Introduction

This report details the technical work carried out on tenures #563872 - KLASKINO 5 and #624623 - KLASKINO6. The two tenures consist of 18 cells or 372 hectares. The tenures are owned 100% by myself, Vincent John Buddick, FMC #205212. A project of prospecting, rock sampling and mapping was performed on August 28 - September 1, 2009. Approximately 30 hectares was examined in this quest. 42 hours of field work was recorded when the project completed.

Location

The tenure is situated on traditional lands of The Quatsino First Nations. A 2009 letter of intention was sent to their respective band office, describing the nature of planned projects.

Located on northwest Vancouver Island, NTS grid 92L/5, it can be accessed with a high clearance vehicle via Highway 19/Port Alice Highway/South Road/Marine Drive/Teeta Main/K Main/I Main/J Main/B Main/Klaskino Main. Driving Distance from Port Alice to the tenure boundary is 90 kms. A camp was set up on the shores of Klaskino Inlet.

Klaskino Road is the only driveable road on the tenure. All other mapped roads and spurs have become densely overgrown with alders. Access from these spurs is quite labourious, but does allow for inspection of outcrop.

Three maps illustrate the tenures' location in 1:250,000, 1:50,000 and 1:20,000 scales. See figures 1, 2 and 3.

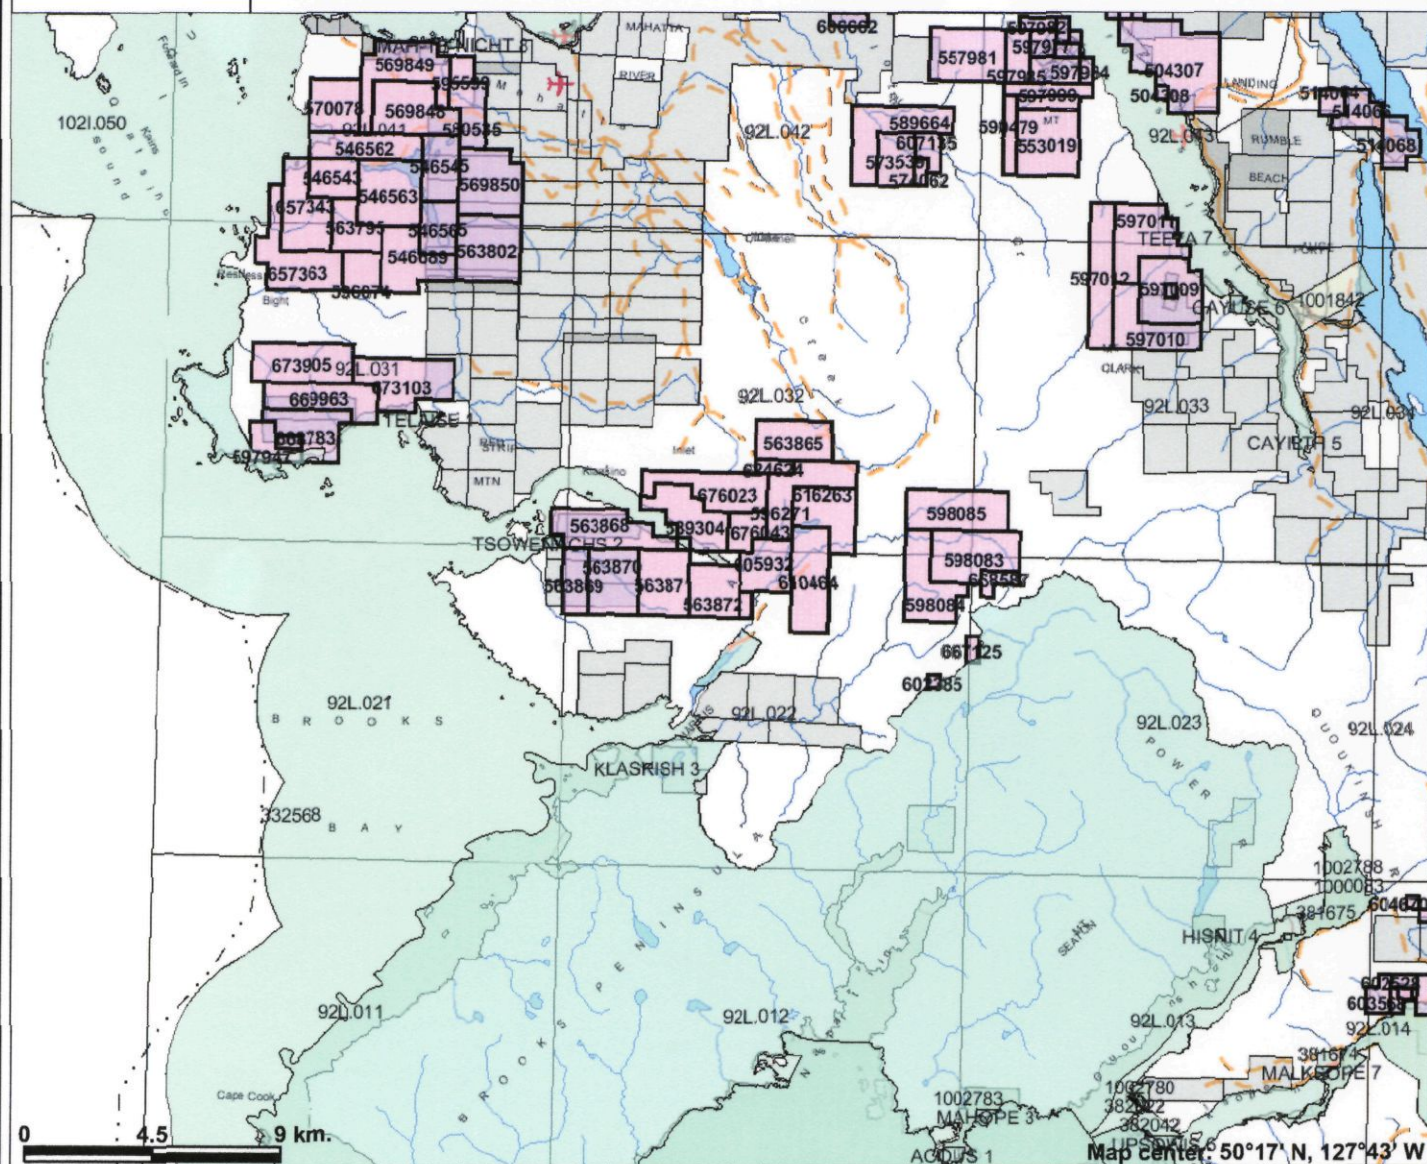

Topography, Vegetation and Climate

The topography consists of moderately steep mountainous terrane. Elevations rise from 0m along the shores of Klaskino Inlet to 600m at the highest point along the southwest boundary. Numerous small creeks drain into Klaskino Inlet to the north and the Klaskish River to the south. The area has been partially logged and is in various stages of regeneration.

Vegetation is typical of a clear-cut logged area. The secondary growth is well advanced in areas near the inlet and relatively young in areas to the south. It was challenging to traverse around the remnant logs. The extremely thick alder growth on the logging roads can hinder access equally. In some areas a traverse thru the second growth, paralleling the densely overgrown logging road, proved the safer and more efficient route.

The area is in direct proximity to the Pacific Ocean and receives above average west coast rainfalls from October thru March. .

History

ARIS 11226: In 1982 BP Minerals showed interest in the Klaskino area. A project involving geological mapping, stream and soil geochemical testing and rock chip sampling was conducted on the north and south shore of Klaskino Inlet. Resulting geochemistry suggested the widespread distribution of arsenic bearing minerals with local associations of gold, silver, copper, mercury and antimony. Further work was deemed to be warranted based on the potential for an epithermal gold mineralization.

ARIS 30215: Details my 2008 discovery of talus sample RF001. Lab results show the sample to be highly mineralized with anomalies in **Cu (>10 000ppm)**, Zn (834ppm), **Ag (6130ppb)**, Ni (268ppm), Co (439ppm), As (103ppm), **Au (126ppb)**, Hg (344ppb) and Fe (15%).

Geology

Vancouver Island belongs to the Insular Tectonic Belt, the westernmost subdivision of the Canadian Cordillera. Wrangellia, *an accreted oceanic plateau* (Green Andrew R., et al), forms the dominant terrane. See figure 4, Distribution of Wrangellia.

The Wrangellia Terrane is a complex and variable terrane that extends from Vancouver Island to central Alaska. Wrangellia is most commonly characterized by widespread exposures of Triassic flood basalts and complementary intrusive rocks (Jones et al., 1977). Triassic flood basalts extend in a discontinuous belt from Vancouver and Queen Charlotte Islands (Karmutsen Formation), through southeast Alaska and the Kluane Ranges in southwest Yukon, and into the Wrangell Mountains and Alaska Range in east and central Alaska (Nikolai Formation). This belt of flood basalt sequences has distinct similarities and is recognized as representing a once-contiguous terrane (Jones et al., 1977).

Wrangellia has a long and diverse geologic history spanning much of the Phanerozoic. On Vancouver Island, the oldest rocks of Wrangellia, which lie at the top of an imbricated stack of northeast-dipping thrust sheets (Monger and Journeay, 1994), are Late Silurian to Early Permian arc sequences (Muller, 1980; Brandon et al., 1986; Sutherland Brown et al., 1986). In the Late Triassic, rapid uplift associated with a rising plume head lead to eruption of voluminous flood basalts as part of an extensive oceanic plateau (Richards et al., 1991). As volcanism ceased, the oceanic plateau soon began to subside and accumulate deep-water carbonate sediments (Jeletzky, 1970; Carlisle and Suzuki, 1974). Sedimentation within the Wrangellia Terrane lasted until the Early Jurassic, when the resurgence of arc volcanism developed in response to subduction, forming the Bonanza arc (Armstrong and MacKevett, 1977; DeBari, 1999).

The enormous exposures of the Karmutsen appear to represent a single flood basalt event (Richards et al., 1989). A mantle plume initiation model has been proposed for the Wrangellia flood basalts based on (1) relatively limited geochemical data, (2) the nature of the underlying and overlying formations, (3) rapid uplift prior to volcanism, (4) the lack of evidence of rifting associated with volcanism and (5) the short duration and high eruption rate of volcanism (Richards et al., 1991). The basalt flows are estimated to have erupted a minimum volume of $1 \times 10^6 \text{ km}^3$ (Panuska, 1990) within a maximum of five million years (Carlisle and Suzuki, 1974).

During the 80 million years or so between arc activity and emergence of oceanic plateau flood basalts, as the continents gathered into a great landmass, Wrangellia became part of a composite terrane (Plafker et al., 1989). By the Middle Pennsylvanian, Wrangellia may have joined with the Alexander Terrane (Gardner et al., 1988) or been in close proximity (stratigraphic continuity) with the Alexander Terrane (Yorath et al., 1985). The ocean-bound Wrangellia Terrane amalgamated with the Taku Terrane of southeast Alaska and the Peninsular Terrane of southern Alaska by as early as the Late Triassic (Plafker et al., 1989). Paleomagnetic and faunal evidence indicate the Wrangellia Terrane originated far to the south of its present position (Hillhouse, 1977; Yole and Irving, 1980; Hillhouse et al., 1982; Hillhouse and Gromme, 1984). Wrangellia accreted to the North American craton by the Late Jurassic or Early Cretaceous (Monger et al., 1982; Tipper, 1984; Plafker et al., 1989; Gehrels and Greig, 1991; van der Heyden, 1992; Monger et al., 1994.

The regional geology consists of two thick volcanic/sedimentary cycles. The first is the Vancouver Group of Triassic age consisting of Karmutsen volcanics, Parson Bay and Quatsino limestones. Secondly the Bonanza Group volcanics of Lower Jurassic age. These packages are intruded by the Island Intrusives of the Middle Jurassic age, see figure 5, Regional Mesozoic-Cenozoic Stratigraphy of Northern Vancouver Island (modified after Muller, et al. 1974, 1981). The area was mapped for the GSC in 1974 by Muller, Northcote and Carlisle.

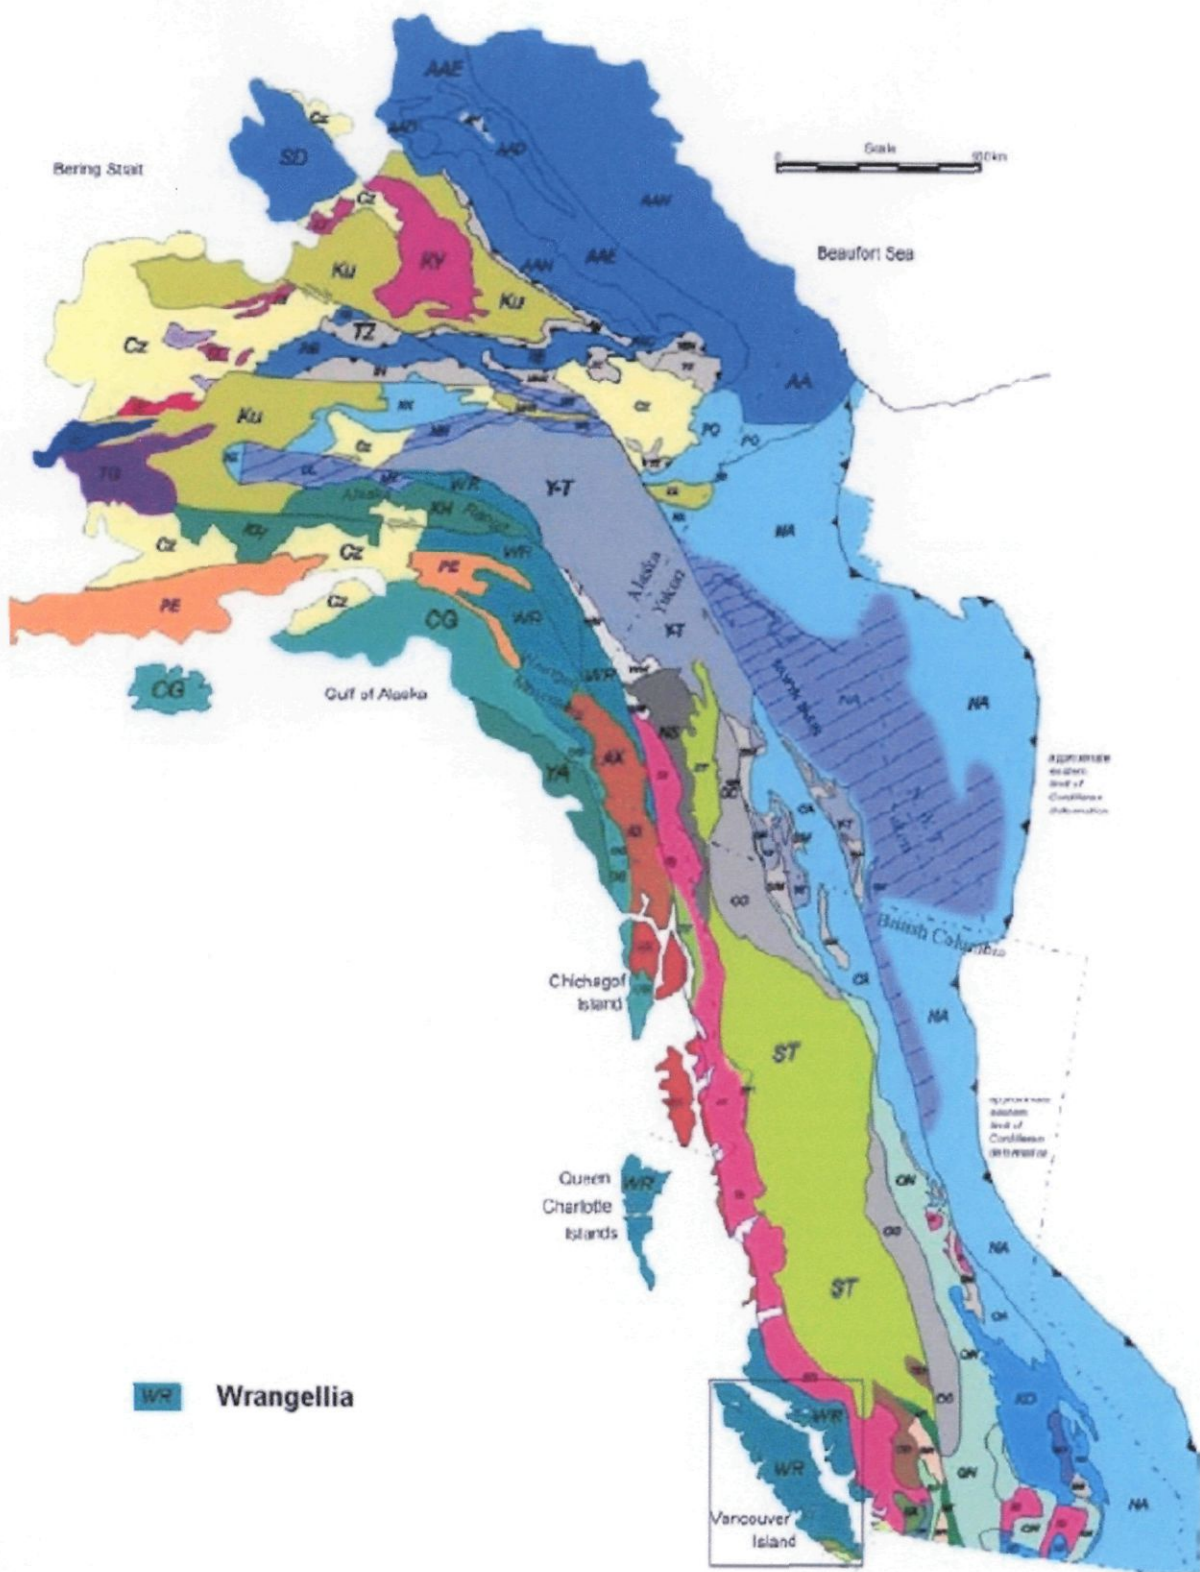

Local geology consists of Karmutsen volcanics, Bonanza volcanics and Parson Bay limestone, see figure 6, KLASKINO 5/6 - Local Geology. This map shows the Mineral Titles On-line grid transposed on the Digital Geology Map of British Columbia, January 2005, N.W.D. Massey, et al.

The south portion of the tenure is overlain by a raised fault-bounded block of Parson Bay limestone, possibly a small horst feature. This relates to the anomalous Vancouver Group uplift of the local area. A large gneissic body may form the basement and outcrops 7kms south, forming the Brooks Peninsula.

Vancouver Island has numerous highly mineralized areas. Strongly mineralized zones are known to exist in the northwest area of the island. Five specific deposit types are found:

- 1) Porphyry copper-molybdenum deposits
- 2) Copper-iron-gold skarns
- 3) Base metal skarns
- 4) Copper bearing quartz veins and shear zones (with precious metals)
- 5) Epithermal gold deposits

Summary of Work

This project of prospecting, rock chip sampling and mapping focussed on a target area surrounding mineralized talus sample RF001 discovered during the 2008 project (ARIS 30205). A 200 meter wide perimeter surrounding the sample location was defined. Road cut was examined and sampled in greater detail. Detailed inspection and sampling of numerous bluffs and other areas of exposed outcrop was completed on manageable traverses.

A few heavily overgrown logging road were inspected for outcrop up to their terminus or tenure boundary. A full day was spent inspecting a creek near the northeast corner of the tenure. All study areas, outcrops and areas of interest were mapped and stored as GPS waypoints. 17 samples were collected for further study. Rock samples were sent in for analysis from 14 locations. All data was recompiled and hand drawn on 1:5,000 maps, which are keyed into a main mapping grid. See figures 7 -10.

Notes on Mapping

Note 1: Disseminated pyrite noted in black limestone. The lowest layer of the Parson Bay Formation. 14-16mm shell fossils noted in black limestone.

Note 2: Parson Bay limestone sits unconformably above volcanics. Limestone beds strike 170', dip 75' W.

Notes on Rock Sampling

Rock samples collected during field projects are placed in clean plastic snap-tight containers and labelled on-site. The specimens are further studied and stored at the office. Specimens chosen for lab analysis are weighed and divided in 2 with one half prepared for analysis the other half stored for future study, field recognition or retesting. Some more notable samples are photographed. Analysis samples are placed in numbered kraft paper envelopes and packaged for shipment.

Samples were delivered to ACME Analytical Laboratories (Vancouver), and tested for 36 elements using the 1DX analytical package, 15gm sample. Samples are crushed, split and pulverised to 200 mesh, then processed using the Aqua Regia digestion and Ultratrace ICP-MS analysis procedure. Due to highly combustible sulphides, sample RF012 is inaccurate, (Acme Labs).

Conclusion

The results of this year's limited project are very encouraging. Analytical results from hard rock sampling in the target zone surrounding the initial discovery (talus sample RF001 - ARIS 30205) show several highly mineralized zones. These alterations in jointed and fractured silicified dark volcanics most likely relate to quartz/calcite veins and associated epidotization. Further rock and soil sampling would be recommended. A few trenches would be warranted in future projects.

General reconnaissance in new areas revealed a few minor mineralizations and assisted in understanding local stratigraphy.

Author's Qualification

I, Vincent John Buddick, of 1508 Marina Way, Nanoose Bay, British Columbia, hereby certify;

1) I have completed the British Columbia Institute of Technology, Introduction to Prospecting and Exploration course, in two parts; mine 1003/spring 2007 and mine 1004/fall 2007.

2) I have been physically prospecting for 3 years.

3) I am the sole owner of North Island Exploration, 1508 Marina Way, Nanoose Bay, British Columbia, and currently hold 100% interest in the tenure.

Vince Buddick

Date: Jan. 14, 2010

Vince Buddick,
Prospector
