samples inserted into the drill core sample stream. Horizontal lines show the known value of the standard, as well as 2 standard deviations and 3 standard deviations as reported from the laboratory supplying the sample material. .

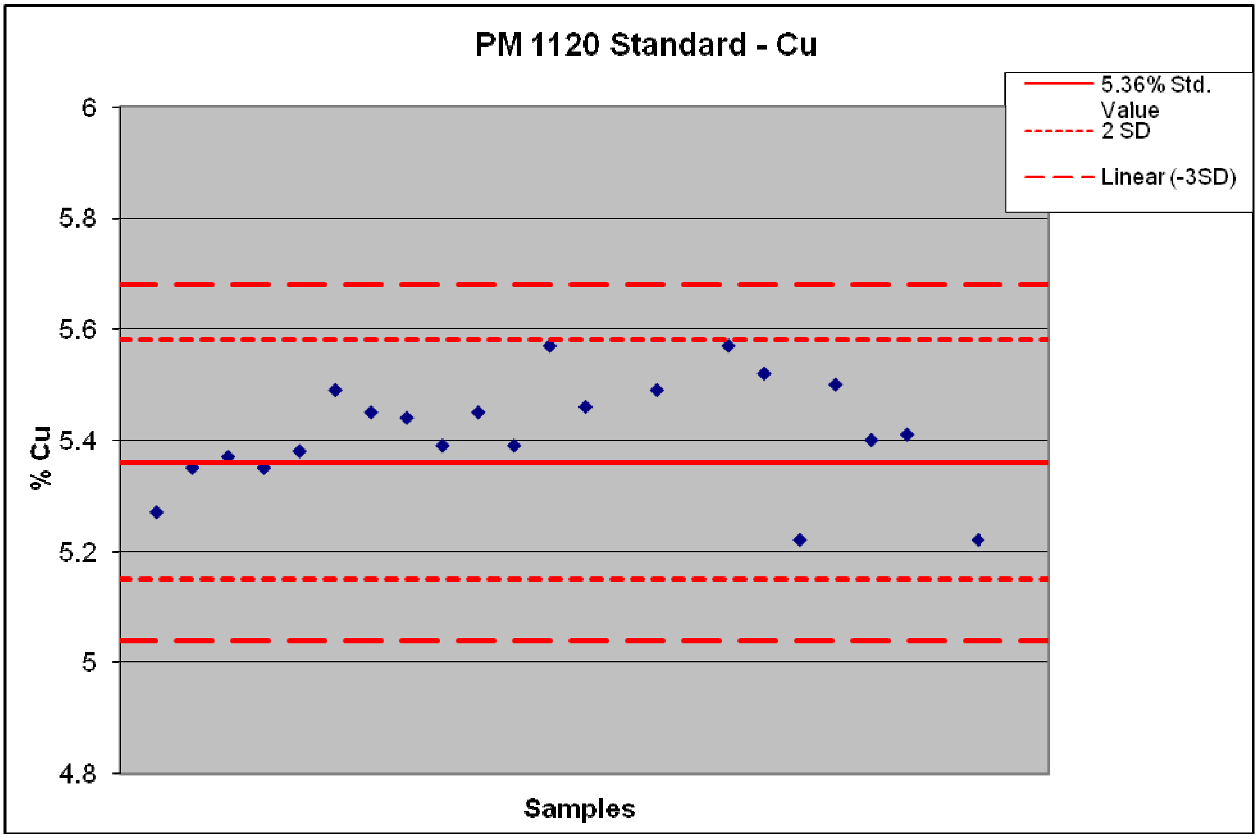

Figure 3: Comparison of Cu results from 21 standard PM 1120 samples inserted into the drill core sample stream. Horizontal lines show the known value of the standard, as well as 2 standard deviations and 3 standard deviations as reported from the laboratory supplying the sample material.

IV Field Duplicate Analysis

Field duplicates are separate samples taken in the same manner from the same location. They are used to measure inherent variability in metal content from a single location and sample medium, and give an idea of sample reproducibility in the field. Core duplicates were produced by longitudinally sawing the core in half, and then sawing the half into quarters to form two separate samples with the other half retained on site.

a. Core Duplicates

Forty-six pairs of field duplicates were inserted into the core sample stream in the field (approximately every 20th sample). ALS Chemex analyzed the duplicates along with the core samples by Au fire assay and 34 element ICP. The Thompson and Howarth method of estimating analytical precision for lab duplicates was applied and is illustrated in Figures 4 and 5 for Au and Ag respectively. Core duplicates were reproducible at 60% precision for Au and 20% for Ag. Variability in the Au values can likely be attributed to the vein style of mineralization of the Tannis Zone where differences in mineralization are observed to occur on a very small scale.

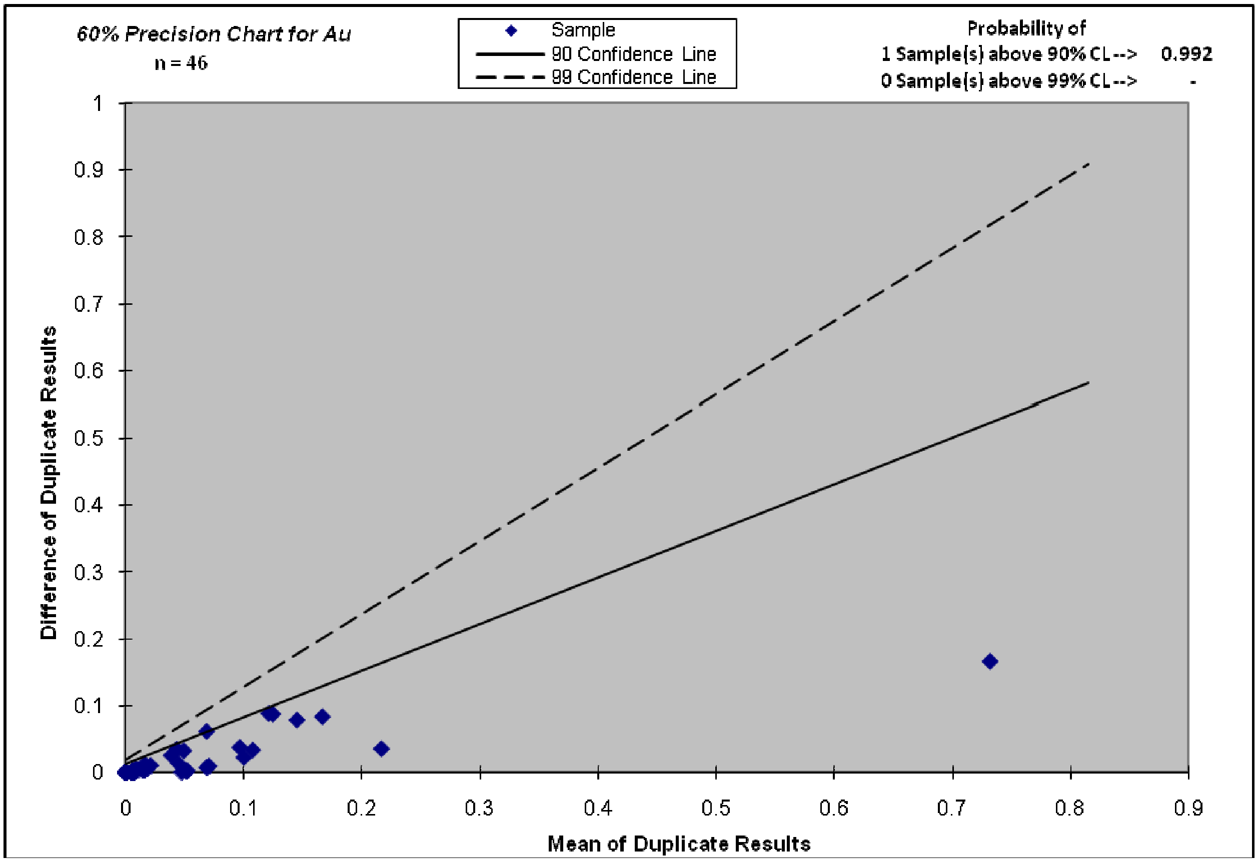

Figure 4: Graph illustrating Thompson and Howarth estimation of analytical precision for lab duplicates. The data points represent duplicate pairs, the solid line represents the 90% confidence line of the population, and the dashed line the 99% confidence line of the population (n=46 duplicate pairs). In this case, the probability is 99.2% that the difference in analytical results will exceed the 90% confidence line for 1 out of 46 sample pairs, implying that the Au analyses are most likely reproducible at a 60% precision level.

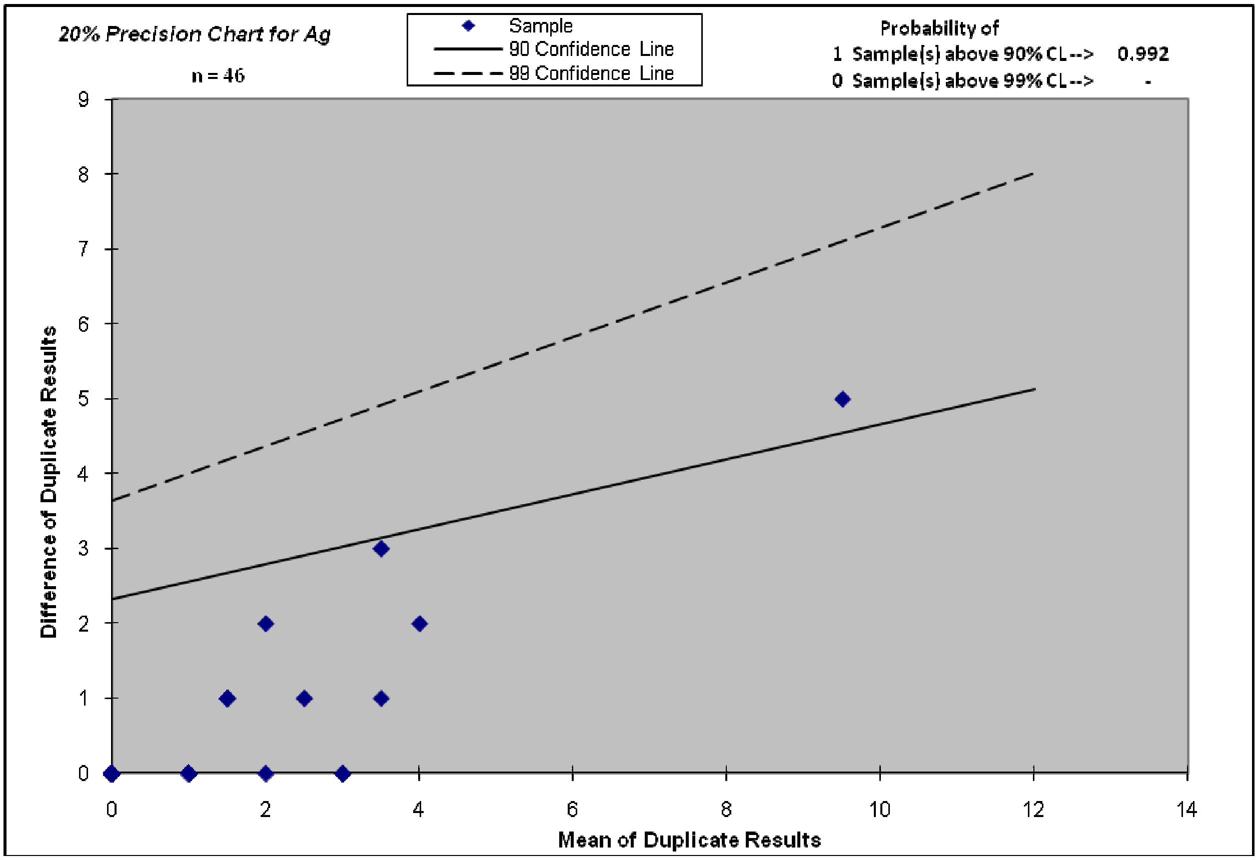

Figure 5: Graph illustrating Thompson and Howarth estimation of analytical precision for lab duplicates. The data points represent duplicate pairs, the solid line represents the 90% confidence line of the population, and the dashed line the 99% confidence line of the population (n=46 duplicate pairs). In this case, the probability is 99.2% that the difference in analytical results will exceed the 90% confidence line for 1 out of 46 sample pairs, implying that the Au analyses are most likely reproducible at a 20% precision level.

V Conclusions

- There is no evidence of tampering with the samples between collection and the laboratory.
- Consistently low values for metals of interest (Au and Ag) in the blank analyses indicate that contamination of samples with respect to these elements did not take place in the field, or in the lab.
- Analyses of reference material of known value show that Ag is consistently underreported, however all values are within an acceptable range of variation from the reference value. Values for Au and Cu are generally scattered about the reference value and lie within two to three standard deviations.
- Field duplicates show that analytical values are reproducible at the 60% precision level for Au and 20% precision level for Ag.
- By finalizing their analytical certificates, ALS Chemex confirms that their internal QA/QC sampling convinced them that contamination, reproducibility and accuracy are within acceptable limits within the laboratory.

Finalized Date: 2-OCT-2008
Account: EIATYE

CERTIFICATE TR08122793

Project: TYE-08-02

P.O. No.:

This report is for 48 Rock samples submitted to our lab in Terrace, BC, Canada on 29-AUG-2008.

The following have access to data associated with this certificate:

HENRY A JEREMY MAJOR	ENERAL EQUITY ENGINEERIN	TRACY HURLEY

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
CRU-QC	Crushing QC Test
PUL-QC	Pulverizing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
As-AA46	Ore grade As - aqua regia/AA	AAS
Pb-AA46	Ore grade Pb - aqua regia/AA	AAS
Au-AA23	Au 30g FA-AA finish	AAS
Au-GRA21	Au 30g FA-GRAV finish	WST-SIM
ME-ICP41a	High Grade Aqua Regia ICP-AES	ICP-AES
Ag-GRA21	Ag 30g FA-GRAV finish	WST-SIM

To: **EQUITY EXPLORATION CONSULTANTS LTD.**
ATTN: JEREMY MAJOR
700 - 700 WEST PENDER ST.
VANCOUVER BC V6C 1G8

This is the Final Report and supersedes any preliminary report with this certificate number. Results apply to samples as submitted. All pages of this report have been checked and approved for release.

CERTIFICATE TR08134921

Project: Golden Eagle

P.O. No.: TYE08-02

This report is for 44 Rock samples submitted to our lab in Terrace, BC, Canada on 22-SEP-2008.

The following have access to data associated with this certificate:

HENRY A JEREMY MAJOR	ENERAL EQUITY ENGINEERIN	TRACY HURLEY

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-22	Sample login - Rcd w/o BarCode
CRU-QC	Crushing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
As-AA46	Ore grade As - aqua regia/AA	AAS
Pb-AA46	Ore grade Pb - aqua regia/AA	AAS
Au-AA23	Au 30g FA-AA finish	AAS
Au-GRA21	Au 30g FA-GRAV finish	WST-SIM
ME-ICP41a	High Grade Aqua Regia ICP-AES	ICP-AES
Ag-GRA21	Ag 30g FA-GRAV finish	WST-SIM

To: **EQUITY EXPLORATION CONSULTANTS LTD.**
ATTN: JEREMY MAJOR
700 - 700 WEST PENDER ST.
VANCOUVER BC V6C 1G8

This is the Final Report and supersedes any preliminary report with this certificate number. Results apply to samples as submitted. All pages of this report have been checked and approved for release.

CERTIFICATE TR08116372

Project: Golden Eagle TYE08-02

P.O. No.:

This report is for 98 Drill Core samples submitted to our lab in Terrace, BC, Canada on 19-AUG-2008.

The following have access to data associated with this certificate:

HENRY A JEREMY MAJOR	ENERAL EQUITY ENGINEERIN	TRACY HURLEY

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-24	Pulp Login - Rcd w/o Barcode
LOG-22	Sample login - Rcd w/o BarCode
CRU-31	Fine crushing - 70% <2mm
CRU-QC	Crushing QC Test
PUL-QC	Pulverizing QC Test
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
As-AA46	Ore grade As - aqua regia/AA	AAS
Cu-AA46	Ore grade Cu - aqua regia/AA	AAS
Au-AA23	Au 30g FA-AA finish	AAS
Au-GRA21	Au 30g FA-GRAV finish	WST-SIM
ME-ICP41a	High Grade Aqua Regia ICP-AES	ICP-AES

To: **EQUITY EXPLORATION CONSULTANTS LTD.**
ATTN: JEREMY MAJOR
700 - 700 WEST PENDER ST.
VANCOUVER BC V6C 1G8

This is the Final Report and supersedes any preliminary report with this certificate number. Results apply to samples as submitted. All pages of this report have been checked and approved for release.

CERTIFICATE TR08121071

Project: Golden Eagle

P.O. No.: TYE08-02

This report is for 127 Drill Core samples submitted to our lab in Terrace, BC, Canada on 26-AUG-2008.

The following have access to data associated with this certificate:

HENRY A JEREMY MAJOR	ENERAL EQUITY ENGINEERIN	TRACY HURLEY

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-24	Pulp Login - Rcd w/o Barcode
LOG-22	Sample login - Rcd w/o BarCode
CRU-QC	Crushing QC Test
PUL-QC	Pulverizing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
As-AA46	Ore grade As - aqua regia/AA	AAS
Cu-AA46	Ore grade Cu - aqua regia/AA	AAS
Au-AA23	Au 30g FA-AA finish	AAS
Au-GRA21	Au 30g FA-GRAV finish	WST-SIM
ME-ICP41a	High Grade Aqua Regia ICP-AES	ICP-AES
Ag-GRA21	Ag 30g FA-GRAV finish	WST-SIM

To: **EQUITY EXPLORATION CONSULTANTS LTD.**
ATTN: JEREMY MAJOR
700 - 700 WEST PENDER ST.
VANCOUVER BC V6C 1G8

This is the Final Report and supersedes any preliminary report with this certificate number. Results apply to samples as submitted. All pages of this report have been checked and approved for release.

CERTIFICATE TR08121072

Project: Golden Eagle TYE 08-02

P.O. No.: TYE08-02

This report is for 86 Drill Core samples submitted to our lab in Terrace, BC, Canada on 26-AUG-2008.

The following have access to data associated with this certificate:

HENRY A JEREMY MAJOR	ENERAL EQUITY ENGINEERIN	TRACY HURLEY

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-24	Pulp Login - Rcd w/o Barcode
LOG-22	Sample login - Rcd w/o BarCode
CRU-QC	Crushing QC Test
PUL-QC	Pulverizing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
As-AA46	Ore grade As - aqua regia/AA	AAS
Cu-AA46	Ore grade Cu - aqua regia/AA	AAS
Au-AA23	Au 30g FA-AA finish	AAS
Au-GRA21	Au 30g FA-GRAV finish	WST-SIM
ME-ICP41a	High Grade Aqua Regia ICP-AES	ICP-AES
Ag-GRA21	Ag 30g FA-GRAV finish	WST-SIM

To: **EQUITY EXPLORATION CONSULTANTS LTD.**
ATTN: JEREMY MAJOR
700 - 700 WEST PENDER ST.
VANCOUVER BC V6C 1G8

This is the Final Report and supersedes any preliminary report with this certificate number. Results apply to samples as submitted. All pages of this report have been checked and approved for release.

CERTIFICATE TR08122792

Project: TYE08-02

P.O. No.:

This report is for 127 Drill Core samples submitted to our lab in Terrace, BC, Canada on 29-AUG-2008.

The following have access to data associated with this certificate:

HENRY A JEREMY MAJOR	ENERAL EQUITY ENGINEERIN	TRACY HURLEY

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-24	Pulp Login - Rcd w/o Barcode
LOG-22	Sample login - Rcd w/o BarCode
PUL-31d	Pulverize Split - duplicate
SPL-21d	Split sample - duplicate
PUL-QC	Pulverizing QC Test
CRU-31	Fine crushing - 70% <2mm

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
As-AA46	Ore grade As - aqua regia/AA	AAS
Cu-AA46	Ore grade Cu - aqua regia/AA	AAS
Au-AA23	Au 30g FA-AA finish	AAS
Au-GRA21	Au 30g FA-GRAV finish	WST-SIM
ME-ICP41a	High Grade Aqua Regia ICP-AES	ICP-AES
Ag-GRA21	Ag 30g FA-GRAV finish	WST-SIM

To: **EQUITY EXPLORATION CONSULTANTS LTD.**

CERTIFICATE TR08123742

Project: Golden Eagle TYE08-02

P.O. No.: TYE08-02 Shipment #5

This report is for 80 Drill Core samples submitted to our lab in Terrace, BC, Canada on 2-SEP-2008.

The following have access to data associated with this certificate:

HENRY A JEREMY MAJOR	ENERAL EQUITY ENGINEERIN	TRACY HURLEY

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-24	Pulp Login - Rcd w/o Barcode
LOG-22	Sample login - Rcd w/o BarCode
PUL-QC	Pulverizing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
As-AA46	Ore grade As - aqua regia/AA	AAS
Cu-AA46	Ore grade Cu - aqua regia/AA	AAS
Au-AA23	Au 30g FA-AA finish	AAS
Au-GRA21	Au 30g FA-GRAV finish	WST-SIM
ME-ICP41a	High Grade Aqua Regia ICP-AES	ICP-AES
Ag-GRA21	Ag 30g FA-GRAV finish	WST-SIM

To: **EQUITY EXPLORATION CONSULTANTS LTD.**
ATTN: JEREMY MAJOR
700 - 700 WEST PENDER ST.
VANCOUVER BC V6C 1G8

This is the Final Report and supersedes any preliminary report with this certificate number. Results apply to samples as submitted. All pages of this report have been checked and approved for release.

CERTIFICATE TR08125700

Project: Golden Eagle

P.O. No.: TYE08-02 Shipment # 6

This report is for 162 Drill Core samples submitted to our lab in Terrace, BC, Canada on 3-SEP-2008.

The following have access to data associated with this certificate:

HENRY A JEREMY MAJOR	ENERAL EQUITY ENGINEERIN	TRACY HURLEY

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-24	Pulp Login - Rcd w/o Barcode
LOG-22	Sample login - Rcd w/o BarCode
CRU-QC	Crushing QC Test
PUL-QC	Pulverizing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
As-AA46	Ore grade As - aqua regia/AA	AAS
Cu-AA46	Ore grade Cu - aqua regia/AA	AAS
Au-AA23	Au 30g FA-AA finish	AAS
Au-GRA21	Au 30g FA-GRAV finish	WST-SIM
ME-ICP41a	High Grade Aqua Regia ICP-AES	ICP-AES
Ag-GRA21	Ag 30g FA-GRAV finish	WST-SIM

To: **EQUITY EXPLORATION CONSULTANTS LTD.**
ATTN: JEREMY MAJOR
700 - 700 WEST PENDER ST.
VANCOUVER BC V6C 1G8

This is the Final Report and supersedes any preliminary report with this certificate number. Results apply to samples as submitted. All pages of this report have been checked and approved for release.

CERTIFICATE TR08126242

Project: Golden Eagle TYE 08-02

P.O. No.: TYE08-02

This report is for 189 Drill Core samples submitted to our lab in Terrace, BC, Canada on 8-SEP-2008.

The following have access to data associated with this certificate:

HENRY A JEREMY MAJOR	ENERAL EQUITY ENGINEERIN	TRACY HURLEY

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-24	Pulp Login - Rcd w/o Barcode
LOG-22	Sample login - Rcd w/o BarCode
CRU-QC	Crushing QC Test
PUL-QC	Pulverizing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
As-AA46	Ore grade As - aqua regia/AA	AAS
Cu-AA46	Ore grade Cu - aqua regia/AA	AAS
Au-AA23	Au 30g FA-AA finish	AAS
Au-GRA21	Au 30g FA-GRAV finish	WST-SIM
ME-ICP41a	High Grade Aqua Regia ICP-AES	ICP-AES
Ag-GRA21	Ag 30g FA-GRAV finish	WST-SIM

To: **EQUITY EXPLORATION CONSULTANTS LTD.**
ATTN: JEREMY MAJOR
700 - 700 WEST PENDER ST.
VANCOUVER BC V6C 1G8

This is the Final Report and supersedes any preliminary report with this certificate number. Results apply to samples as submitted. All pages of this report have been checked and approved for release.

CERTIFICATE TR08134920

Project: Golden Eagle

P.O. No.: TYE08-02

This report is for 64 Drill Core samples submitted to our lab in Terrace, BC, Canada on 22-SEP-2008.

The following have access to data associated with this certificate:

HENRY A JEREMY MAJOR	ENERAL EQUITY ENGINEERIN	TRACY HURLEY

SAMPLE PREPARATION

ALS CODE	DESCRIPTION
WEI-21	Received Sample Weight
LOG-24	Pulp Login - Rcd w/o Barcode
LOG-22	Sample login - Rcd w/o BarCode
CRU-QC	Crushing QC Test
PUL-QC	Pulverizing QC Test
CRU-31	Fine crushing - 70% <2mm
SPL-21	Split sample - riffle splitter
PUL-31	Pulverize split to 85% <75 um

ANALYTICAL PROCEDURES

ALS CODE	DESCRIPTION	INSTRUMENT
Cu-AA46	Ore grade Cu - aqua regia/AA	AAS
Au-AA23	Au 30g FA-AA finish	AAS
Au-GRA21	Au 30g FA-GRAV finish	WST-SIM
ME-ICP41a	High Grade Aqua Regia ICP-AES	ICP-AES
Ag-GRA21	Ag 30g FA-GRAV finish	WST-SIM

To: **EQUITY EXPLORATION CONSULTANTS LTD.**
ATTN: JEREMY MAJOR
700 - 700 WEST PENDER ST.
VANCOUVER BC V6C 1G8

This is the Final Report and supersedes any preliminary report with this certificate number. Results apply to samples as submitted. All pages of this report have been checked and approved for release.

Appendix I: Compact Disc

Report text, geochemical and drill databases, geophysical files, drafting and plot files, photographs

Appendix J: Geologist's Certificates

GEOLOGIST'S CERTIFICATE

Jeremy M.P. Major
408 Houston St.,
Nelson, BC, Canada

I, Jeremy Major, am a Geoscientist employed by Equity Exploration Consultants Ltd., with offices at #700–700 West Pender Street in the City of Vancouver, B.C., in the Province of British Columbia.

I am a graduate of Simon Fraser University (2006) with a Bachelor of Science degree in Earth Science, and I have practiced my profession continuously since 2006.

Since 2006 I have been involved in mineral exploration for gold, silver, copper, molybdenum, lead, zinc and uranium in Canada.

I am presently a Consulting Geologist and have been so since June 2006.

Dated at Nelson, British Columbia, this 19th day of December, 2008.

Jeremy Major, B.Sc.

GEOLOGIST’S CERTIFICATE

Justin D. MacDonald
821 Cambie St.,
Vancouver, BC, Canada

I, Justin MacDonald, am employed as a Geoscientist by Equity Exploration Consultants Ltd., with offices at Suite 700–700 West Pender Street in the City of Vancouver, B.C., in the Province of British Columbia.

I am a graduate of Memorial University of Newfoundland (2006) with an Honours Bachelor of Science degree in Geology, and I have practiced my profession periodically since 2005.

Since 2005 I have been involved in mineral exploration for gold, silver, copper, lead and zinc in Canada.

I am presently a Graduate student at the University of Waterloo and a Consulting Geologist and have been so since January 2007.

Dated at Vancouver, British Columbia, this 2nd day of December, 2008.

Justin MacDonald, B.Sc.
