### **3.0 SUMMARY**

The South Rim property is prospective for shear hosted gold-silver-molybdeum-copper mineralization. The property consists of 21 contiguous claim blocks that covers known early stage structurally controlled gold bearing polymetallic vein occurrences identified in the BC Ministry of Mines (BCMEM) Minfile database as the COLES SHOWING (Minfile No. 093E110) and CINDERELLA SHOWING (Minfile No. 093E106). The claims are located in the Tahtsa Lake-White Sail Lake Exploration District approximately 30 kilometers south of the Huckleberry Mine.

The South Rim Property is situated south of Coles Lake, west of Coles Creek, north of Little White Sail Lake. Present access is by helicopter from Smithers, Houston or Burns Lake. It is approximately 0.7 and 0.9 hours to the property by helicopter from Houston and Smithers, respectively.

Molybdenite mineralization was first noted in float boulders by Al Potter while prospecting in the area in 1967. During 1978, Silver Standard Mines Limited conducted prospecting in the area. Extremely high molybdenite values were noted from float in moraine material which was traced for over 600 metres up slope almost to the edge of the glacier. Assay values of from 0.042 to 1.28% Mo were reported with a 256 pound grab sample taken by Mr. Potter in 1967 assaying 0.12% Mo. The molybdenite was observed to occur in pockets with sericitization of the adjacent rocks resulting in a green tint to the plagioclase.

Four kilometres to the east of the molybdenite mineralization quartz veins containing anomalous gold mineralization were first noted in the area during the summer of 1982 by Richards, Suratt, Holden and Bell while engaged in a reconnaissance exploration program in the Whitesail Lake area. Early work was targeting the anomalous precious metal values noted in the north trending structures. Epithermal quartz veins and silicified rocks are associated with shear zones and range from stringers to three metres in width. The quartz is described as generally white, and occurring as vuggy, coxcomb, sugary, massive and cherty types in veins that are discrete, banded, stockworks or boxwork structures (Richards, 1984). Twelve mineralized showings were identified with the best Au assay of 24 ppm over a meter.

The 2010 exploration program carried out by Downtown Industries consisted of a geological review of the Tahtsa Lake to White Sail Lake Exploration District, a GIS compilation of all historic technical data within and adjoining the South Rim Property, a lineament study from a 2007 orthophoto, a petrographic study, a verification rock geochemical sampling and infill soil sampling program designed to evaluate the on strike projections of known mineral showings. A total of 1283 soil samples and 81 rock samples were collected during the 2010 exploration program.

The results of the 2010 exploration program successfully verified the known mineral showings referred to as “Main Creek”, “High View”, “East Side”, “Center View”, and “V.P” showings.

Gold values up to 3460 ppb were observed on the property. The petrographic study verified the epithermal nature of the mineralization. The lineament study successfully showed a correlation between known mineralization and large scale first order lineament observations. The lineament study also indicated 3 favourable directions of mineralization and identified a number of structures that could hold the potential of undiscovered mineralization.

In the authors opinion based on the results of the 2010 exploration program the South Rim property is a property of merit and deserves further exploration.

## 4.0 Property Description and Location

### 4.1 Property Description and Location

St. Elias Mines holds a 100% interest in 21 contiguous mineral tenures (8,221.51 hectares) that cover a staircase shaped triangle of ground located approximately 25 kilometers south of Huckleberry in west central BC. All of the claims which comprise the South Rim Property were staked pursuant to the BC Ministry of Energy and Mines MTO system (Mineral Titles Online System). The earliest expiry date of the claim package is October 15, 2010. The location of the property relative to other mining claims, local communities, parks and access roads is shown in Figure 1. The individual claim tenure numbers are shown in Figure 4. The South Rim the property is locates within the NTS Mapsheet 92E06.

The mineral cell title claim statistics are summarized in Table 1; note that this claim information is not a legal title opinion but is a compilation of claims data based on the author's review of the government of the British Columbia Mineral Rights inquiry website (BC Mineral Titles September 25, 2010). The mineral claims do not have to be legally surveyed; since they are BC Government established mineral cell title claim.

Table 1. Mineral Tenures for the South Rim Property

## **5.0 Accessibility, Infrastructure, Climate and Physiography**

### **5.1 Accessibility and Infrastructure**

The South Rim Property is situated south of Coles Lake, west of Coles Creek and north of Little White Sail Lake approximately 30 kilometers south of the Huckleberry Mine. Present access is by helicopter from Smithers, Houston or Burns Lake. It is approximately 0.7 and 0.9 hours to the property by helicopter from Houston and Smithers, respectively.

The Morice-Tahtsa forest service road (Huckleberry Mine road) leads to a suitable gravel pit/staging area, 4 kilometers west of the 113 kilometer turn off. From this staging area the South Rim property is approximately 0.2 hours south. Driving time from Houston to the Huckleberry staging area is approximately 1.5 hours. Experienced field personnel and drilling contractors are available in the community of Smithers.

### **5.2 Climate and Physiography**

The South Rim property extends south from Coles Lake and covers ground rising from 900 metres to about 1,900 metres above sea-level. The claims continue, to the south, to the north western shore of Little White-sail Lake at about 853m elevation above sea level. The topography varies from mountainous in the central claims area to hilly and locally flat in the northern claims. The south side of the mountainous terrain is very steep and rugged to the northern shore of Little White Sail Lake. Several lakes and streams on the property carry adequate amounts of water for exploration and mining. Mature balsam and hemlock cover much of the northern and eastern lower elevations of the property while the western upper elevations are sparsely covered by subalpine scrub. Swampland occurs in areas near Coles Lake. Glaciers and moraine material occur on the mountainous western part of the property south of Coles Lake. Snow is present on the property from mid-October until about early-June.

## 6.0 History of Exploration

### 6.1 Exploration carried out by Silver Standard Mines (ARIS: 7801)

Molybdenite mineralization was first noted in float boulders by Al Potter while prospecting in the area in 1967. During 1978, Silver Standard Mines Limited conducted prospecting in the area. Extremely high molybdenite values were noted from float in moraine material which was traced for over 600 metres up slope almost to the edge of the glacier. Assay values of from 0.042 to 1.28% Mo were reported with a 256 pound grab sample taken by Mr. Potter in 1967 assaying 0.12% Mo. The molybdenite was observed to occur in pockets with sericitization of the adjacent rocks resulting in a green tint to the plagioclase. Elevated radioactivity was noted in mineralized alaskite, possibly caused by secondary uranium salts. Early sampling by Mr. Potter returned assays of from 4.0 PPM to 0.029% U<sub>3</sub>O<sub>8</sub>, in addition to the significant assays of Mo and up to 5.70% F. Float material of calcareous volcanics with up to 50% garnet, 10% pyrite, minor chalcopyrite, galena, sphalerite and some molybdenite were also reported by Mr. Potter from the eastern contact of the intrusive. There is no record of the source of this material being evaluated.

Silver Standards claim outline with respect to the South Rim property is shown in Figure 4. Silver Standards maps have been georeferenced and sample locations have been plotted in Figure 5. The molybdenum float train identified by Al Potter is shown in Figure 6. Associated geochemistry and UTM coordinates for these samples was compiled and can be found in Appendix 3. A summary of work done by Silver Standards on ground currently covered by the South Rim property is provided in Table 2.

### 6.2 Exploration carried out by Nuspar Resources (ARIS: 12666, 12802, 13070, 13866, 14531)

Quartz veins containing anomalous gold mineralization were first noted in the area during the summer of 1982 by Richards, Suratt, Holden and Bell while engaged in a reconnaissance exploration program in the Whitesail Lake area. The Cole 1 through 4 claims were subsequently staked in 1983 by Dr. Tom Richards and were optioned to Nuspar Resources Ltd. Work in 1984 and 1985 included geological mapping, prospecting and rock geochemistry. This work was targeting the anomalous precious metal values noted in the north trending structures lying to the east of the intrusive contact. Epithermal quartz veins and silicified rocks are associated with shear zones and range from stringers to three metres in width. The quartz is described as generally white, and occurring as vuggy, coxcomb, sugary, massive and cherty types in veins that are discrete, banded, stockworks or boxwork structures (Richards, 1984). Pyrite is the dominant sulphide, ranging from nil to 10%; minor chalcopyrite was also reported. All the veins are accompanied by some degree of alteration along the selvage of the shear or vein.

Propyllitization is the most common alteration, extending from less-than one meter to in excess of 5 meters from the vein margin. Bleaching (argillic alteration) is most noted immediately adjacent vein walls and in fragments of wall rock included within the vein.

Seven showings were identified: High View Showing, Camp View Showing, Center View Showing, Chalco Showing, South Side Showing, Low View Showing and East Side Showing. All significant mineralization was found to be related to shear zones. The claims were allowed to lapse.

Nuspar Resources claim outline with respect to the South Rim property is shown in Figure 4. Nuspar Resources maps have been georeferenced and sample locations have been plotted in Figure 5. The showings identified by Nuspar Resources are shown in Figure 6. Associated geochemistry and UTM coordinates for these samples was compiled and can be found in Appendix 3. A summary of work done by Nuspar Resources on ground currently covered by the South Rim property is provided in Table 3.

Table 3. Summary of Work Carried out by Nuspar Resources

Owner/Property	Geochemistry	Geophysics	Trenching	Drilling	Reference
Nuspar Resources Cole Property	78 rocks 52 soils				Richards, T.A. (1984a) ARIS: 12666

Nuspar Resources Coles Property	134 rock				Richards, T.A. (1985b) ARIS: 14531

### 6.3 Exploration carried out by QPX Minerals (ARIS: 16677, 17962)

In 1987 the claims were restaked and optioned to QPX Minerals Inc. During 1987, Mine Quest Exploration Associates Ltd. performed preliminary geological mapping, rock chip sampling and soil sampling. A further five mineralized showings were discovered. These include the Amethyst, Main Creek, Northwest, V.P. and West Side showings. Gold values range from trace to 24,000 ppb across 1 metre (Chalco Showing, L.J.Lee, 1987). Significant silver values (25.6

ppm in float) as well as anomalous values of As, Sb, Bi, Se, and Te have been detected. At the West Side Showing, while neither gold or silver were anomalous, values of up to 1,500 ppb Hg and 5,723 ppm As, with anomalous Sb, Se and Te were reported (L.J.Lee, 1987).

QPX Minerals claim outline with respect to the South Rim property is shown in Figure 4. QPX Minerals maps have been georeferenced and sample locations have been plotted in Figure 5. QPX Minerals maps have been georeferenced and sample locations have been plotted in Figure 6. Associated geochemistry and UTM coordinates for these samples was compiled and can be found in Appendix 3. A summary of work done by Nuspar Resources on ground currently covered by the South Rim property is provided in Table 4.

Table 4. Summary of Work Carried out by QPX Resources

QPX Minerals Cole Property	78 rocks				Gourlay, A.W. (1988) ARIS: 17962

#### 6.4 Exploration carried out by Hi Ho Silver Resources (ARIS: 29662)

In 2007 Hi Ho Silver Resources put a field program together to relocate, sample and find the source of the previously reported high grade molybdenite mineralization, found by Silver Standards and to carry out reconnaissance geological mapping to look for prospective geology and mineralized showings. An area of approximately three square kilometres was mapped in a reconnaissance fashion. Five float samples were collected that returned anomalous values of Mo, Cu, Pb and Zn.

## **7.0 Geological Setting**

Regional mapping of the Whitesail area by Duffell (1959), Hodder and MacIntyre (1980), Tipper et al. (1979) and Woodsworth (1980) shows that the area of interest lies along the eastern margin of the Coast Plutonic Complex. Lower Jurassic volcanics and interbedded sediments of the Hazelton Group predominate to the east of this complex. Overlying the Hazelton volcanics are epiclastic rocks of the Upper Jurassic Ashman Formation and the Lower Cretaceous Skeena Group. These are in turn overlain by the Upper Cretaceous volcanic rocks of the Kasalka Group. Finally, Tertiary volcanism deposited the siliceous volcanic rocks of the Ootsa Lake Group and the basalts of the Endako Group. Intrusive rocks, ranging in composition from granites to gabbros, are also present in the area. These intrusives vary in age from Tertiary to possible as old as Paleozoic (Figure 2).

Richards (1984) and Woodsworth (1980) have mapped a resurgent caldera, at least 20 km in diameter, immediately north of the claims. The collapsed caldera center consists of Kasalka and Skeena Group rocks, with a number of intrusions. Several potentially economic mineral deposits occur in association with small granodiorite stocks which may be located at the intersection of ring and radial fractures related to the caldera formation (Hodder and MacIntyre, 1980). It appears that a section of the caldera ring fractures zone underlies the South Rim property. The area of interest is also cut by a series of north to north-easterly trending faults (Figure 3).

Mapping on the South Rim Property has shown that the area is primarily underlain by volcanic and minor sedimentary rocks of the Lower Jurassic Telkwa Formation of the Hazelton Group (Figure 3). The rocks generally dip steeply north-west and consist mainly of subaerial, thick-bedded purple to green lapilli tuffs and volcanic breccias. Minor interbedded sediments, mainly mudstones, are also present. Intermediate dykes are relatively common cutting through the volcanics. A series of north trending faults cross the property. Less major northeast and northwest trending faults are also present. The faults are generally marked by steep banked creeks; quartz-feldspar porphyry dykes often occur in the fault zones. Richards (1985) reports the presence of hornblende - feldspar porphyry dykes, in addition to those mentioned above. Fault breccias, silicified zones and quartz-carbonate veining are also common in fault zones. According to Richards (1985), the western most creek present on the property represents a major north to northwest trending shear zone. Rocks to the west of the fault consist of indurated and hornfelsed Hazelton Group volcanics. The volcanics are cut by numerous dykes associated with the nearby Coast Intrusions. The normal component of the fault is thought to be down to the east. It is believed that the vein system resulted from tension-gash openings resulting from movement along this fault. The movement is thought to be coincident with the emplacement of the Coast intrusions and evolution of the Tahtsa caldera. Mineralization developed as a result of volcanic-tectonic activities.

## **8.0 Deposit Types**

References for deposit characteristics are the British Columbia government mineral deposit profiles web site and the Northern Miner “Geology 101” web site (Section 21 References).

### *Shear Hosted Gold-Silver ( $\pm$ polymetallic) Vein deposits*

South Rim property mineralization is similar to most shear related lode gold deposits. Mineralization is epigenetic in nature and formed from structurally focussed hydrothermal fluids, which create a system of low sulphide quartz veins, veinlets or stockworks. These deposits are normally associated with major regional scale structural “breaks” or faults. Deposits are often located in or near a plutonic body. Vein systems often occur in the central parts of discrete shear zones within a larger regional fault, where rotational or simple shear strains predominate. Vein systems are tabular, sub vertical structures of varying thickness and lateral extent; where typical thickness is measured in metres and the strike-dip dimensions are measured in tens or hundreds of metres. The economically viable part of the vein system may be considerably smaller than the whole shear system; often forming discreet shoots of mineralization. Precious metal mineralization often occurs as coarse individual grains. As a result of the coarse individual grains this type of deposit difficult to evaluate, due to a “nugget effect” on sample analyses.

Quartz veins usually have sharp contacts with wallrocks and exhibit a variety of textures, including massive, ribboned or banded and stockworks with anastamosing gashes and dilations. Textures may be modified or destroyed by subsequent deformation. Wallrock alteration is characterized by silicification, pyritization and potassium metasomatism generally occurring adjacent to veins (usually within a metre) within a broader zone of carbonate alteration, extending up to tens of metres from the veins. Quartz-carbonate altered rock (listwanite) and pyrite are often the most prominent alteration minerals in the wallrock. Fuchsite, sericite, tourmaline and scheelite are common where veins are associated with felsic to intermediate intrusions.

Ore mineralogy can include: gold, silver, arsenopyrite chalcopyrite, pyrite, sphalerite, tetrahedrite, argentite, pyrrhotite, galena, tellurides, scheelite, and bismuth.

Gangue mineralogy includes: quartz and carbonate (calcite, dolomite, ankerite or siderite), hematite-limonite, mariposite (fuchsite), sericite, muscovite, chlorite, tourmaline, graphite.

Typical geophysical signature: Associated structures may be defined by ground magnetic, very low frequency or electromagnetic surveys. Airborne surveys may identify prospective regional-scale major structures.

Other similar British Columbia lode gold deposits include Bralorne-Pioneer and Premier mining camps. Other well-known examples of lode gold mining camps are Red Lake (Ontario) and Kirkland Lake (Ontario).

## **9.0 Exploration**

### **9.1 Summary of exploration work carried out in 2010**

The 2010 exploration program carried out by Downtown Industries consisted of a geological review of the Tahtsa Lake to White Sail Lake Exploration District, a GIS compilation of all historic technical data within and adjoining the South Rim Property, a lineament study from a 2007 orthophoto, a petrographic study, a verification rock geochemical sampling and infill soil sampling program designed to evaluate the on strike projections of known mineral showings referred to by QPX Minerals as “Main Creek”, “High View”, “East Side”, “Center View”, and “V.P” showings. A total of 1285 soil samples and 81 rock samples were collected during the 2010 exploration program. The location of each soil and rock sample station was noted, in UTM coordinates (NAD83 zone 9), with the aid of a hand-held GPS (Garmin 60CSx) and are shown in Figures 7, 8 and LF1 and they are also listed in Appendix 2 and 3.

The soil grid covered an area of 1.5 km x 1.0 km with station spacing at 25m in the east-west direction and line spacing at 50m in the north-south direction.

All samples collected during the 2010 exploration program were submitted to SGS (formerly Assayers Canada), of Vancouver, for analysis. Rock samples were crushed, split, and ring pulverized (250g, > 95% -150 mesh). 15 grams of the -150 mesh (<106 µm) sieved fraction of the rock sample was fire assayed with an atomic absorption finish for gold and 0.5 grams of the sample was digested with 5 mL 3:1 HCl/HNO<sub>3</sub> at 950C for 2 hours and diluted to 25 mL with a 50-element ICP-MS finish. The top 10 gold assays for the rock samples were also tested analysed for coarse metallic. The coarse metallic method involves ring pulverizing a 500 gram sample and sieving through -250 mesh and analyzes both the fraction that passes through the mesh and that is left behind. The assay is then weight averaged. Soil samples were dried and sieved to -80 mesh. 15 grams of the -80 mesh (<180 µm) sieved fraction of the rock sample was fire assayed with an atomic absorption finish for gold and 0.5 grams of the sample was digested with 5 mL 3:1 HCl/HNO<sub>3</sub> at 950C for 2 hours and diluted to 25 mL with a 34-element ICP-OES finish. The elements analyzed for each rock sample and their detection and upper limits are listed in Table 6. The elements analyzed for each soil sample and their detection and upper limits are listed in Table 7.

SGS employs standard QA and QC protocols on all sample analyses including inserting one blank, reference standard and duplicate analysis in every twenty samples analyzed. Based on the fact that the sampling program was designed to verify and follow up previous exploration work completed by QPX Minerals and Nuspar Resources in the 1980's no additional QA and QC procedures were implemented as part of the program. Sample Certificates from the 2010 exploration program are included in Appendix 6.

In the authors opinion the sample security employed by the field personnel involved in the sample collection and the sample preparation and analytical procedures employed by SGS are adequate for the exploration program carried out by Downtown Minerals on the South Rim Property.

## 9.2 Soil Geochemical Results

The 2010 soil program resulted in the collection of 1285 soil samples. All samples were collected from the B-horizon which generally was at 15 cm depth. Samples, “A-samples”, were taken between 20 and 35 cm with the use of a shovel or an auger. At random a second sample, “B-sample”, was taken from the same hole at a deeper interval typically between 35 and 50 cm. 155 of the 1285 soil samples were such “B-samples”. The “B-samples” were collected to test for a possible depth related mineral horizon.

Graph 3 shows scatter plots for SGS laboratory replicates and A vs. B depth samples for Zn, Cu, and Au elements. Both sets of plots have a linear (slope = 1) relationship. In the case of the laboratory scatter plots this indicates that the analytical error by the lab is very small. In the case of the “A” versus “B” depth scatter plots this indicates that there is little difference in sample geochemistry between 15 and 50 cm.

Statistical values of Au, Ag, As, Ba, Cu, Hg, Mo, Pb, Zn for the 2010 soil are presented in Table 8. Background concentrations as well as weak and strong anomaly concentration cutoffs were established using box plots created from the 2010 data. Defining Q1 and Q3 to be the first and third quartile and IQR to be the interquartile range ( $Q3 - Q1$ ), the background concentration cutoff is defined as: Background  $< Q3 + 1.5 \times IQR$ ; A strong anomaly is defined as: Strong anomaly  $> Q3 + (3 \times IQR)$ . A weak anomaly is defined as greater than the background but less than a strong anomaly.

Table 8. Geochemical Summary Statistics: North Slope Poly Zone

	Au (ppb)	Ag (ppm)	As (ppm)	Cu (ppm)	Hg (ppm)	Mo (ppm)	Pb (ppm)	Zn (ppm)
Background	7	0.2	5	24	1	2	23	76.5
S. Anomaly	10	0.2	5	36	1	2	32	108
Average	4.7	0.2	5.4	9.6	1	2.1	13	35
Max	172	5.1	99	160	6	19	539	378
Min	2	0.2	5	1	1	2	2	1
50th percentile	3	0.2	5	8	1	2	11	34
70th percentile	4	0.2	5	12	1	2	14	45
80th percentile	5	0.2	5	13	1	2	15	48
90th percentile	8	0.3	6	17	1	2	17	55
95th percentile	10	0.4	7	21	1	2	20	61

Ten anomalous Au zones have been identified from thematizing the 2010 soil geochemical survey using the background, weak and strong anomaly cut-offs determined in the geochemical summary statistics table. Figure LF1 shows the outline of these anomalous zones.

### 9.3 Rock Geochemical Results

The 2010 outcrop verification/prospecting program culminated in the collection of 81 rock samples. 4 samples were collected as float samples and 77 were chip samples across shear zones, breccia bodies, and quartz veins. For this program composite chip samples were collected from within mineralized areas believed to correspond to the areas sampled by QPX Minerals and Nuspar Resources in the 1980's.

Statistical values of Au, Ag, As, Ba, Cu, Hg, Mo, Pb, Zn for the 2010 rock samples are presented in Table 9.

Table 9. Geochemical Summary Statistics: North Slope Polymetallic Shear Zone

	Au (ppb)	Ag (ppm)	As (ppm)	Cu (ppm)	Hg (ppm)	Mo (ppm)	Pb (ppm)	Zn (ppm)
Median	23	1.1	15.5	20.1	0.023	18.4	12.4	55
Average	161	6	27	83	0.099	54	75	74
Max	3460	150.6	256.1	2871.6	2.002	671.1	2936.6	592
Min	2	0.1	0.5	2.3	0.005	0.5	1.2	7
50th percentile	23	1.1	15.5	20.1	0.023	18.4	12.4	55
70th percentile	70	2.8	24.2	32.5	0.039	38.2	26.8	70
80th percentile	124	4.3	30.9	47.6	0.076	74.2	41.7	90
90th percentile	164	5.3	51.8	73.1	0.208	127.6	88.6	139
95th percentile	314	14.2	84.3	163.3	0.345	206.9	211.6	197

The top ten gold samples were selected for coarse metallic and the results are shown in Table 10.

Table 10. Coarse metallic analyses and original 15g fire assay Au

Sample Name	Wt Total g	Wt +150 g	+150 Au mg	-150 Au g/tonne	Metallic Au g/tonne	Net Au g/tonne	Original Au (15g)
SR20100901	447.4	34.35	0.097	2.16	0.22	2.21	2.675
SR20100904	397	1.33	<0.001	0.5	<0.01	0.5	0.665
SR20100909	434.8	1.64	<0.001	0.17	<0.01	0.17	0.18
MS20100012	412.7	4.35	<0.001	0.23	<0.01	0.23	0.314
SR20100921	506.6	4.17	0.006	0.12	0.01	0.13	0.164
SR20100924	516.9	4.48	<0.001	0.2	<0.01	0.2	0.164
SR20100934	525.7	5.18	0.074	2.38	0.14	2.5	2.279
SR20100935	517.3	6.96	0.001	0.15	<0.01	0.15	0.166
SR20100958	503.3	8.51	0.002	0.17	<0.01	0.17	0.197
SR20100963	514.9	5.9	0.017	3.75	0.03	3.74	3.46

The coarse metallic analyses shows a good likeness to the Au assays from the 15 gram fire assay analyses and thus the 15 gram fire assay is sufficient in identifying the gold grade of the sample collected.

#### **9.4 Mineralization**

Previous exploration work in the 1980's on the ground now covered by the South Rim Property identified several gold and other precious metal exploration targets (referred to as the High View Showing, Camp View Showing, Center View Showing, Chalco Showing, East Side Showing, Low View Showing, Main Creek Showing, Northwest Showing, South Side Showing, V.P. Showing, Amethyst Showing and West Side Showing). The results of the verification program are described below in the context of each of the mineral showings revisited,

##### ***High View Showing***

This showing is located between 613400m and 613525m East, 5923225m and 5922675m North at an elevation between 1475 and 1750 meters in the north central part of the property (Figure 7). It comprises three parallel shear zones up to 3 meters width. The shear zone is a brecciated structure composed of a box-work of vuggy quartz cementing angular, altered fragments of lapilli tuff. Numerous other veins and lenses up to 3 meters width were noted as splays off the main vein. Pyrite is less than 1%, minor sphalerite noted. Fluorite is locally common. Sixteen samples were collected in 1984 which yielded gold assays up to 440 ppb, and silver to 27.7 ppm.

The High View Showing was visited and anomalous gold was verified by the 2010 verification program. Thirteen samples were taken from this showing (**SR20100934, SR20100935, SR20100936, SR20100937, SR20100938, SR20100939, SR20100940, SR20100941, SR20100942, SR20100943, SR20100946, SR20100947 and SR20100953**). Four samples (**SR20100934, SR20100935, SR20100936, SR20100939 and SR20100947**) returned gold values of **2279, 166, 117, 124, 150** ppb. A number of samples collected were also anomalous in Mo, Re, Cu and Zn.

The High View Showing was observed, by the author, to extend over **600m** striking approximately 150 degrees and dipping approximately 80 degrees. The showing consists of 3 parallel shear zones that make up this showing and vary in width from 40cm to 3m. It is open, but currently not accessible, in both directions. To the north the showing becomes buried by rock fall and to the south the showing becomes covered by snow.

##### ***Camp View Showing***

The Camp View Showing is located between 612700m and 612900m East, 5923475m and 5923725m North at an elevation between 1400 and 1500 meters (Figure 7). It comprises a single main vein traceable intermittently through talus and overburden for some 300 meters. It comprises grey, banded, fine-grained vuggy quartz. Minor stringers are associated. It pinches and swells from stringer to 1 meter width, mainly less than 50 cm. Twenty-one samples, collected in 1985, gave values up to 430 ppb Au, with 12 in excess of 100 ppb Au confirming the values confirming the values to 640 ppb noted in 1983. A proximal float sample of quartz gave values of 1,625 ppb Au and 25.6 Ag.

The Camp View Showing was not revisited during the 2010 verification program.

### *Center View Showing*

This showing is located between the High View Showing and Camp View Showing and was recognized late in the 1983 program (Figure 7). Follow up in 1984 revealed complex set of branching veins, stringers and breccias that includes up to 20 separate units, ranging in thickness from stringers to 4 meters width. Twenty to 100 cm widths are the norm. Fifty-two samples were collected in 1984. Values range from n.d. (not detected) to 1,500 ppb Au. Two veins gave consistently anomalous results in excess of 100 ppb Au, both from the western portion of the showing. Most significant is a northwest trending branch that represents the most southwesterly of the known veins from the showing. Twelve samples from this vein gave values of 110 to 1,150 ppb Au, with two values in excess of 1,000 ppb. The vein pinches and swells, ranging from a stringer-stock work system to massive quartz up to 60 cm width. The quartz is typically fine-grained, vuggy, colloform banded, to planar banded. Local pockets of calcite and fluorite are present. The vein can be traced for 200 meters. A second vein containing significant gold values exposed for about 100 meters, range from 5 cm to 40 cm width and contains gold values up to 870 ppb.

Other veins within the center View showing gave results less than 100 ppb. All except one are less than 20 cm width. An exception is a 3 to 6 meter wide, north-striking silicified breccia zone comprised of angular fragments of bleached volcanics in a matrix of fine-grained dense quartz. One meter wide wedges of sheared, propyllitized volcanics are included within the zone. Chips from this zone gave up to 90 ppb Au.

The showing was visited and anomalous gold was verified by the 2010 verification program. Thirty-two samples were taken from this showing (SR20100901 to SR20100924, SR20100932, SR20100933, SR20100944, SR20100962, SR20100963, SR20100967, MS201013 and SR201014). Nine samples returned gold values over 100 ppb and 2 samples returned gold values of 3460 and 2675 ppb. A number of samples collected were also anomalous in Ag, Mo, Pb, Cu and Zn.

The Center View Showing was observed, by the author, to consist of three dominant structures each extending over 500m. Two of these structures strike and dip in similar directions ( $200\text{ }|\text{ }80$ ) and are approximately 150m apart. These structures are cut by a third structures striking approximately 135 degrees and dipping approximately 80 degrees.

### *Chalco Showing*

This showing was discovered in 1984 and is approximately 500m east of the High View Showing. The showing comprises two components. A northwest trending quartz vein occupies the base of the slope, above extensive talus wash. Trending off this vein, in a north-easterly direction is a series of veins, stringers, silicified and propyllitized alteration pods that carry pyrite and chalcopyrite. From one of these zones, measuring up to 1 meter width, a prospector-grab sample gave a 24,000 ppb Au value. Other values from this zone gave 730 and 340 ppb Au and up to 28 ppm Ag.

The Camp View Showing was not revisited during the 2010 verification program.

### *East Side Showing*

This showing was discovered in 1983 during reconnaissance coverage of this portion of the claims and is about 1000m south of the Chalco Showing. It gave the highest value of gold (1,580 ppb). Follow up sampling in 1984 verified the earlier anomaly with the discovery of values from 430 ppb up to 4,100 ppb Au. Mineralization appears to be associated with quartz stringers and veins (up to 1m) and pyritic-rusty propyllitized and bleached volcanics. Minor galena occurs with this system.

The showing was visited and anomalous gold was verified by the 2010 verification program. Four samples were taken from this showing (SR20100949 to SR20100952). One sample returned a gold value of 70 ppb.

The East Side Showing was observed, by the author, to consist of one structure extending over 350m. The structure strikes and dips approximately 160 and 60 degrees.

### *Low View Showing*

The Low View consists of a 0.5 to 2 m wide quartz vein and breccia zone containing disseminated pyrite in a major shear zone. Numerous stringers are also associated with the system. The vein margins are strongly bleached and locally have a propylite halo extending to 10m from the shear, which may be an extension of the main shear zone hosting the High View and South Side Showings. Previous sampling in 1984 gave values up to 240 ppb Au. Two further rock samples were collected from the showing in 1987, one of which returned values of 385 ppb Au and 30.3 ppm Ag. Anomalous Se, Te and Bi also occurred.

The Low View Showing was not revisited during the 2010 verification program.

### *Main Creek Showing*

The Main Creek Showing consists of a number of parallel quartz veins, up to 50 cm in width, which pinch and swell along their length. The veins are primarily composed of pyritized volcanic breccia fragments in a drusy quartz matrix, and less abundantly are made up of coarsely crystalline quartz. Pockets of calcite commonly occur in the quartz vein. Minor pyrite stringers may also occur. The veins are exposed in a northeast trending creek which follows a fault trace through Hazelton Group lapilli tuffs. The shear zone ranges up to 1.5 m in width and quartz veining is exposed essentially continuously for about 100 metres. At the southern limit the vein system trends in to flat and swampy ground with no outcrop. At the northern end, the northeast trending creek intersects the main, north trending creek which hosts the Center View and High View Showings to the south. At the intersection of the creeks the rocks consist of badly sheared, pyritic, silicified volcanics.

Eight samples were collected from the showing in 1987, giving values of up to 1075 ppb Au and 2.2 ppm Ag. Anomalous values of As and Hg also occurred in the Main Creek Showing.

The showing was visited and anomalous gold was verified by the 2010 verification program. Twelve samples were taken from this showing (SR20100954 to SR20100961 and MS201009 to MS201012). Five samples returned gold values over 100 ppb. A number of samples collected were also anomalous in Mo, Pb, Cu and Zn.

The Main Creek Showing was observed to consist of one dominant structure extending over 175m. The structure strikes and dips approximately 220 and 80 degrees, respectively.

#### *Northwest Showing*

The Northwest Showing is reported to consist of a pyritic shear zone exposed in a northeast trending creek. Three samples were taken from the zone in 1987. Gold values were only slightly above background levels (15 ppb) but values of 2.4 ppm Ag and anomalous As, Sb, Se, and Te suggest that further sampling in the area would be warranted.

The Northwest Showing was not revisited during the 2010 verification program.

#### *South Side Showing*

The South Side Showing consists of a grey to milky, fine grained quartz and quartz breccia vein, up to 3m in width. Minor pyrite and chalcopyrite are present. Sampling of the showing in 1987 gave a maximum of 132 ppb Au and 4.4 ppm Ag, with anomalous Hg, As, and Te. It appears that the South Side Showing is located on the same major shear zone as the High View Showings.

The showing was visited and anomalous gold was verified by the 2010 verification program. One sample was taken from this showing (SR20100974). The sample returned gold value of 56 ppb. The sample also was anomalous in Mo and Ag, 207.1 and 52.4 ppm, respectively.

#### *V.P. Showing*

The V.P. Showing is a north trending shear zone exposed in the same major creek but north of the Amethyst Showing. Carbonate alteration is common and quartz - carbonate veinlets to 5 cm in width occur in a 1 to 2 m wide shear zone. Four samples were taken from the zone in 1987. Two of these samples gave values over 1000 ppb Au. Anomalous values of Hg, Sb, Se and Te were also found in the zone, along with strongly anomalous arsenic values (to 1031 ppm).

The showing was visited and anomalous gold was verified by the 2010 verification program. Five samples were taken from this showing (SR20100968 to SR20100972). Gold values were up to 41 ppb. One sample returned a Hg value of 2 ppm.

The V.P. Showing was observed to consist of one dominant structure extending over 100m.

#### *Amethyst Showing*

The Amethyst Showing was discovered in 1987. It consists of a several metre wide shear zone exposed in a major north to north-west trending creek. The zone consists of well sheared, pyritic volcanics with abundant quartz stringers and silicification. Lenses of amethyst occur at the southern end of the showing; carbonate alteration is also common. Very minor amounts of galena are associated with the amethyst lenses. The zone is traceable along strike for about 70 metres and is immediately overlain by a coarse grained quartz - feldspar porphyry dyke. Five samples were taken from the zone. Gold values are only slightly above background in one sample (the only one which contained amethyst). Silver values are 17.8 ppm in this sample,

however, and anomalous As, Sb, Bi, Se and Te were detected in this and other samples making the zone of interest.

The Amethyst Showing was not revisited during the 2010 verification program.

#### *West Side Showing*

The West Side Showing was discovered in 1988. It consists of pyritic, siliceous and argillic shear zones along a northwest trending creek and near the junction of this creek with the major north trending creek discussed in section 2.2. The zone is reported to range up to several metres in width. Neither gold nor silver values are anomalous, however, values of up to 1500 ppb Hg and 5723 ppm As with anomalous Sb, Se and Te make this showing of interest.

The West Side Showing was not revisited during the 2010 verification program.

## **9.5 Petrographic Report**

Twenty hand samples collected from the verification program were submitted to Vancouver Petrographics for polished thin section preparation and examined by the author using a transmitting and reflected light petrographic microscope.

The samples examined showed very similar textural characteristics between individual samples and showings. Most samples showed a high degree of open space filling quartz veins cutting a chlorite altered lapilli tuff. There were various episodes of fracturing and sealing of quartz veins and vuggy quartz alteration is also prevalent. A few late fracture-filling veins contain euhedrally terminated quartz grains growing into a cavity that was filled slightly to strongly by orange-brown limonite/hematite, which in part has a botryoidal texture. The hydrothermal event also transported sulphide bearing fluids. The sulphides are dominated by pyrite which has been variably oxidized to hematite. In some areas pyrite grains have been completely replaced by hematite and only the relic euhedral shape of the pyrite grain remains.

The samples submitted are listed below and their detailed petrographic description is given in Appendix 5.

#### *Main Creek Showing*

Seven samples (MS2010010, MS2010011, MS2010012, SR20100954, SR20100957, SR20100959 and SR20100960) were examined from the Main Creek showing.

#### *Center View Showing*

Five samples were examined from the Center View Showing (MS2010013, SR20100914, SR20100916, SR20100962, SR20100963).

#### *V.P. Showing*

Four samples from the V.P. Showing were examined (SR20100969, SR20100970, SR20100971, SR20100972).

#### *South Side Showing*

One sample from the South Side Showing was examined (SR20100974)

*Other Mineralization*

Two samples from mineralized areas outside of the previously known mineralized zones were also examined (SR20100973 and SR20100965).

## **9.6 Lineament Report**

A 2D lineament study was carried out for the South Rim property. The method for lineament determination used a 2007 Government of British Columbia orthophoto of the area and plotting lines over linear features. A 3D interpretation using the TRIM DEM was attempted but the detail of the TRIM DEM didn't capture the features obviously present from the orthophoto. From the lineament study carried out, 390 lineaments of varying length were identified (Figure 11 and 12). The lineaments were recorded in Mapinfo so that the orientation and length could be compiled into a rose diagram. Graph 1 and 2 show the summary of the lineament study and the dominant three directions that the lineaments fall into, which are: 320 to 345 degrees, 355 to 005 degrees and 040 to 060 degrees. It is within these the directions that the mineralized showings tend to strike.

## **10.0 Conclusions and Recommendations**

Verification sampling at the Center View, East Side, Main Creek, South Side and V.P. Showings confirmed the strongly anomalous gold, silver, lead and zinc values reported by QPX Minerals and Nuspar Resources in the 1980's. Systematic GPS surveying of showings, historical compilation work, petrographic work and lineament interpretation from a 2007 orthophoto suggest that the South Rim Property is host to epithermal mineralized structures which may be part of a more extensive mineralized zone and that the zone may be continuous to the north, under overburden, and to the south in steep rugged terrain. These structures should be systematically sampled to confirm the high precious metal content and to determine if additional trenching and drill testing is warranted. As there is a lack of governmental geophysical data covering the South Rim property an airborne EM and magnetics survey of the area would be ideal for identifying structures buried by over burden and focus future exploration programs.

## **11.0 Statement of Qualifications**

I James G.M. Thom certify that:

1. I am an independent consulting geologist residing at 118B - west 14<sup>th</sup> ave, Vancouver BC, V5Y 1W9 and can be contacted at thomjgm@gmail.com
2. I obtained a B.Sc. in Earth and Ocean Sciences at the University of Victoria [2002] and graduated with a M.Sc. in Geology from the University of Toronto [2003].
3. I have worked in the mineral exploration industry since 1999
4. I supervised the 2010 exploration program described in this report
5. I have carried out petrographic reporting since 1999

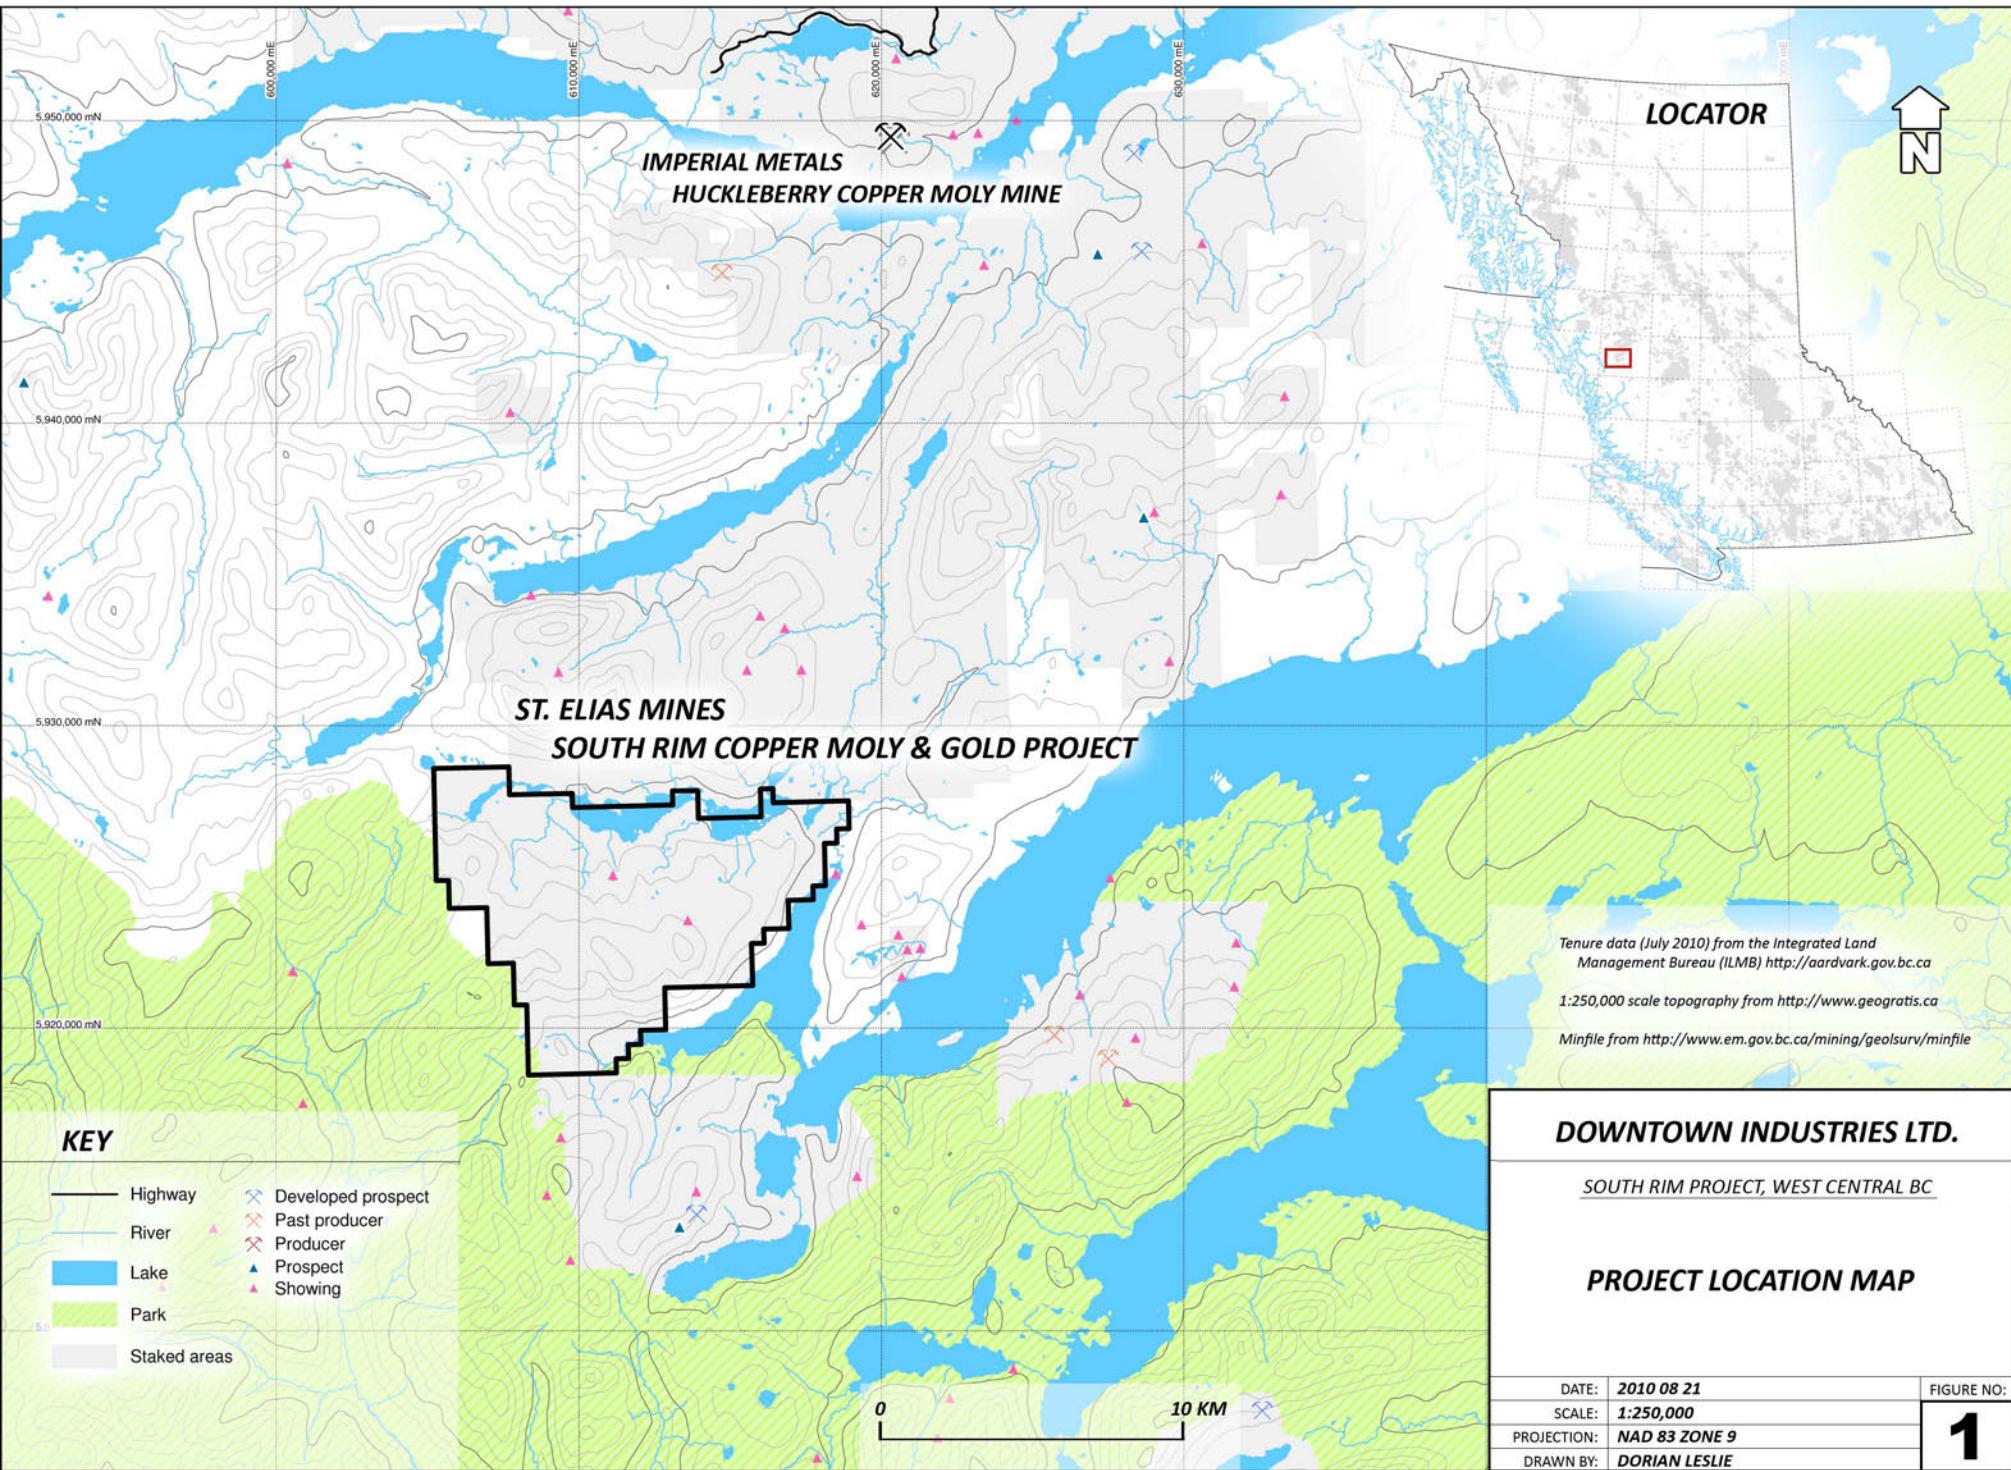

X James Thom

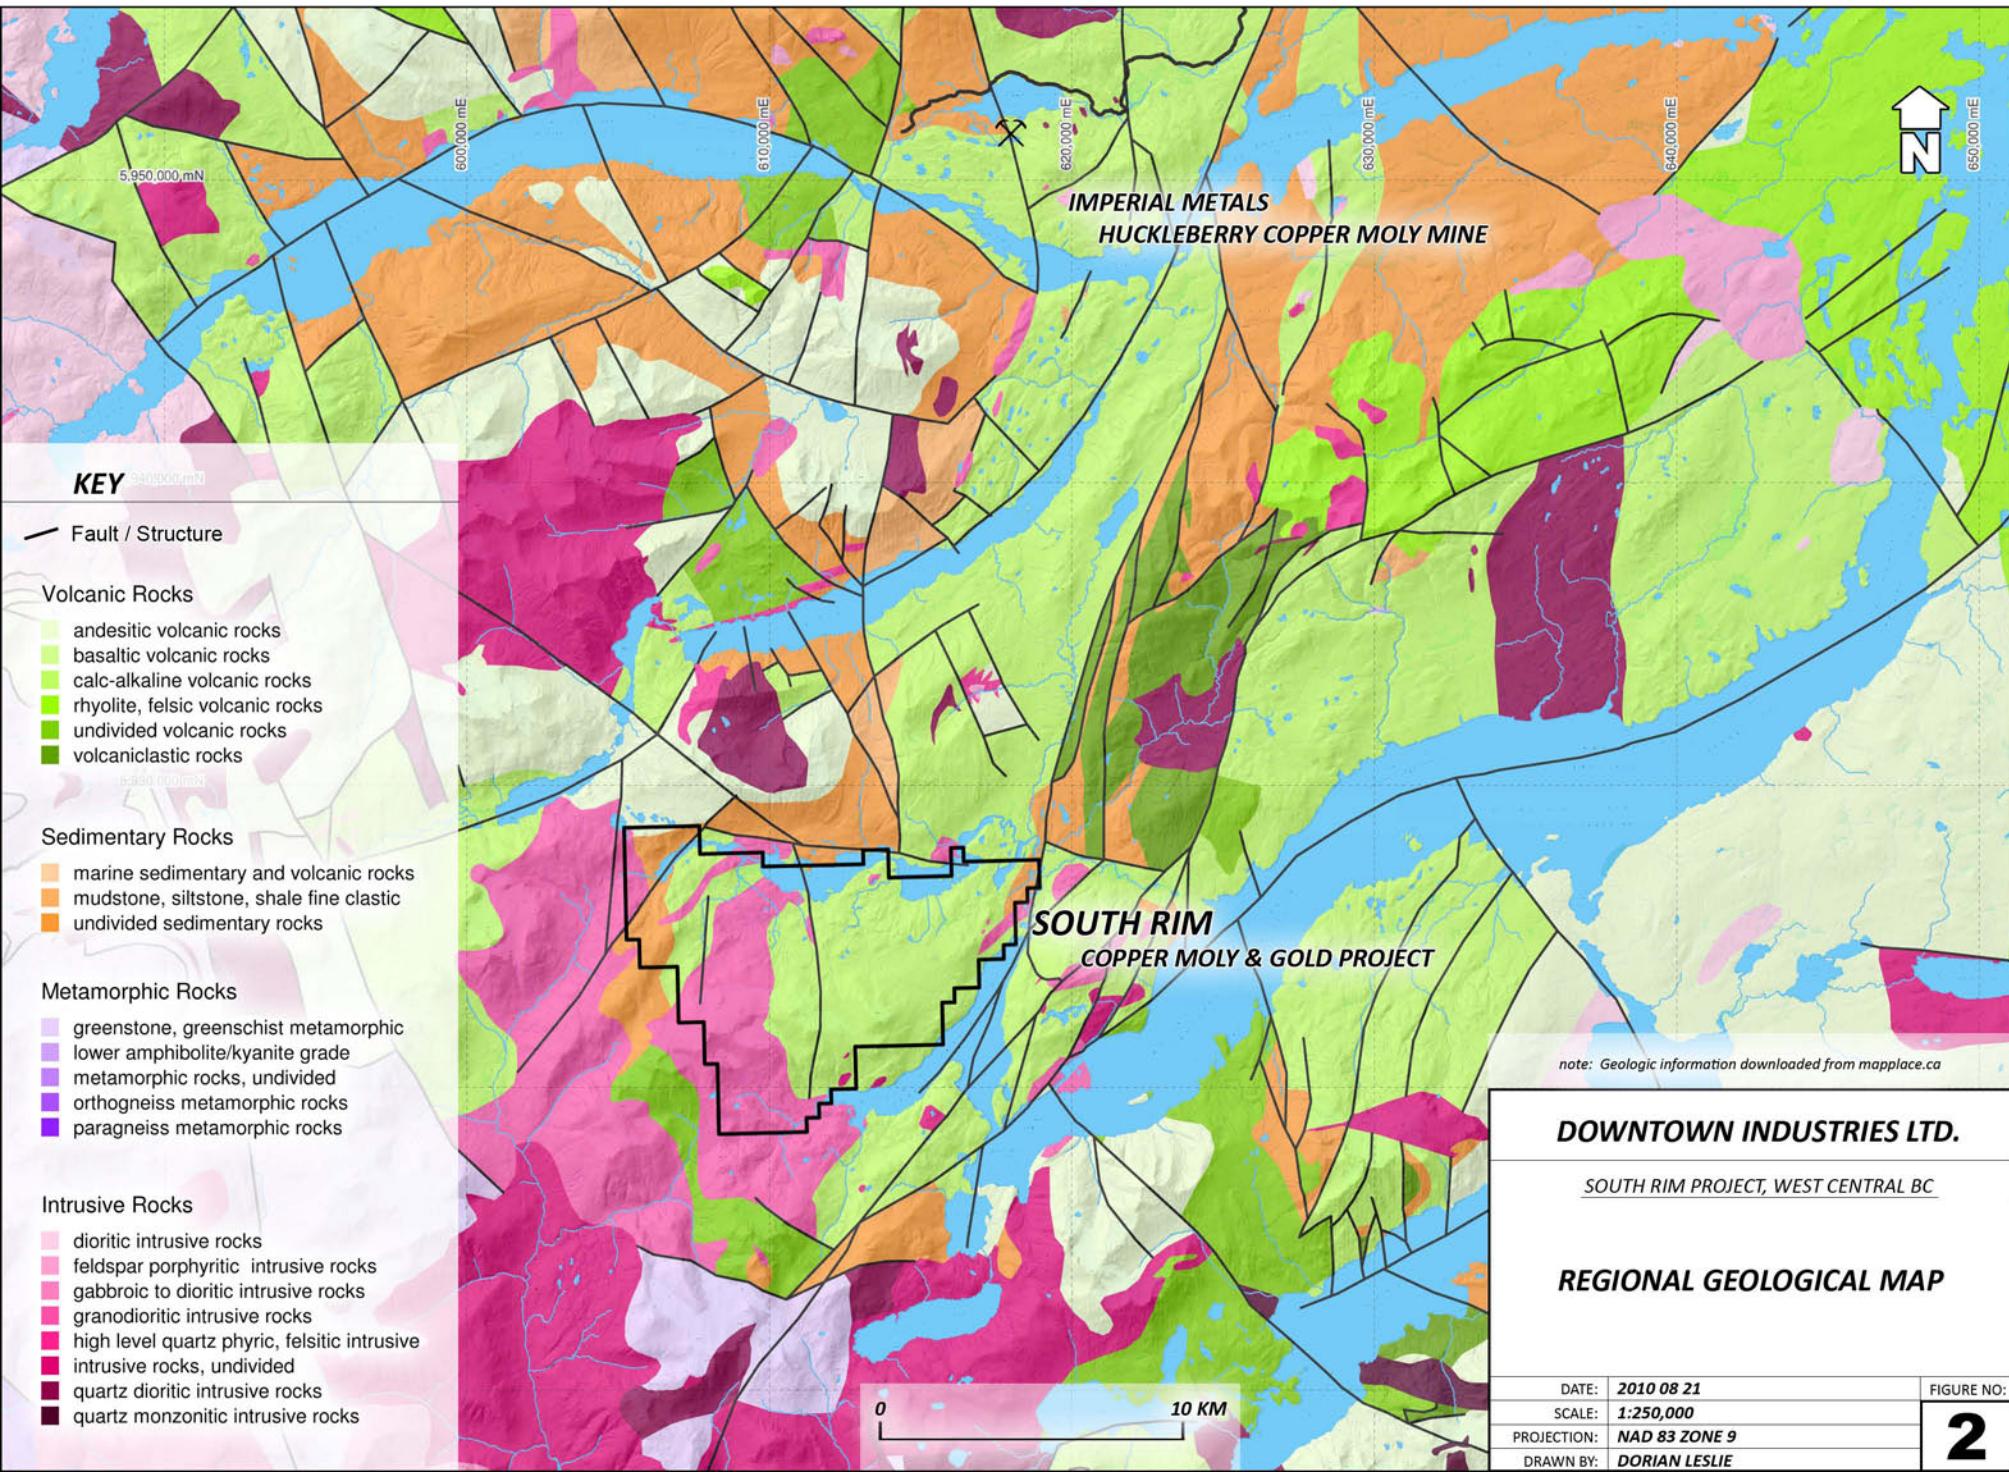

**FINAL COSTS FOR SOUTH RIM PROJECT - FALL 2010**

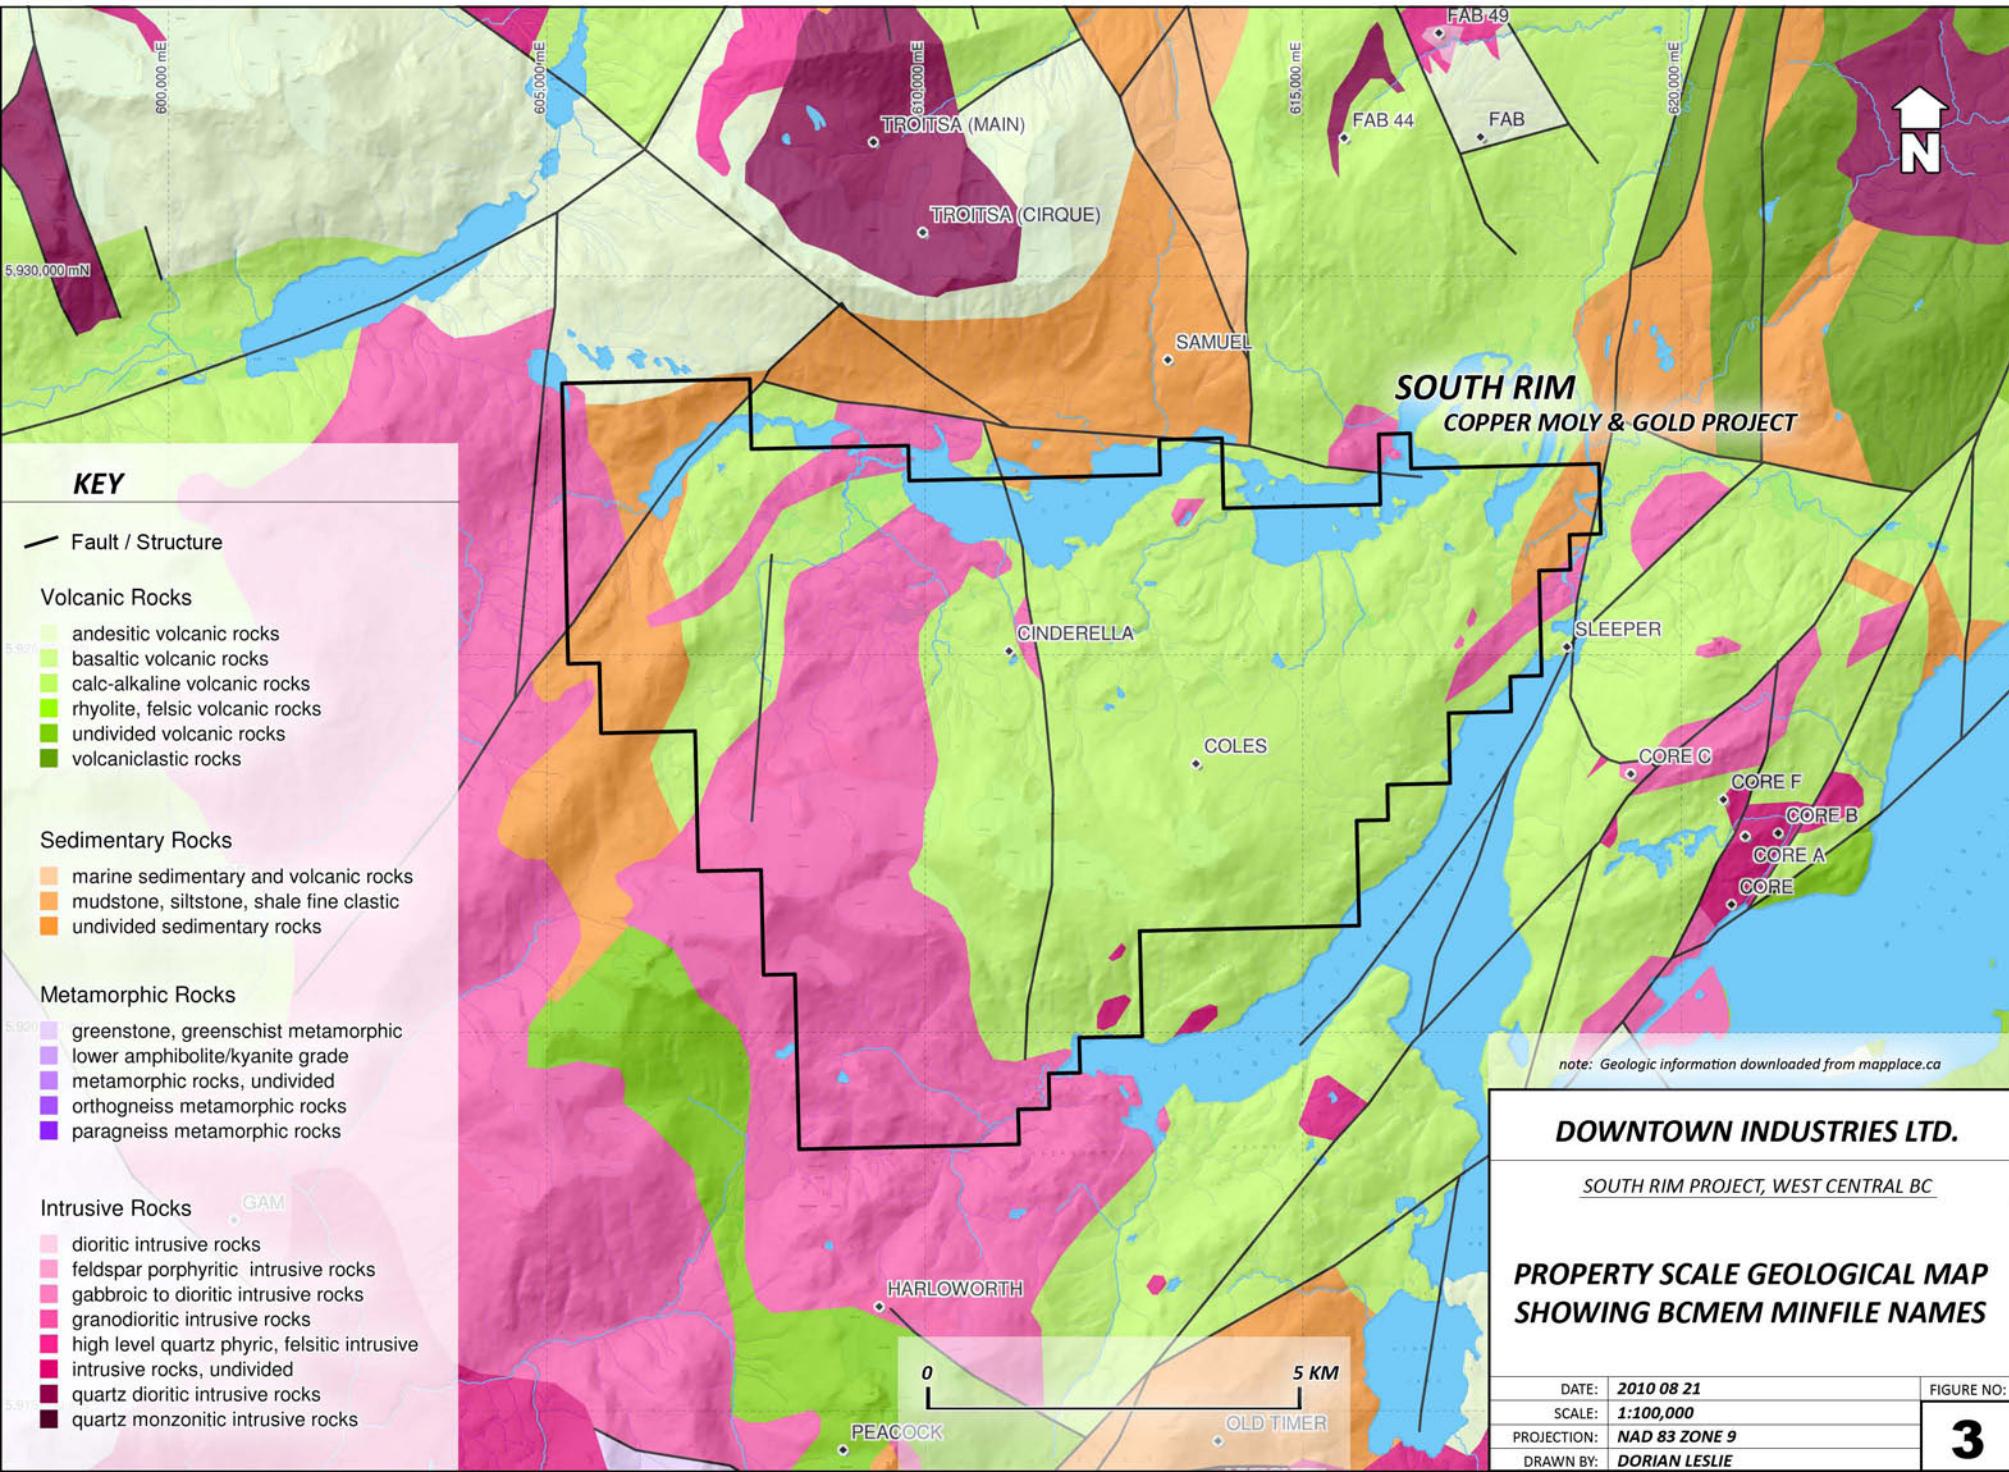

<b>Personnel:</b>		
Project Manager	4 days @ \$500.00	\$ 2,000.00
Project Geologist James Thom, M.Sc.	13 days @ \$600.00	7,800.00
Senior prospector/Geographer Gerard Gallissant, BA	12 days @ \$400.00	4,800.00
Prospector/Field Assistants (x3)	12 days @ \$1,125.00/day ( 3 x \$375.00 per man)	13,500.00
In-Town swamper/gopher	3 days @ \$250.00	750.00
In-Town Food Prep/Chef	2 days @ \$300.00	600.00
<b>Field Costs:</b>		0
Field Camp	13 days @ \$175.00/day	2,275.00
Field Equipment	13 days @ \$150.00/day	1,950.00
Field Communications	Long Distance charges + Motorola 2 way field radios	400.00
Field Communications	Sat phone 2.0wks x \$150/wk	300.00
Camp Consumables	Food, fuels, wood, rope& fuel (including truck fuel) Rock and soil sample bags, rice bags, survey flagging, pickets, topofil thread etc.	5,254.31

**ROCK SAMPLES**

2010 Historic sample

Sample

■ (Dark Red) >164 90%+

■ (Red) 124 to 164 90%

■ (Orange) 70 to 124 80%

■ (Light Blue) 23 to 70 70%

■ (White) 0 to 23 50%

**SOIL SAMPLES**

2010 Historic sample

Sample

● (Dark Brown) >50 Strongly anomalous

● (Orange) 20 to 50 Strongly anomalous

● (Yellow) 10 to 20 Strongly anomalous

● (Light Blue) 7 to 10 Weakly anomalous

● (White) <7 Background

# ROSE DIAGRAM SHOWING LINEAMENT DIRECTION WEIGHTED BY LENGTH

GRAPH NO. 1

## Rose Diagram Statistical Summary

Calculation Method: Length

Class Interval: 5.0 Degrees

Min.Length Filtering: Deactivated

Max.Length Filtering: Deactivated

Azimuth Filtering: Activated

Minimum Azimuth #1: 0.0 Degrees

Maximum Azimuth #1: 360.0 Degrees

Data Type: Bidirectional

Population: 491

Maximum Percentage: 6.1 Percent

Mean Percentage: 2.8 Percent

Standard Deviation: 1.4 Percent

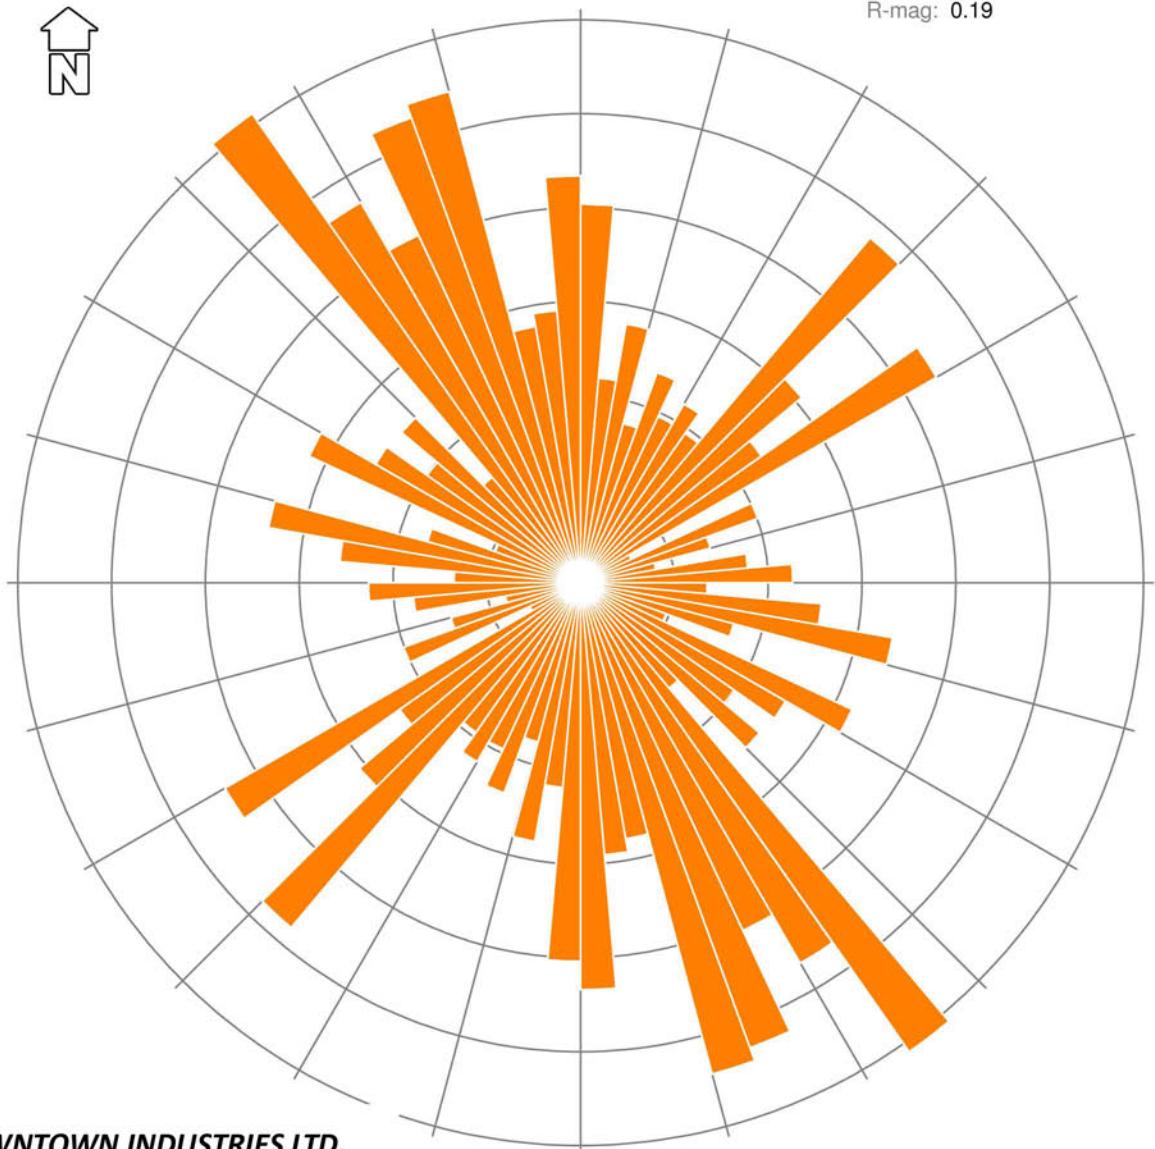

Vector Mean: 165.0 Degrees

345.01 Degrees

Confidence Interval: 18.9 Degrees

( 95 Percent )

R-mag: 0.19

# APPENDIX 5

## -Petrographic Report-

## Sample: MS2010010 / BX-11

### Sample Type: Chlorite-Schist

The sample is a chlorite-schist that is cut by fracture filling veinlets of quartz. The original rock was a lapilli tuff. Lithic fragments can be seen in hand sample and in thin section. In thin section the lithic fragments have been altered to chlorite and muscovite with some quartz. There are trace amounts of pyrite present in the sample. Pyrite is coarser in the quartz veins and brecciated zones and disseminated in the host rock.

**Hand sample:** Green (Chlorite altered) lapilli tuff. Fracture filled veins. Little or no sulphide oxidation. No visible sulphides.

	Mineral	Area	Size
Host Rock:	Chlorite	40 to 50%	<2um
	Muscovite	20 to 30%	<2um
	Biotite	25 to 35 %	<2um
	Quartz	10 to 20%	<5um
Veins:	Quartz	100%	5-50um
Sulphides:	Pyrite	Trace	8-120um
Oxides:	Hematite Goethite	Trace	

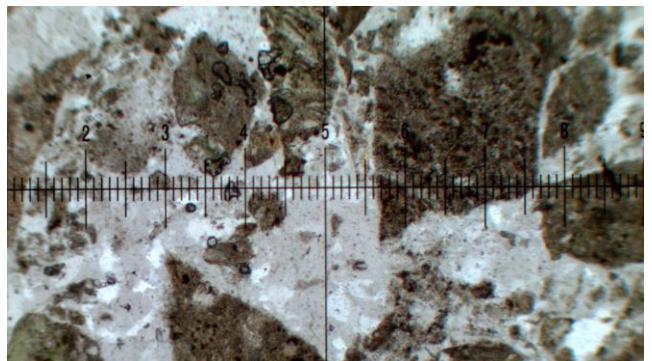

A. Cut face of the green lapilli tuff. Ruler for scale.

B. Prepared section off-cut. Field of view is approximately 26mm x 46 mm

C. Photomicrograph showing cross cutting quartz veinlets in a green lapilli tuff. PPL. FOV is 0.09 mm x 0.16 mm.

D. Photomicrograph showing a brecciated zone of host rock cemented with quartz. PPL. FOV is 0.09 mm x 0.16 mm.

## Sample: MS2010011 / BX-12

### Sample Type: Quartz Veinlets

The sample has multiple quartz veinlets cutting through the green lapilli host rock. Quartz grains show episodic growth in open space fractures. Pyrite grains are euhedral and show a small amount of oxidation on grain boundaries. They are dominantly found disseminated in the host rock.

**Hand sample:** Banded fracture filling quartz vein (2 cm) in contact with green lapilli tuff. Lapilli tuff shows pervasive quartz veinlets.

	Mineral	Area	Size
Host Rock:	Chlorite	40 to 50%	<2um
	Muscovite	20 to 30%	<2um
	Quartz	10 to 20%	<5um
Veins:	Quartz	100%	
Sulphides:	Pyrite	Trace	4-30um
Oxides:	Hematite Goethite	Trace	

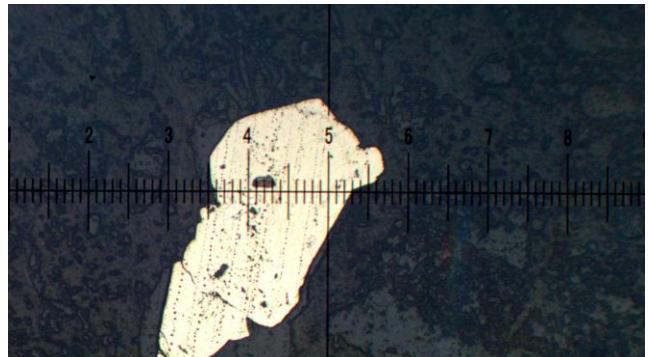

A. Banded fracture filled quartz vein in contact with sheared green lapilli tuff. Ruler for scale.

B. Prepared section off-cut. Field of view is approximately 26mm x 46 mm

C. Photomicrograph showing the columnar open space filling quartz crystals. XPL. FOV is 0.09 mm x 0.16 mm.

D. Photomicrograph showing pyrite grains. FOV is 0.09 mm x 0.16 mm.

## Sample: MS2010012 / BX-13

The sample has multiple quartz veinlets cutting through the green lapilli host rock. Quartz grains show episodic growth in open space fractures. Pyrite grains are euhedral and show a small amount of oxidation on grain boundaries. They are dominantly found disseminated in the host rock.

**Hand sample:** Banded fracture filling quartz vein in contact with green lapilli tuff. Lapilli tuff shows pervasive quartz veinlets.

	Mineral	Area	Size
Host Rock:	Chlorite	40 to 50%	<2um
	Muscovite	20 to 30%	<2um
	Quartz	10 to 20%	<5um
Veins:	Quartz	100%	
Sulphides:	Pyrite	Trace	4-30um
Oxides:	Hematite Goethite	Trace	

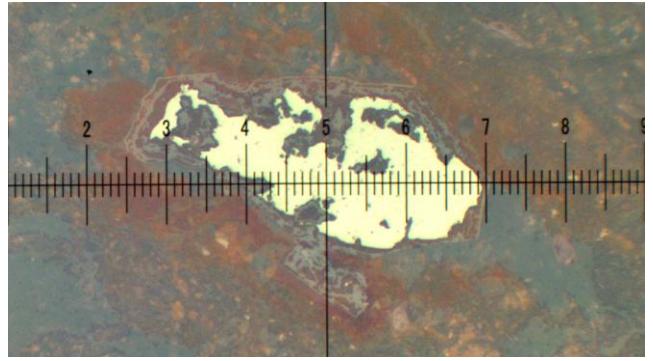

A. Cut face of green lapilli tuff showing fracture filling quartz veinlets. Ruler for scale.

B. Prepared section off-cut. Field of view is approximately 26mm x 46 mm

C. Photomicrograph showing the quartz veinlets in a chlorite altered green lapilli tuff. PPL. FOV is 0.09 mm x 0.16 mm.

D. Photomicrograph showing pyrite oxidation. RL. FOV is 0.036mm x 0.064mm.

## Sample: MS2010013 / BX-14

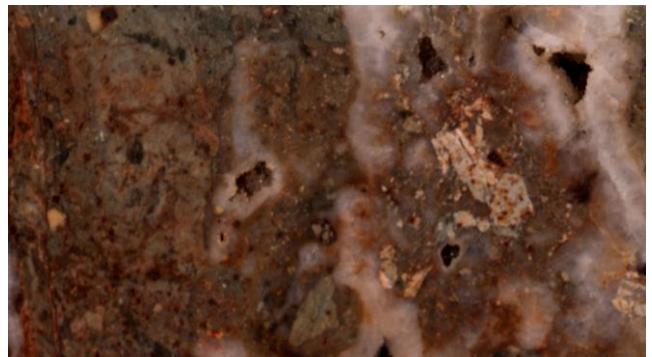

The sample shows silica flooding a chlorite altered lapilli tuff. Breccia and open space textures are common. Pyrite grains are almost completely oxidized to hematite are found mostly in the lapilli tuff. Relic shapes indicate the pyrite was euhedral.

**Hand sample:** Silicified green lapillit tuff with vuggy quartz.

	Mineral	Area	Size
Host Rock:	Chlorite	40 to 50%	<2um
	Muscovite	20 to 30%	<2um
	Quartz	10 to 20%	<5um
Veins:	Quartz	100%	
Sulphides:	Pyrite	Trace	
Oxides:	Hematite Goethite	Trace	

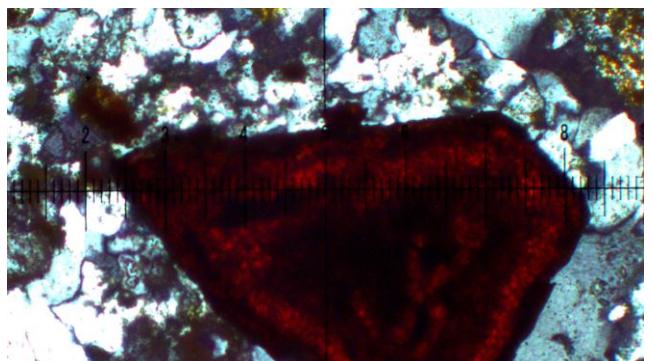

A. Cut face of a green lapillit tuff showing vuggy quartz flooding. Ruler for scale

B. Prepared section off-cut. Field of view is approximately 26mm x 46 mm

C. Photomicrograph showing open space filling quartz crystals. PPL. FOV is 0.09 mm x 0.16 mm.

D. Photomicrograph showing a pyrite grain completely replaced by hematite in a quartz ground mass. XPL. FOV is 0.036mm x 0.064mm.

## Sample: SR20100914 / BX-1

The sample shows a silicified braccia that underwent multiple silica flooding events. Pyrite grains show variable states of oxidation, depending on which quartz veins they are associated with.

	Mineral	Area	Size
Host Rock:	Chlorite	40 to 50%	<2um
	Muscovite	20 to 30%	<2um
	Quartz	10 to 20%	<5um
Veins:	Quartz	100%	
Sulphides:	Pyrite	Trace	15-90um
Oxides:	Hematite Goethite	Pervasive	

A. Brecciated lapilli tuff cemented with quartz. Abundant sulphides in quartz matrix. Ruler for scale.

B. Prepared section off-cut. Field of view is approximately 26mm x 46 mm

C. Photomicrograph of a relic euhedral pyrite grain completely oxidised to hematite. RL. FOV is 0.036mm x 0.064mm.

D. Photomicrograph of a poikilolitic pyrite grain. RL. FOV is 0.036mm x 0.064mm.

## Sample: SR20100916 / BX-2

The sample shows a silicified breccia. Fragments were likely remnants of the green lapilli tuff however they appear to have seen a higher degree of metamorphism.

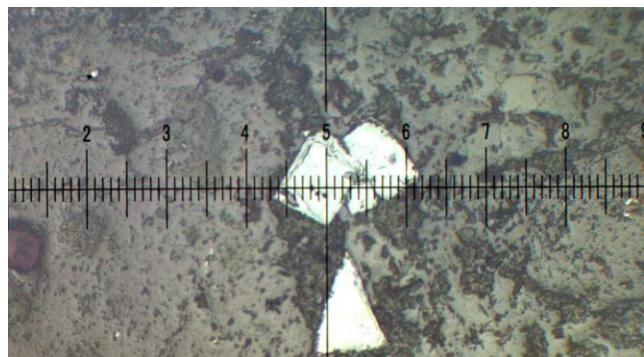

Hand sample: Silicified brecciated lapilli tuff.

	Mineral	Area	Size
Fragments:	Chlorite	70 to 80%	<2um
	Muscovite	5 to 10%	<2um
	Quartz	2 to 7%	<5um
	Plagioclase	10 to 20%	<5um
Groundmass:	Quartz	35-45%	
	Biotite	20-30%	
	Muscovite	15-25%	
Sulphides:	Pyrite		
Oxides:	Hematite		
	Goethite		

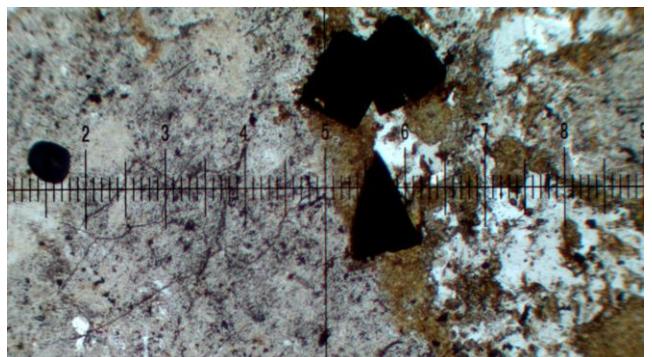

A. Cut face of a silicified breccia of lapilli tuff.  
Abundant oxidation in matrix. Ruler for scale.

B. Prepared section off-cut. Field of view is approximately 26mm x 46 mm

C. Photomicrograph showing pyrite grain in the breccia ground mass. RL. FOV is 0.09 mm x 0.16 mm.

D. Photomicrograph showing pyrite grain in the breccia ground mass. PPL. FOV is 0.09 mm x 0.16 mm.

## Sample: SR20100954 / BX-3

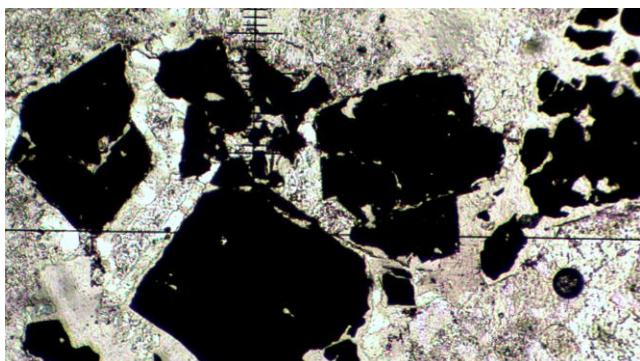

The sample shows a fine grained chlorite altered ash tuff. There are multiple criss crossing fractures filled with quartz and pyrite. Pyrite grains are euhedral and only slightly or not at all oxidized.

	Mineral	Area	Size
Host Rock:	Chlorite Muscovite	90 to 95% 5 to 10%	<2um <2um
Veins:	Quartz	100%	
Sulphides:	Pyrite	trace	up to 150um
Oxides:	Hematite Goethite		

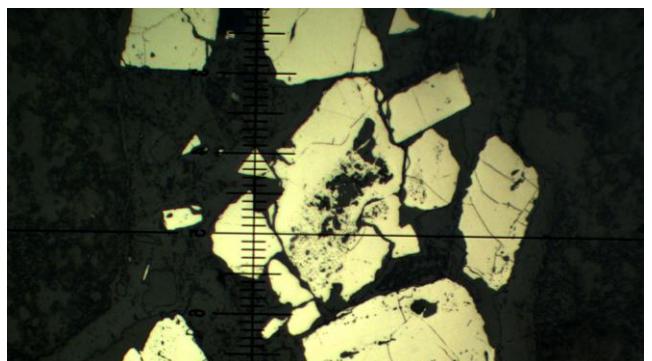

Silicified green lapilli tuff. Showing fracture filled quartz veins and veinlets;. Abundant sulphides can be seen to fill the fractures. Ruler for scale.

Prepared section off-cut. Field of view is approximately 26mm x 46 mm

C. Photomicrograph showing euhedral pyrite grains in quartz veinlet's. PPL. FOV is 0.09 mm x 0.16 mm.

D. Photomicrograph showing euhedral pyrite grains in quartz veinlet's. RL. FOV is 0.09 mm x 0.16 mm.

## Sample: SR20100957 / BX-4

The sample shows a sharp contact with a fine grained chlorite altered tuff. The quartz vein shows open space growth. Pyrite grains are euhedral and show a small amount of oxidation on grain boundaries. They are dominantly found disseminated in the host rock.

	Mineral	Area	Size
Host Rock:	Chlorite	40 to 50%	<2um
	Muscovite	20 to 30%	<2um
	Quartz	10 to 20%	<5um
Veins:	Quartz	100%	
Sulphides:	Pyrite	Trace	4-75um
Oxides:	Hematite Goethite	Trace	

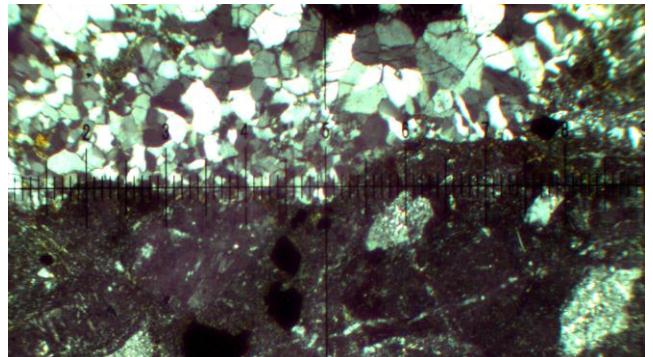

Quartz vein in contact with green lapilli tuff. Ruler for scale.

Prepared section off-cut. Field of view is approximately 26mm x 46 mm

C. Photomicrograph showing an area of coarser chorite grains. PPL. FOV is 0.036mm x 0.064mm.

D. Photomicrograph showing contact between quartz vein and chlorite altered lapilli tuff. XPL. FOV is 0.036mm x 0.064mm.

## Sample: SR20100959 / BX-15

The sample shows a quartz vein hosted in a green lapilli tuff. Quartz textures shows open space growth and multiple layers of growth. Very few sulphides were observed in this sample.

	Mineral	Area	Size
Host Rock:	Chlorite	40 to 50%	<2um
	Muscovite	20 to 30%	<2um
	Quartz	10 to 20%	<5um
Veins:	Quartz	100%	
Sulphides:	Pyrite	Trace	4-75um
Oxides:	Hematite Goethite	Trace	

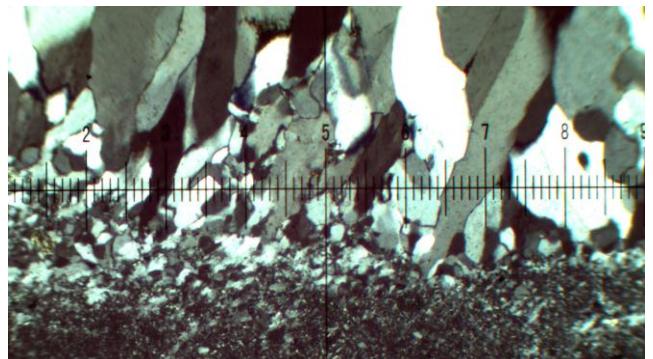

A. Cut face of green lapilli tuff showing fracture filled quartz veinlet. Ruler for scale.

B. Prepared section off-cut. Field of view is approximately 26mm x 46 mm

C. Photomicrograph of contact between quartz vein and lapilli tuff. RL. FOV is 0.09 mm x 0.16 mm.

D. Photomicrograph of quartz open space filling quartz grains. XPL. FOV is 0.09 mm x 0.16 mm.

## Sample: SR20100960 / BX-5

The sample shows a quartz vein and silica flooding. Very few sulphides were observed in this sample.

	Mineral	Area	Size
Host Rock:	Chlorite	10-20%	<2um
	Muscovite	15-25%	<2um
	Quartz	60-70%	<2um
Veins:	Quartz	100%	
Sulphides:	Pyrite		
Oxides:	Hematite Goethite		

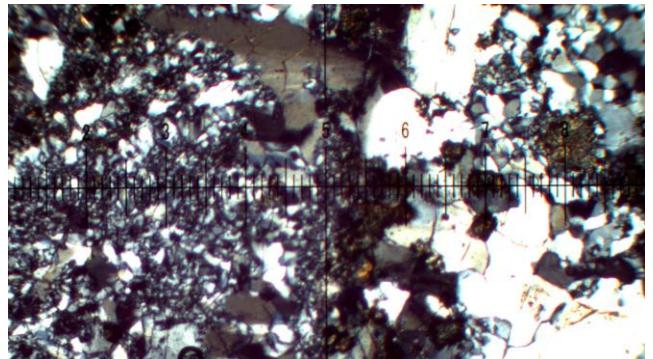

A. Cut face of a highly silicified green lapilli tuff.

B. Prepared section off-cut. Field of view is approximately 26mm x 46 mm.

C. Photomicrograph. XPL. FOV is 0.036mm x 0.064mm.

D. Photomicrograph. XPL. FOV is 0.09 mm x 0.16 mm.

## Sample: SR20100961 / BX-16

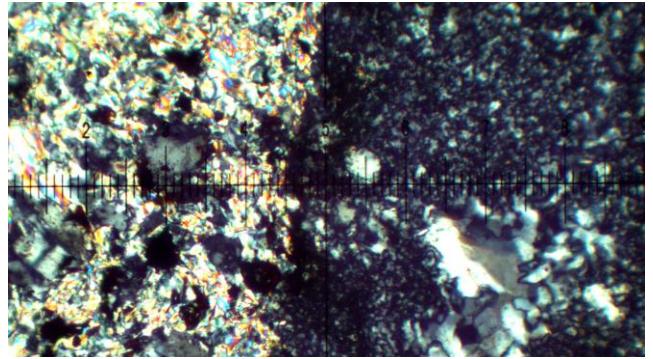

The sample shows a contact between the green and purple lapilli tuff.

	Mineral	Area	Size
Green Tuff:	Chlorite	40-50%	
	Plagioclase	40-50%	
Purple Tuff:	Chlorite	15-25%	
	Muscovite	45-50%	
	Quartz	25-35%	
Sulphides:	Pyrite		
Oxides:	Hematite		
	Goethite		

A. The sample shows a contact between the green and purple lapilli tuff.

B. Prepared section off-cut. Field of view is approximately 26mm x 46 mm

FOV is 0.09 mm x 0.16 mm.

FOV is 0.036mm x 0.064mm.

## Sample: SR20100962 / BX-17

The sample shows open space filling quartz.

	Mineral	Area	Size
Host Rock:	Chlorite Muscovite Quartz		
Veins:	Quartz	100%	
Sulphides:	Pyrite		
Oxides:	Hematite Goethite		

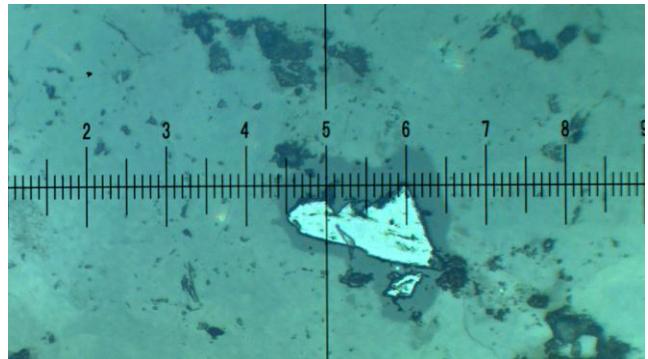

A. Cut face of vuggy open space filled quartz.

B. Prepared section off-cut showing multiple stages of quartz growth into open spaces. Field of view is approximately 26mm x 46 mm

FOV is 0.09 mm x 0.16 mm.

FOV is 0.036mm x 0.064mm.

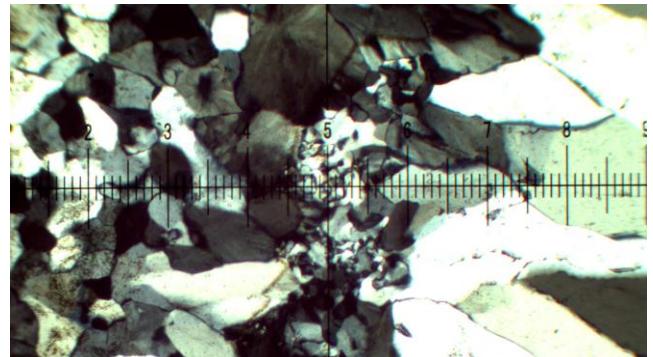

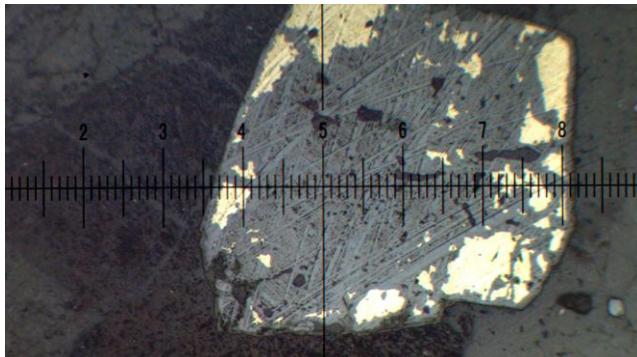

## Sample: SR20100963 / BX-6

This sample shows quartz.

	Mineral	Area	Size
Host Rock:	Chlorite Muscovite Quartz		
Veins:	Quartz	100%	
Sulphides:	Pyrite		
Oxides:	Hematite Goethite		

Prepared section off-cut. Field of view is approximately 26mm x 46 mm

FOV is 0.09 mm x 0.16 mm.

FOV is 0.09 mm x 0.16 mm.

## Sample: SR20100965 / BX-7

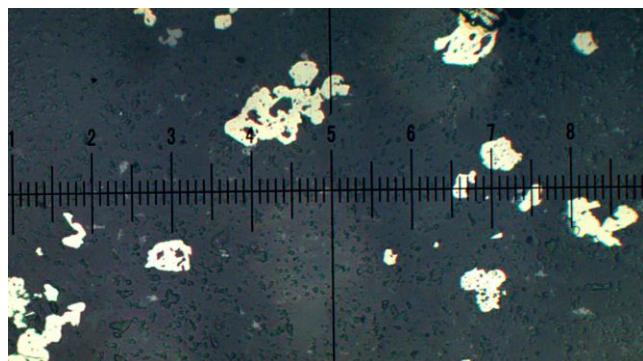

The sample shows chlorite altered basalt. There are multiple criss crossing fractures filled with pyrite. Pyrite grains are anhedral and are also found disseminated throughout the sample.

Hand sample: Silicified green lapilli tuff. Showing fracture filled quartz veins and veinlets;. Abundant sulphides can be seen to fill the fractures.

	Mineral	Area	Size
Host Rock:	Chlorite Muscovite Quartz		
Veins:	Quartz	100%	
Sulphides:	Pyrite		
Oxides:	Hematite Goethite		

Prepared section off-cut. Field of view is approximately 26mm x 46 mm

FOV is 0.036mm x 0.064mm.

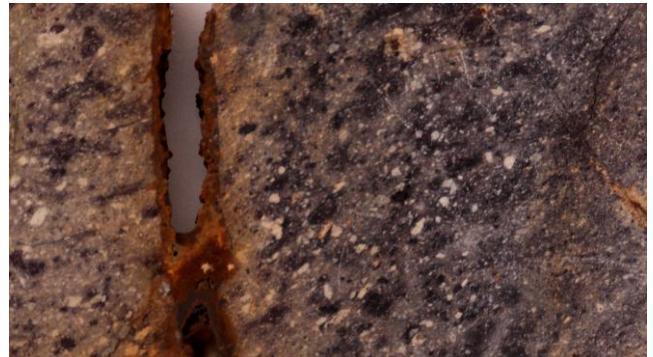

FOV is 0.09 mm x 0.16 mm.

## Sample: SR20100969 / BX-8

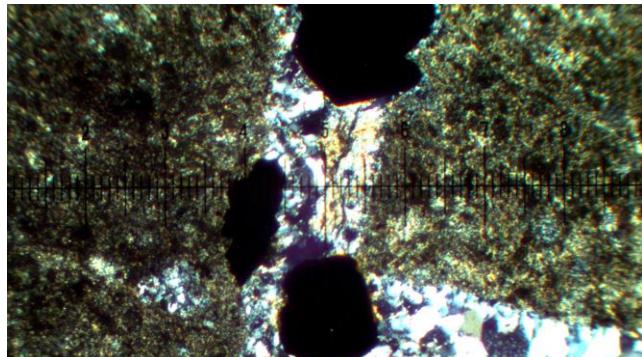

The sample shows is a fine grained chlorite altered ash tuff. There are multiple criss crossing fractures filled with quartz and pyrite. Pyrite grains are mostly oxidized.

	Mineral	Area	Size
Host Rock:	Chlorite	40 to 50%	<2um
	Muscovite	20 to 30%	<2um
	Quartz	10 to 20%	<5um
Veins:	Quartz	100%	
Sulphides:	Pyrite		
Oxides:	Hematite Goethite		

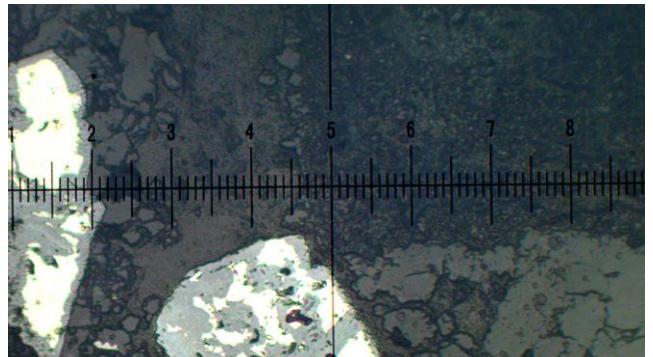

A. Silicified green lapilli tuff. Showing fracture filled quartz veins and veinlets;. Abundant sulphides can be seen to fill the fractures. Ruler for scale.

Prepared section off-cut. Field of view is approximately 26mm x 46 mm

FOV is 0.09 mm x 0.16 mm.

FOV is 0.036mm x 0.064mm.

## Sample: SR20100970 / BX-18

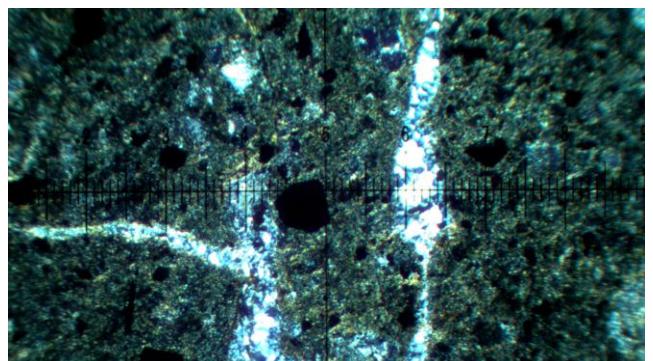

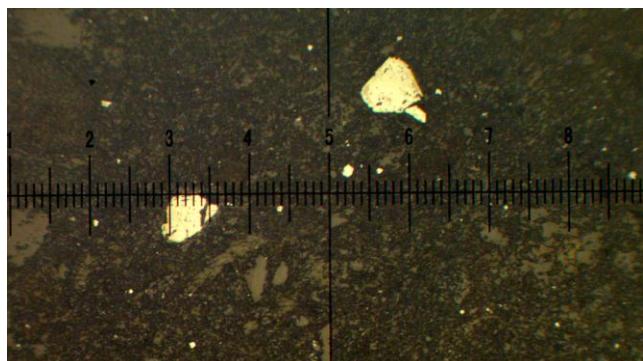

The sample shows chlorite altered basalt. There are multiple criss crossing fractures filled with pyrite. Pyrite grains are anhedral and are also found disseminated throughout the sample.

	Mineral	Area	Size
Host Rock:	Chlorite Muscovite Quartz		
Veins:	Quartz	100%	
Sulphides:	Pyrite		
Oxides:	Hematite Goethite		

A. Silicified green lapilli tuff. Showing fracture filled quartz veins and veinlets;. Abundant sulphides can be seen to fill the fractures. Ruler for scale.

Prepared section off-cut. Field of view is approximately 26mm x 46 mm

FOV is 0.09 mm x 0.16 mm.

FOV is 0.09 mm x 0.16 mm.

## Sample: SR20100971 / BX-19

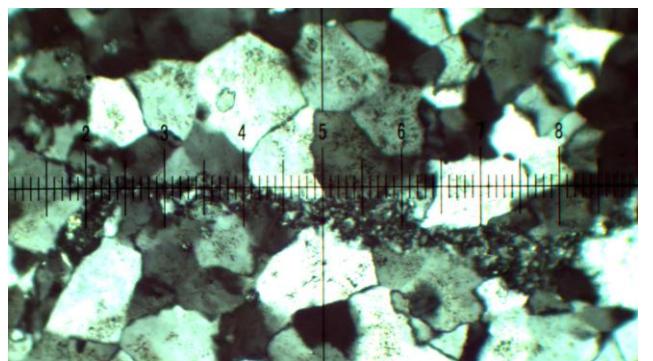

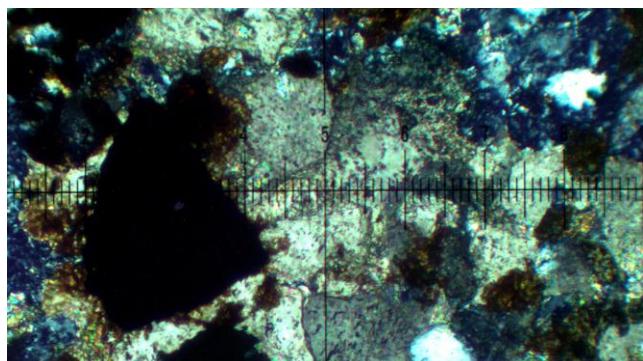

The sample shows is a calcite quartz breccia

	Mineral	Area	Size
Host Rock:	Chlorite Muscovite Quartz		
Veins:	Quartz	100%	
Sulphides:	Pyrite		
Oxides:	Hematite Goethite		

A. Cut face of a calcite quartz breccia.

Prepared section off-cut. Field of view is approximately 26mm x 46 mm

C. Photomicrograph of FOV is 0.036mm x 0.064mm.

## Sample: SR20100972 / BX-9

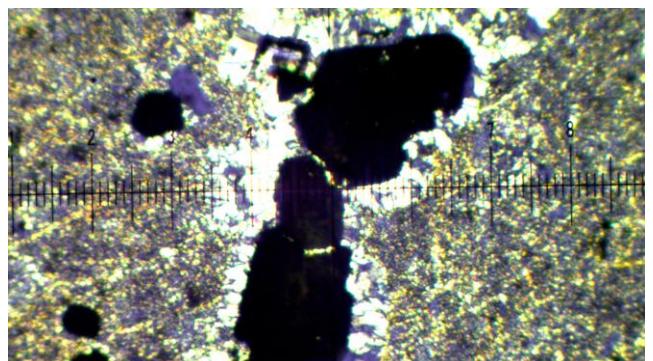

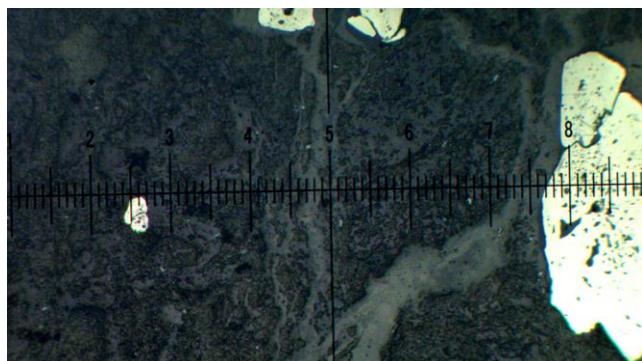

The sample shows is a fine grained chlorite altered ash tuff. There are multiple criss crossing fractures filled with quartz and pyrite. Pyrite grains are mostly oxidized.

	Mineral	Area	Size
Host Rock:	Chlorite	40 to 50%	<2um
	Muscovite	20 to 30%	<2um
	Quartz	10 to 20%	<5um
Veins:	Quartz	100%	
Sulphides:	Pyrite		
Oxides:	Hematite Goethite		

A. Silicified green lapilli tuff. Showing fracture filled quartz veins and veinlets;. Abundant sulphides can be seen to fill the fractures.

Prepared section off-cut. Field of view is approximately 26mm x 46 mm

FOV is 0.09 mm x 0.16 mm.

FOV is 0.09 mm x 0.16 mm.

## Sample: SR20100973 / BX-10

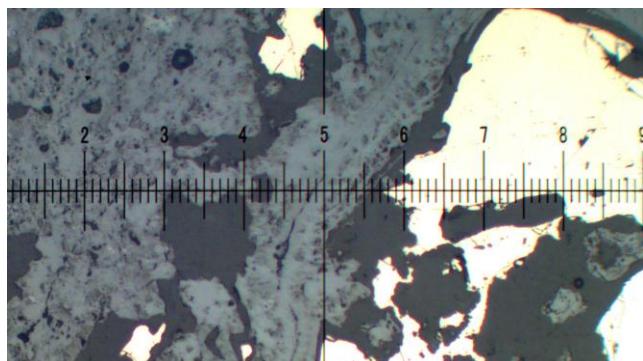

The sample shows a fine grained chlorite altered ash tuff. There are multiple criss crossing fractures filled with quartz and pyrite. Pyrite grains are mostly oxidized.

	Mineral	Area	Size
Host Rock:	Chlorite Muscovite Quartz		
Veins:	Quartz	100%	
Sulphides:	Pyrite		
Oxides:	Hematite Goethite		

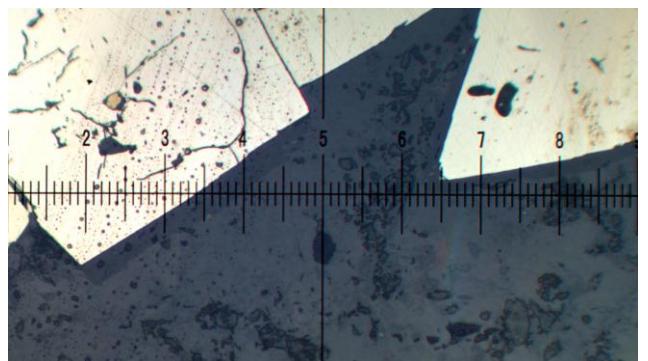

A. Silicified green lapilli tuff. Showing fracture filled quartz veins and veinlets. Abundant sulphides can be seen to fill the fractures. Ruler for scale.

Prepared section off-cut. Field of view is approximately 26mm x 46 mm

C. Photomicrograph showing the oxidation of various pyrite grains (yellow) to hematite (dark grey). RL. FOV is 0.036mm x 0.064mm.

C. Photomicrograph showing euhedral pyrite grains (yellow) with very little oxidation. RL. FOV is 0.036mm x 0.064mm.

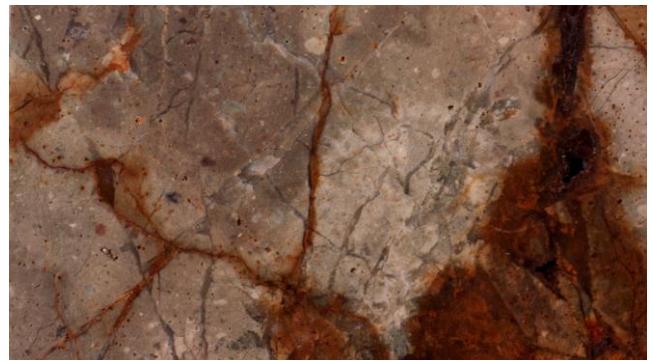

## Sample: SR20100974 / BX-20

The sample shows a fine grained chlorite altered ash tuff. There are multiple criss crossing fractures filled with quartz and pyrite. Pyrite grains are mostly oxidized.

	Mineral	Area	Size
Host Rock:	Chlorite Muscovite Quartz		
Veins:	Quartz	100%	
Sulphides:	Pyrite		
Oxides:	Hematite Goethite		

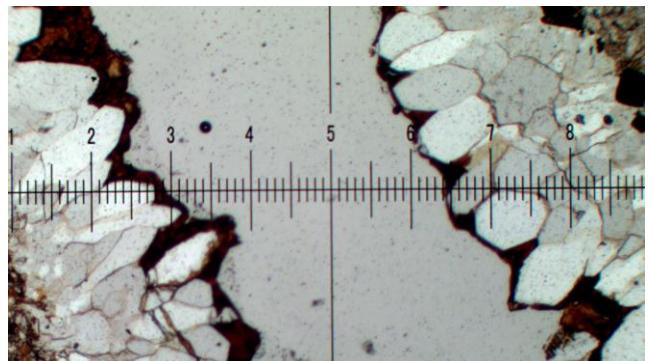

A. Silicified green lapilli tuff. Showing fracture filled quartz veins and veinlets. Abundant sulphides can be seen to fill the fractures. Ruler for scale.

B. Prepared section off-cut. Field of view is approximately 26mm x 46 mm

C. Photomicrograph of quartz vein in a lapilli tuff. XPL. FOV is 0.09 mm x 0.16 mm.

D. Photomicrograph of an open quartz vein with a hematite crust on the open quartz face. PPL. FOV is 0.09 mm x 0.16 mm.

A .5 gm sample is digested with 5 ml 3:1 HCl/HNO3 at 95°C for 2 hours and diluted to 25ml.

**St. Elias Mines**

Project : SOIL

**Multi-Element ICP-AES Analysis**

Aqua Regia Digestion

Attention : James Thom

Sample type : SOIL

A .5 gm sample is digested with 5 ml 3:1 HCl/HNO3 at 95°C for 2 hours and diluted to 25ml.

**St. Elias Mines**
**Project :** SOIL

**Attention :** James Thom

**Multi-Element ICP-AES Analysis**

Aqua Regia Digestion
