APPENDIX V- 2012 EXPLORATION MAPS

SUMMARY

The Hit Property consists of two original mineral claims, totalling 752.4 hectares covering the Hit and Miss Minfile occurrences and the adjoining ASPEN GROVE SOUTH property of 45 mineral claims totalling 13,538.86 hectares covering 18 other Minfile occurrences. The combined property totals 47 mineral claims covering 20 Minfile occurrences and area of 14,291.30 hectares. The property is located approximately 30 kilometres north of the community of Princeton, British Columbia. The Property is centered at latitude: 49° 40' north, longitude: 120°. 25’ west, and is located on BCGS map sheet 092H. The Property can be accessed by a series of well-maintained gravel forest service roads originating either from the paved Merritt-Princeton Highway 5A in the west, paved Highway 97 C in the north and the paved Princeton-Summerland road in the south and east.

The region surrounding and underlying the property is underlain by the Nicola Group volcanic arc portion of the Upper Triassic Quesnel Terrane Lithologies include alkalic to calc-alkalic subaqueous to subarea1 volcanic rocks, coeval intrusive bodies and associated sedimentary rocks, including limestone.

The property is prospective for alkalic and calcalkalic porphyry copper +/- gold +/- molybdenum and later orogenic gold-quartz deposit type vein targets.

During 2012 a total of 2335 soil samples were collected principally from road cuts and were analysed by a portable XRF Niton, of which 161 of them were also submitted to Acme Analytical Labs in Vancouver for ICP analysis and Fire Assay Gold. A surficial geology study was also undertaken by Dr. Vic Levson of the property to gain a better understanding of the glacial cover and its constraints on exploration. The 2012 work filed under statement of work # 5396431 resulted in the expenditure of $ 67,500.

The results of this work indicate that quick reconnaissance soil/till sampling and subsequent analysis by portable XRF is a cheap, effective prospecting tool in particular for copper, however caution must be used when sampling glacial material far removed from bedrock.

Anomalous copper areas for follow up include the area north of Rampart Lake in the vicinity of the Golden Minfile occurrences and also in the area of the Pine and Al Minfile occurrences near the edge of the Allison Lake Pluton.

Detailed prospecting, grid soil sampling and contingent Induced Polarization surveys in areas of anomalous copper values and on geological trend of the Axe Minfile occurrence is also recommended. Gold fire assay analysis of the stored soil samples is also recommended as XRF analysis is not adequate for gold.

PROPERTY DESCRIPTION AND LOCATION

The claims comprising the Hit-ASPEN GROVE SOUTH Property (Property) are located on Crown and private land in the Similkameen Mining Division on BCGS map sheets 092H. The Property is located approximately 30 km north of the community of Princeton, British Columbia (Figure 1). The configuration of the various mineral claims is illustrated in Figures 2 3 and the claim information is as set out in Table 1 below. The claims cover an area of 14,291.30 hectares.

Colorado Resources has assembled the property through various option agreements, originally on the initial Hit claims (Tenures 514826 and 514829) and then subsequently by agreements with Richard Billingsley and Dwayne Kress of the Aspen Grove South claim block which covers 8587.8 hectares. Colorado subsequently acquired thru MTO application additional ground.

Exploration work on mineral properties in British Columbia resulting in physical disturbance requires the filing of a Notice of Work and Reclamation with the Ministry of Energy, Mines and Petroleum Resources. The issuance of a permit facilitating such work may involve the posting of a reclamation bond. As of the date of this report a $25,000 reclamation bond (MX-4-593) exists for mechanical disturbance including stripping, trenching, access trail construction and diamond drilling on and around the Hit prospect is being maintained by Colorado.

Mineral claims in British Columbia may be kept in good standing by incurring assessment work or by paying cash-in-lieu of assessment work in the amount of $5 per hectare per year during the first three years following the location of the mineral claim. This amount increases to $10 per hectare in the fourth and succeeding years.

Portions of the property especially along the Merritt-Princeton Highway corridor, the Summer's Creek valley and parts of the east claims (Vale portion) are also covered by private land. To access these areas landowner notification is required.

Hit/Aspen Grove Claims

ACCESSIBILITY, CLIMATE, INFRASTRUCTURE AND PSYSIOGRAPHY

The property is readily accessible by forest service roads originating either from the Coquihalla Connector in the north, Highway 5 A along the western boundary of the claim or the Princeton – Summerland road on the south and eastern sides of the claims.

The property is located approximately half way between Merritt and Princeton where most supplies can be found, if not Kelowna is located approximately 1- 1.5 hours travel east of the property. High and medium voltage power lines and a natural gas pipeline cross through the western part of the property west of the Ketchan-Delrich forest service roads.

The terrain at the Property ranges from small flat plateaus to steep sided valleys such as the Summers Creek Canyon (Figure 2). The highest point on the claims is the Missezula Mountain summit at 1654 metres above sea level. The lowest point is the Summers Creek Canyon at less than 1,000 metres.

Vegetation occurs as erratically occurring groves of lodge pole pine, spruce, Douglas fir, balsam and poplar. Most of the area covered by the claim blocks has been logged with most of the pine trees devastated by the pine beetle. The climate is moderately dry and snow cover accumulates from late October and lasts to mid-April at lower elevations to mid-May on the plateaus over 1300 metres.

HISTORY

The earliest exploratory work in the area dates back to the 1930's, and appeared to focus primarily on volcanic hosted red bed copper mineralization occurring in several small showings in and around the current Property boundaries. High grade shear hosted copper mineralization on the Axe prospect (Figure 4) south of the Property was also targeted and explored (Preto, 1979).

During the late 1960's through to the 1980's exploration focused primarily on porphyry style copper (gold) deposits on the nearby Axe, Rum-Coke, Pine and Log prospects.

With the discovery of the Siwash gold veins northeast of the property in the mid 80’s much of the more recent exploration has been focussed on gold.

In 1987 the Sadim gold vein system which occurs less than 300 metres north of the main Hit property boundary was discovered. This discovery has seen several intensive exploration programs.

In 1990 logging activity exposed gold bearing vein float and the Hit prospect was discovered. Modest drill programs followed at both the Hit and Miss Minfile occurrences.

The general area remained fairly dormant until mid to late 2000's when commodity prices began to rise again.

During 2007 and 2010 Walcott Geophysics Ltd. completed a small IP survey covering slightly more than a 1 km square area over the Hit and Hit North showing areas with lines at 200 metre spacing. (Walcott, unpublished data.). The surveys confirmed results from two lines completed in 2007 that the Hit Zone was underlain by a moderate chargeability response and a fairly strong resistivity low. This anomalous feature continues to the south for a short distance and to the north-northwest thru the west side of the Hit North zone beyond the property boundary towards the SADIM gold zone. Several other sub parallel zones labelled from east to west A to F (Hit is zone 'D') were also identified.

In 2010 Orofino Minerals acquired a large land position in the area that approximates the Aspen Grove South portion of the property and conducted an airborne magnetic survey and regional stream sediment sampling under an option agreement with Richard Bilingsley and Dwayne Kress, which they subsequently dropped.

In 2011 Colorado Resources completed a stripping and trenching program at the main Hit occurrence to better understand the complex nature of the vein system. Colorado also optioned the Aspen Grove Property and other claims from Richard Bilingsley and Dwayne Kress and also acquired claims of their own to comprise the entire property detailed in this report.

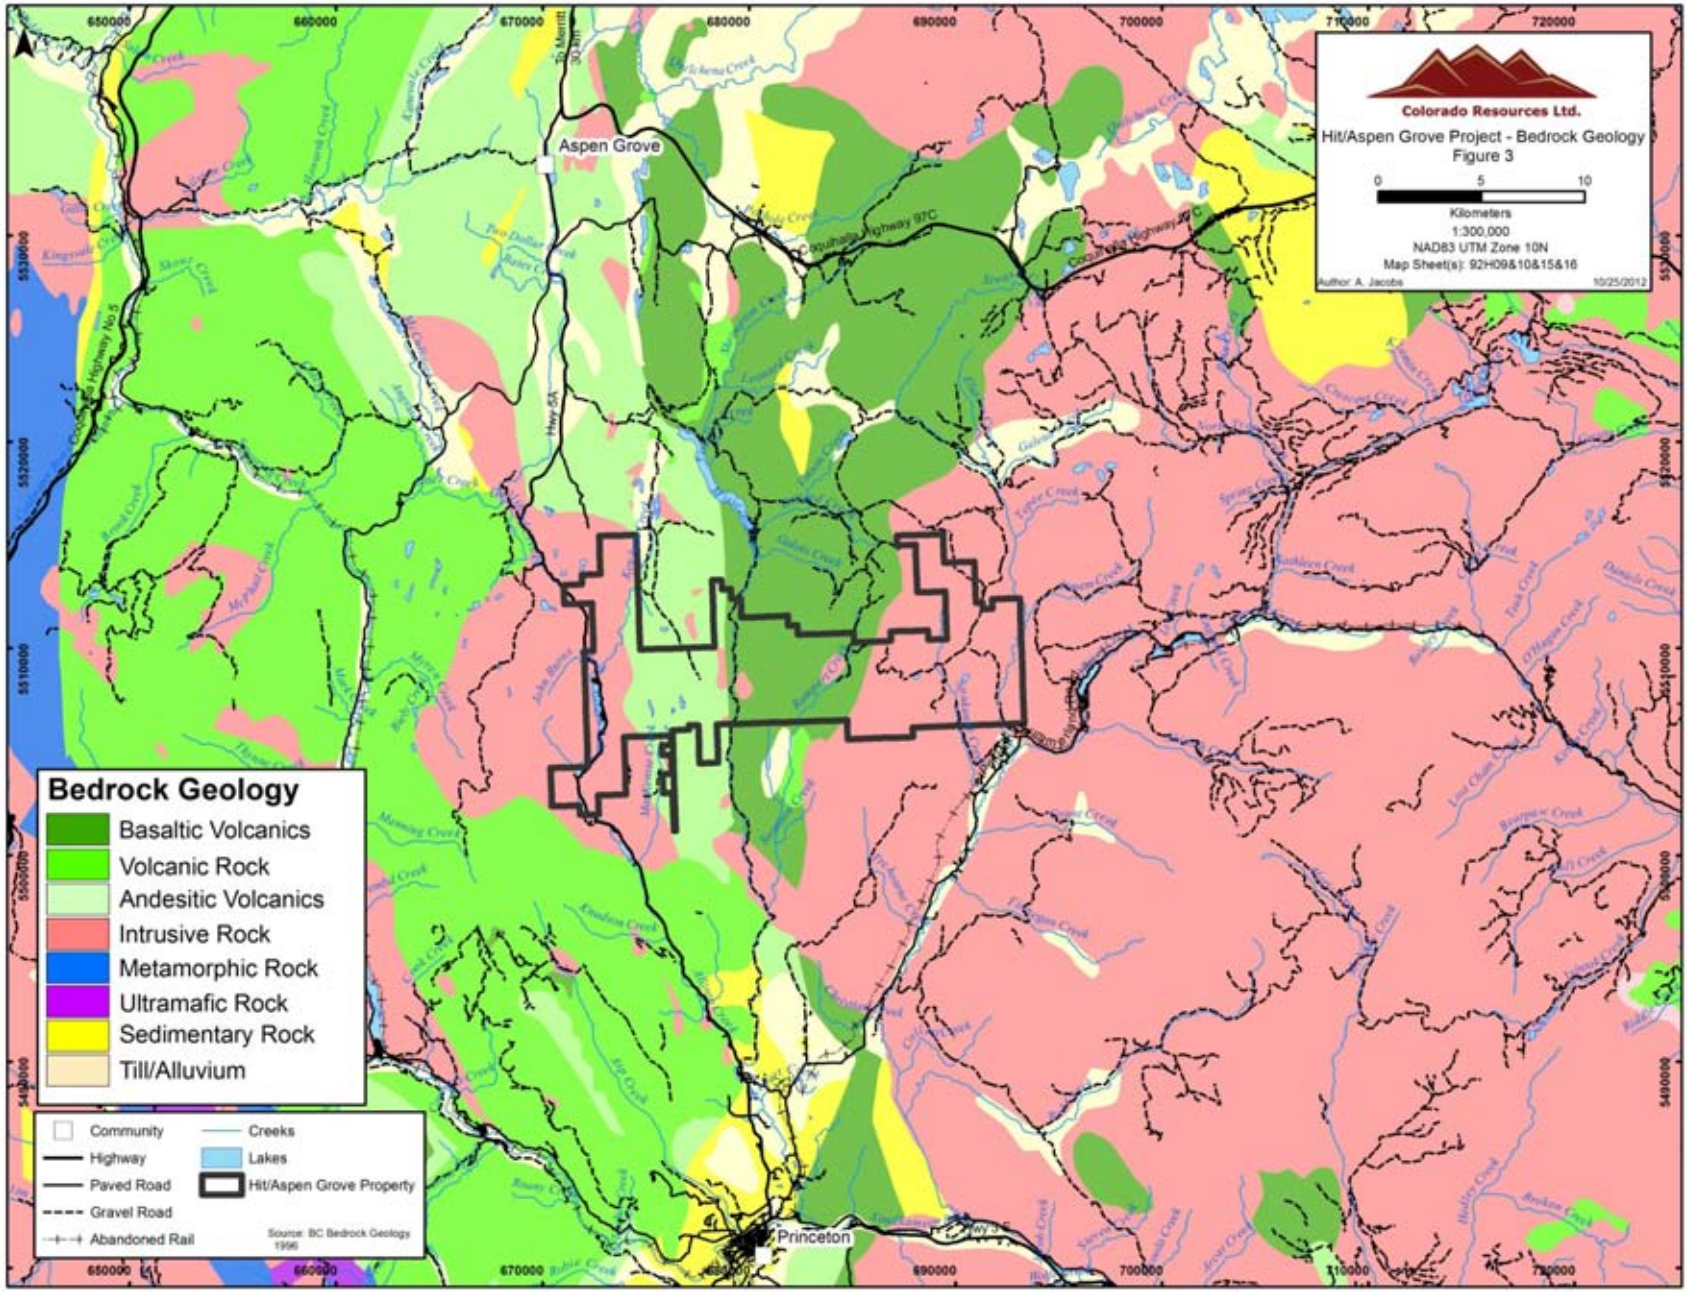

REGIONAL AND PROPERTY GEOLOGY

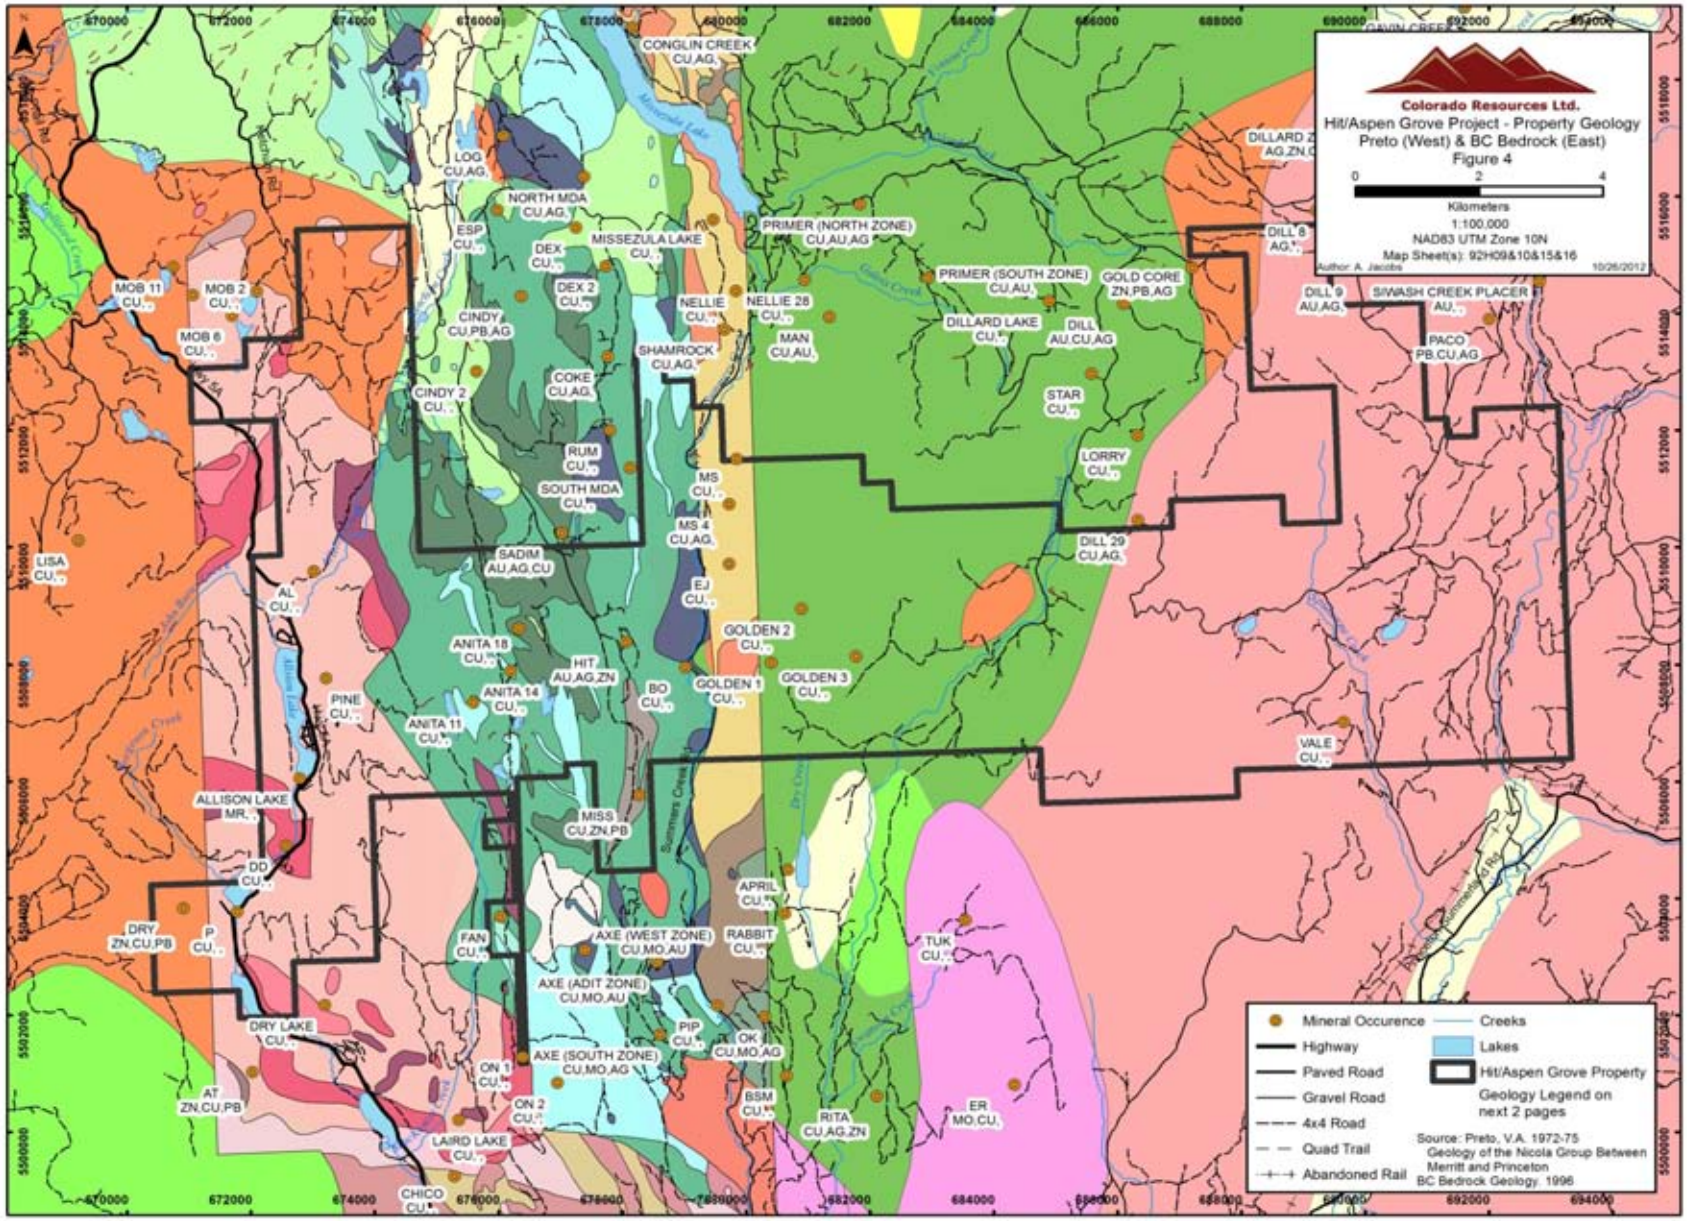

The most common lithologies underlying the region are the Nicola Group portion of the Quesnel Terrane, a west facing obducted volcanic arc of late Triassic to early Jurassic age. The Nicola Group extends as a continuous belt from near the US border (the 49th parallel) to just north of Kamloops Lake, where it is covered by extensive Tertiary volcanic rocks. Further north the Nicola Group is exposed near Little Fort and extends to the 62nd parallel.

The Nicola Group near Merritt, from oldest to youngest rock units is comprised of:

(i) A western belt of calc-alkalic extrusive volcanic rocks, coeval intrusive and derived sedimentary rocks;
(ii) A central belt of alkaline to calc-alkalic volcanic rocks;
(iii) Intrusion and minor sedimentary rocks (including carbonates); and
(iv) An eastern belt of alkaline volcanic rocks, coeval alkalic intrusive rocks, and contemporaneous and older sedimentary rocks, some of which are believed to be arc derived (Preto 1979).

These rocks have been intruded by several generations of mid Mesozoic to Eocene intrusive rocks and are intermittently overlain by several mixed sedimentary-volcanic assemblage.

LEGEND

Geology of the Nicola Group between Merritt and Princeton

V.A. Preto 1972-75

BC Bedrock Geology-1996

In the Allison Lake - Vale area, the Nicola Group rocks are confined to a relatively narrow north trending fault bound sequences of the central and eastern volcanic facies units. These are separated by the Summers Creek Fault, a long lived regional structure that may extend for hundreds of kilometres (Preto 1979).

The central volcanic facies rocks are generally upright to moderately dipping (east and west). Preto interprets the belt as a series of north trending eruptive centers evidenced by coarse subareal and submarine trachybasalts and andesites with remnant aprons of epiclastic sediments and locally discontinuous sequences of argillaceous and carbonate rocks. These eruptive centers are often partially invaded by coeval dioritic to monzonitic intrusive bodies and related hydrothermal breccias that have the potential to host economic porphyry copper+/-gold+/-PGM deposits. Near the Property the Axe, Rum-Coke and similar mineralized zones are continued areas of exploration activity. The property hosts the Pine occurrence. Further discussion on these and other mineral showings are explained in the following "mineralization" section.

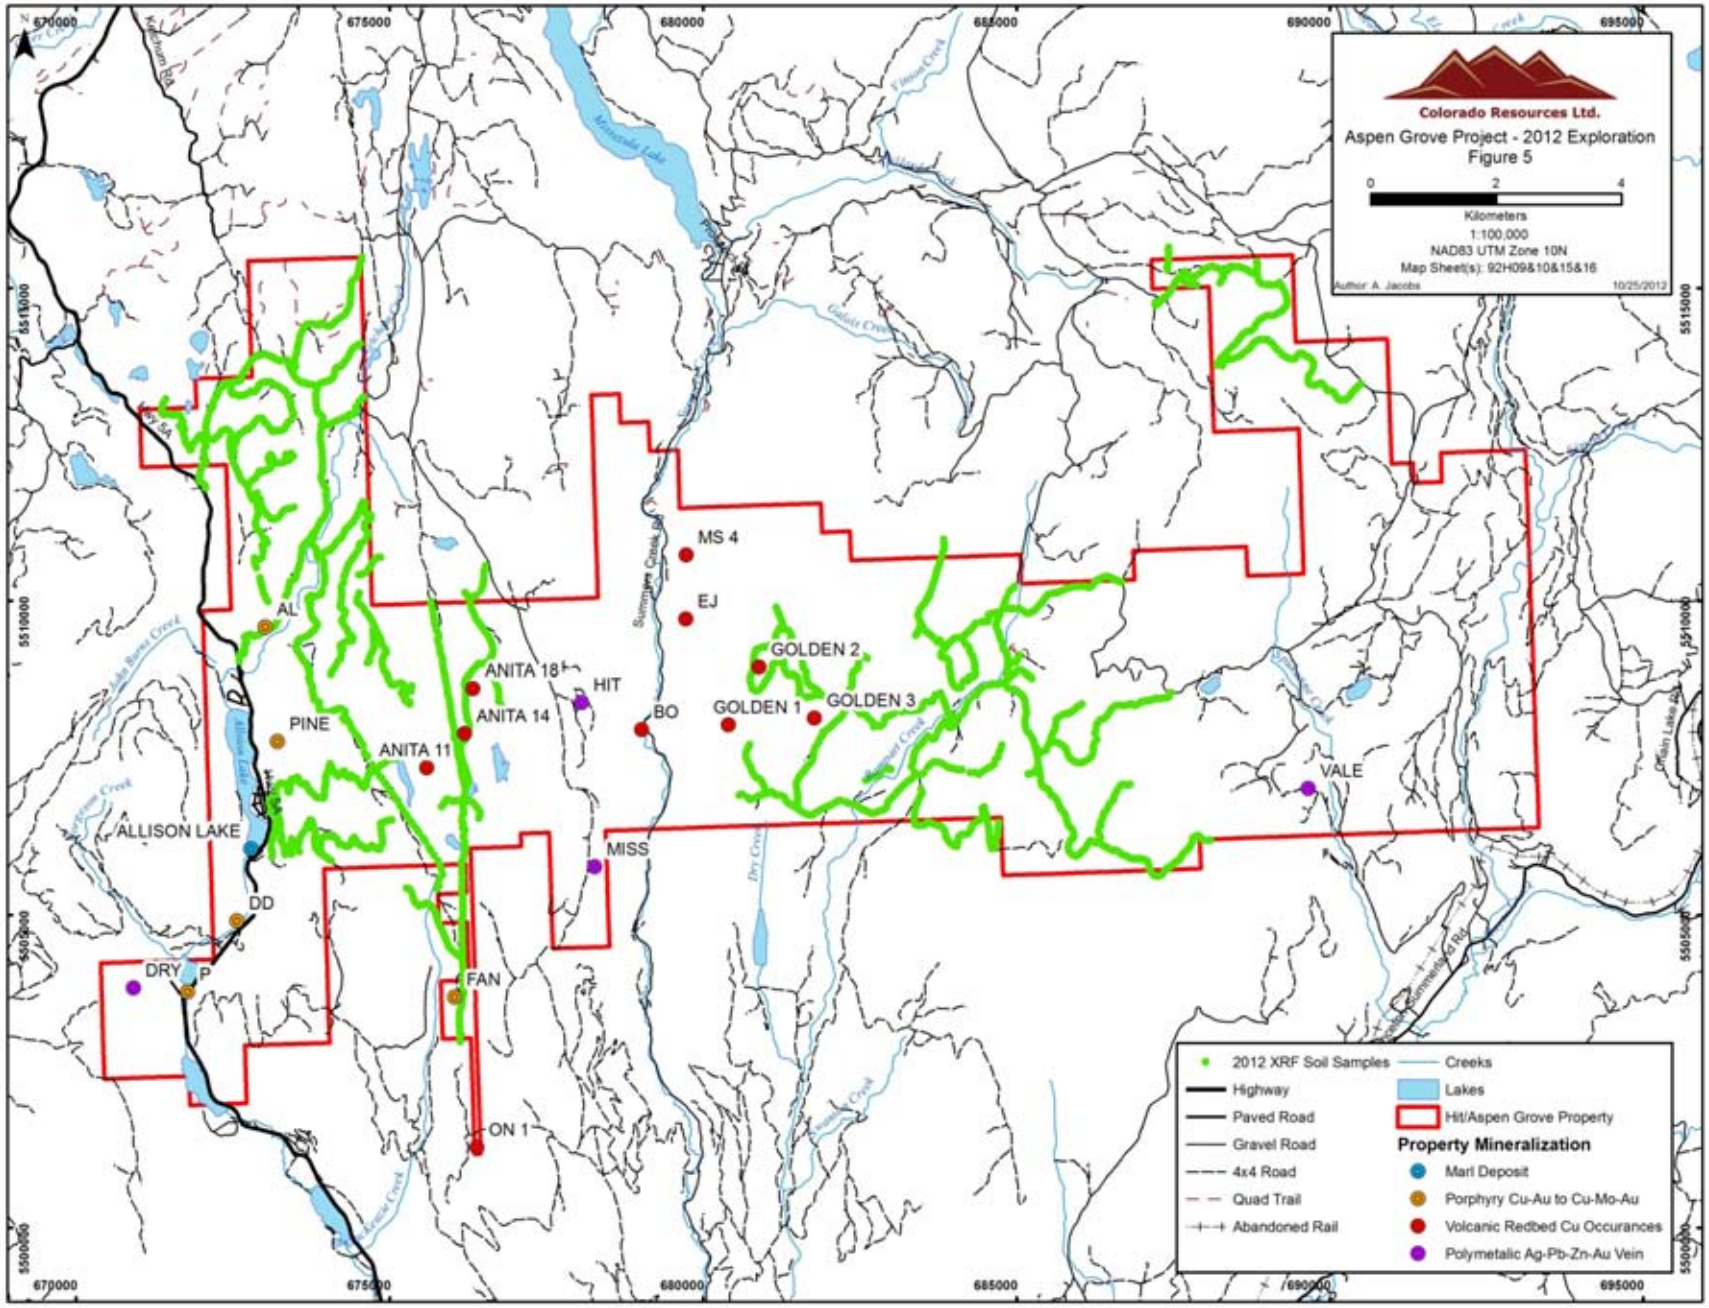

The eastern volcanic belt contains alkalic volcanics and related coeval intrusive centres and adjoining epiclastic and argillaceous sediments and carbonates. These rocks host the uncommon but globally important alkalic copper-gold porphyry copper deposit type. These include the Copper Mountain, Iron Mask, Mt. Polley intrusive complexes that host multiple mineralized deposits. The Prime-Man area just north of the central property area is the closest known deposits group of this type. Also intruding these rocks are slightly later Jurassic batholithic sized intrusive such as the nearby Pennask Batholith that hosts the Brenda copper-molybdenum deposit.

Other potentially economic metallic deposits types that may occur in the region include volcanic red bed type copper. More important economically are widespread Cretaceous and Tertiary epigenetic gold-silver enriched quartz vein fissure and shear zone associated deposits. The HIT, SADIM, and past producing ELK gold deposits are some of the most important deposits of this type in the region.

PROPERTY MINERALIZATION

The Property is host to 20 Minfile occurrences; these occurrences group approximately into five main groupings and include the following;

A marl deposit at Allison Lake, five occurrences called the Al, P, Pine, Fan and DD alkalic porphyry copper-gold to porphyry copper-molybdenum gold occurrences associated with the eastern contact of the Allison Lake Pluton Ten occurrences called Golden 1, Golden 2, Golden 3, MS, EJ, MS 4, Bo, Anita 11, Anita 14, and Anita 18 noted as volcanic redbed copper occurrences in two main clusters both east and west of Summers Creek

Porphyry Cu-Au to Cu-Mo-Au
Volcanic Redbed Cu Occurances
Polymetalic Ag-Pb-Zn-Au Vein

Four polymetalic silver-lead-zinc-gold vein occurrences called the Hit, Miss, Dry and Vale occurrences

Regionally alkalic copper gold porphyry deposits such as the Copper Mountain Mine to the south and Afton Mine to the north are the most economically significant and locally occurrences such as Mann- Primer and Axe currently held by others have seen substantial work and attest for the potential for these types of deposits on the current property.

The region is also host to dozens of small high and less commonly larger shear associated medium grade gold+/- silver bearing vein deposits. The most notable nearby occurrences are the ELK past producer northeast of the Property and the Sadim immediately north of the Hit zone These are part of a protracted Cretaceous to early Tertiary aged gold depositional event spanning the entire length of North America.

On and near the Property are the SADIM, HIT and MISS zones. These targets have received intermittent but substantial exploration efforts since the mid 1980's. The Hit zone is the most important known prospect on the Property. It appears to be spatially associated with a complex north trending structural zone which may be a part of the Summers Creek fault system to the east called the Missezula Shear Zone.

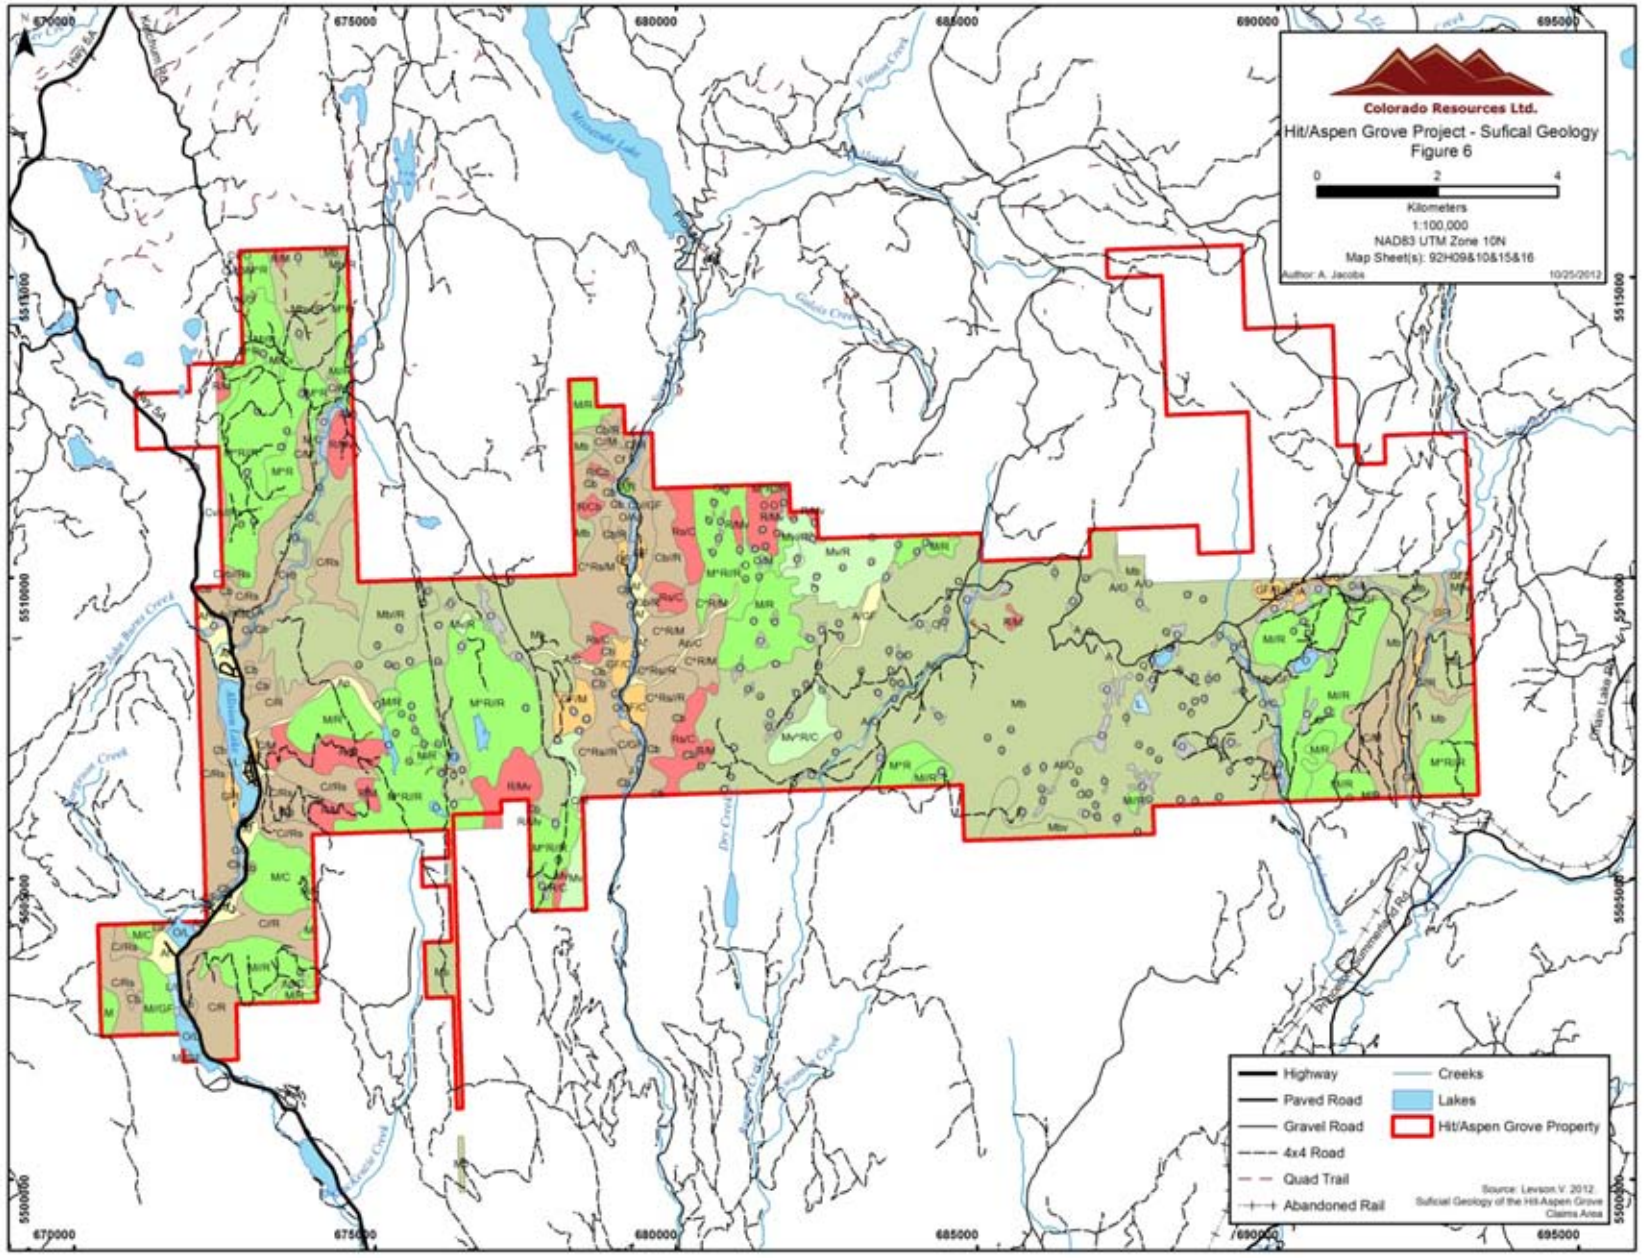

2012 EXPLORATION PROGRAM

The 2012 exploration program was initiated in April 2012 and was completed by mid-July. This work consisted of the collection of a total of 2335 soil/till samples primarily from forest service road cuts taken at 50 m sample spacing's.

A total of 161 of these 2355 samples were selected for ICP and Fire Assay analysis at Acme Labs in Vancouver to compare with the XRF results.

The 2012 exploration also consisted of a detailed surficial geology mapping study undertaken by Dr. Vic Levson to provide guidance for the the sampling medium and approach for the 2012 field exploration. It is important to note that almost all of the mineral occurrences on the property are on the west half where there is relatively good exposure. The dominant ice flow direction was generally to the south-southeast (about 170 degrees). Understanding the medium that you are sampling and its correlation to the underlying bedrock is of utmost importance.

For details of Dr. Levson's work please refer to Appendix IV.

Sufficial Geology of the Hit-Aspen Grove Claims Area

SURFICIAL GEOLOGY MAP LEGEND - HIT PROJECT AREA

QUATERNARY DEPOSITS

HOLOCENE (NONGLACIAL) SEDIMENTS

- ORGANIC DEPOSITS: mainly peat mosses, sedges, reeds and organic muds occurring in bog and fen environments; typically less than a few metres thick; formed by the accumulation of plant material in various stages of decomposition; mainly occurs in closed depressions overlying clay-rich, poorly drained till or glaciolacustrine sediments; hydromorphic geochemical signature reflecting groundwater drainage basin characteristics.
- A ALLUVIAL DEPOSITS: river, stream and alluvial fan deposits up to several metres thick; includes sorted sands and gravels, floodplain silts and organic detritus; commonly stratified.
- Ap Floodplain deposits: mainly overbank silts, clays and organic detritus overlying sands and gravels; occurs at or near modern creek levels; sands and gravels occur at surface along active and recently active channels; organic rich muds common at surface; unvegetated in recently active areas and with shrub or partial tree cover elsewhere; geochemical signature mainly detrital from distal sources possibly with some local hydromorphic signals.
- Af Alluvial fan deposits: moderately well to poorly sorted silt, sand, gravel and diamicton; usually at least several metres thick forming fans along stream channels at the break of slope in valley bottoms; geochemical signature detrital and reflects entire fan drainage basin.
- C COLLUVIAL DEPOSITS: slope deposits and other mass wasting debris varying from less than a metre to several metres thick; unsorted, massive to crudely stratified diamicton deposited by gravity-induced movement; composition dependent on source material; occurs mainly along steep stream valley walls and below rock cliffs (talus); detrital and hydromorphic transport perpendicular to slope dominates; source areas typically close.
- Cv Colluvial veneer: thin (typically < 2 m), discontinuous cover of slope debris; mainly diamicton; occurs mainly on steep valley slopes and around rocky hill tops; geochemical source areas typically close and directly upslope.
- Cb Colluvial blanket: slope deposits generally up to 10 m thick; mainly diamicton including debris flow deposits and talus debris below rock cliffs; slopes moderately steep; slope movements slow or largely inactive; mainly detrital downslope transport; source areas more distal than Cv.
- Cf Colluvial fan: debris flow dominated fan deposits generally up to 10 m thick; mainly diamicton; includes debris flow deposits and talus debris below rock cliffs; mainly detrital downslope transport; drainage basin source areas.
- L LACUSTRINE DEPOSITS: mainly silts, clays and fine sands often in association with organic deposits; typically several few metres thick; mainly occurs in in valley bottoms and closed depressions overlying clay- rich, poorly drained till or glaciolacustrine sediments; geochemical signature typically masked by basin-sourced detrital sediments.

LATE-GLACIAL SEDIMENTS

- GF GLACIOFLUVIAL DEPOSITS: stratified sand and gravel with minor diamicton; deposited by glacial meltwater; most common in large valleys; locally discontinuous and interspersed with glacial deposits (e.g. FG/Mb); geochemical signature of underlying rock usually completely masked.
- GFt Glaciofluvial terraces: sands and gravels occurring as elevated valley side benches; typically tens of metres above modern valley bottoms; detrital geochemical signature is highly distal.

GLACIAL SEDIMENTS

- M Morainal deposits: glacially derived diamicton (mixture of mud, sand and gravel) deposited by the Cordilleran Ice Sheet; typically massive, matrix- supported and up to several metres thick; includes lodgement till deposited at the base of the glacier as well melt-out till derived from within the ice; basal tills are dominated by detrital geochemical signatures with proximal up-ice source areas; melt-out tills have much more distal source areas.
- Mb Till blanket: glacial sediment (mainly basal till), typically a few to several metres thick, forming flat to gently undulating topography; generally fine-grained (silt and/or clay rich); clasts commonly striated; drumlins and flutes uncommon in the map area; distance to up-ice sources increases with till depth.
- Mv Morainal veneer: glacial sediments forming a thin veneer over bedrock; common in hilly topography; proximal up-ice source areas.

PRE-QUATERNARY DEPOSITS

- R BEDROCK: Rock outcrops on hill tops and steep slopes; typically interspersed with colluvial sediments (R/Cv) or thin till (R/Mv); some areas with thicker cover but still strong bedrock-controlled topography (e.g. Mb^R).

SAMPLING METHOD AND APPROACH

Portable XRF units have recently become both affordable and practical for early stage exploration and the concept was to first try road till sampling across areas of known mineralization and previously anomalous copper in soil conventional geochemistry to determine whether quick road sampling followed by XRF analysis would be an effective exploration tool.

A review determined that sampling at 50 metre intervals along road cuts even of till relatively close to bedrock (eg. Basal tills as opposed to glacial lacustrine or outwash gravels) generally showed anomalous copper results similar to previous soil sampling.

Soil or till sampling along roads thus provide a quick method to conduct sampling and teams were generally able to collect up to 300 samples per day from the road bank with the use of a mattock and which had variable depths below original ground from 10 centimetre's to as much as 5 metres.

SAMPLE PREPARATION, ANALYSIS AND SECURITY

Soil or till samples were collected in conventional kraft soil bags and labelled with an area letter (eg. R for Rampart) and number with a corresponding numbered pink and blue flag tied at the sample location.

Samples were stored in a locked garage where they were dried until ready for XRF analysis.

A trained XRF technician put the dried kraft bag with the sample inside the XRF lead lined box and read the sample on both sides.

The XRF units data was downloaded and matched to the GPS location collected in the field and plotted by Colorado GIS staff.

Samples are stored in a locked container in Peachland for future reference and 161 of the samples were selected from the storage and put in a secure rice sack with zip ties and sent via courier to Acme Labs in Vancouver for analysis.

EXPLORATION RESULTS

A review of the XRF copper results (see Figure 8a in Appendix V) confirms that the historical copper anomaly that occurs over the Primer occurrence is detected by XRF analysis and our sampling technique. Anomalous copper in XRF results are concentrated in the vicinity of the historical Golden 1, 2 & 3 Minfile occurrences and road sampling in this area has returned higher copper values then historically reported. Individual and sometimes multi-station copper in XRF anomalies are noted further east of the Golden occurrences but not to the same extent. Spot copper highs are also noted in the western portion of the property near the Allison Lake Pluton. XRF samples were not taken in the vicinity of the Al and Pine occurrences as for the most part the previously anomalous areas are along steep creek banks.

A review of the XRF arsenic results (see Figure 8b in Appendix V) which is often a pathfinder to porphyry copper deposits and an element quite reliably read by portable XRF units) indicates that's there elevated arsenic in our XRF samples taken at the Primer occurrences. Our results also indicate that the Golden 1, 2 and 3 Minfile area has returned highly anomalous arsenic values. Spotty high arsenic is noted in the western portion of the property and within the Allison Lake pluton. A fairly continuous arsenic anomaly is noted south of Gill Lake approximately 2 kilometres south of the Anita 18 Minfile occurrence. Prospecting work in this area has shown the area to be underlain by skarned sediments within the Triassic Nicola volcanic. Rock sampling has been undertaken but results are not yet back and are not part of this report.

A review of the 161 samples selected from the XRF database and sent to Acme Labs (see Figures 9, 10 a, b, c &d in Appendix V) indicates that there is anomalous gold (highs to 61 ppb), molybdenum (highs to 40.2 ppm) associated with the Golden 1, 2 & 3 Minfile occurrences area. This work also confirmed the anomalous XRF copper with results up to 481.3 ppm copper in ICP analysis and arsenic with results up to 59.4 ppm Arsenic in ICP.

XRF Samples were also selected in two other areas, one of which occurs east of the power line in the vicinity of the Anita 11, 14 &18 occurrences after a discrepancy between the first and second XRF readings were noted. This area failed to return significant results in ICP analysis confirming our suspicion of spurious results on the second readings, probably as a result of incomplete drying of the samples prior to XRF. The second area that was selected for ICP analysis was in the vicinity of a historical copper in soil anomaly located approximately 3 kilometres north of the Al Minfile occurrence. Samples were taken over this area for XRF analysis and failed to return anomalous results, this was confirmed with the ICP analysis and hence put into question the historical anomaly.

A review of the XRF results and ICP results in context with the surficial geology report completed by Vic Levson (see Appendix IV and Figure 11) indicate that outcrop and colluvium deposits which have a close spatial relationship to bedrock occur principally along the Allison Lake and Summers Creek valley. These areas are best suited to conventional geochemistry and also are the areas where the most showings have been found. Large morainal cover occurs in the eastern portion of the property, hindering exploration.

CONCLUSION AND RECOMMENDATIONS

The XRF soil/till sampling program has shown to be an effective prospecting tool for copper in areas of relatively modest glacial cover. However in areas of thicker till accumulation or more distant sources it uses is somewhat speculative. Further work should include examining the results in differing populations dependent upon the underlying medium. Rapid sampling followed by XRF analysis should be taken in un-sampled portions of the property.

The Allison Lake area on the western side of the property is prospective for calc- alkalic copper+/-molybdenum+/- gold+/- silver. Several areas of elevated copper and associated elements and the presence of mineralized shears may indicate the upper levels of a porphyry system are present along the east portion of the Allison Lake Pluton.

The area east of Summers Creek is prospective for alkalic porphyry copper-gold-PGE deposits. Numerous copper bearing “red bed’ copper occurrences and the presence of nearly alkalic porphyry copper deposits make this area prospective for this deposit type. This has been confirmed by both initial XRF soil sampling and subsequent ICP analysis.

Several Cretaceous to Tertiary aged gold-silver bearing veins and shear system are present in the region including the HIT property. The Vale area in the eastern part of the property hosts several unexplained gold in soil anomalies from previous workers. Also one strong gold and weak to moderate silver-copper silt anomaly previously located by Orofino occurs in the east Summers Creek area. XRF analysis is not adequate for gold as it is usually in such minute quantities to be read reliably by the portable XRF unit and as such a fire assay gold is the only adequate method.

Airborne geophysical surveys have been completed in the past by previous workers and the government and these provide a basis for understanding the underlying geology particularly in areas of cover. These areas thought to be underlain by favourable geology hence form a higher priority.

Anomalous geochemistry and previous Minfile occurrences and areas along prospective strike of known occurrences should serve as a starting point for future exploration such as induced polarization surveys and more detailed grids and prospecting.

Continued expansion of the forestry road network in the harvest of pine beetle infected wood will continue to increase access and exposure and should be closely monitored.

CERTIFICATE OF QUALIFIED PERSON

I, Adam Robert Travis, do hereby certify that:

I am a consulting geologist currently residing at 5389 Buchanan Road, Peachland B.C. VOH 1X1.

I am a graduate of the University of British Columbia with a Bachelor of Sciences (BSc) in And Major in Geology, (1990).

I have worked continuously in Mineral Exploration and Mine Geology in Canada, the United States, Africa, China and Mexico on a full-time since 1990.

I am responsible for the preparation of the report entitled Geological, Prospecting and Geochemical Assessment Report on the Hit Property dated October 26, 2012 including the conclusions reached, and the recommendations made.

As of the date of the certificate, to the best of the qualified person's knowledge, information and belief, the technical report contains all scientific and technical information that is required to be disclosed to make the technical report not misleading.

Dated this 26 day of October, 2012

_____

Signature of Adam Travis

APPENDIX III

2012 ACME LAB RESULTS

Acme Analytical Laboratories (Vancouver) Ltd.
1020 Cordova St. East Vancouver BC V6A 4A3 Canada

www.acmelab.com

Client: **Colorado Resources Ltd.**
110 - 2300 Carrington Road
West Kelowna BC V4T 2N6 Canada

Submitted By: Adam Travis
Receiving Lab: Canada-Vancouver
Received: July 30, 2012
Report Date: August 10, 2012
Page: 1 of 5

CERTIFICATE OF ANALYSIS VAN12003567.1

CLIENT JOB INFORMATION

Project: HIT
Shipment ID: Hit-12-001
P.O. Number
Number of Samples: 108

SAMPLE DISPOSAL

RTRN-PLP Return
DISP-RJT-SOIL Immediate Disposal of Soil Reject

Acme does not accept responsibility for samples left at the laboratory after 90 days without prior written instructions for sample storage or return.

SAMPLE PREPARATION AND ANALYTICAL PROCEDURES

Method Code	Number of Samples	Code Description	Test Wgt (g)	Report Status	Lab
Dry at 60C	108	Dry at 60C			VAN
SS80	108	Dry at 60C sieve 100g to -80 mesh			VAN
3B	108	Fire assay fusion Au by ICP-ES	30	Completed	VAN
1DX	108	1:1:1 Aqua Regia digestion ICP-MS analysis	0.5	Completed	VAN

ADDITIONAL COMMENTS

Invoice To: Colorado Resources Ltd.
110 - 2300 Carrington Road
West Kelowna BC V4T 2N6
Canada

CERTIFICATE OF ANALYSIS VAN12003568.1

CLIENT JOB INFORMATION

Project: HIT
Shipment ID: Hit-12-002
P.O. Number
Number of Samples: 125

SAMPLE DISPOSAL

RTRN-PLP Return
DISP-RJT-SOIL Immediate Disposal of Soil Reject

Acme does not accept responsibility for samples left at the laboratory after 90 days without prior written instructions for sample storage or return.

SAMPLE PREPARATION AND ANALYTICAL PROCEDURES

Method Code	Number of Samples	Code Description	Test Wgt (g)	Report Status	Lab
Dry at 60C	124	Dry at 60C			VAN
SS80	124	Dry at 60C sieve 100g to -80 mesh			VAN
3B	124	Fire assay fusion Au by ICP-ES	30	Completed	VAN
1DX	124	1:1:1 Aqua Regia digestion ICP-MS analysis	0.5	Completed	VAN

ADDITIONAL COMMENTS

Invoice To: Colorado Resources Ltd.

INTRODUCTION

This surficial geology mapping project was conducted at the request of Colorado Resources Ltd. The study includes the Hit and Aspen Grove Claims, referred to in this report for brevity as the Hit project area. The property is located about 25 km north of Princeton and extends from the Allison Creek valley in the west to the Siwash Creek valley in the east. The project area is within the Aspen Grove copper belt, which extends from Princeton to Aspen Grove and contains numerous copper showings and deposits within the Nicola Group, the most significant being the Copper Mountain deposit at Princeton. Much of the project area has been logged so road access is relatively good.

The project involved air photo interpretation following the surficial geology mapping conventions of the British Columbia Terrain Classification System (Howes and Kenk, 1997) and the Geological Survey of Canada (Deblonde et al., 2012). Color air photos at an approximate scale of 1:30,000 were obtained from the British Columbia government. Air photo interpretation was not verified by field checking so must be used with caution until confirmed in the field. This report provides a summary of the air photo interpretation work and some comments on soil geochemical data in the region. The surficial geology map produced as a result of this work accompanies this report. A previous report, focusing only on the Hit claims, discussed the surficial geology of those claims and provided a brief review of previous soil geochemical work conducted in the area (Levson, 2012). Some of the information in that report has been included here for completeness. For the Hit property, a review of assessment reports (e.g. Debicki, 1982, 1985; Peto, 1982), geochemical data and Lidar images compiled by Colorado Resources Ltd for the Hit claims only was completed. The results of that work are not duplicated here.

No previous published work related to surficial geology of the Hit project area was encountered. On the glacial map of Canada (Fulton, 1995) the area is mapped as till covered with generally north-south trending ice flow features. The bedrock geology of the study area consists of a central belt of basaltic volcanics that is flanked on the east by a large Jurassic granitic intrusive and on the west by a large granodiorite intrusive body. Most mineral occurrences in the area, including the Hit, Miss, Golden, Anita, Rum, Sadim and Axe occurrences, are within the central volcanic belt which is intruded by many, relatively small, granodiorite bodies. The large granodiorite intrusion on the west side of the study area hosts the Pine, Allison Lake, Al, DD, Dry and P occurrences. The Jurassic granite in the east hosts the Vale mineral occurrence and a number of other occurrences including the Siwash Creek placer north of the study area. Almost all

of the mineral occurrences on the property are on the west half where there is relatively good exposure.

PHYSIOGRAPHY

The Hit project area is located in the heavily glaciated terrain of the Thompson Plateau physiographic region. Elevations range from 873 m asl at Allison Lake to 1654 m asl at the top of Missezula Mountain. Bedrock controlled topography dominates the west side of the property, mainly west of the Summers Creek valley. Relatively steep slopes (up to about 30 degrees) occur in this area especially along the sides of the Allison and Summers creek valleys. These valleys, along with the Siwash and Spukunne creek valleys on the east side of the property are meltwater channels now occupied by small misfit streams. Bedrock outcrops are common along steeper slopes in these valleys and throughout higher relief regions in the western part of the area. The east side of the project area is dominated by rolling to hilly terrain, typical of the Thompson Plateau. The terrain in this area is dominated by glacial deposits and areas of extensive bedrock outcrop are uncommon. The Thompson Plateau in this area has been described by previous workers as having a “prohibitively thick overburden approaching 10 metres in thickness” (Peto, 1982). Although largely till covered, numerous boggy areas with organic deposits also occur in low lying areas on the plateau. Glaciofluvial deposits occur locally in the region, mainly along meltwater channel valleys. Alluvial and organic deposits occur along the many streams that drain the region and alluvial fans occur at the bottom of the larger streams that issue out in the main meltwater valleys.

SURFICIAL GEOLOGY

The surficial geology of the Hit project area is dominated by morainal sediments deposited during the last (Late Wisconsinan) glaciation (see accompanying map). These sediments include basal tills, deposited at the bottom of the glacier mainly by lodgement and basal meltout processes, as well as supraglacial and englacial ablation tills deposited on the surface and margins of the glacier by meltout processes and sediment gravity flows. Basal tills are typically dense, matrix-supported diamicts with high silt/clay contents and have abundant striated and faceted clasts.

Basal tills are derived by glacial erosion of bedrock and other substrate materials and exhibit relatively short transport distances in the down-ice direction (typically hundreds of metres to a few kilometres). In contrast, supraglacial and englacial ablation tills are typically loose, have a sandy matrix, and glacially abraded clasts are not abundant. Transport distances of supraglacial and englacial tills are typically large (tens to

hundreds of kilometres). The topography in areas of ablation till is often hummocky and commonly referred to as knob and kettle topography. This type of topography is not widespread in the Hit project area suggesting that supraglacial and englacial tills, if present, are not thick. Tills in the map area are common and mainly mapped as morainal blankets (Mb).

Also abundant throughout the map area, and interspersed with morainal sediments, are organic soils. These include both thick organic deposits such as occur in boggy areas and thin organic veneers. Organic deposits are most common in the map area within closed depressions in morainal areas and around lakes and swamps in valley bottoms. The abundance of organics within morainal areas often indicates the presence of fine-grained basal tills which are typically poorly drained.

Colluvial sediments are relatively common in the map area, especially in the west where steep bedrock-controlled topography is most dominant. They occur mainly as slope deposits on the sides of steep valley walls such as along the Allison Creek and Summer Creek valleys. They also occur in association with the bedrock uplands in the eastern part of the map area, mainly as colluvial veneers around areas of outcrop. Thick talus deposits are rare, occurring only at the base of the steepest rock slopes in the area.

Glaciofluvial deposits are locally present in the map area, mainly along the north-south trending meltwater channels that cut through the area. Glaciofluvial features with distinctive morphology such as kames and eskers are rare in the map area. Glaciolacustrine deposits were not mapped in the region but may occur locally. The presence of thin glaciolacustrine sediments in most cases can only be identified in the field. They are typically composed of well bedded silts, clays and fine sands and they are often overlain by organics or Holocene lake sediments. For example, glaciolacustrine deposits may underlie lacustrine sediments mapped in the Allison Creek valley.

Fluvial deposits are confined mainly to the floodplains of the larger creeks in the area including Allison, Summers, Rampart, Spukunne and Siwash creeks as well as other smaller tributary streams. They include stratified sands and gravels that are commonly overlain by silts interbedded with organic deposits.

GLACIAL HISTORY

The Hit project area was entirely covered by the Cordilleran Ice Sheet during the last (Late Wisconsinan) glaciation. There is widespread evidence for a thick ice cover in the area at the last glacial maximum including the presence of thick morainal sediments,

widespread glacially streamlined terrain, ice-marginal meltwater channels and other glacial landforms. Glacially streamlined landforms show little deflection by the local topography indicating that the ice sheet was thick enough to over-run bedrock highs with little or no influence on ice flow. During the waning stages of the last glaciation, the ice probably thinned relatively quickly as indicated by the lack of topographically controlled ice flow landforms. There may have been local deflection of the thinning ice around the highest bedrock hills in the area such as Missezula Mountain but field studies are required to confirm this.

During deglaciation, relatively open drainage to the south is indicated by the presence of numerous south-trending meltwater channels cutting through the project area. Many of these channels may have initially formed subglacially and later been occupied by proglacial meltwater but the lack of eskers or other subglacial landforms within the channels prohibits a definitive conclusion. If subglacial landforms were present, they may have been removed or buried by later meltwater activity. Glaciofluvial deposits are relatively common along the Allison, Summers and Siwash creek valleys. These north-south trending valleys were significant conduits for meltwater from the retreating ice sheet. Several small ice marginal meltwater channels along the sides of the Allison Creek valley suggest that the glacier may have downwasted into that valley but clear evidence of ice stagnation is lacking throughout the project area. From a till geochemical exploration perspective, this suggests that basal till sampling in the region would likely to be unhindered by thick supraglacial meltout till deposits.

Immediately after ice retreat, the project area was modified by paraglacial processes including extensive colluviation of the recently exposed terrain. This resulted in downslope transport of surface glacial sediments and exposed bedrock on high relief slopes throughout the area. Colluvial blankets and fans formed along the lower slopes of steep valley sides and bedrock highs. Most of the erosion and deposition likely occurred shortly after deglaciation when the unconsolidated sediments were first exposed and before vegetation became well established. Colluviation has continued to the present day, albeit at a much slower rate. Subsequent deposition of organic and lacustrine deposits in closed depressions, along streams and in low lying areas has further modified the surficial geology in the area.

ICE FLOW DIRECTIONS

Well developed drumlins, flutings, crag-and-tail ridges and other regional ice flow indicators are not widespread in the Hit project area but enough are present in the area and in the surrounding region to derive the dominant late glacial ice flow direction (see accompanying surficial geology map). A field study of smaller scale bedrock erosional

features such as striae records would provide more information on the ice flow history of the area than can be determined from air photos alone.

Based on the orientation of drumlins, flutings and crag-and-tail ridges in the region, the dominant ice flow direction was generally to the south-southeast (about 170°). The orientation of these landforms generally shifts from southerly (170-180°) in the area east of the Summers Creek valley to more southeasterly (about 150°) in the central part of the area (north and south of Missezula Mountain). This may reflect some late stage, thin ice deflection around Missezula Mountain. The more regional southerly flow that characterizes the plateau area on the east side of the property also occurs in the north part of the region. The southeasterly and southerly flows may have been broadly synchronous but the relative timing and significance of these events in terms of glacial transport can only be determined by field study of striated outcrops.

IMPLICATIONS FOR INTERPRETATION OF SOIL GEOCHEMISTRY

Background

The geochemistry of near surface soils is often considered to reflect the geochemistry of the underlying bedrock, although it is well known that many other factors are involved such as overburden thickness, the genesis of the surface sediments and permeability. Although residual soils and thin colluvial deposits do reflect the underlying bedrock, most soil types in glaciated areas do not. In these areas, the genesis of the parent material in which the soil is developed is often the strongest controlling factor on the soil geochemistry and it is critical to understand the genesis of the sampled material in order to effectively interpret geochemical exploration results. The reason for this is that in glaciated areas there are a wide variety of surficial sediments, that may be transported into the area of interest, that do not strongly reflect the local geology. In particular, glacial and glaciofluvial sediments may be transported long distances by ice and glacial meltwaters and deposited in an area with little or no incorporation of local bedrock. Even where these sediments are thin, they tend to mask the underlying bedrock and any associated mineral deposits that might be present. Conventional sampling of soils within these sediments would not lead to the detection of the buried mineralization.

Fortunately, glaciated areas do contain widespread deposits of basal till that can be very useful for locating buried mineralization. Basal tills are formed by erosion of bedrock at the glacier base and redeposition, usually within relatively short transport distances. In addition, due to glacial dispersal processes, basal tills leave relatively large geochemical footprints in comparison to the size of the original bedrock source. As a consequence, these basal till sampling programs require significantly fewer samples than do soil programs. Basal till geochemical anomalies are also easier to interpret and

can be more easily traced to source than soil anomalies. For these reasons and others, basal tills are widely considered to be an ideal sample media in glaciated areas. Plouffe et al. (2010) provide an excellent example and summary of the methodology used in till geochemical surveys in the Interior Plateau region of British Columbia. For a successful basal till geochemistry program, it is critical to avoid sampling other glacially transported sediments such as englacial and supraglacial ablation tills, which typically have large transport distances, as well as other sediment types such as glaciolacustrine and glaciofluvial deposits.

Anomaly Interpretation in the Hit Project Area

The large variety of surficial sediment types that are present in the Hit project area make interpretation of soil geochemistry results challenging. Samples taken in areas with thin colluvial or morainal veneers over bedrock are the easiest to interpret as these sediment types typically reflect nearby bedrock sources, with short transport distances, either downslope or down-ice. Soil geoechemical exploration programs in glaciated areas are most effective where these types of sediments dominate.

In areas mapped as morainal blankets, the soil geochemistry largely reflects glacial transport but a number of factors should be considered. In particular, surface reworking of morainal deposits by eluvial, colluvial, and biogenic processes is common down to depths of about 10 cm to 1 m. These processes generally result in removal of silts and clays in the near surface and a consequential decrease in metal concentrations in comparison with the underlying unaltered parent materials. In some cases, metal concentrations in this altered surface soil layer can be higher than the parent material creating a “false anomaly”. Notes on soil texture of the samples, if available, may be useful in detecting these altered samples or false anomalies.

Another factor to consider in the Hit project area is the widespread presence of organic soils. Organics accumulate in soils by a wide variety of processes so they should be treated as a separate data set. In areas with abundant organics, geochemical programs can be designed specifically that address their complicated origins. Organics often attract metals that have been transported by hydromorphic processes through the soil or, as is the case in most peat bogs, they may be hydrologically isolated from their surroundings and receive their nutrients mainly from precipitation (ombrotrophic soils). As a result, organic soils may be either enriched or depleted in metals, in comparison to the underlying mineral soils. Organic soils usually develop in wet, poorly drained sites such as closed depressions overlying clay-rich sediments with low permeability. In the Hit area they commonly occur in association with glacial deposits, especially in low areas within rolling moraine.

The widespread presence of glaciofluvial sediments with morainal sediments in the Hit project area is an additional consideration. These sediments occur as discrete mappable units such as outwash terraces but they also occur as discontinuous veneers interspersed with morainal sediments, especially in areas of rolling moraine. Even in areas where basal tills are common, washing by meltwater during ice retreat often creates a discontinuous surface veneer of sandy or gravelly soil that is geochemically distinct from the underlying till. These types of washed sediments may be recognized by detailed sample descriptions.

Implications for future geochemical surveys in the area

Conventional soil geochemical sampling in the Hit area will be most effective where bedrock is relatively close to surface and the surficial sediments are mainly colluvial in origin. This is the case in the more hilly topography in the west-central part of the area. In areas mapped as morainal blankets, soil geochemistry will only be useful if basal tills are distinguished during the sampling process from ablation (englacial and supraglacial) tills, glaciofluvial sediments and organic soils, all of which are widely interspersed with the morainal deposits.

Conventional geochemical soil sampling will be of little value in areas where extensive fluvial and glaciofluvial sediments have been mapped, such as along the main valleys. Soil samples that have been collected in any of these areas should be, at a minimum, treated as separate population in the data interpretation. Parceling of the results by sediment type would be useful for interpretation purposes, especially if soil sample descriptions were made in the field.

A basal till geochemical sampling program would be effective for identifying buried mineralization in much of the Hit project area as basal tills are widespread in the area. Basal tills can often be located below other sediment types if a program is developed to specifically target them as the sample media. Since basal tills create large, linear, dispersal anomalies, significantly fewer basal till samples are required and they can be more easily traced to source than with conventional soil samples. Most of the Hit project area has good potential for a basal till geochemistry program.

COMPARISON OF REGIONAL SOIL GEOCHEMISTRY AND SURFICIAL GEOLOGY

Numerous soil geochemical surveys have been conducted in the Hit project area and surrounding regions. The data has been compiled into a single data set and the results are compared here with the distribution of mapped surficial geology units. A total of 5637 sample sites occur within the project area. There are some leveling issues with the different data sets due to different detection limits and variable eras of data collection

and analysis. This could be resolved with a more refined compilation of the data sets. Due to the leveling problems only a few elements were used in this comparison and only high values (~95th percentile or greater) were included. The distribution of soil sites with elevated gold (>10 ppb, 286 sites), silver (>1.6 ppm, 140 sites), and copper (>130 ppm, 255 samples) largely corresponds with the distribution of colluvial sediments, areas of exposed outcrop, and thin till or colluvium overlying bedrock.

The highest concentrations of elevated metal sites occur in the vicinity of the Hit and Miss showings on the Hit claims. The high density in these areas in part reflects the relatively high density of sampling. Many of the elevated metal sites occur along the steep slopes of the Summers Creek valley. It is likely that these high metal values reflect the relatively thin cover of the bedrock in this area compared to the adjacent parts of the property where a thick cover of glacial sediments is present. Mineralization exposed along the slopes of the Summers Creek valley likely extends under the glacial cover on the upland to the west. The occurrence of the Hit prospect on the upland just west of the Summers Creek valley supports this suggestion. In the vicinity of the Miss showing, most high gold, silver and copper sites occur where the mapped surficial unit is thin till over-lying bedrock with interspersed outcrops (M^R//R and Mv). Preto (1979) and Debicki (1982) interpreted the elevated gold (up to 390 ppb) along the steep slopes of the Summers Creek valley, where thin colluvial soils and scattered outcrops are present, as down slope (eastward) displacement from mineralized rock above the valley side.

The Hit prospect is one of the few areas in the region where elevated gold, silver and copper in soils occurs in an area mapped as a morainal blanket. In the eastern part of the project area, elevated gold also occurs at sites mapped as till (Mb) and at a few areas of organics (O). Many elevated silver sites occur in areas mapped as colluvium over bedrock (C^R, C^Rs) or colluvium interspersed with outcrop (C/R, Rs/C). A few sites occur in areas mapped as a till veneer over bedrock (Mv^R). Likewise, most sites with elevated copper occur in areas mapped as colluvium (C, Cb, Cv, Cvb), colluvium and bedrock (C/R, C/Rs, Rs/C, C^Rs//R), or colluvium and other sediment types (e.g. C/M, Cb/FG). Other than on the Hit claims, only a few sites with elevated copper occur in areas mapped as dominantly till (Mb, M^R) and a few sites occur over organics, possibly reflecting hydromorphic dispersion from surrounding areas.

Gold (see accompanying gold map)

Other than in the vicinity of the Hit and Miss showings, the highest concentration of soil sites with elevated gold (>10 ppb) occurs in a large area in the central part of the claims between Summers and Dry creeks, approximately centred on the Golden 1 mineral occurrence. The Golden 2 and 3 showings also occur in this area. Most of the elevated gold sites in this area occur in colluvial sediments and in areas where outcrops are

extensive suggesting that the elevated gold in this area may be reflecting elevated gold concentrations in the bedrock. In addition, a relatively high number of elevated gold sites occur in the largely till covered area directly to the northeast suggesting the potential for buried mineralization in this area. There are also some elevated copper sites in the region. No known mineral occurrences have been recorded in this area. In the east half of the project area there are two other areas with elevated gold in largely till covered terrain. The first occurs east of Rampart Creek and the second is in the Spukunne Creek area. Both these areas have a relatively thick cover of till (map unit Mb) so the large number of elevated gold sites suggests that there is potential for buried mineralization in these areas. In addition, there are scattered sites with elevated copper in the area. A modern till geochemical survey in this region would be necessary to evaluate the mineral potential of these areas.

Copper (see accompanying copper map)

The highest concentrations of soil sites with elevated copper (>130 ppm) occur in the central part of the project area on both sides of the Summers Creek valley. This region includes the Hit, Miss, Golden 1,2, and 3, Bo, EJ, MS and MS4 mineral occurrences. Most of the elevated copper sites occur within colluvial soils suggesting relatively local bedrock sources. The north-south alignment of many sites along the Summers Creek valley may be related in part to the uneven data distribution and to data leveling problems. However, the relatively high concentrations of sites on the east side of the valley in both the north and the south parts of the project area suggest that follow-up work in these areas is warranted. Several areas show clusters of elevated copper sites that do not directly coincide with known mineral occurrences. For example, directly northeast of the Miss showing a cluster of colluvial soil sites with elevated copper occurs in the vicinity of a small granodiorite intrusive mapped on the west side of Summers Creek. Elevated gold in soils and rock also occurs in this area.

Two other areas with elevated copper concentrations occur on the western side of the project area. The first is located at the north end of Allison Lake, almost entirely in colluvial soils suggesting a local upslope origin. The Pine mineral showing occurs in this area. The other area occurs in the northwest part of the project area west of Allison Creek. The area is largely till covered and no mineral occurrences are reported there suggesting potential for a new discovery.

Silver (see accompanying silver map)

Relatively high concentrations of soil sites with elevated silver (>1.6 ppm) occur in the vicinity of the Hit and Miss occurrences. Significantly, the presence of numerous sites between the two occurrences and to the northwest of the Hit prospect, all in largely till covered areas, suggests that more mineralization is undoubtedly buried along this

trend. This is supported by a similar distribution of gold, and to a lesser extent copper, sites in the till covered area.

Numerous soil sites with elevated silver also occur along the Summers Creek valley in the north central part of the project area. Most of the soils occur in colluvial soils suggesting local bedrock sources. The coincidence of elevated copper in soils in this region suggests that more work is warranted.

DISCUSSION

Different types of surficial materials are clearly present in the Hit project area including glacial sediments, colluvium, glaciofluvial sands and gravels, organic deposits and alluvial sediments. Since all of these deposits have different origins, the geochemical signatures that they contain reflect different derivations. Glacial sediments, for example, may contain far travelled debris that masks the signal of local mineralization (if transported on or within the ice, i.e. englacial or supraglacial tills) or they may contain mainly locally derived debris (if transported at the base of the glacier, i.e. basal tills). Likewise, glaciofluvial deposits usually dilute geochemical indications of buried mineralization whereas alluvial sediments generally concentrate them. Organic deposits are likely to reflect hydromorphic dispersion of metals and colluvial deposits reflect down-slope mechanical transport. For successful interpretation of geochemical results, it is critical to know the origin of the sampled material.

Areas with clusters of soils sites with relatively high concentrations of metals occur mainly in regions mapped as colluvial soils and areas with outcrop. This highlights one of the main problems with traditional soil surveys. Soils developed on bedrock, or colluvial soils derived directly from bedrock, have higher background concentrations of metals compared to soils developed on glacial parent materials. Glacial sediments may have background concentrations one or two orders of magnitude lower than colluvial and residual bedrock soils. Thus, soil surveys typically lead to discoveries mainly in areas of colluvial soils whereas till covered regions are usually under investigated. This is particularly problematic as many major mineral deposits in the Cordillera are recessive and/or fault controlled and they therefore commonly occur in till covered valleys. Examples from the interior of BC include the Sullivan, Highland Valley, Endako and Huckleberry mines.

One way to deal with this problem is to parcel the soil geochemical data into populations based on the dominant surficial material. Surficial geology mapping can be used to help differentiate the variety of surficial materials present but variations at a local scale cannot be mapped with air photos and it is necessary to use field data. Unfortunately most soil sampling programs do not collect adequate descriptive data and new field

studies are often required. The comparison of soil geochemical data and surficial geology presented above, however, does highlight a number of areas where metal concentrations in largely till covered areas are elevated. Further work in these areas is warranted as metal concentrations are above 95th percentile concentrations. Media-specific surveys, such as basal till geochemical sampling, are recommended in these areas.

Routine B-horizon sampling of soils on the till covered parts areas of the Hit project area will almost certainly produce erratic results similar to the previous soil surveys there (Peto, 1982; Debicki, 1982) due to the thick cover of glacially transported sediments. The most effective method of geochemical exploration in areas with a thick glacial cover is to selectively sample basal tills that reflect deep erosion at the base of the glacier. One suggestion that this method might be effective in the area is the presence of a north-south trending linear zone of elevated gold (up to 135 ppb) south of the Hit prospect (Levson, 2012). This gold anomaly is down-ice of the Hit prospect and trends parallel to the direction of ice flow there. Numerous other areas with elevated gold in soil occur in the project area and selective basal till sampling in these areas is needed to define glacial dispersal plumes.

Basal tills have specific sedimentologic characteristics that allow for their identification in the field such as over-consolidation, fissility, high clay content, and abundant striated clasts. The main advantage of the till geochemical method is that glacial dispersal of mineralization results in relatively large dispersal plumes that can be detected with relatively few samples. Once an area of anomalous metal concentrations has been discovered, the original source of the mineralization can be located by following the dispersal plume in the up-ice direction. In areas of thick till, this usually requires profile sampling in deep excavations to determine the angle of climb of the dispersal plume and the distance to source. Methods and applications of till geochemistry for mineral exploration in the Cordillera are described by Levson (2001).

Due to the relatively arid climate in the Hit project area, it is possible that geochemical methods that attempt to detect buried mineralization by the upward movement of ions may be applicable. For example, recent work in BC at a deposit buried by up to 40 m of glacial and glaciofluvial sediments found that conventional soil sampling (i.e. -80 mesh, B-horizon, aqua regia) was ineffective (Heberlein and Samson, 2010). In fact, all of the methods that tested the B horizon performed poorly, including extractions designed specifically for detecting deeply buried mineralization such as MMI-M, Ionic Leach, Enzyme Leach and Bioleach. The best responses for ore and pathfinder elements (Cu, Au, Ag, W, As, Sb and Ca) were found using an aqua regia digestion of the Ah horizon (Heberlein and Samson, 2010). Other methods such as soil gas hydrocarbons found to

be effective at detecting mineralization buried under 2 to 25 m of glaciofluvial sediments and till at Mount Milligan (Heberlein, 2010), may also be applicable in this area.

RECOMMENDATIONS

1) Field verify the airphoto-based surficial geology mapping accompanying this report; confirm surficial map units and determine the thickness of overburden cover where possible; and, supplement the ice-flow history data based on landform mapping with outcrop and striae data collected in the field.
2) Follow-up elevated metal concentrations in soils identified in previous geochemical sampling programs on the property to determine the origin of the sampled material (i.e. colluvial, glacial, glaciofluvial, etc.). The intent of this work would be to determine if the specific anomalous areas reflect down-slope or down-ice mechanical dispersal or hydromorphic dispersion.
3) Conduct a reconnaissance basal till geochemical sampling program over the entire property with more detailed sampling in till covered areas on the eastern half of the property especially in those areas highlighted by elevated metal concentrations in soils developed on morainal sediments. The survey should initially include sampling of basal tills along easily accessed road and river cuts and other exposures throughout the area.
4) Conduct a geochemical orientation survey in a few selected areas to determine the best geochemical sampling media and methods for more detailed follow-up. The survey could include soil profile sampling of multiple horizons (e.g. Ah, Bf, and C horizons) over and around known areas of mineralization such as the Hit prospect or other prospects in the area. Other geochemical methods such as soil gas hydrocarbons and biogeochemistry could also be evaluated.
5) Conduct detailed geochemical sampling in the areas highlighted by the results of #2 and #3 above, using the most appropriate sampling and analytical methods for detection of buried mineralization in the area (based on the results of #4 above).
6) Complete spatial and statistical analyses of all the geochemical data including contouring and mapping of coincident multi-element, multi-site geochemical anomalies. Compare the results of the geochemical analyses with geophysical and geological data to further refine target areas and to select drill sites.

APPENDIX 1 - SURFICIAL GEOLOGY MAP LEGEND - HIT PROJECT AREA

QUATERNARY DEPOSITS

HOLOCENE (NONGLACIAL) SEDIMENTS

O **ORGANIC DEPOSITS:** mainly peat mosses, sedges, reeds and organic muds occurring in bog and fen environments; typically less than a few metres thick; formed by the accumulation of plant material in various stages of decomposition; mainly occurs in closed depressions overlying clay-rich, poorly drained till or glaciolacustrine sediments; hydromorphic geochemical signature reflecting groundwater drainage basin characteristics.

A **ALLUVIAL DEPOSITS:** river, stream and alluvial fan deposits up to several metres thick; includes sorted sands and gravels, floodplain silts and organic detritus; commonly stratified.

Ap **Floodplain deposits:** mainly overbank silts, clays and organic detritus overlying sands and gravels; occurs at or near modern creek levels; sands and gravels occur at surface along active and recently active channels; organic rich muds common at surface; unvegetated in recently active areas and with shrub or partial tree cover elsewhere; geochemical signature mainly detrital from distal sources possibly with some local hydromorphic signals.

Af **Alluvial fan deposits:** moderately well to poorly sorted silt, sand, gravel and diamicton; usually at least several metres thick forming fans along stream channels at the break of slope in valley bottoms; geochemical signature detrital and reflects entire fan drainage basin.

C **COLLUVIAL DEPOSITS:** slope deposits and other mass wasting debris varying from less than a metre to several metres thick; unsorted, massive to crudely stratified diamicton deposited by gravity-induced movement; composition dependent on source material; occurs mainly along steep stream valley walls and below rock cliffs (talus); detrital and hydromorphic transport perpendicular to slope dominates; source areas typically close.

Cv **Colluvial veneer:** thin (typically < 2 m), discontinuous cover of slope debris; mainly diamicton; occurs mainly on steep valley slopes and around rocky hill tops; geochemical source areas typically close and directly upslope.

Cb **Colluvial blanket:** slope deposits generally up to 10 m thick; mainly diamicton including debris flow deposits and talus debris below rock cliffs; slopes moderately steep; slope movements slow or largely inactive; mainly detrital downslope transport; source areas more distal than Cv.

Cf **Colluvial fan:** debris flow dominated fan deposits generally up to 10 m thick; mainly diamicton; includes debris flow deposits and talus debris below rock cliffs; mainly detrital downslope transport; drainage basin source areas.

L **LACUSTRINE DEPOSITS:** mainly silts, clays and fine sands often in association with organic deposits; typically several few metres thick; mainly occurs in in valley bottoms and closed depressions overlying clay-rich, poorly drained till or glaciolacustrine sediments; geochemical signature typically masked by basin-sourced detrital sediments.

LATE-GLACIAL SEDIMENTS

GF **GLACIOFLUVIAL DEPOSITS:** stratified sand and gravel with minor diamicton; deposited by glacial meltwater; most common in large valleys; locally discontinuous and interspersed with glacial deposits (e.g. FG/Mb); geochemical signature of underlying rock usually completely masked.

GFt **Glaciofluvial terraces:** sands and gravels occurring as elevated valley side benches; typically tens of metres above modern valley bottoms; detrital geochemical signature is highly distal.

GLACIAL SEDIMENTS

M **Morainal deposits:** glacially derived diamicton (mixture of mud, sand and gravel) deposited by the Cordilleran Ice Sheet; typically massive, matrix-supported and up to several metres thick; includes lodgement till deposited at the base of the glacier as well melt-out till derived from within the ice; basal tills are dominated by detrital geochemical signatures with proximal up-ice source areas; melt-out tills have much more distal source areas.

Mb **Till blanket:** glacial sediment (mainly basal till), typically a few to several metres thick, forming flat to gently undulating topography; generally fine-grained (silt and/or clay rich); clasts commonly striated; drumlins and flutes uncommon in the map area; distance to up-ice sources increases with till depth.

Mv **Morainal veneer:** glacial sediments forming a thin veneer over bedrock; common in hilly topography; proximal up-ice source areas.

PRE-QUATERNARY DEPOSITS

R **BEDROCK:** Rock outcrops on hill tops and steep slopes; typically interspersed with colluvial sediments (R/Cv) or thin till (R/Mv); some areas with thicker cover but still strong bedrock-controlled topography (e.g. **Mb^R**).

Compound Units: In areas where the surficial cover forms a complex pattern, compound units are used. The dominant component is listed first and separated from the secondary unit by a single slash (e.g. Mb/O). A double slash (//) is used when the main surficial material is considerably more extensive than the subordinate unit (e.g. Mb//O). Where underlying units are known, the unit label shows the surface unit is separated from the underlying unit by an up arrowhead symbol (e.g. Mb^R).
