## **1.0 INTRODUCTION**

Claims 1017825, 1017829 and 1017830 were acquired by Barry Hanslit in March 2013. The claims are 262.28 ha in size and lie within National Topographic System (NTS) 1:50,000-scale map sheet 104N/12 in the Atlin Mining District of British Columbia, approximately 8.5 km east of Atlin along Spruce Creek (Figure 1 and 2).

Regional geology in the area is primarily Cache Creek Complex Nakina Formation basaltic volcanic rocks. Gold exploration in the area has been active since 1898 with the main continuous focus being placer exploration. The Spruce Creek area has been intensively explored for gold by both above and below ground techniques.

In the fall of 2013, prospecting and geophysical work was performed on the claims by Barry Hanslit. This report documents that work, and also provides a description of claims, location, access, physiography and other relevant information. A discussion of the deposit mineralogy follows a description of regional and property scale geology.

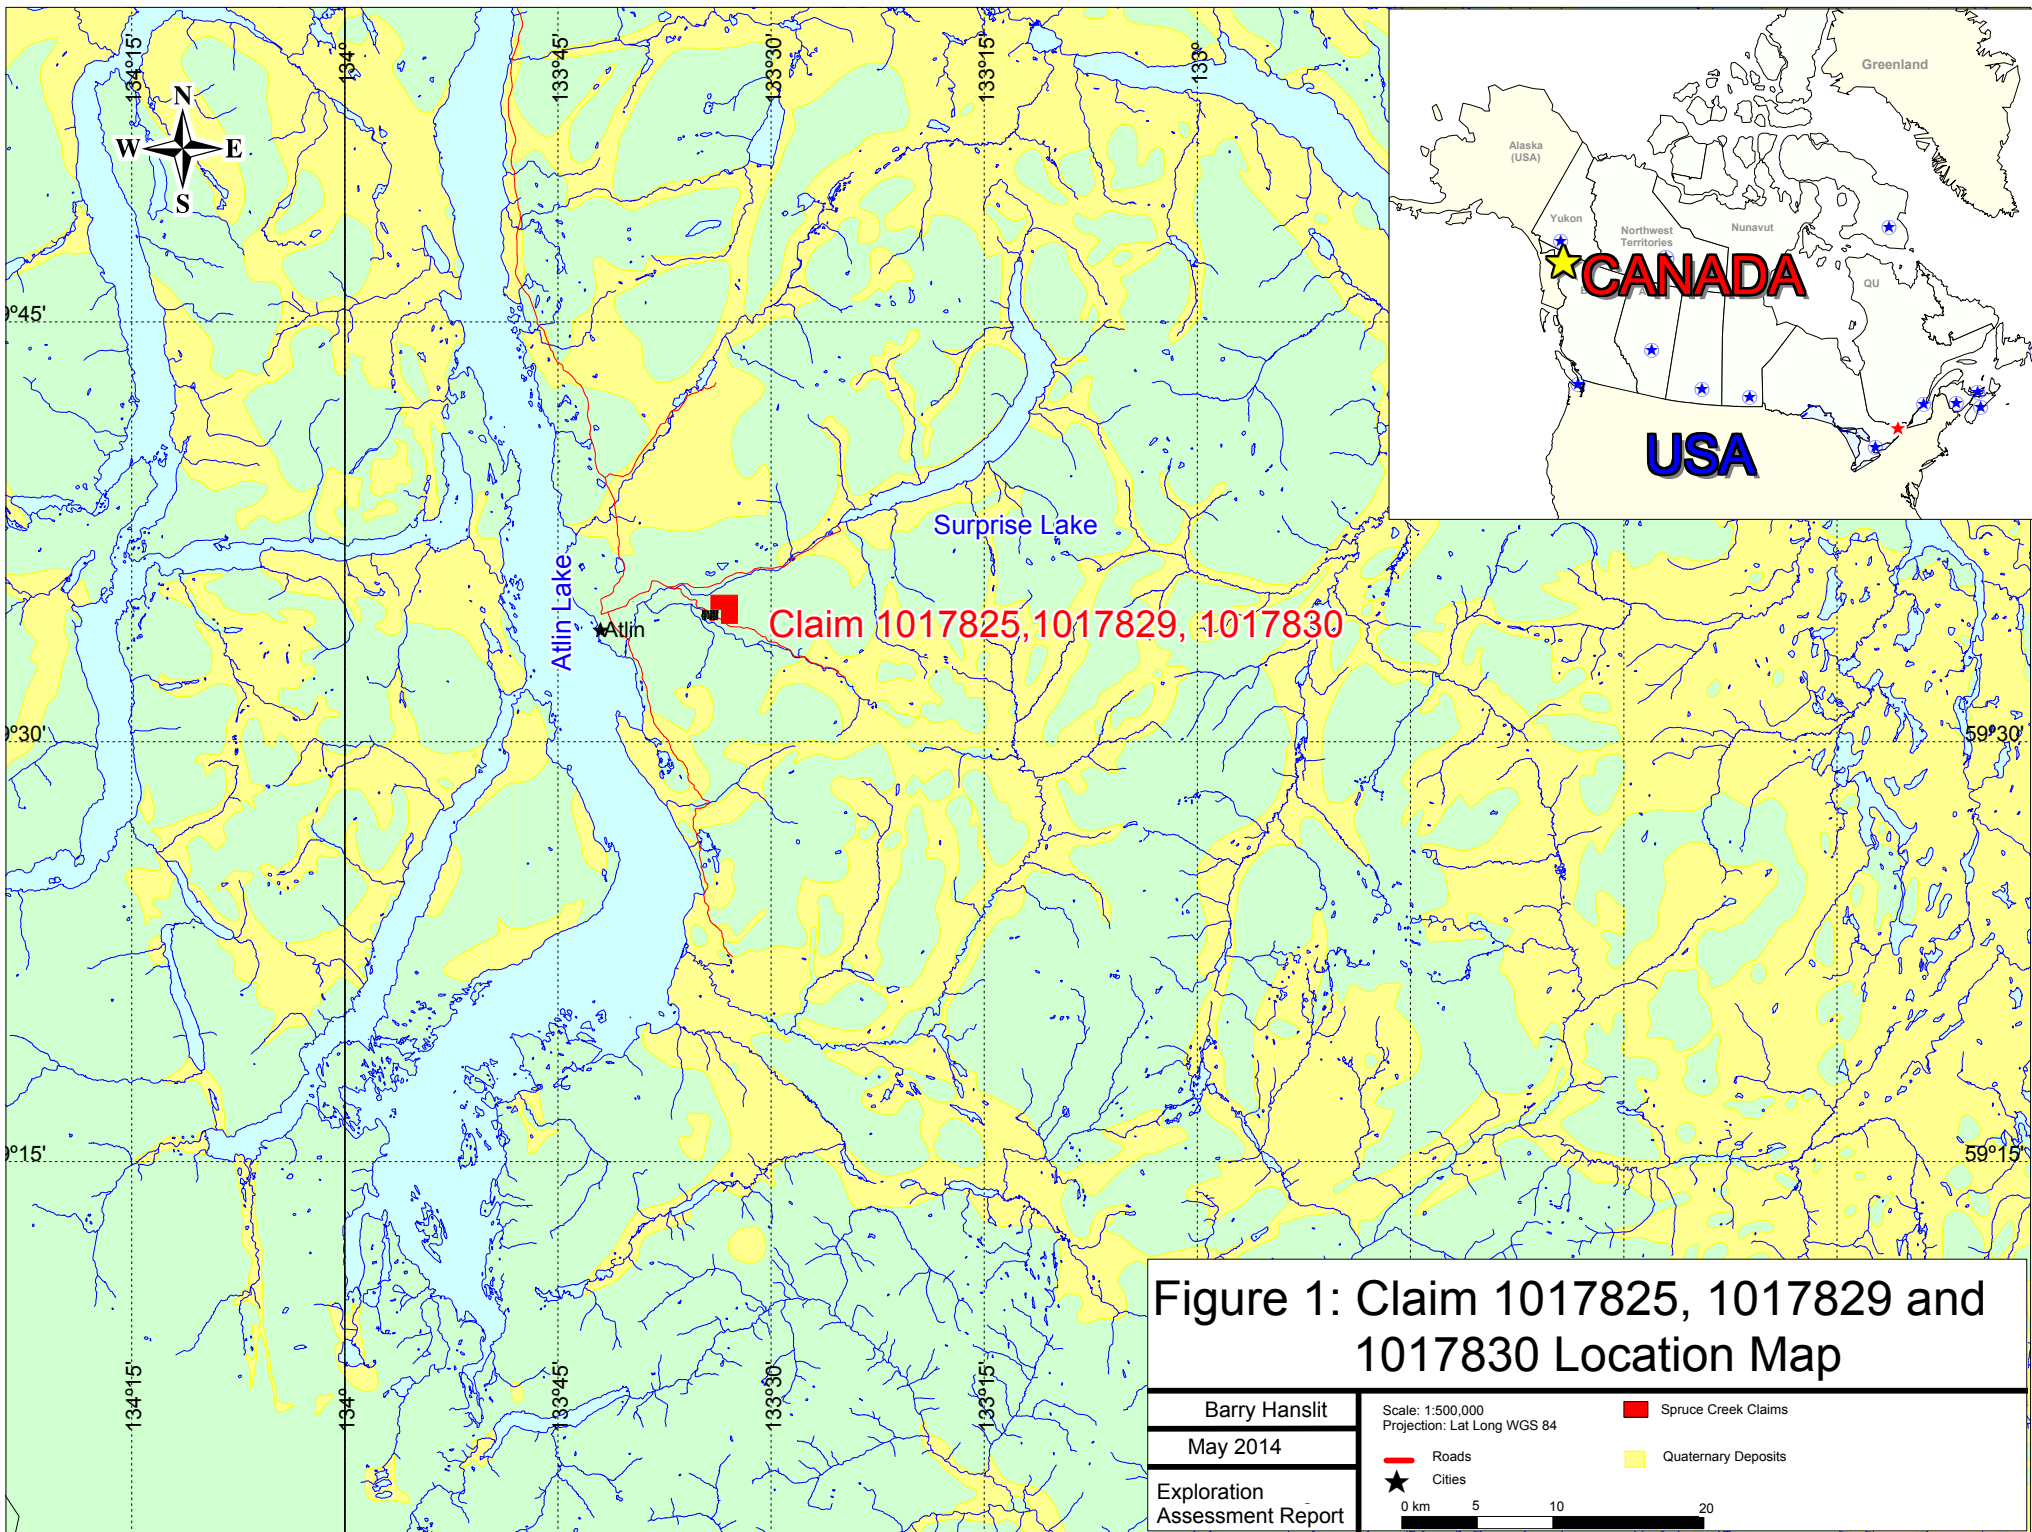

## **2.0 DESCRIPTION OF LANDHOLDINGS**

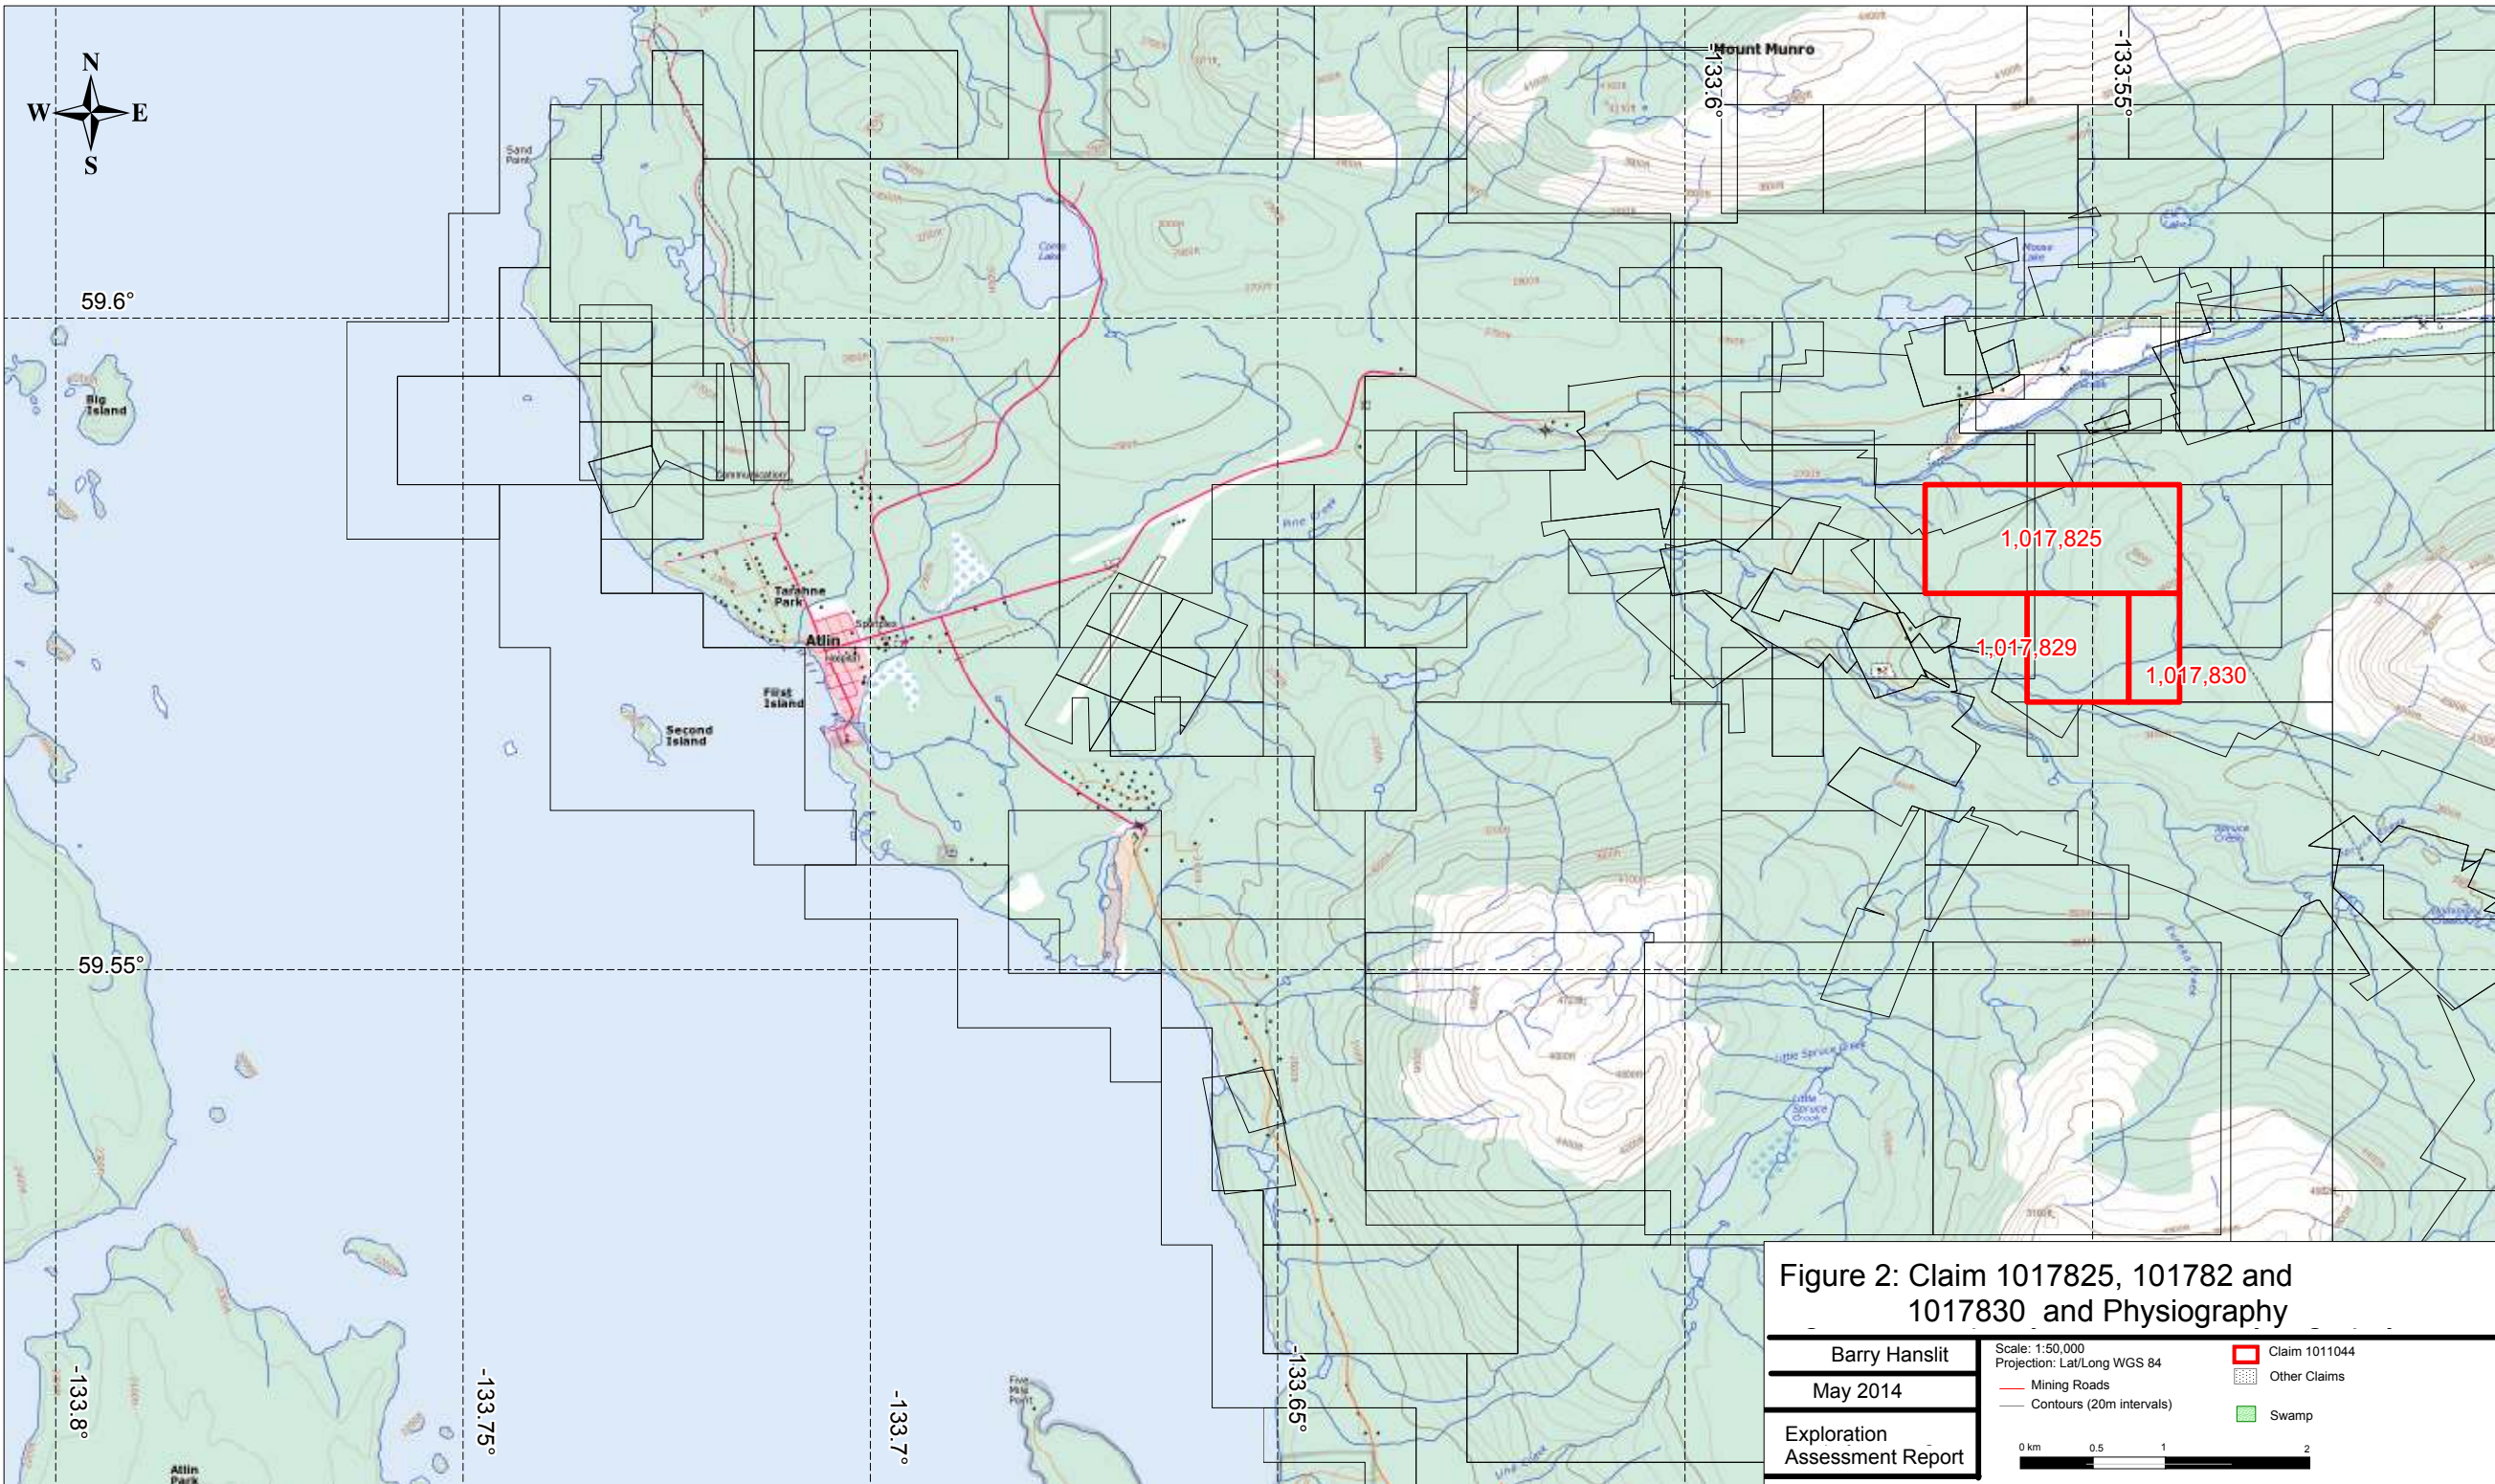

### ***2.1 Location and Mineral Claims***

The claims are 262.28 ha and are located between Spruce and Pine Creek within National Topographic System (NTS) 1:50,000-scale map sheet 104N/12 in the Atlin Mining District of British Columbia, approximately 8.5 km east of Atlin, BC.

### ***2.2 Access***

Situated east of the coastal range, Atlin is the northern most community in BC and is located 98 km from Jake's Corner in the Yukon via the Atlin Highway. Most services and supplies can be purchased in Whitehorse roughly 200km to the north. These services include an international airport with regular service to southern Canada. The long history of exploration in Atlin has resulted in an extensive network of roads and trails that can be easily navigated by ATV or vehicles equipped with 4WD. The claim is accessible from Spruce Creek road.

### **2.3 *Physiography, Flora and Fauna***

The claims are relatively flat topographically (from 3500ft to 2900ft) sandwiched between Spruce Creek and Pine Creek. Atlin's climate is relatively dry with winter temperatures averaging -15°C and winter snow anywhere from one to two meters. Summer high temperatures can typically fluctuate from 15 – 20°C with overnight lows closer to 0°C. Summer precipitation is highly variable, but often less than 20cm (Environment Canada, 2012).

The property is well vegetated with many trees and shrubs. Ungulates such as caribou and moose are common in the area. Other wildlife in the region includes black and grizzly bears. In addition, trout and grayling occupy some of the lakes and rivers.

### **2.4 *Property History***

Atlin village was founded after Fritz Miller and Kenneth MacLaren discovered gold on Pine Creek in 1898. This started a gold rush that swelled the population of Atlin up to 10,000 inhabitants. Placer mining still goes on beside Pine Creek with significant amounts of gold and the occasional sizable nugget still to be found (Atlin Center, 2012).

Since the initial discovery in Pine Creek, the majority of the drainages in the Atlin area have become areas of exploration for placer deposits, notably Spruce, McKee, Ruby, Boulder, Birch and Otter Creek. Spruce Creek has been the focus of both above ground and below ground mining operations. The general area has been drilled, tested by seismic geophysical surveys and had numerous test pits. Information on this exploration is publicly available through the Assessment Report Indexing System (ARIS; <http://www.empr.gov.bc.ca/mining/geoscience/aris/pages/default.aspx> ).

## **3.0 GEOLOGY**

### **3.1 *Regional Geology***

Regional geology is excerpt from Ash, 2001. The Atlin region lies within the north-western corner of the Cache Creek Terrane (Figure 3). In this area of the terrane is a fault-bounded package of late Paleozoic and early Mesozoic oceanic lithospheres, which are intruded by post-collisional Middle Jurassic, Cretaceous and Tertiary felsic plutonic rocks.

**Figure 3: Atlin Regional Geology**  
 (Northern Cache Creek Terrane map after Monger, 1977A)

The Cache Creek terrane is comprised predominately of graphitic argillite and pelagic sedimentary rocks, which also contain minor amounts of metabasalt and limestone occurrences in the form of pods and slivers. Oceanic crust and upper mantle lithological remnants are concentrated along the western margin of the terrane.

From north to south, the Atlin, Nahlin and King Mountain assemblages have been described as dismembered ophiolitic packages. Each package contains imbricated mantle harzburgite, crustal plutonic ultramafic cumulates, gabbros and diorite, together with hypabyssal and extrusive basaltic volcanic rocks. The western part of the terrane is dominated by thick sections of late Paleozoic shallow-water limestone that are associated with alkali basalts. The limestone is interpreted as carbonate accumulations that formed ancient marine islands within the former Cache Creek oceanic basin. A combination of plutonic and stratigraphic evidence shows that the Northern Cache Creek Terrane was positioned over the Nahlin Fault-bounded Whitehorse Trough sediments (late Triassic to lower Jurassic) during the middle Triassic. The youngest sediments deformed by the King Salmon Fault are Bajocian rocks that are underlain by organic-rich sediments of Aalenian age. The deformed sediments are interpreted to reflect loading along the western margin of Stikinia by the Cache Creek Terrane during its initial emplacement.

The oldest post-collisional plutons that intrude the Cache Creek Terrane to the west of Dease Lake are dated at  $173 \pm 4$  Ma by K-Ar methods and in the Atlin area they are dated at  $172 \pm 3$  Ma by U-Pb zircon analyses. Considering the age of these plutons and its relationship with the orogenic event, the descriptive term late syn-collisional is preferable.

The eastern portion of the Northern Cache Creek Terrane is bordered mainly by the Thibert Fault that trends northward along the Teslin lineament. Discontinuous exposures of altered ultramafite along the fault suggest that it has previously undergone significant reverse motion and may be a reactivated thrust or transpressional fault zone. The latest movement along this fault during the pre-late Cretaceous is believed to be dextral strike-slip.

The Northern Cache Creek Terrane is mainly made up of sub-greenschist, prehnite-pumpellyite facies rocks. Local greenschist and blueschist metamorphism are recorded. The terrane is characterized by a northwesterly-trending structural grain fabric. In the Atlin-Sentinel Mountain area there is a marked deviation from this regional orientation with a dominant northeasterly trend. Reasons for the difference in structural grain fabric are poorly understood.

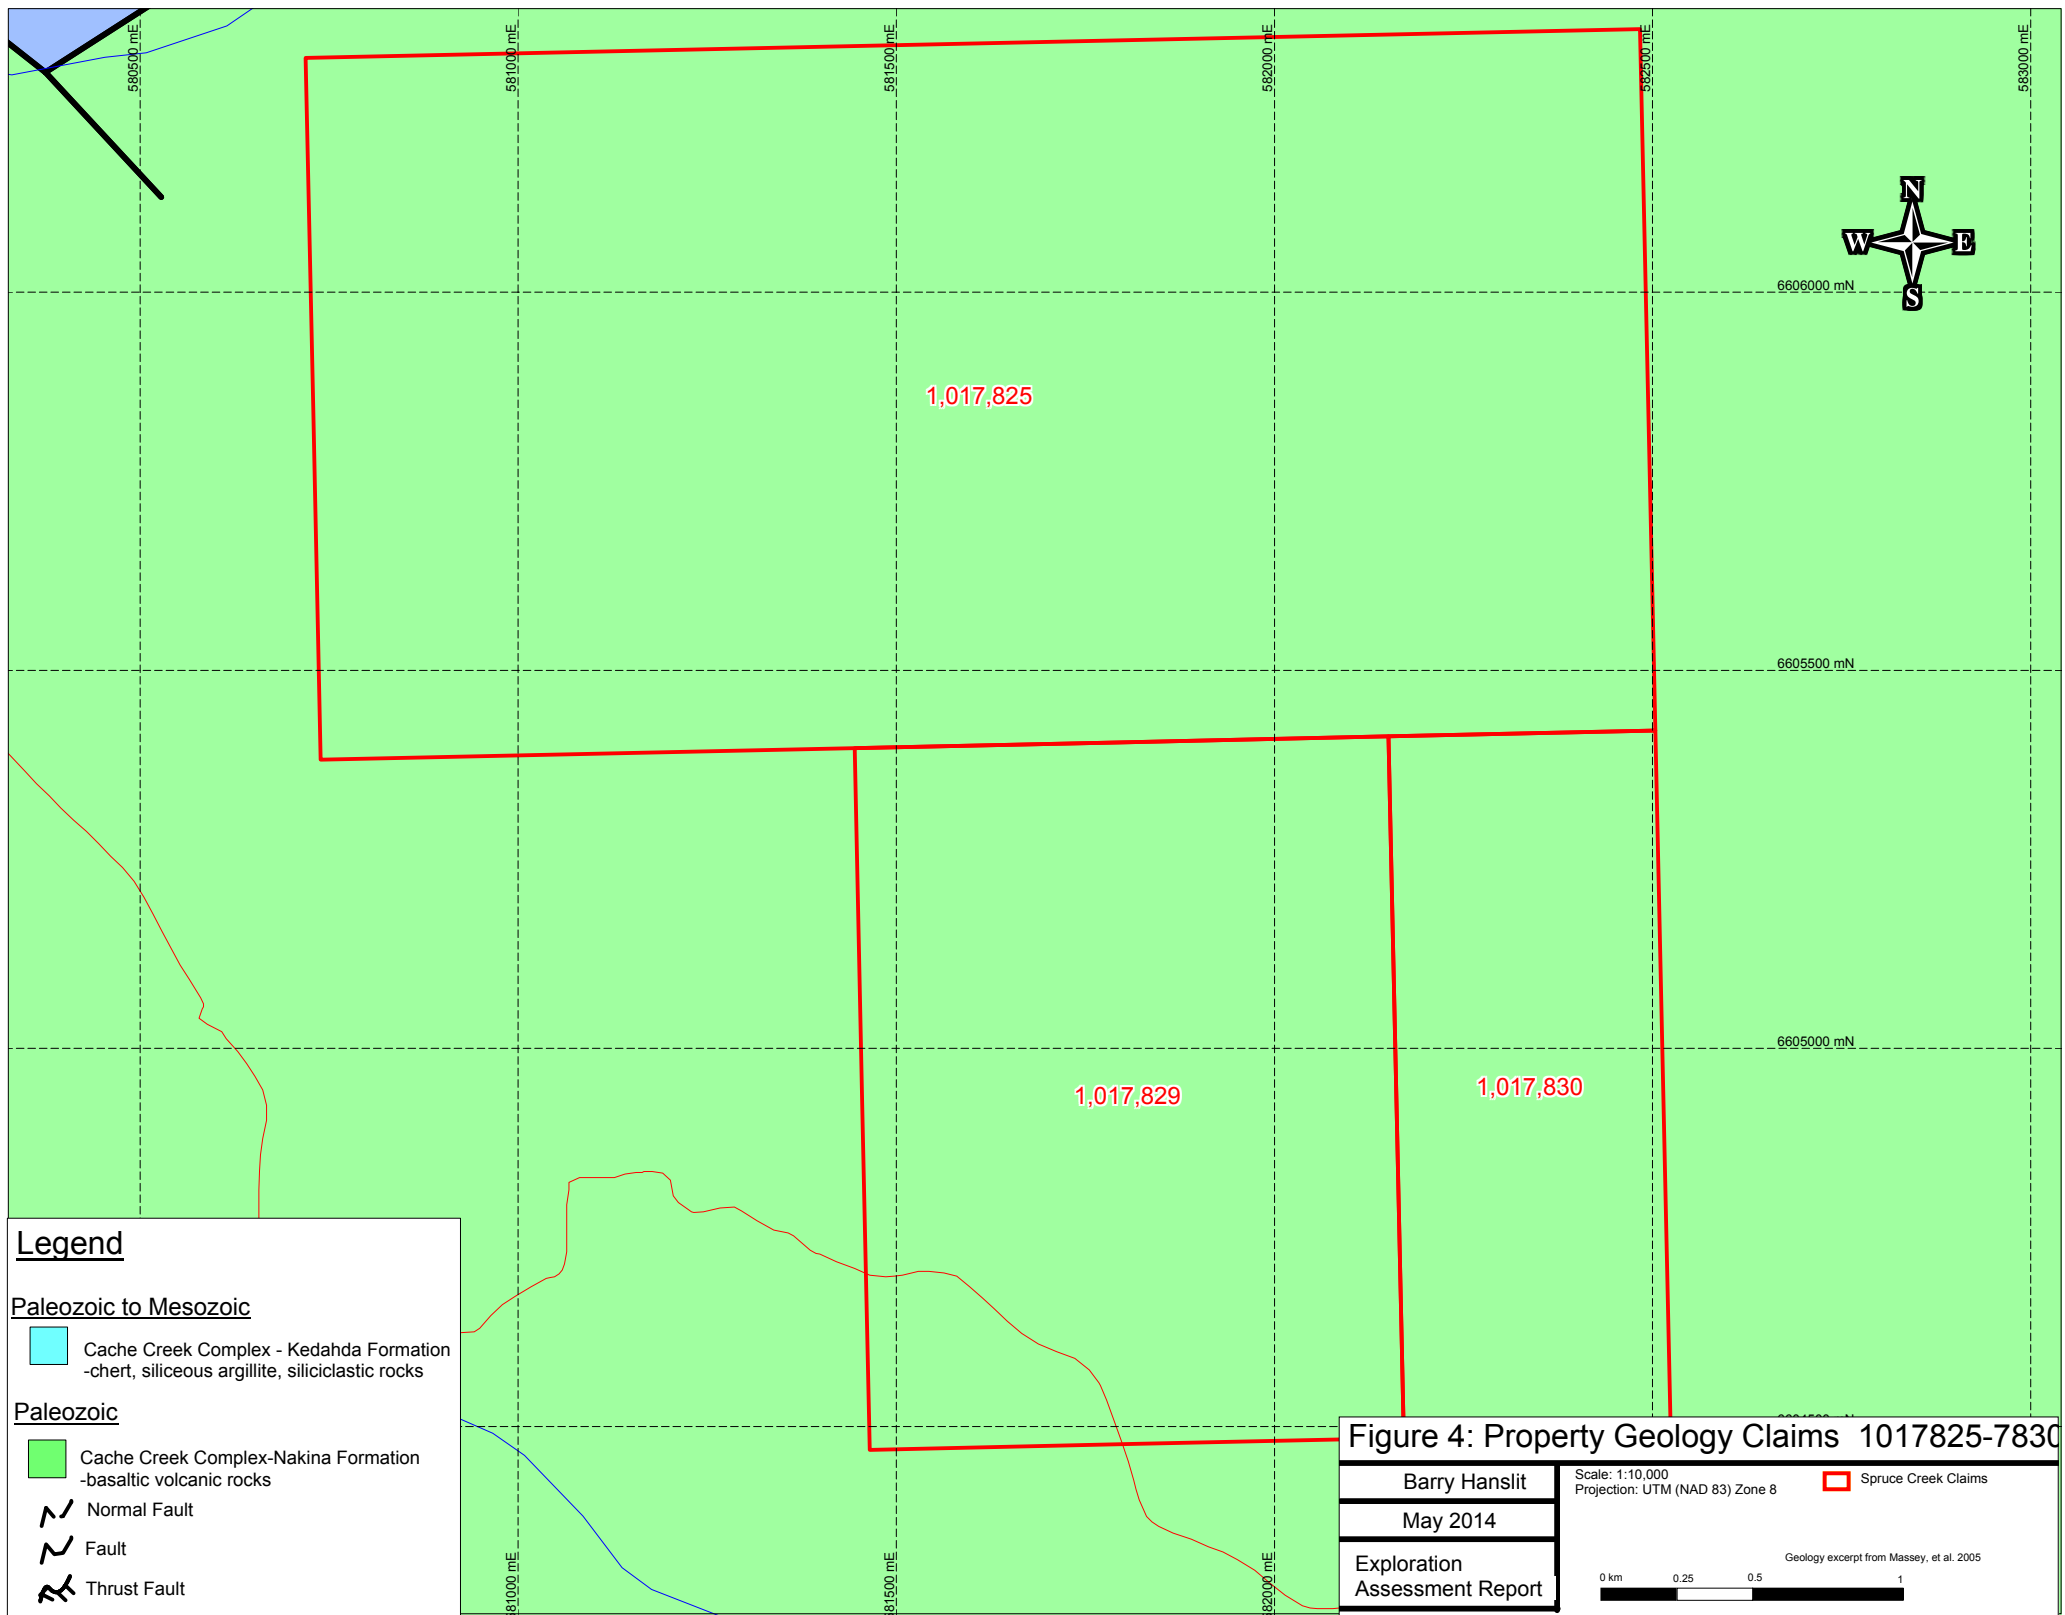

### **3.2 Property Geology**

The property geology map provided in Figure 4 is based on the compilation created by Massey et al in 2005. The claims are underlain by rocks of the Mesozoic to Paleozoic Cache Creek Complex Nikina Formation (Massey et al, 2005). A description of the Nakina formation follows as per Mihalynuk, 1999.

Basalt of probable Mississippian to Pennsylvanian age that form parts of the western and northern Atlin Complex are dominant constituents of the Nakina Formation (Monger, 1975). Nakina lithologies include fine-grained, massive black basaltic flows and tuff, mint green basaltic tuff and tuffaceous sediments, and possible flows. Rare primary textures are preserved: these show the local brecciated, pillowed, or amygdaloidal nature of the formation. Peculiar gabbroic patches, which may represent the interiors of flows or large pillows, and widespread networks of feldspar veinlets, are more characteristic. Pervasive, randomly oriented black shears and sheared layers containing cataclasts 0.1 to 1 centimeter in size are also distinctive, and may be in part a primary slump or autoclastic feature (as is commonly recognized in core recovered from the Ocean Drilling Program). Weathered outcrops are generally massive, black, green to grey-green and heavily lichen covered. Feldspar and pyroxene phenocrysts are uncommon, but can comprise up to a few percent of the outcrop. It has been suggested that the Nakina Formation rocks form the base of the Cache Creek stratigraphic succession (Monger, 1975).

### **3.2 Deposit Mineralogy**

The claims are a simple placer gold deposit type. Native gold likely sourced from quartz stringers in the surrounding host rocks is concentrated by alluvial action in the creek. Gold being dense is found amongst the magnetite rich black sands, and within cracks in the bedrock beneath the current and historical creek channels.

## **4.0 2013 EXPLORATION PROGRAM**

### **4.1 Introduction**

Test pits were dug and a ground magnetic survey was performed on the property to determine possible locations for placer mining. Results of the pits are provided in Appendix III and the locations of the pits are shown on Figure 5. The ground geophysical survey results are shown in Figure 6 and the raw data is provided in Appendix IV. Costs associated with the program and personnel are listed in Appendix I and II. The details and results of the program will be discussed in the subsequent section.

### **4.2 2013 Prospecting Results**

Twenty-four test pits were excavated by hand on the property. Pits were dug to a depth of approximately 1m and then sieved and panned by hand to determine the number of gold grains. Testing took six days and revealed significantly higher gold grades in the southerly test pits closest to Spruce Creek. The majority of test pits were boulder-rich and all pits except 19 did return gold grains. Gold grains recovered were flat flakes and no larger nuggets were discovered. Bedrock was not encountered in any of the pits.

### **4.3 2013 Geophysical Results**

The total magnetic field survey was performed with the intention of uncovering a possible paleo-channel in an area of deep sediments. Transects of the property were performed with a GEM Overhauser Magnetometer with a base station. A total of ~32 line kilometers were surveyed over seven days one and a day was spent in data recovery, calibration and preparation. Readings were taken approximately every 10m along the traverse lines.

The ground geophysics could be considered in two zones; a dramatically changing northern zone in claim 1017825 and a lower amplitude zone in claims 1017829 and 1017830. In the northern zone measurement increase greatly from greater than 57650nT to 57390nT over 700m. The transition to the southern zone is interesting in this background, and there is some indication of a possible broadly spread low grade lineation running roughly northeast from -133°33'13"W, 59°34'17" to -133°32'41", 59°34'33". With the limits of the survey, this may represent a simple change in bedrock rather than a possible indication of a paleo channel. The amplitude in the southern zone undulates from 57380nT to 57355nT. There appears to be a broad plateau of slightly elevated signature stretching east-west at 59°34'36" from -133°32'55" to -133°32'28" and north-south at -133°32'39" from 59°34'27" to 59°34'44".

## **5.0 CONCLUSIONS AND RECOMMENDATIONS**

The 2013 ground geophysical survey gave possible indications of a paleochannel. A survey that traversed the creek and extended to the south and east would give a better sense of the meaning or existence of the possible lineation. Test pits to a depth of 1m as excavated in this program are inadequate for testing the presence of a paleo-channel that could easily be beneath 20 feet or more of overburden. Testing for the presence of a high-grade pay-channel could either be conducted by an extensive excavation and testing program to bedrock. Alternately, a tightly spaced drilling program that bisected the lineation would be an effective method for determining the change in sediments that may indicate an ancient pay channel.

The hand-dug test pits in this year's program indicate higher gold values in the southern reaches of the claim particularly in and around Spruce Creek. The values are not high enough to warrant large scale processing at this time. However, should further exploration reveal a higher grade channel beneath these sediments, the overburden could be processed to offset mining costs.

## **Appendix V**

### **Certificate of Authors**

## **CERTIFICATE OF AUTHORS**

I, Janet L. P. Miller, of Whistler, British Columbia, Canada do hereby certify that:

1. I was an employee of Strongbow Exploration Inc. formerly Navigator Exploration Corp., 800-625 Howe St., Vancouver, British Columbia, Canada from 2000 to 2005.
2. I graduated from the University of British Columbia (2004) with a BSc in Honours Geology with a minor in Biology.
3. I have been employed continuously in geology during the summer terms of my education with a focus in diamond exploration.
4. I have been active in the field aspects of diamond and base metal exploration for four years (2002-2005) in the Northwest Territories and Nunavut, including project management, planning and implementation, as well as detailed mapping of surficial deposits, sampling, prospecting, and ground truthing geophysical anomalies on various properties.
5. I have been involved in data compilation, and analysis for diamond and base/precious metal exploration since 2000 under the supervision of a registered professional geologist, and have been involved in a number of aspects of projects in the Northwest Territories, British Columbia, and Nunavut.

Janet L.P. Miller

Whistler, BC, Canada  
June 9, 2014

I, Barry Hanslit, of 1120 Maughan Road, Nanaimo, British Columbia do hereby declare the following:

1. I have completed a "Prospecting Course" in 1991 given by a representative of Manitoba Natural Resources at Falcon Lake, Manitoba.
2. I have been prospecting for the last 12 years in both Manitoba, and more recently British Columbia.
3. I have worked on several prospects and developed prospects in Manitoba during the years 1990 to 1994
4. Held the position of Project Operations Manager with Stornoway Diamonds from 2004 to 2005.
5. Currently president of Zinex Mining Corp.

Barry A. Hanslit
