Summary

The Nicoamen Property, located in the Kamloops Mining Division, is being explored for its low sulphidation epithermal precious metal potential. The centre of the Nicoamen Property lies 17 kilometres (km) southeast of Lytton, B.C. and 34 kilometres northeast of Boston Bar. All parts of the property are easily accessible by forestry roads.

The Nicoamen Project area lies within the Intermontane Belt of the central interior of British Columbia. The south-western part of the Property is underlain by the Permian to upper Triassic Mount Lytton Igneous Complex. The predominant lithology of the Mount Lytton Igneous Complex on the southern half of the property is quartz diorite with local exposures of meta-sedimentary rocks. The northern half of the project area is underlain by the lower Cretaceous Spences Bridge Group volcanics. This group of rocks are a belt of andesitic volcanic arc rocks stretching from the north of Princeton to the west of Cache Creek and are the main focus of current precious metal exploration.

Almaden Minerals Ltd. (Almaden) has 100% ownership of the Property, which is comprised of nine claims totalling 3,331.843 hectares (ha).

This report presents the results of a grid controlled soil geochemical program that extended coverage produced by previous surveys which, together with a 2009 geophysical survey, indicate that further exploration is warranted. Past exploration projects have identified four anomalous zones - the Discovery, West Central and Canyon Zones. The Discovery and West Zones were identified by reconnaissance exploration that turned up a large number of significant gold-bearing quartz float occurrences in 2004. The Canyon and Central Zones were defined by geophysical survey: both zones exhibit a strong linear resistivity anomaly, weak chargeability and an anomalous gold-arsenic-antimony in soil geochemical trend.

The 2010 soil sampling program was successful in defining a similar soil geochemical signature for both the Discovery and West Zone prospects. Both showings are defined by a distinct gold-arsenic-antimony-molybdenum in soil anomaly with a boarder anomalous halo of lead and zinc soil values. Soil sampling in 2010 failed to extend the gold-arsenic-antimony Central Zone anomaly to the southeast, but a boarder halo of anomalous silver and lead in soil values does extend to the south and east.

List of Appendices

1.0 Introduction

This report summarizes the results of a soil sampling program conducted in October and November, 2010. Samples were stored and submitted for analysis in March, 2011 and results were first received on April 4, 2011. The work was funded by Fairmont Resources Inc., who at the time had an option to acquire an interest in the property from owner Almaden Minerals Ltd. The option agreement has since been terminated.

Coast Mountain Geological Ltd. was contracted by Fairmont Resources Ltd. in October of 2010 to review the historical data and design, and implement an exploration program on the Nicoamen Property.

2.0 Property Description and Location

2.1 Property Location

The Nicoamen property lies within the Kamloops Mining Division, British Columbia and is located within NTS Map Sheet 92I/03 and TRIM Map sheet 092I/014. The centre of the property lies 18 km southeast of Lytton and 34 km northeast of Boston Bar. The geographic centre of the Property is approximately 619000mE and 5559000mN (UTM ZONE 10; NAD 83) and at 50°10' N Latitude and 121° 20' W Longitude (Figure 1).

2.2 Property Description

The Property consists of nine mineral tenures totalling 3,331.843 ha. According to the latest records from Mineral Titles Online BC, all tenures are registered to Almaden Minerals Ltd. of Vancouver, BC. Pertinent tenure information is listed in Table 1 and displayed in Figure 2.

3.0 Accessibility, Climate, Local Resources, Infrastructure, First Nations and Physiography

The accessibility, climate, local resources, infrastructure and physiography description of the Nicoamen Property was adapted from Carlson (2010).

3.1 Accessibility

The Property can be reached from Boston Bar or Lytton, both located within the Fraser River canyon on Trans Canada Highway 1. Boston Bar and Lytton are located 215 km and 255 km respectively along Highway 1 east and then north from Vancouver.

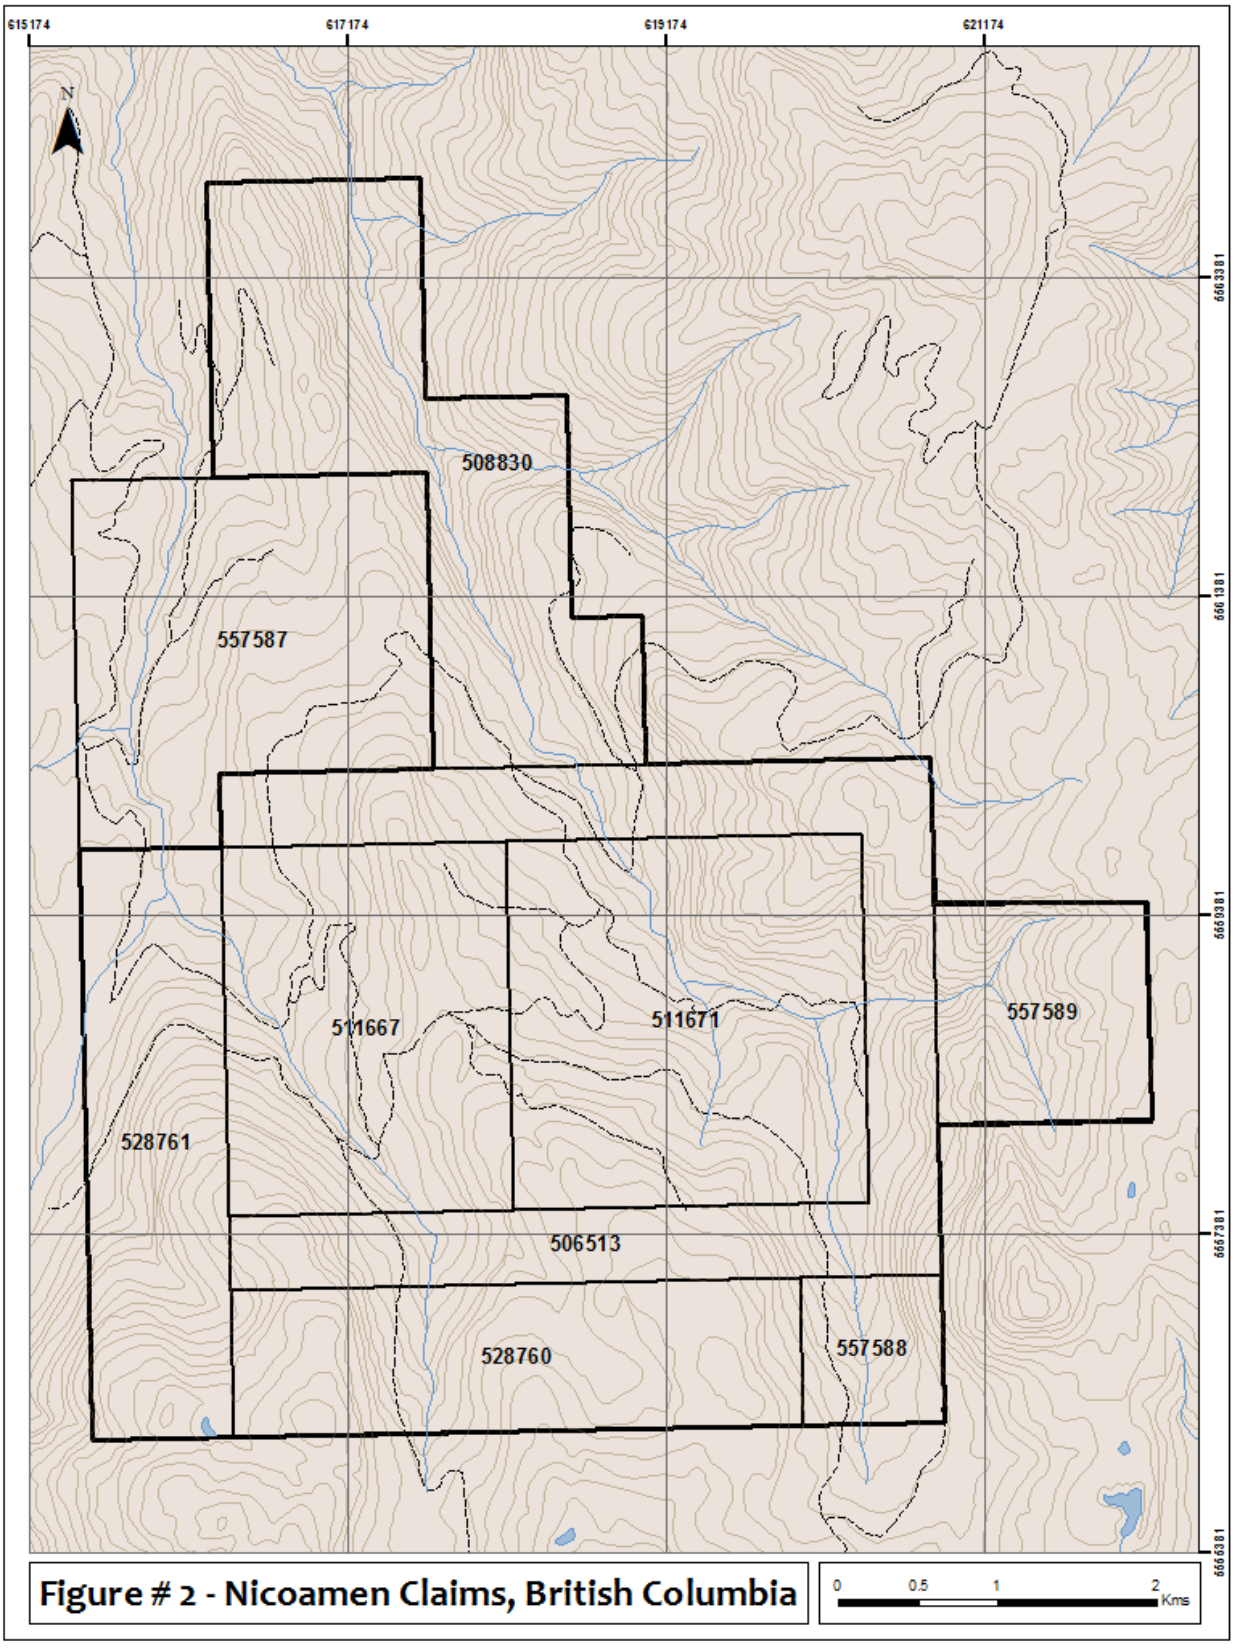

Figure # 2 - Nicoamen Claims, British Columbia

The Property lies 17 km southeast of Lytton and 34 kilometres northeast of Boston Bar. From Lytton, drive northeast on the Trans Canada Highway, along the Thompson River, for 17 km to the

mouth of the Nicoamen River. From this point, travel south for 24.5 km on the Nicoamen Forest Service Road ("FSR") to a junction with the Ainslie North–Mowhokam FSR. When navigating from Boston Bar, travel north on the Trans Canada Highway for 11 km to the Ainslie North–Mowhokam FSR and then travel along this road north-northeast for 27.5 km to the Nicoamen FSR. These forestry roads join near the southwest corner of the Property. From this point the main branch roads lead to networks of logging spurs which extend for several kilometres into the central and southern claim areas.

3.2 Climate

The climate of this part of the province is typical of the southern interior of British Columbia. The summer field season generally starts mid to late April and extends through till late October or early November. The weather is generally warm and dry, with daily high temperatures ranging from $+20^{o}$C to $+30^{o}$ C. Winters are cold with the potential of significant snow accumulation and temperatures can drop to -20^{o} C for extended periods.

3.3 Local Resources and Infrastructure

The logistics of working in this part of the province are excellent. Gravel road access allows the movement of supplies and equipment by road to all parts of the Property. Heavy equipment is available locally in Boston Bar or Merritt, as are supplies, fuel and lodging. Unskilled labour is also available locally. Skilled labour and exploration contractors are available from Kamloops, Vancouver and the Okanagan. Depending on the type of exploration program to be conducted, the field season generally extends from late April to early November.

3.4 First Nations

The Nicoamen Property lies within the traditional lands of the Nicoamen Indian Band who are part of the Niaka'pamux First Nation. Almaden initiated discussions with members of the Nicoamen Indian Band to help in modifying any concerns regarding mineral exploration. In follow-up meetings in 2010 with personnel from Fairmont Resources Inc. and Coast Mountain Geological Ltd., various concerns were expressed about scenarios regarding more advanced staged or de-commissioned mines which were causing headlines in the news. Careful explanations were used to try and alleviate these concerns and explain that the Nicaomen Project is still at an early or "grass roots" stage of exploration.

More valid concerns expressed by members of the band council include the effect on the water quality and areas of the Nicoamen River as well as any economic benefits for the persons of the Nicoamen First Nation. It was noted that the Nicoamen River has undergone high degrees of siltation in the recent past due to rock and mud slides from slopes presumably de-stabilized by recent logging. In regards to the economic opportunities for persons of the Nicoamen First Nation, the group was hoping that some local young adults can acquire experience in the mineral exploration sector. Representatives of Fairmont and Almaden indicated that in lieu of future exploration programs, these companies would work closely with the Nicoamen First Nation to ensure that there is minimal impact to the water and there is some employment and training opportunity for local residents of the Nicoamen First Nation.

3.5 Physiography

The Property lies within the rolling uplands and steep dissected valleys of the Interior Plateau physiographic province. Topography is moderate to locally steep, with elevations ranging from 750 m above sea level (ASL) in the north in the steep-walled canyon of the Nicoamen River, climbing steadily to 1750 m above sea level on the southern boundary of the claim group. The Property covers part of the drainage of Nicoamen River, which flows northward to join the Thompson River 15 km east of Lytton. Vegetation consists mainly of widely spaced Lodgepole pine and Douglas fir changing to dense balsam, fir, spruce, and cedar along creek valleys. Thick brush consisting of alder and willow is common along most of the stream gullies and road cuts, and in swales between topographic highs. Approximately 60% of the Property area has been logged since 1990.

Soil and glacial till cover is extensive and generally shallow, but includes locally relatively deeper deposits of glacial till. Overall bedrock exposure is poor to moderate, but is locally abundant in road cuts and in some of the stream gullies, as well as on steep upper slopes, ridge crests, and in the Nicoamen River canyon.

4.0 History

Placer gold was discovered along the Thompson River at the mouth of the Nicoamen River in 1858, sparking the Fraser Canyon Gold Rush and subsequent rush to the gold fields of the Cariboo. The Nicoamen property lies near the headwaters of Nicoamen River and within the Spences Bridge Group rocks, a northwest trending belt of Cretaceous volcanics of island arc affinity. The belt, which stretches from Princeton north-westerly to Lillooet, with smaller outliers continuing further north-westerly to Gang Ranch, has recently been shown to be the locus of several epithermal style gold occurrences. (Carlson, 2010)

The Nicoamen property was discovered by Almaden in 2003 as part of a regional exploration program evaluating the 1994 Regional Geochemical Survey results for gold for Sheet 092I. Prior to staking in 2004, Almaden re-visited the area twice, taking an additional 41 stream sediment, 15 reconnaissance soil and 16 rock grab samples. This program included detailed road cut and stream gully prospecting in conjunction with further geochemical sampling. The 2004 work resulted in the identification of numerous significant gold-bearing quartz float occurrences, including two altered outcrop exposures at the Discovery and West Zones, each carrying anomalous gold values. (Balon and Hylands, 2006).

A larger program was conducted by Almaden in 2005, consisting of an initial grid soil geochemical sampling survey (771 samples), further prospecting and reconnaissance geochemical sampling (7 stream sediment, 56 soil, and 5 rock samples). Well defined gold-in-soil anomalies were reported for the West Zone and southeast of the Discovery Zone Balon and Hylands, 2006). Limited hand trenching was carried out on the Discovery and West Zones with 15 channel samples being collected from six trenches. One trench within the Discovery zone (trench DZT05-3) averaged 1.77 g/T Au over 3.5 m.

In May, 2006, the Property was optioned to Tanqueray Resources Ltd. (“Tanqueray”). Tanqueray conducted infill soil sampling along the initial soil grid placed by Almaden, collecting 1,975

samples on 25 metre by 50 metre grid spacings along with four rock samples (Henneberry, 2007). The infill soil sampling, which was carried out to the south of the Discovery and West Zones, strengthened the original gold-in-soil anomalies identified by Almaden (currently known as the Discovery and West Zone Trends) as well as delineated another two others in the areas of the Discovery Zone, latter to be identified as the "Central Zone" to the southwest and the "Canyon Zone" to the east. The Property was returned to Almaden in May 2007(Carlson, 2010).

Three more claims (Zak 7: 557587, Zak 8: 557588, and Zak 9: 557587) were acquired by Almaden in April 2007 which were added onto the Nicoamen Property. In December 2007, the Property was optioned to Zenith Industries Corp. ("Zenith"). Zenith did no exploration on the Property before returning it to Almaden in December 2008.

In July, 2009 the Nicoamen Property was optioned to Fairmont Resources Inc. Fairmont completed a geophysical survey of the Property from August 11 to September 25, 2009. The program included geological mapping and a ground geophysical survey of line cutting, magnetics and Induced Polarization (IP). A total of 21.0 line km of surveying was completed along east-west oriented lines spaced 200 m apart and ranging from 1,700 m to 4,350 m in length. Previous geological observations were confirmed by the mapping completed, although it was hampered due to a lack rock exposure in many parts of the property.

The ground magnetic survey was successful in identifying the underlying lithologies and therefore the spatial differentiation between the Mount Lytton diorites and the Spences Bridge Group rocks. The IP survey was successful in defining a number of high contrast resistivity anomalies. After combining the results of the IP survey along with that from the 2005 and 2006 soil surveys, four main anomalous zones were identified - the Canyon, Discovery, Central and West (Carlson, 2010).

5.0 Geological Setting (after Carlson [2010])

5.1 Regional Geology

The Nicoamen project area lies within the Intermontane Belt of the central interior of British Columbia. The regional geology as shown in Figure 3 is taken from the BC Geological Survey's Map Place web site. The south-western part of the map area is underlain by Permian to upper Triassic Mount Lytton Complex granodiorite, diorite and amphibolites as well as an unnamed Permian to Jurassic diorite. The eastern part of the map area (and not shown in Figure 3) is underlain by upper Triassic Nicola Group western volcanic facies rocks intruded by late Triassic to early Jurassic intrusions. The centre of the map area is underlain by the lower Cretaceous Spences Bridge Group, the focus of the precious metal exploration.

Volcanics and sediments of the Eocene Princeton and Kamloops groups occur as outliers within the Mount Lytton Complex and unconformably overlie the Spences Bridge Group. Quaternary sediments occur as thick drifts along the main rivers and some of the larger creeks. Related (?) Eocene feldspar porphyries locally intrude Nicola and Spences Bridge Group rocks.

The lower Cretaceous Spences Bridge Group has recently been identified as a significant target for epithermal precious metal mineralization. This group, first described by Duffell and McTaggart (1952), forms a northwest trending volcanic belt consisting of a thick sequence of gently folded volcanics with lesser sediments, dipping shallowly to the northeast. Rocks of the Spences Bridge Group are believed to have formed as a chain of stratovolcanoes associated with subsiding, fault-bounded basins (Thorkelson, l985).

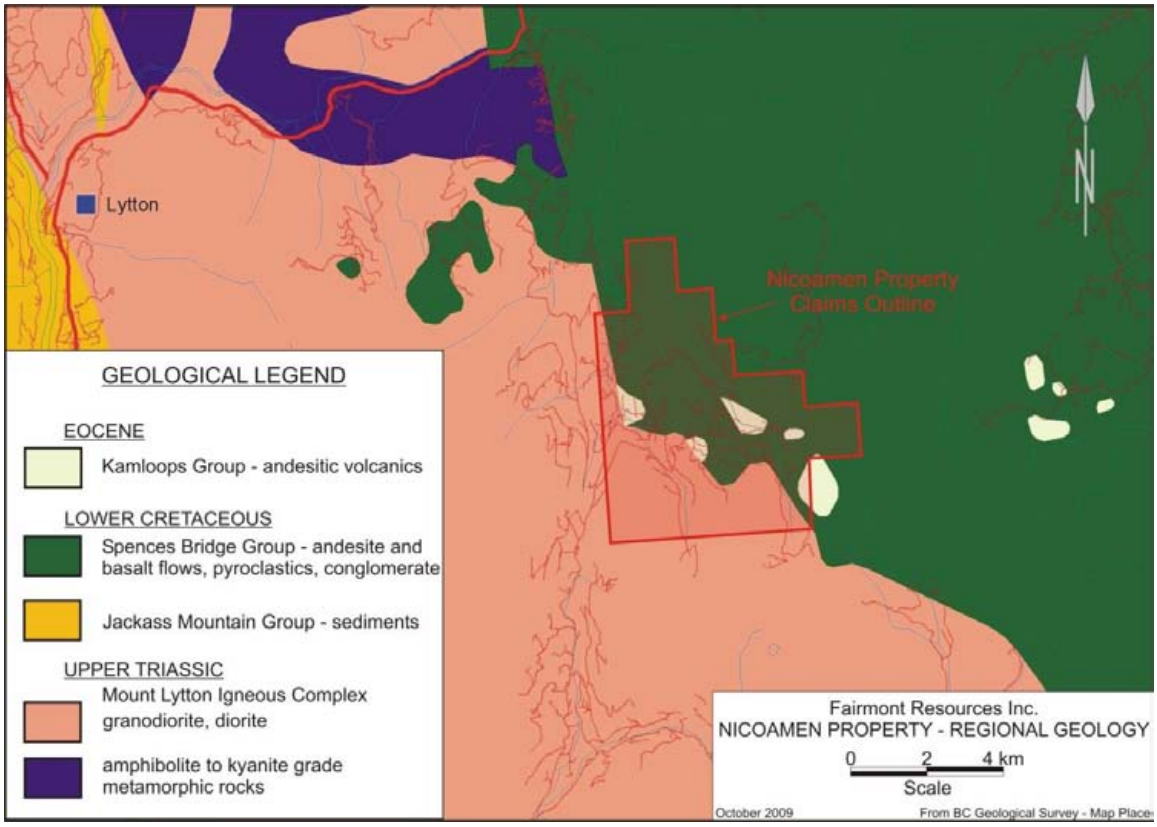

Figure 3. Nicoamen Property Regional Geology Map

Aerially, the Spences Bridge Group forms a northwest trending belt from 3 to 24 kilometres wide extending from north of Princeton to east of Lillooet (Figure 4). A faulted extension of the belt occurs as a series of outliers in the Churn Creek - Empire Valley area west of 100 Mile House (Thorkelson, 2006). The group is estimated to be up to 3400 metres in thickness (Thorkelson, 2006).

The Spences Bridge Group is thought to be the volcanic representation of the closure of the oceanic basin between Wrangellia to the west and the assemblage of Intermontane terranes (the accreted part of ancestral North America) to the east. Spences Bridge rocks were deposited on two main basement types: west of the village of Spences Bridge, they overlie the mainly Paleozoic Cache Creek terrane; to the east and in the area of the Property, they overlie plutonic and volcanic rocks of the late Triassic Nicola Arc, part of the Quesnellia terrane and plutonic rocks of the Triassic Mount Lytton Intrusive Complex (Thorkelson 2006).

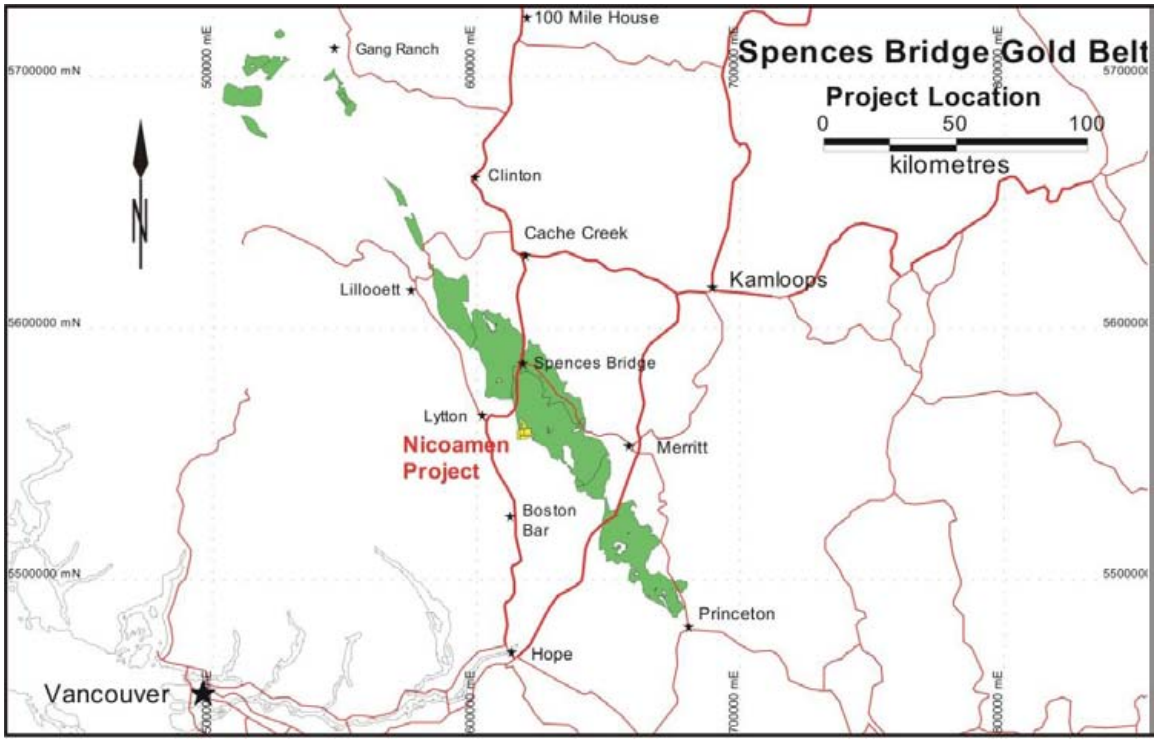

Figure 4. Aerial Extent of Spences Bridge Group.

Shortly after initial eruption of the Spences Bridge Group, tectonism led to the deposition of a basal conglomerate that contains clasts of Triassic granitoids and Nicola volcanic rocks. These clasts commonly show foliations and lower greenschist metamorphism which are not evident in the Spences Bridge Group, suggesting Spences Bridge Group rocks were deposited on the basement after deposition of the Nicola Group, deformation, metamorphism, and exhumation (Thorkelson, 2006).

The Spences Bridge Group consists of two formations: the lower Pimainus Formation and the overlying Spius Formation. The Pimainus Formation is highly variable, containing lava, tephra, fanglomerate, lahar, sandstone and coal. Volcanic compositions range from basalt to rhyolite, but the unit is mostly characterized by thick flow units of medium grained, pyroxene-bearing and feldspathic phyric andesite, felsic pyroclastics, and at least three separate horizons of interlayered conglomerate. It is considered to be a stratovolcano assemblage deposited in a tectonically active basin.

The overlying Spius Formation consists almost entirely of thinly bedded, fine-grained amygdaloidal andesitic lava, ranging from pahoehoe to aa types. In some places the contact with the underlying Pimainus Formation is conformable and difficult to identify, while in other occurrences lacustrine beds separate the two formations (Thorkelson, 2006).

The Spences Bridge Group is preserved in the Nicoamen structural depression, a complex synclinorium crosscut by normal faults. The basin appears to have been forming at the same time as the Spences Bridge Group. Exposures of the Spius Formation are largely confined to the centre of the structural depression. The Formation appears to be the relic of an extensive shield volcano with a few cinder cones (Thorkelson, 2006).

Structurally, the Spences Bridge Group is generally gently tilted with dips from 10^{o} to 40^{o} to the northeast. Individual flows and beds do not appear to extend for appreciable distances. There appears to be some faulting within the group but the lack of marker horizons makes measurement of any displacement difficult (Duffel and McTaggart, 1952).

5.2 Property Geology

The Nicoamen property lies at the western boundary of the Spences Bridge Group with the basement Mt. Lytton Igneous Complex. The dominant lithology on the northern half of the property is Spences Bridge Group volcanics, volcaniclastics and conglomerates (Figure 5). The southern half of the Property is underlain by the Mt. Lytton Igneous Complex, predominantly quartz diorite with local exposures of metasedimentary rocks. The Spences Bridge group has been further divided into a basal conglomerate and volcaniclastic rocks of the Pimainus Formation which are overlain by basalts to andesites of the Spius Formation. Carlson (2010) provides a detailed description of the properties lithologies.

The Nicoamen Fault is a major planar structure trending along the Nicoamen River. Several sub-parallel north-north-easterly trending structures are interpreted from topography, geophysics, and geology to trend through the Property. None of these structures were actually mapped in outcrop and the nature of offset is not known. Some of these structures are expected to be the focus of hydrothermal fluids and possibly epithermal-style precious metal mineralization.

Two different styles of alteration were noted on the Property. While most of the Mount Lytton diorite was fresh, with varying degrees of weathering, in the vicinity of the Discovery Zone and at other locations adjacent to structures, moderate to strong propylitic alteration was noted. In this case, plagioclase is largely altered to sericite and mafic minerals to chlorite, carbonate and epidote (Harris, 2009).

At the West Zone occurrence, alteration is more extreme, such that the original lithology is not discernable. The rock typically consists of a fine intergrowth of granular quartz with fine sericite and clays (Harris, 2009), with disseminated pyrite from trace to 2-3% and locally up to 5%. Also locally, the rock is more extremely silicified and has been hydrothermally fractured and brecciated.

6.0 Mineralization

The exploration target for the Nicoamen Project is a low sulphidation epithermal precious metal deposit. Bedrock mineralization has been found in two locations on the Property.

Two structures have been explored in the past (Balon and Hylands, 2006), the Discovery Zone and the West Zone. Within the Discovery Zone, narrow, rhythmically banded, chalcedonic quartz veins occur in altered quartz diorite basement rock. The West Zone is a broader area of disseminated pyrite mineralization in a locally brecciated quartzofeldspathic rock.

The following descriptions of the two anomalous mineralization zones in the Nicoamen Property are by Carlson (2010).

6.1 Discovery Zone

The Discovery Zone consists of narrow, rhythmically banded, chalcedonic quartz veins in parallel shear zones within altered quartz diorite. The location is believed to be close to the unconformity or possibly near a fault contact with overlying SBG rocks. Alteration consists of kaolinization, silicification, iron oxides and ankerite. Sulphides were not observed in the Discovery Zone. Hand trenching (Balon and Hylands, 2006) traced the zone a distance of approximately 75 metres. The individual quartz veins range from 1 cm to 20 cm in width, with one vein continuous in excess of 10 metres of length.

In 2004, Almaden crews collected two small pieces of iron-stained angular chalcedonic quartz float from a location 600m northwest of the Discovery Zone. A composite sample of this material assayed 64.87 g/t gold ((MC-R194, Balon and Hylands, 2006). These fragments appeared to be derived locally and may have been eroded from an extension of the Discovery Zone. This sample demonstrates the potential for the discovery of bonanza grade epithermal style mineralization on the Property.

6.2 West Zone

The West Zone is hosted in an altered, quartzofeldspathic rock of unknown origin. Alteration ranges throughout the exposed trench from silica with kaolinite or argillic alteration in the northern end to patchy argillic and silica alteration with increasing limonite to the south. Quartz occurs as clasts or sweats in the West Zone. Mineralization consists of up to 5% disseminated pyrite and possible traces of arsenopyrite.

7.0 2010 Field Program

The exploration program was planned and managed by Coast Mountain Geological Limited ("Coast") of Vancouver, BC under the supervision of Peter Dadson, P. Geo (Alberta). A soil sampling program was designed to expand the current surface expression of the Discovery and

West Zone by infill sampling along the established soil grid as well as to delineate the south eastern extent of the Central Zone soil anomaly. The goal of this soil program was to help define further targets for a planned drill program. Coast provided geologists, geological technicians and the necessary field gear.

The 2010 field program was carried out over a 10 day period from October 25th to November 6th, during which a four-man crew completed a soil sampling program within three defined areas, the Discovery and West Zones as well as the south eastern extension to the Central Zone. A total of 903 soil samples (891 samples and 12 duplicates) were collected from the three grid areas. Limited prospecting and rock sampling was conducted at the same time as the soil survey and 6 rock samples were collected. The field crew were billeted at the Green Canyon Motor Inn located in the nearby community of Boston Bar, British Columbia. Total cost of the 2010 soil sampling program was $58,935. A statement of expenditures is appended in Appendix I.

7.1 Grid Establishment and Soil Sampling

Three infill grids based on the original Almaden and Tanqueray grids was created to cover the three areas of interest. Grids were designed to collect samples every 25m on UTM north-south oriented lines spaced 50m apart. UTM coordinates (NAD83, Zone10) were pre-determined for each sample site and sample numbers were based on the last four digits of each sites proposed UTM location (IE. sample 9050-7250 proposed location was 619050mE, 5557250mN).

Soil sample sites were located using hand-held GPS's based on the coordinates established for each site. Samples were collected from the "B" horizon whenever possible and placed in gusseted kraft paper bags which were labelled with the sites unique identifier using a permanent marker. Sample notes concerning the samples depth, colour, soil horizon sampled and additional comments along with the sampler's initials were collected. These notes are tabulated in Appendix II. Soil sample sites were marked by blue and pink flagging with the sample number, date and sampler's initials noted in permanent marker on the flagging.

At the end of the program, soil samples were delivered to the Coast Mountain Geological Ltd. warehouse where they were stored in a secure facility until sent for analysis in the spring of 2011.

7.2 Prospecting and Rock Sampling

During the 2010 soil sampling program, an effort was made to prospect and sample any potential site of visible alteration and mineralization. Rock samples were numbered using a numbered three part sample tag supplied by ACME Analytical Laboratories. Samples were placed into a 6ml plastic bag which was labelled with the sample number in permanent marker. One part of the three part tag was placed in the sample bag which was then sealed with a plastic zip-tie. Sample positions were located using a handheld GPS unit and noted along with other pertinent information about the rock sample. These notes are tabulated in Appendix III. Sample sites were marked with the second part of the sample tag which was tied with flagging to nearby bushes or trees. The sample number, date the sample was collected and sampler's initials were marked on the flagging with permanent marker. All rock samples were then placed into larger plastic rice bags which were sealed with a plastic zip-tie.

8.0 Sample Security and Analysis

8.1 Sample Security

Samples were brought back to camp daily, dried and stored in a secure room at the Green Canyon Motor Inn. At the end of the program, all samples were sorted by line numbers, packed and readied for shipping on site by the field crew. A Coast employee drove the samples directly to Coast's warehouse facilities in Burnaby, B.C. where they were stored on a secure rack until the decision was made to analyze them in March of 2011. A Coast employee then delivered the samples to ACME Analytical Laboratories Ltd. preparation facility in Vancouver, British Columbia.

8.2 Sample Analysis

All samples were analyzed at Acme Analytical Laboratories located at 852 E. Hastings St, Vancouver BC, V6A 1R6. Acme Labs is ISO 9001:2001 certified.

Upon receipt, soil samples were catalogued and noted into the system before being prepared using ACME's preparation method SS80. The SS80 Method involves drying the samples at 60°C and then sieving through an 80 mesh screen to obtain 100 grams of the -80 mesh fraction. The samples were then analyzed using ACME's 1DX2 method in which 15g of sample is leached in a hot (95^{o} C) aqua regia digestion before element concentrations are determined by ICP-MS analysis. Analytical certificates for the soil samples are attached in Appendix IV.

Rock samples were also catalogued and logged into the system before being prepared by AMCE's preparation method R200-250. The R200-250 method involves crushing samples to pass through a 10 mesh screen, splitting off a 250g representative sample and pulverizing until 85% of the split is able to pass through a 200 mesh screen. The pulps were then geochemically analyzed utilizing ACME's 1EX method in which 0.25g of sample is split off, digested and heated in a bath of HNO_3-HClO4-HF to fuming and taken to dryness. The residue is then dissolved in HCl and analyzed by ICP-MS for element concentrations. Rock samples were also tested for gold by ACME's fire assay G601 method. In this method a 30g spit of the pulp is fire assayed and levels are determined by an AA (atomic absorption) finish. Analytical certificates for the rock samples are attached in Appendix V.

9.0 Results and Interpretation

9.1 Soil Sampling

Three areas were tested by infill soil sampling in order to better define the targets for a future drill program. These areas are referred to as the Discovery Zone, West Zone and Central Zone Extension grids (Figure 6). Soil results were complied and anomalous levels were defined using histogram plots to determine anomalous levels for Au, Ag, Cu, Pb, Zn, Mo plus the pathfinders As and Sb. Table 2 lists the different levels of the anomalies which were indicated by the

inflection points in the plots. Using the values listed in Table 2, plots were generated for all soil samples, including historical ones, and are shown in Figures 6 to 13 (as graduated symbols; values are plotted in Figures 15 to 22).

Table 2: Anomalous Levels for Select Elements in Soil for the Nicoamen Property

	Au (ppb)	Ag (ppm)	Cu (ppm)	Pb (ppm)	Zn (ppm)	Mo (ppm)	As (ppm)	Sb (ppm)
Weakly anomalous	7	0.2	34	6.6	90	1.6	20	1.1
Anomalous	10	0.3	46	7.6	120	2.5	30	1.6
Strongly Anomalous	17	0.4	58	9.4	145	3.4	45	2.5

The results for these three areas, the Discovery and West Zones plus the Central Zone extension, are discussed below.

9.1.1 Discovery Zone Grid

The Discovery Zone is centred on the main showing of 5 trenches in which quartz veining and silicified rock returned up to 1.77 g/T Au over 3.5m. During the 2010 soil sampling program, a total of 420 soil samples were collected from 416 sample sites (4 of the samples were duplicates) over an area measuring 625m north-south by 750m east-west. A coincident gold-arsenic-molybdenum- antimony in-soil anomaly occurs over a 150m by 75m long area trending approximately 110-290 and centred on the Discovery Zone. All four elements also show evidence of down slope dispersion to the north-northeast from the Discovery Zone. A wide lead-in-soil anomaly forms a halo around the area of the gold-arsenic-molybdenum-antimony anomaly, and a zinc-in-soil forms a similar, but more dispersed, anomaly. Only a few point anomalies of silver and copper occur within the vicinity of the Discovery Zone.

Gold values are also erratically dispersed along the trend of the Discovery anomaly to the east and west but do not have a coincident molybdenum, arsenic and antimony in-soil signature.

9.1.2 West Zone Grid

The West Zone consists of a siliceous to argillic altered volcanics and/or quartzofeldspathic granulite (?) exposed in a rock cut and mineralized with disseminated pyrite. A total of 232 soil samples were collected from 228 sample sites (4 of the samples were duplicates) over an area measuring 450m north-south and 550m east-west. A very localized, coincident gold-arsenic-molybdenum in-soil anomaly is localized to the west and down slope from the West Zone showing. Antimony-in-soil forms a linear 300m long soil anomaly centred on the West Zone. Anomalous values of zinc-in-soil form a halo around the West Zone showing, along with more dispersed lead-in-soil anomalies. Anomalous copper-in-soil forms a distinct cluster down slope to the west of the West Zone Showing, and along a west-northwest to east-southeast copper-antimony-zinc soil anomaly, highlighted by the 2006 soil samples. Silver values in soil are generally low.

9.1.3 Central Zone Extension Grid

The Central Zone Extension Grid was designed to test the probable south eastern extension of the arsenic-antimony in-soil anomaly which defines the Central Zone. The Central Zone trends roughly 120-300 to 150-330 with defined north-south and east-west anomalies. The largest concentration of anomalous silver and lead in-soil values occurs around the margins of the Central Zone. The Central Zone soil anomaly is centred on an outlier of Spences Bridge Group volcanics within the granodioritic rocks of the Mount Lytton Igneous Complex. A total of 251 soil samples were collected from 247 sample sites (4 of the samples were duplicates) over a backwards "L" shaped area measuring 725m north-south and 550m east-west in 2010. While a weak arsenic-antimony in-soil anomaly does extend to the east and southeast into the Central Zone Extension Grid from the Central Zone soil anomaly, its strength is vastly diminished. The sliver and lead anomaly does extend throughout the Central Zone Extension grid, especially in its southern half.

9.2 Rock Sampling

While collecting soil samples, the samplers were aware to note and prospect for any altered rock in the area of the 2011 soil grids. During the ten day period, a total of six rock samples were collected and sent in for analysis. None of the rock samples were anomalous in any of the precious or base metals and antimony and arsenic. Rock sample descriptions are tabulated in Appendix III and their locations are shown in Figure 14.

10.0 Conclusions and Recommendations

The Nicoamen Property is located in the Kamloops Mining Division in British Columbia. The Property is wholly owned by Almaden Minerals Ltd. and at the time of the 2010 soil program, was under option to Fairmont Resources Inc.. The Nicoamen Property consists of 9 contiguous mineral tenures covering an area of 3,332 hectares.

Previous exploration programs outlined two areas of significant precious metal epithermal mineralization, the Discovery and West Zone. Historical soil sampling outlined four distinct gold-arsenic in-soil anomalies; of which two were related to the Discovery and West Zone mineralization, and two were unexplained soil anomalies, the Canyon and Central Zone.

After a careful review of past data, an infill soil program was proposed to further delineate the two known mineralized prospects, the Discovery and West Zones, and to check for the south and eastern extension of the Central Zone soil anomaly. Coast Mountain Geological Ltd. on behalf of Fairmont Resources Inc. conducted the infill soil program during a 12 day period in late October to early November, 2010. In total 903 soil samples were collected from the three infill grids. A further six rock samples were collected while prospecting in conjunction with the soil sampling.

Distinct gold-arsenic-antimony-molybdenum in-soil anomalies occur centred on the two known mineralized prospects, the Discovery and West Zones. The Discovery Zone is defined by a 150m

by 75m coincident gold-arsenic-antimony-molybdenum in-soil anomaly, while a smaller gold-arsenic-molybdenum anomaly is localized to the west and down slope from the West Zone. Base metal halos of lead and zinc soil anomalies occur around both deposits, but copper in-soil anomalies are only more prevalent down slope from the West Zone showing. Silver only shows a few point anomalies in both the Discovery and West Zone grids.

Weakly anomalous arsenic and antimony values in-soil on the Central Zone Extension grid are the only indication of a southern or south-eastern extension from the previously defined Central Zone gold-arsenic in-soil anomaly. A broad halo of lead and silver in-soil anomalies does extend south-easterly into the Central Zone Extension Grid.

Historical soil anomalies also show a preferred north-south orientation which may be closely related to the Nicoamen fault. Further study is required to determine the relationship between the north-south oriented Nicoamen fault and the possible east-west oriented epithermal structures.

In lieu of the above results the following recommendations can be made:

- In-fill soil sampling between the Discovery infill soil grid and the Canyon Zone to determine if the two zones are located along the same mineralizing structure.
- Follow-up prospecting of known soil anomalies by hand-dug pits to determine the cause of the anomalies and check for evidence of epithermal mineralization and/or alteration.
- Trenching and/or drilling to be based on the results of the hand-dug pits.

Appendix III - Rock Sample Notes

Sample Number	Date	UTM E	UTM N	Zone	ID	Sampler	Description
27801	03-Nov-10	619332	5557726	Central Zone	CN-04	CN	20m long by 2.5m high road cut with 60cm of soil overtop. Pinches out towards the E and W ends. Exposure is cut at 140°. Rock cut is comprised of Granodiorite which exhibits moderate to strong Fe-Ox alteration/ weathering on exposed surfaces. Appears to be weak ankerite alteration locally on fresh surfaces. Moderately cleaved at 260/64 with moderate gouge occurring parallel to cleavage planes. Pictures taken looking towards 240°.
27802	05-Nov-10	619965	5558095	Canyon Zone	CAZ-001-CN	CN	3m long, 0.5m wide subcrop. Felsic, aphanitic and strongly jointed. Appears to be 95% quartz, 5% plag (Quartzite?) Strong cleavage at 256/80 with weaker jointing oriented at 208/80.
27751	30-Oct-10	618947	5558547	Discovery Zone		SP	Red soft aphanitic matrix supported with <0.5cm sub-rounded angular dark green to black mineral (amphibole?) Strike 216/70 possible fault structure? In contact with dark brown green aphanitic vesicular containing white amygdules at 320/35.
27752	03-Nov-10	619247	5557396	Central Zone		SP	Altered granodiorite with red oxide. Located in overturned stump sub-crop.
27753	04-Nov-10	619205	5557348	Central Zone		SP	Altered granodiorite, sericite alteration with red oxidation taken in sub-crop.
27754	05-Nov-10	618554	5559162	Discovery Zone	SP-8	SP	Red-brown, aphanitic vesicular basalt. Highly oxidized basalt with vesicles and smoky white/brown qtz amygdules. FeOx-4. Slicken sides are visible on fractured surfaces and outcrop. No visible orientations on structures/outcrop. Sample taken beside road. Photo taken at 240°.

CERTIFICATE OF ANALYSIS VAN11001296.1

CLIENT JOB INFORMATION

Project: NICOAMEN-CZ
Shipment ID:
P.O. Number
Number of Samples: 251

SAMPLE DISPOSAL

STOR-PLP Store After 90 days Invoice for Storage
DISP-RJT-SOIL Immediate Disposal of Soil Reject

Acme does not accept responsibility for samples left at the laboratory after 90 days without prior written instructions for sample storage or return.

SAMPLE PREPARATION AND ANALYTICAL PROCEDURES

Method Code	Number of Samples	Code Description	Test Wgt (g)	Report Status	Lab
SS80	251	Dry at 60C sieve 100g to -80 mesh			VAN
Dry at 60C	251	Dry at 60C			VAN
1DX2	251	1:1:1 Aqua Regia digestion ICP-MS analysis	15	Completed	VAN

ADDITIONAL COMMENTS

Invoice To: Fairmont Resources Inc.

CERTIFICATE OF ANALYSIS VAN11001934.1

CLIENT JOB INFORMATION

Project: NICOAMEN
Shipment ID:
P.O. Number Nicoamen
Number of Samples: 6

SAMPLE DISPOSAL

STOR-PLP Store After 90 days Invoice for Storage
DISP-RJT Dispose of Reject After 90 days

Acme does not accept responsibility for samples left at the laboratory after 90 days without prior written instructions for sample storage or return.

SAMPLE PREPARATION AND ANALYTICAL PROCEDURES

Method Code	Number of Samples	Code Description	Test Wgt (g)	Report Status	Lab
R200-250	6	Crush, split and pulverize 250 g rock to 200 mesh			VAN
G601	6	Fire Assay fusion Au by ICP-ES	30	Completed	VAN
1EX	6	4 Acid digestion ICP-MS analysis	0.25	Completed	VAN

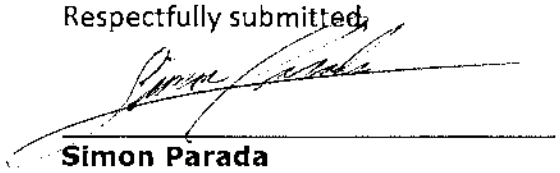
Appendix VI
Statement of Qualifications

I, Simon Parada, DO HEREBY CERTIFY that:

1. I am a graduate of the British Columbia Insitute of Technology, with a Diploma in Mining technology (2007)
2. I am presently employed as a geotechnician by Coast Mountain Geological Ltd.
3. I have worked as an exploration geotechnician for 6 years.
4. I am the author and am, in part, responsible for the preparation of the report titled "Assessment Report Covering 2010 Geochemcial Sampling On The Nicoamen Property" dated November 9, 2011 which is based on my review of available literature and data collected on the Property by myself and co-workers between October, 2010 and June, 2011.

Dated 1st of Feburary, 2011 in Salmon Arm, BC

Respectfully submitted,



Simon Parada

Coast Mountain Geological Ltd.
