Summary

In late June of 2014 Canada Zinc Metals conducted a short soil sampling program on the Yuen North property located in north eastern British Columbia. The program was designed to confirm the historical soil results and infill and expand upon the known anomalies. A total of 222 samples were collected across 13, 400 metre spaced lines. The expenditures from this work has been applied to the two mineral claims that comprise the Yuen North property.

The Yuen North property is situated in the Kechika Trough, the southern extension of the Selwyn Basin. The Kechika Trough/Selwyn basin is host to numerous SEDEX type mineral deposits. The Kechika Trough is bounded to the west and east by carbonates and shallow water clastic rocks of the Cassiar and MacDonald platforms, respectively and hosts a sequence of upper Devonian to Mississippian basinal facies clastic sedimentary rocks that are a regional target for SEDEX type zinc lead silver deposits. Deposits in the district include the Cardiac Creek deposit with a NI 43-101 compliant indicated resource of 12.7 Mt at a 5% Zn cut-off grading 8.38% Zn, 1.68% Pb 13.7g/t Ag and inferred resource of 16.3 Mt grading 7.38% Zn, 1.34% Pb, 11.6g/t Ag, (Sim 2012) and the nearby Cirque deposit (non 43-101 compliant resource of 24.7 Mt grading 8.5% Zn, 2.3% Pb and 50.8g/t Ag (BC MINFILE). Exploration in the district has focused on the upper Devonian black siliceous shales of the Gunsteel Formation that are host to the above deposits. Historical mapping on the Yuen North property identified two northwest-trending thrust panels of Gunsteel Formation shales.

Exploration of the Yuen North property (previously known as the South Kwad property) was limited to the early 1980's by Cominco Ltd. Early work included mapping which outlined a series of nodular, laminar to massively bedded barite outcroppings that occur within the western thrust repeated panel of Earn Group stratigraphy. Subsequent soil sampling programs outlined a prominent Ba anomaly with localised Pb, Zn and Ag anomalies within the western panel that were attributed to the baritic horizons outlined in the mapping. The 2014 soil sampling program also targeted the western panel of prospective stratigraphy with a primary objective to confirm the trends observed in the historical data, obtain a wider suite of elements including known trace elements of SEDEX style deposits and infill and expand upon the known soil anomalies.

The results from the 2014 soil sampling program confirmed the trends observed in the historical programs. The 2014 Pb, Zn, Ag and Ba results correlated well with historical trends though the Zn and Ag results displayed some differences in the two data sets across the main portion of the grid. In addition, the 2014 Pb results appeared to expand the historical anomaly further to the west. The results also generated three areas of interest. The first area is a linear trend extending approximately 2.4 kilometres and 200 metres wide oriented at 134 degree cutting across the main portion of the grid and coincident in Pb, Zn, Ag and Ba with values reaching 247.24 ppm, 2,484.1 ppm, 4,318 ppb and >5,000 ppm respectively. The second area is located in a west facing cirque in the south eastern portion of the grid and is coincident in Pb, Zn, Ag, Tl, Fe and Ba with values reaching 132.46 ppm, 1,968.9 ppm, 5,127 ppb, 14.81 ppm, 11.62 %, and 21,619 ppm respectively. This area of interest is hosted entirely within the Earn Group stratigraphy in proximity to the west bounding thrust fault and numerous iron seeps and ferricrete deposits. The source of the multi-element anomaly is unknown and requires follow up work. The third area is also a linear feature extending approximately 2.8 kilometres long and situated along the western edge of the grid parallel to the river valley and is best defined by Ba and Fe with values reaching 27,736 ppm and 14.52 % respectively. This anomaly appears to be associated with the mapped horizons of nodular, laminar to bedded barite hosted in Gunsteel Formation shales in the vicinity.

A number of sample sites from the 2014 program exhibit elevated values in a unique suite of elements including Ni, U, Tl, Re +/- Zn, Pb, Co, As, Sb, V, Hg, P, and Se. This suite of elements bears similarities with the recent discovery of Nick style mineralisation in drill core at the Akie property and the Nick deposit in the Yukon. Most of the sample sites are clustered within the second area of interest in the southeastern portion of the grid. The source of these values is unknown and requires further follow up work. Additional work including soil sampling, mapping and litho-geochemical rock sampling are recommended,

LIST OF APPENDICES

1.0 Introduction & Terms of Reference

This report documents exploration work carried out in 2014 by Canada Zinc Metals Corp. (the company) on the Yuen North. Expenditures related to the exploration work have been applied to the two mineral claims that comprise the property. The author directed the field work that is the subject of this report and was supported by an able field crew supplied by Coast Mountain Geological Ltd., and the Kwadacha National Resources Limited Partnership (KNRLP). The exploration activities on the Yuen North property consisted of soil sampling and a limited amount of rock sampling. Field data was recorded in Universal Transverse Mercator (UTM) projection using North American Datum (NAD 83), located within Zone 10. All measurements in this report are in metric units. Monetary amounts are expressed in Canadian dollars.

2.0 Property Location & Description

The Company holds 100% of the claims that are incorporated into the Yuen North property block. The Yuen North property block consists of 2 mineral claims covering a total area of 2,687 hectares. The property is located in the western ranges of the Northern Rocky Mountains in the province of British Columbia, Canada (Figure 2-1). The claims are in good standing until 1 February 2018 (Table 2-1). The property can be seen in Figure 2-2. The Yuen North property is part of the company's much larger contiguous Kechika Trough mineral tenure holdings that have an approximate strike extent in excess of 140 kilometres (Figure 2-1). This contiguous package consists of 230 claims covering an area totalling 79,781 hectares. The nearest town is Mackenzie BC, located approximately 290 kilometres southeast of the Yuen North property (Figure 2-1). The Yuen North property is located within NTS topographic map sheets 94F11.

3.0 Accessibility, Infrastructure, Climate & Physiography

The Yuen North property is accessible by helicopter only. Exploration was conducted from the company's Akie exploration camp located approximately 40 kilometres to the southeast of the property. The Akie exploration camp is situated at the 24.5 kilometre mark on the Akie FSR (Forestry Service Road) (Plate 7-1). Chartered aircraft from Northern Thunderbird Air (NT Air) currently provides air transport services on a semi-daily basis during the week to a gravel airstrip at the village of Tsay Keh Dene, BC. Tsay Keh Dene is located at the northern end of Williston Lake and is approximately 60 kilometres southwest of the Akie exploration camp.

Prince George is the largest population centre in central British Columbia located approximately 420 kilometres to the south. The city is a major hub for supplies, transportation, communications, and commerce. Some supplies are derived locally in Tsay Keh Dene or from Mackenzie; the latter is located at the southern end of Williston Lake 250 kilometres southeast of the property (Figure 2-1). A series of year round accessible gravel forestry service roads connect Tsay Keh Dene with Mackenzie. These local communities have an active forestry industry as well as a growing mining and exploration industry. Nearby mines include the recently closed Kemess South mine and the newly opened Mt Milligan mine.

Tenure #	Claim Name	Owner (100%)	Expiry Date	Area (Ha)
1024832	Yuen North 1	202429	1 Feb 2018	1734
1024833	Yuen North 2	202429	1 Feb 2018	953

Table 2-1: Tenure listing for the Yuen North property.

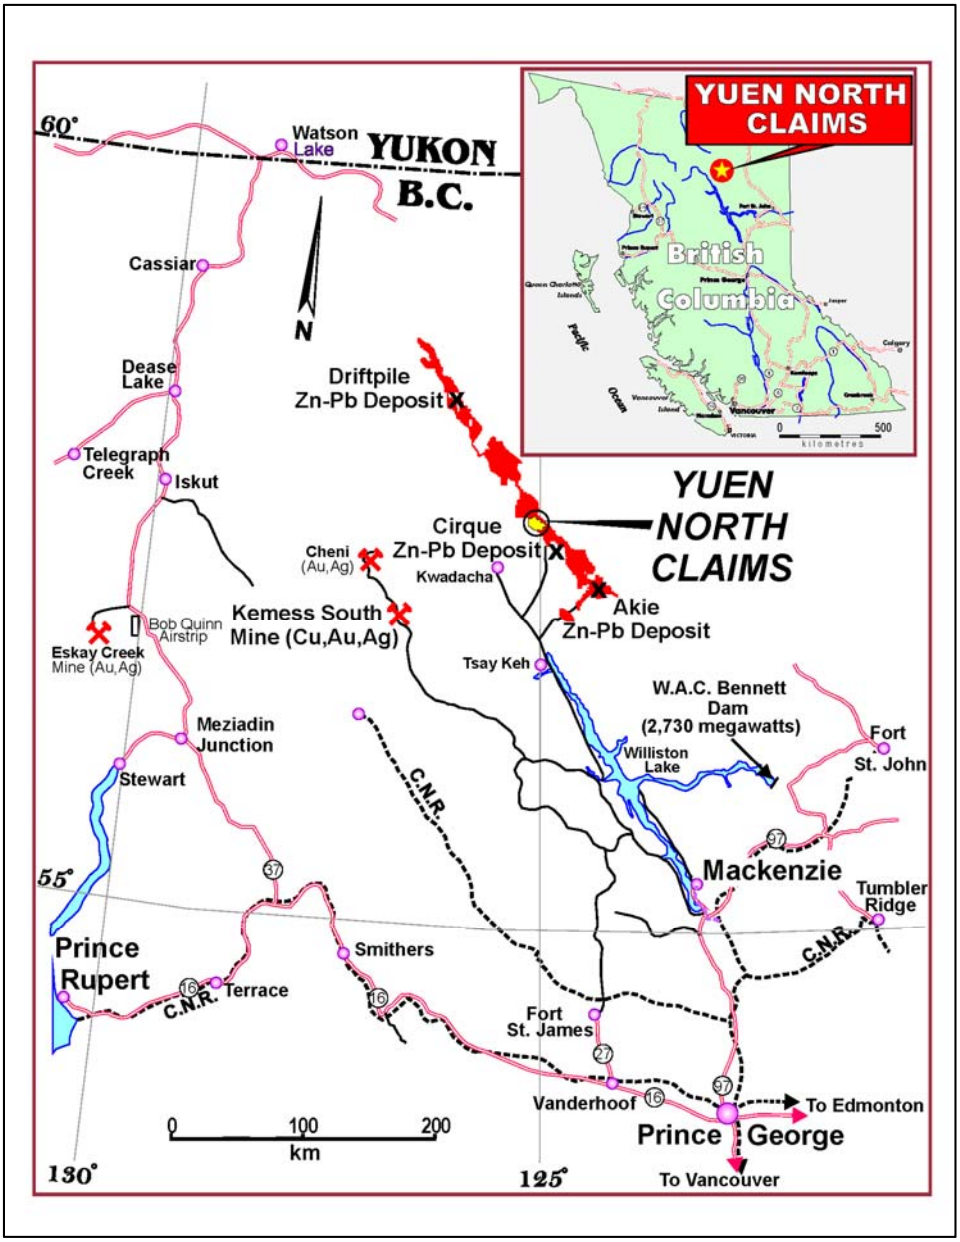

Figure 2-1: Property location map.

The nearest BC Hydro electric transmission power source is the W.A.C. Bennett dam, capable of generating up to 2,730 megawatts of electricity, located on the Peace River approximately 220 kilometres southeast of the property (Figure 2-1). The privately owned Kemess power line runs north from BC Hydro's Kennedy substation, near Mackenzie, to the idled Kemess South mine west southwest of the Yuen North property. The straightline distance from the Yuen North property to the Kemess mine is approximately 150 kilometres. Diesel generators supply electricity to the local villages.

The property and surrounding region is an area of moderate to steep mountainous terrain, ranging between 800 to 2,300 metres above sea level. Mountain tops and ridgelines above the treeline are typically covered by alpine meadows with mosses, lichen and alpine flowers in the summer. Sparsely vegetated talus and

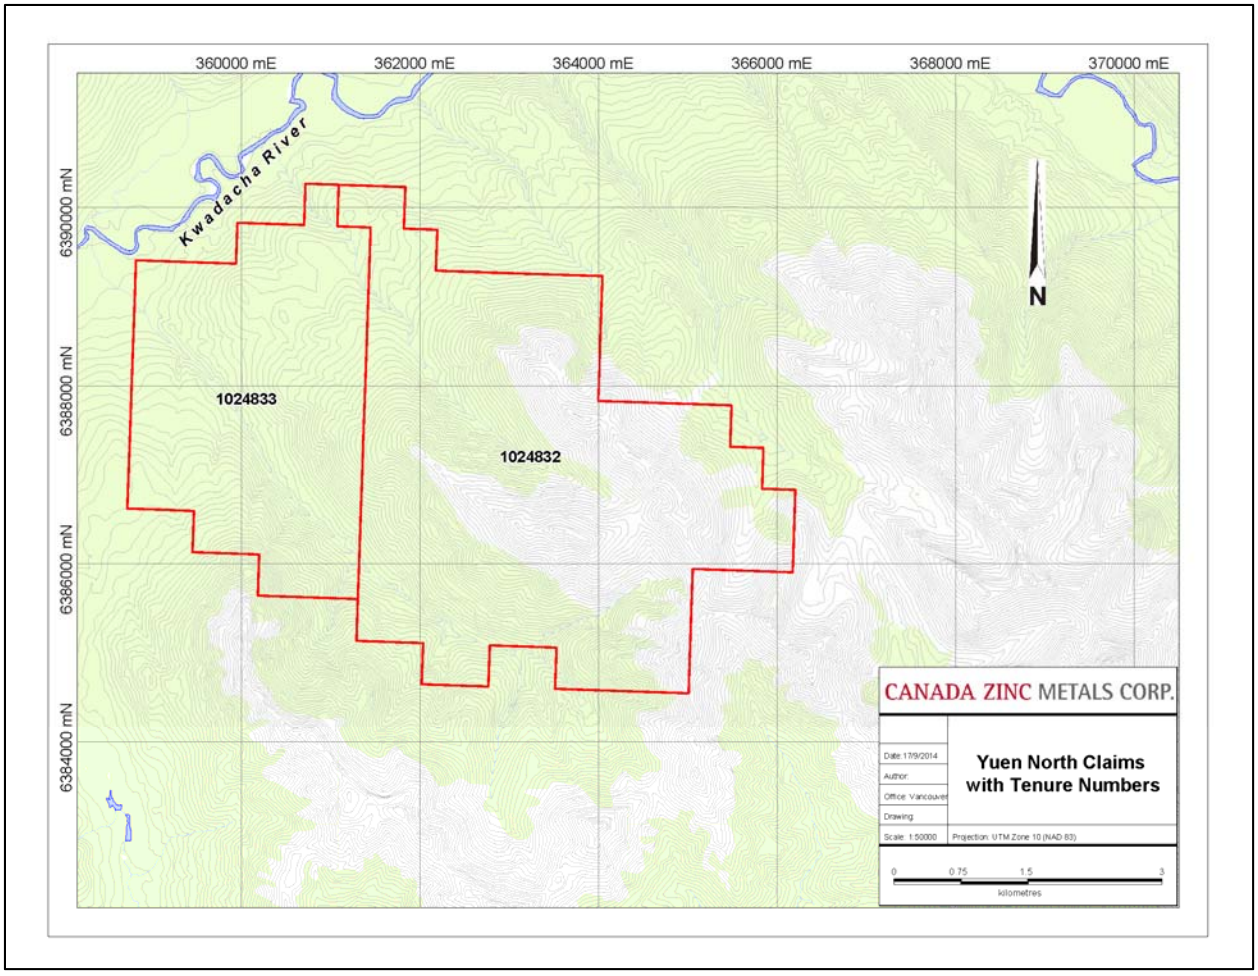

Figure 2-2 Mineral tenure map for the Yuen North property.

scree commonly cover steep slopes. At lower elevations hillsides are thickly forested with a mixture of lodgepole pine and black spruce giving way to willows, alders and black birch in the river valleys.

Northwest – southeast trending ridges predominate, following the dominant geological strike direction, transected by northeast trending drainages such as the Akie, Paul and Kwadacha rivers. In general, northeast facing ridge slopes are generally steep with abundant outcrop exposure while southwest facing ridge slopes tend to dip more moderately and are covered in vegetation.

The climate is influenced by both the Pacific Coast and the Rocky Mountains, resulting in variable, localized conditions for rainfall, snowfall, temperature and hours of daylight. During the summer months temperatures range between +5 to +30 degrees Celsius with moderate rainfall and/or snowfall at higher altitudes. During winter, temperatures can drop to minus 40 degrees Celsius, and can be accompanied by moderate accumulations of snow. The optimal season for field work is from May or June; when valleys become free of snow, through to late September; when winter weather generally returns.

4.0 Exploration History

The exploration history of the Yuen North property is very limited, occurring in the early 1980's. The area was originally staked as the South Kwad property with the initial work conducted by Cominco Ltd. Exploration activities have consisted of grassroots prospecting, sampling and mapping and more recently airborne geophysics. The following table (Table 4-1) outlines a summary of exploration activities that have occurred on the property.

Table 4-1: Yuen North Exploration History

Year	Operator	Exploration Work
1980	Cominco Ltd.	Historical property was staked to cover baritic shales of the Gunsteel Formation. Preliminary mapping was completed and silt and soil sampling conducted.
1981	Cominco Ltd.	Mapping further defined baritic shales of the Gunsteel Formation. Extensive soil sampling program undertaken and litho-geochemical rock samples collected..
1986	Cominco Ltd.	Additional rock sampling conducted.
2011	Canada Zinc Metals Corp.	Airborne VTEM survey flown over the Yuen North property.

5.0 Geology

5.1 Regional Geology

For a comprehensive review of the regional geology of the Akie River district, which includes the Yuen North property, the reader is referred to the 1998 British Columbia Geological Survey, Bulletin 103 entitled *Geology, Geochemistry and Mineral Deposits of the Akie River Area, Northeast British Columbia* by Don G. MacIntyre. The following represents a summary of the information contained within that report.

The Yuen North property is located within the Rocky Mountain fold and thrust belt of northeastern British Columbia and in the central region of the Kechika Trough. The Kechika Trough is interpreted to be the southeastern extension of the large sedimentary Selwyn Basin bounded by the shallow water sedimentary rocks of the Cassiar (west) and MacDonald platforms (east) (MacIntyre, 1998). Situated along the ancestral continental margin of North America, the basin is host to clastic and carbonate rocks ranging in age from the late Cambrian to late Triassic (MacIntyre, 2005) (Figure 5-1). A generalized stratigraphic column of the lithological units summarized below is presented in Figure 5-2.

5.1.1 Windermere Supergroup and Gog Group (Proterozoic to Cambrian)

The oldest rocks exposed in the Kechika Trough are the Proterozoic to early Cambrian coarse grit units thought to be representative of the Windermere Supergroup and the early to late quartzites and massive limestone correlative to the Gog Group (MacIntyre, 2005). These rocks are not exposed in the general vicinity of the property. They are restricted to the northern and northeastern edge of the Kechika Trough and to the immediate west of the property (Gog Group) (MacIntyre, 2005). The grit units of the Windermere Supergroup are thought to act as important aquifers for fluids involved in the formation of sediment and carbonate hosted lead-zinc-silver deposits of the Selwyn Basin and Kechika Trough (MacIntyre, 2008).

5.1.2 Kechika Group (Cambrian to Ordovician)

A thick, approximately 1,500 metre succession of cream coloured to light grey weathered, talcy, phyllitic mudstone and wavy banded nodular (boudinaged) limestone characterize the rocks of the Kechika Group (MacIntyre, 2005; Demerse and Hopkins, 2008). Volcanic activity is marked by the presence of thinly

bedded green weathered tuffs (MacIntyre, 2005) and cross cutting thin felsic dykes within the sediments of the Kechika Group. Kechika Group rocks are prominent in the southern Kechika Trough thinning northwards where they are rare to absent altogether (MacIntyre, 2005).

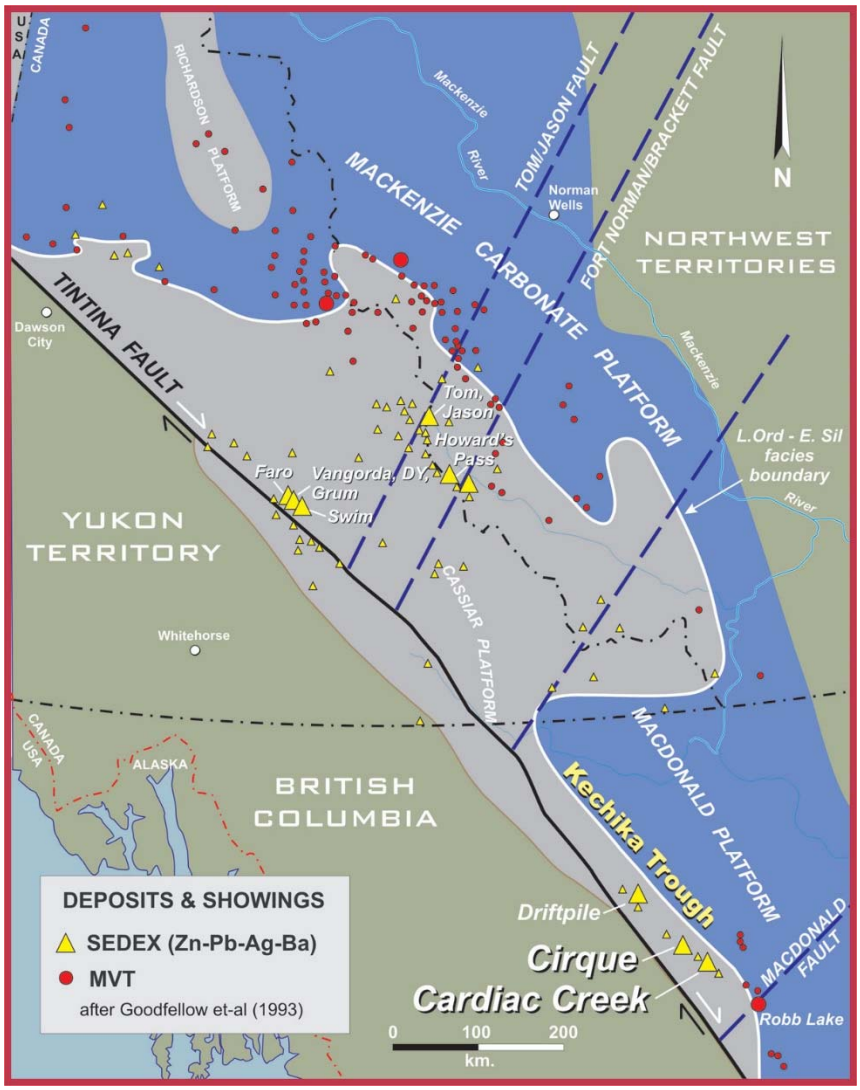

Figure 5-1: Geological setting of the Selwyn Basin and Kechika Trough (modified after Goodfellow et al, 1993).

5.1.3 Skoki Limestone (Ordovician)

Locally, in the vicinity of Pesika Creek and the Kwadacha River (the southern and eastern section of the Kechika Trough, respectively), an approximate 500 metre thick buildup of thinly bedded limestone of Ordovician age overlie the Kechika Group rocks. These rocks are generally absent in the Northern Kechika Trough (MacIntyre, 2005).

5.1.4 Road River Group (Ordovician to early Devonian)

The rocks of the Road River Group unconformably overlie those of the Kechika Group and are represented by a collection of fine-grained clastics, carbonates and minor volcanics of Ordovician to early Devonian age (MacIntyre, 1998). They are pervasive throughout the Kechika Trough and can be informally broken into three distinct groups: the Lower Road River Group, the Ospika Volcanics and the Silurian Siltstone (MacIntyre, 2008). The Road River Group is thought to represent the transition between platformal and marine basinal rocks (MacIntyre, 2008).

The Lower Road River Group is comprised of a basal cream, beige to reddish brown weathered, thin-bedded calcareous siltstone and shale with minor limestone turbidites and debris flows. This siltstone grades up section into a distinct middle to late Ordovician aged black graptolitic shale (MacIntyre, 1998). The graptolite fossil assemblage allows for relatively easy differentiation from the lithologically similar and prospective rocks of the Devonian (MacIntyre, 2008). Locally the shale is interbedded with black chert horizons in the vicinity of the REB massive pyrite lens in the southern Kechika Trough and in the east they are locally interbedded with quartz wackes, arenites and pebble conglomerates.

The Ospika Volcanics are present throughout the central Kechika Trough area (Akie River, Paul River and Ospika River) represented by a series of discontinuous lenses and beds of green mafic flows, microdioritic sills and orange weathered ankeritic crystal lapilli tuffs that are interbedded with the rocks of the Lower Road River Group. It is suggested that based on their orientation these rocks were emplaced along fault structures bounding the basin (MacIntyre, 1998). In 2009, a gabbro/diorite intrusive plug was discovered along the Del Creek which is thought to represent one such possible bounding fault structure as well as the source for the thin lenses of volcanic rocks found in the area (Demerse and Hopkins 2008).

The upper Road River Group is represented by the early to middle Silurian Siltstone and unconformably overlies the Ordovician graptolitic black shale (MacIntyre, 2008). At the base, a 0 to 20 metre thick unit consisting of thin-bedded to cross laminated limestone and dolostone beds is interbedded with laminated grey calcarenite, dark grey dolomitic shale and minor debris flows. To the east the limestone/dolostone beds are commonly interbedded with quartz wacke and arenite and is known as the Silurian limestone. The Silurian limestone is overlain by a 100 to 500 metre thick tan to orange brown weathered dolomitic thin-bedded to platy siltstone with minor orange weathered limestone and dolostone interbeds. The thicker bedded siltstone is commonly bioturbated, containing worm burrows and feeding trails. Minor graptolites and sponge impressions are present in the thinly bedded to platy sections (MacIntyre, 2008).

The last unit of the Road River Group is informally recognized as the Paul River Formation (Pigage, 1986) and consists of deep water marine turbidites comprised of black chert, interbedded black shale with limestone debris flows, and rusty weathered, dark grey to brown weathered silty shale and siltstone (MacIntyre, 2008). In the Akie River area the rusty weathered silty shale partially onlap with the early to middle Devonian Akie and Kwadacha Reefs. These reefs can range up to 200 metres in thickness and are characterized by medium to thick-bedded micritic to bioclastic limestone interbedded with minor shale beds. Locally, to the east, pebble conglomerates directly overlie these reefs (MacIntyre 2008). It is the author's opinion that the Paul River Formation rocks are of the Earn Group based on observations made from the Akie drill core.

5.1.5 Earn Group (Middle Devonian to Mississippian)

Rocks of the Earn Group conformably overlie those of the carbonate reefs as well as the Silurian Siltstone and are characterized by carbonaceous, siliceous shale, cherty argillite, phyllitic shale and coarse quartzose turbidites of Middle Devonian to Mississippian age (MacIntyre, 1998). The Earn Group has been subdivided into three distinct Formations: the Warneford, the Akie and the Gunsteel (Pigage, 1986; MacIntyre, 1998). These rocks are representative of a major marine transgression that halted reef growth,

resulting in the onlapping of fine clastic sediments onto the MacDonald platform to the east (MacIntyre, 1998).

The rocks of the Gunsteel Formation are the oldest within the Earn Group of Middle to Late Devonian age. They weather to a distinctive "gunsteel" silvery blue and are comprised of carbonaceous and siliceous shale, argillite and cherty argillite (MacIntyre, 1998). The Gunsteel Formation is the primary group of prospective rocks within the Kechika Trough hosting the Cirque, Cardiac Creek and Driftpile deposits as well as the Fluke, Elf, Pie and Mount Alcock prospects. Occurrences of laminar pyrite and nodular barite are common and are characteristic of Gunsteel Formation rocks. They are overlain by the Akie Formation characterized by soft, medium to dark grey phyllic shale to silty shale and siltstone which typically weather to a rusty brown, tan or silvery colour (MacIntyre, 1998; Demerse and Hopkins, 2008).

The youngest group of rocks within the Earn Group (the Warneford Formation) are interpreted to be proximal to medial turbidites represented by grey weathered chert pebble conglomerates, quartz wacke and siltstone and are intercalated with the soft shale of Akie Formation (MacIntyre, 1998). The rocks of the Earn Group are present on the Yuen North property.

5.1.6 Triassic Siltstone (Mississippian to Triassic)

The youngest rocks of the Kechika Trough occur in the core of a major northwest trending synclinorium in the area northwest of the Kwadacha River. They are represented by dolomitic siltstone and limestone similar in character to the Silurian siltstone but can be differentiated by the presence of Triassic brachiopods (MacIntyre, 1998).

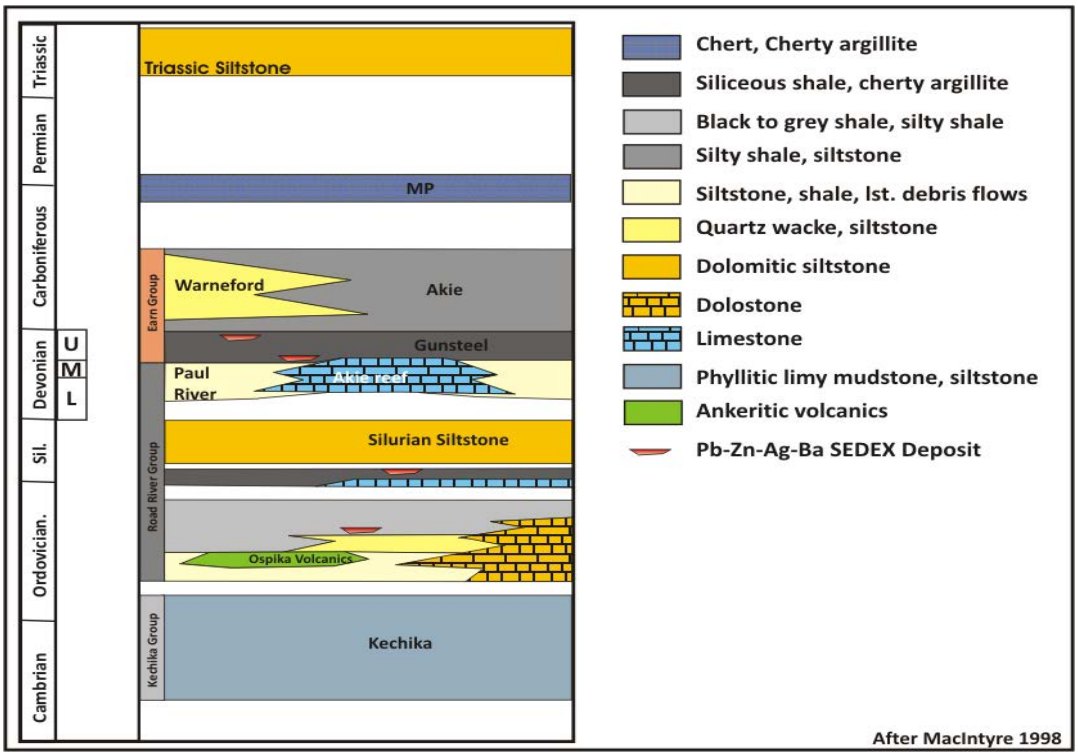

Figure 5-2: Kechika Trough generalised stratigraphic section (after MacIntyre 1998)

5.2 Regional Structure

The following section is an unabridged excerpt from the technical report entitled *Geology, Diamond Drilling and Preliminary Resource Estimation, Akie Zinc-Lead-Silver Property, Northeast British Columbia, Canada* by Donald G. MacIntyre and Robert C. Sim, 2008. The contained information remains current and is applicable to the Yuen North property. The report can be found at www.sedar.com.

"The linear nature of the geology of the Akie River area reflects the "thin-skinned" tectonic style of the Rocky Mountain Fold and Thrust Belt. Northeast-directed compression resulted in detachment of the Paleozoic strata from a rigid crystalline basement and partial stacking of the detached plates along a series of imbricate thrust faults. The thrust plates, which are composed of relatively incompetent basinal facies rocks, have been internally folded during thrusting. In general, incompetent strata below overriding thrust plates have tight isoclinal folds with southwest-dipping axial planes whereas rocks in the overriding plate are asymmetrically folded and often have northeast-dipping axial planes. This style of folding may be related to the development of inversion structures similar to those described by McClay et al., (1989) in the Driftpile Creek area.

The structural style changes from west to east across the map area. In the west, imbricate, southwest dipping reverse faults bound asymmetric overturned folds with southwest dipping to vertical axial planes. To the east, large scale upright folds occur within major synclinoriums that are bounded by outward dipping reverse faults that truncate folds within overriding anticlinoriums. Devonian strata are preserved within the synclinoriums. This structural style suggests that high angle growth faults bounding depositional troughs in Devono-Mississippian time were reactivated during Tertiary compression and became the locus of major thrust faults in the district. That major high angle thrust faults may be localized along much older crustal breaks is also suggested by close spatial association of Paleozoic mineralization, reef building, coarse clastic fans and volcanism to such faults.

Detailed studies of the structure of the Cirque deposit led to the recognition of two coaxial phases of deformation (Pigage, 1986). The earliest deformation, which is recognizable throughout the study area, includes northwest-trending, tight asymmetric folds that verge northeast and have gently dipping southwest limbs and steep to overturned northeast limbs. The steep limbs are often broken and offset by high angle reverse faults, resulting in the juxtaposition of Ordovician and Silurian strata against the Mid- to Late-Devonian Gunsteel formation shale. The high angle reverse faults may coalesce at depth into a major detachment surface possibly rooted in the highly attenuated Kechika Group. Shale typically has a pervasive slatey cleavage that is axial planar to the macroscopic folds; a closely-spaced fracture cleavage is found in the more competent strata.

The second phase of deformation folds the early slatey cleavage and develops a penetrative crenulation cleavage. This cleavage is axial planar to the late folds, which may have an amplitude of up to 30 metres (Pigage, 1986). The folds are open to upright, trend northwest and have northeast convergence. High-angle listric normal and reverse faults are also common in the Akie River area and generally trend parallel or at slight angles to the major high angle thrust faults. These faults are probably related to brittle failure of thrust plates during detachment and thrusting. Displacements of up to several hundred metres have been documented at the Cirque deposit (Pigage, 1986).North to northeast trending high angle faults offset earlier thrust and listric normal faults. Some of these faults have a strike-slip movement and may be synthetic shears related to an oblique compressional stress regime. This compressional event is believed to be Tertiary in age."

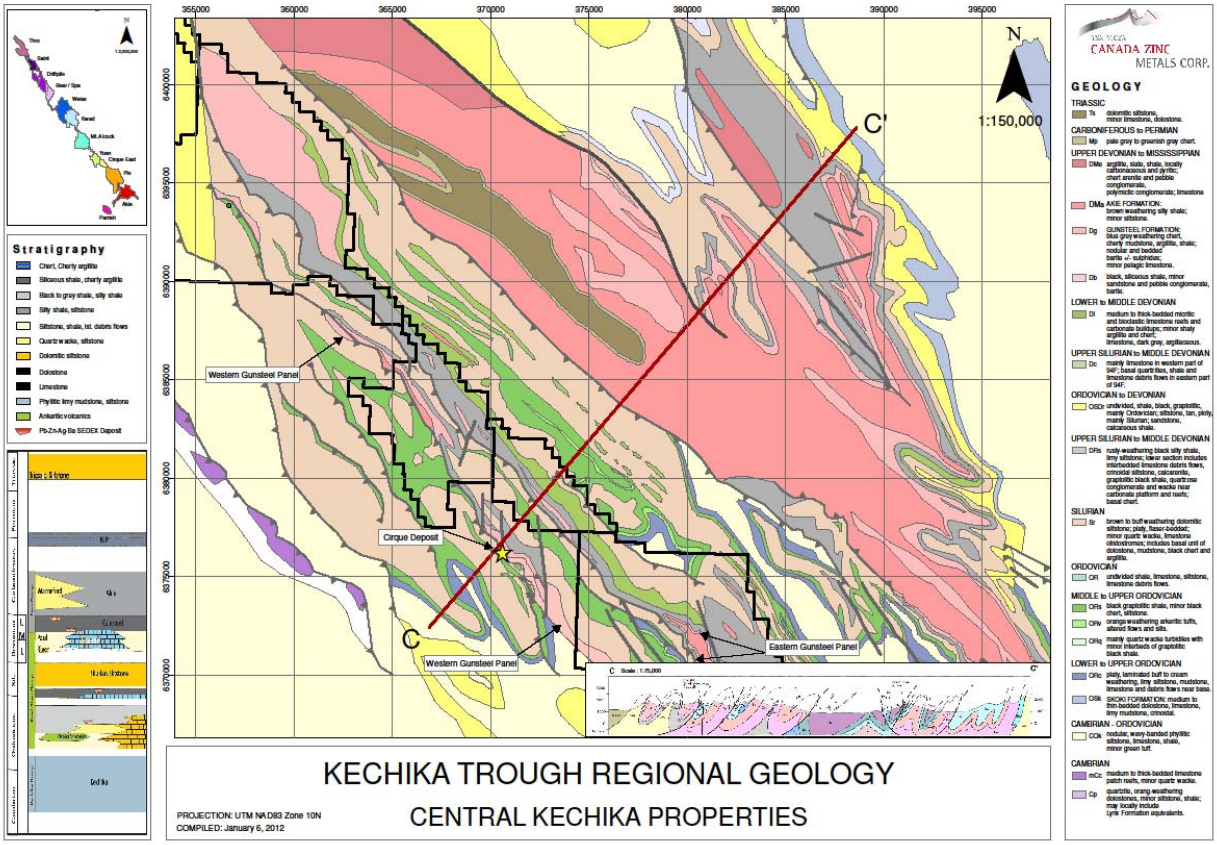

Figure 5-3: Regional geology of the Central Kechika Trough which includes the Yuen North property (after MacIntyre 1998)

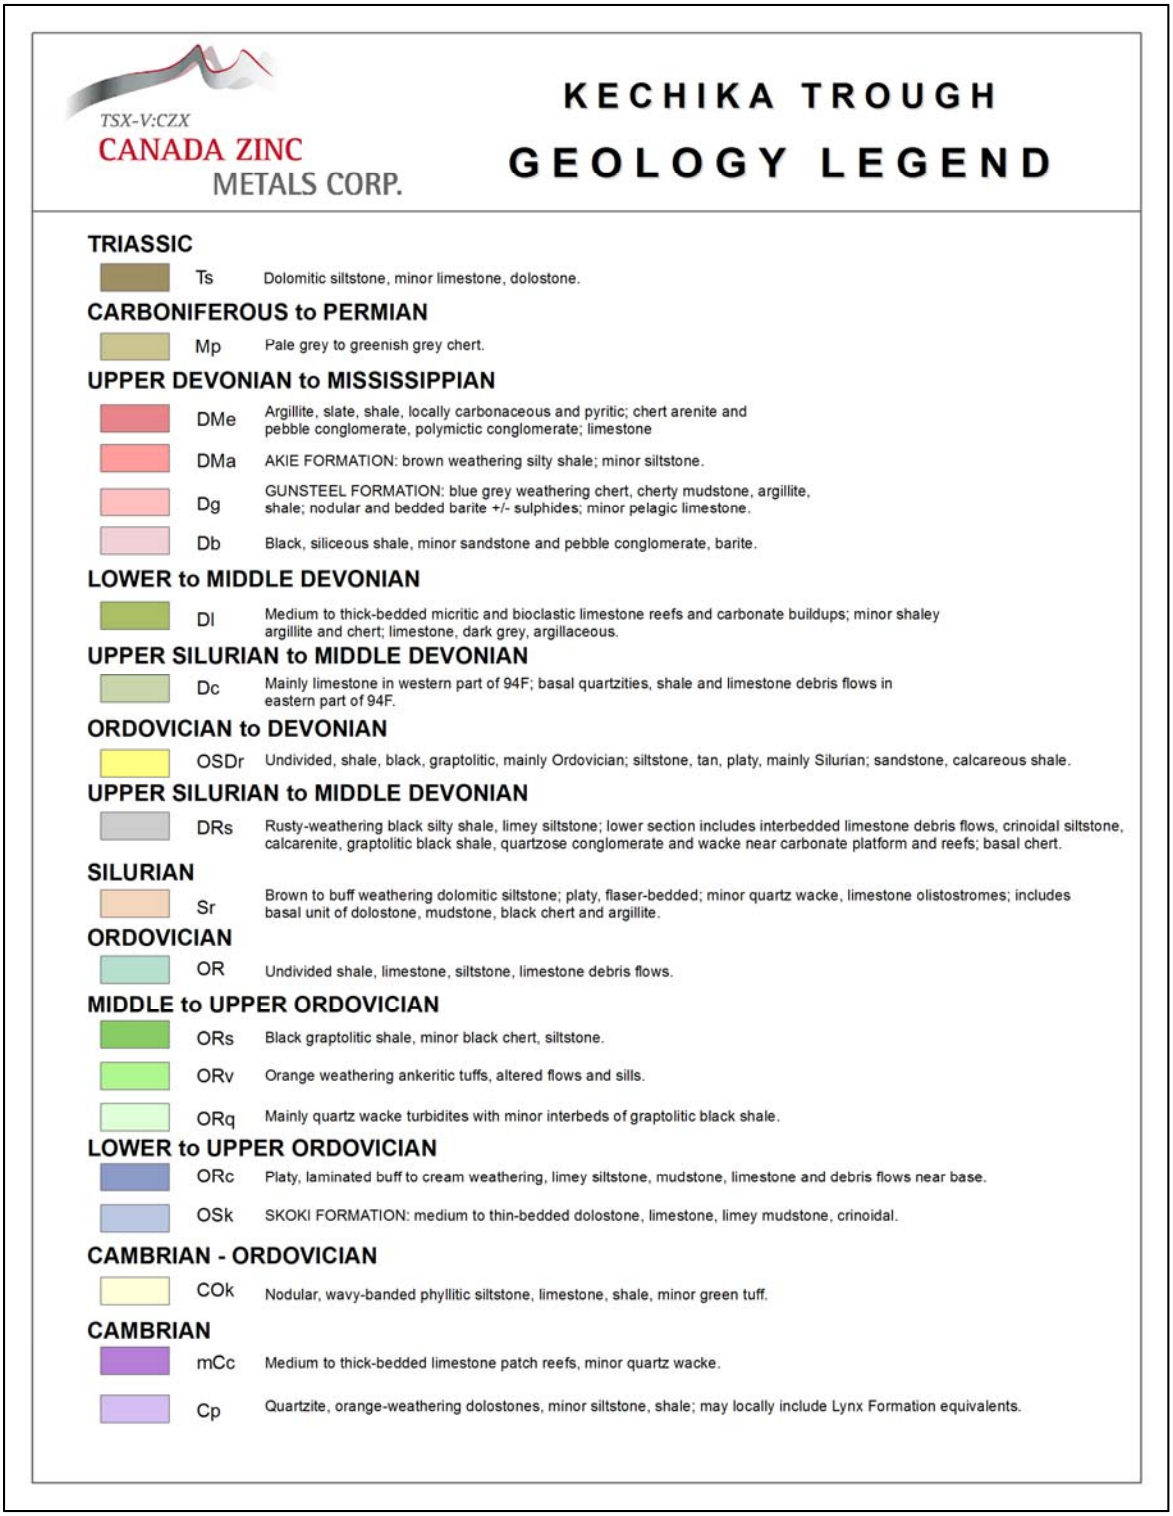

Figure 5-4: Legend for the regional geology displayed in Figure 5-3 (after MacIntyre 1998).

5.3 Property Geology

There has been no detailed property scale mapping completed on the Yuen North property since the 1981 mapping program by Cominco Ltd. Waters (1981) described the geology of the area containing the Yuen North property as:

"The geology of the area is dominated by NE vergent, SW dipping thrust faults probably developed during the Mesozoic Columbian orogeny, which induce the prevalent NW strike and SW dip of most lithologies. The faults have exploited the lithological contacts between the Cambrian, Ordovician, Silurian, Lower Devonian and Upper Devonian and have produced tight folding and strong cleavage in all the clastic lithologies, (limestones show folding only) resulting in an overall tectonic shortening of around 50%. The lithological composition of the Ordovician and Silurian does not vary significantly across the area, but the thrusted lower Devonian sections suggest a progression from limestone reef deposition on an elevated ridge in the east of the claim to a restricted basinal turbiditic shale deposition across the centre of the area. This basinal environment is believed to have controlled the deposition of the Upper Devonian "Gunsteel" shales."

The Earn Group stratigraphy and prospective "Gunsteel" Formation shales appear to be restricted to two thrust repeated panels on the Yuen North property, an eastern and western. The western panel is bound and in thrust contact with the older Road River Group rocks including the Silurian siltstone, limestone and Ordovician graptolitic black shales to the west. The western panel of Earn Group stratigraphy trends NW-SE and contains the various mapped sub-units of the Gunsteel Formation which include, black carbonaceous shales, cherty shales, silty shales, chert grits and baritic to pyritic shales. In general, the Earn Group lithologies of the western panel strike to the southeast and dip moderately to the southwest and are folded into a series of antiforms and synforms. A persistent moderately to steeply dipping cleavage is present across the property that strikes southeast and dips to the southwest paralleling the primary bedding. The western panel is underlain by the Silurian siltstones of the Road River Group which is in thrust contact with the Earn Group rocks of the eastern panel. The western panel is situated directly along strike of the Mt. Alcock barite showing known to contain Pb-Zn-Ag mineralisation to the NW and the Cirque Pb-Zn-Ag deposit to the SE. The eastern panel of Earn Group rocks, also trending NW-SE, is thrust bound by rocks of the older Road River Group to the west and underlain by the fossiliferous limestones of the Kwadacha Reef and the Silurian siltstones of the Road River Group. The eastern panel represents the strike extension of the same thrust panel that is host to the Cardiac Creek Pb-Zn-Ag deposit and Fluke and Elf advanced prospects.

A compiled version of the 1981 geological map presented in Assessment Report 09727 is in Appendix 1.

6.0 Deposit Type & Model

The Cardiac Creek, Cirque, Driftpile, and other Pb-Zn-Ag-Ba occurrences within the Kechika Trough are characterized as sedimentary exhalative (SEDEX) deposits. The following is a summary of this deposit type and its characteristics. For a detailed review of SEDEX deposits the reader is referred to the excellent overview paper of Canadian SEDEX deposits by Wayne D. Goodfellow and John W. Lydon, entitled *Sedimentary Exhalative (SEDEX) Deposits* from the publication *Mineral Deposits of Canada: A Synthesis of Major Deposit Types, District Metallogeny, the Evolution of Geological Provinces, and Exploration Methods* by the Geological Association of Canada, Mineral Deposits Division, Special Publication No. 5.

The Pb-Zn-Ag-Ba deposits and occurrences found within the Kechika Trough (e.g. Cirque, Driftpile and Cardiac Creek), the Selwyn Basin (e.g. Howards Pass, Tom, Jason, Faro and Grum), the Belt-Purcell District (e.g. Sullivan, Ruddock Creek), in Australia (e.g. HY, Century, Mount Isa), and the Brookes Range in Alaska (Red Dog) all share common characteristics and are generally considered to be SEDEX deposits (Goodfellow and Lydon, 2007). Carne and Cathro (1982) popularized the SEDEX deposit type in their early description of the deposits of the Selwyn Basin and Kechika Trough. In general, SEDEX deposits are characterized as a stratiform, tabular body of sulphide mineralisation that is interbedded with its host sediments, typically shales, siltstones and occasionally sandstones. This type of deposit shares many similar characteristics with VMS (volcanogenic massive sulphide) and MVT (Mississippi Valley Type) deposits suggesting a shared genetic link (Goodfellow and Lydon, 2007).

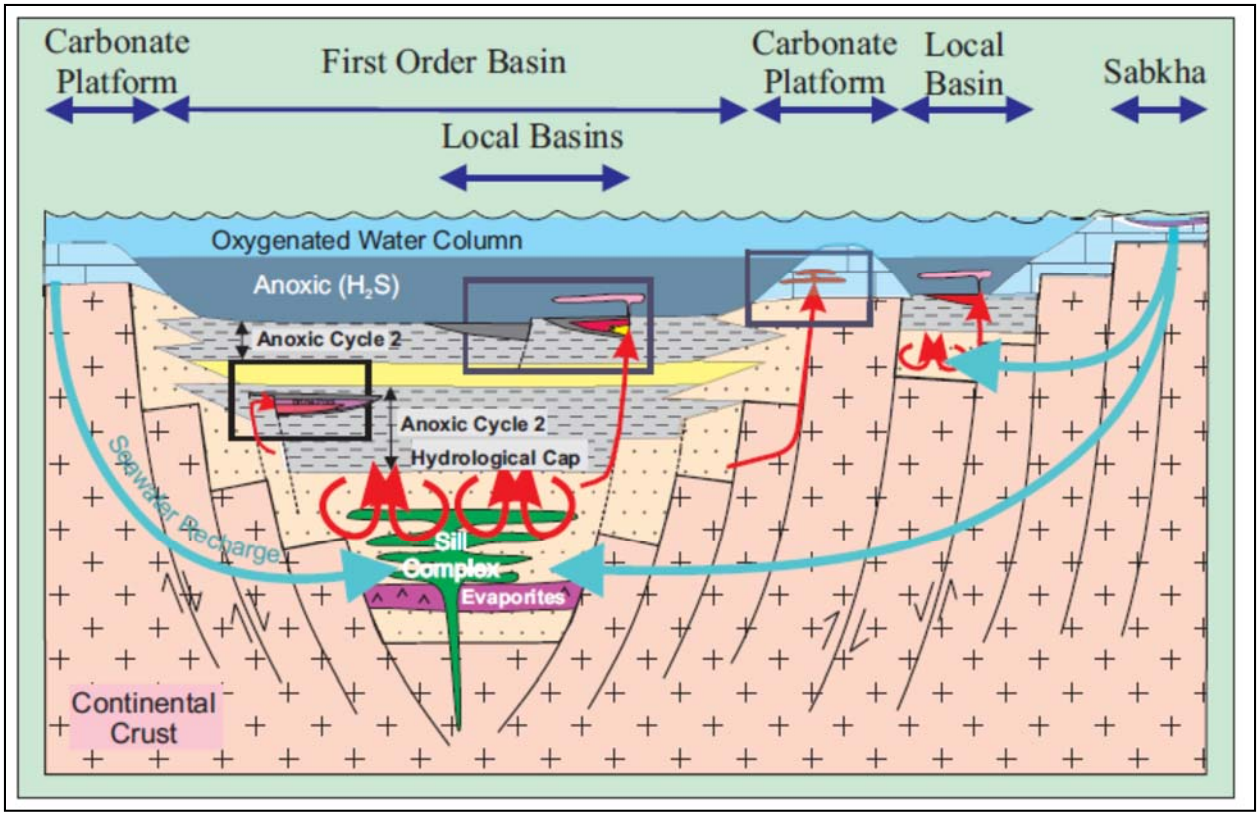

Figure 6-1: Genetic model of SEDEX deposit formation (Goodfellow & Lydon 2007).

Extensive research has been conducted on SEDEX deposits examining the geological characteristics, genetic models and the physiochemical controls (MacIntyre, 2008). This work has resulted in a general consensus regarding the formation of SEDEX deposits within the Selwyn Basin and Kechika Trough. It is

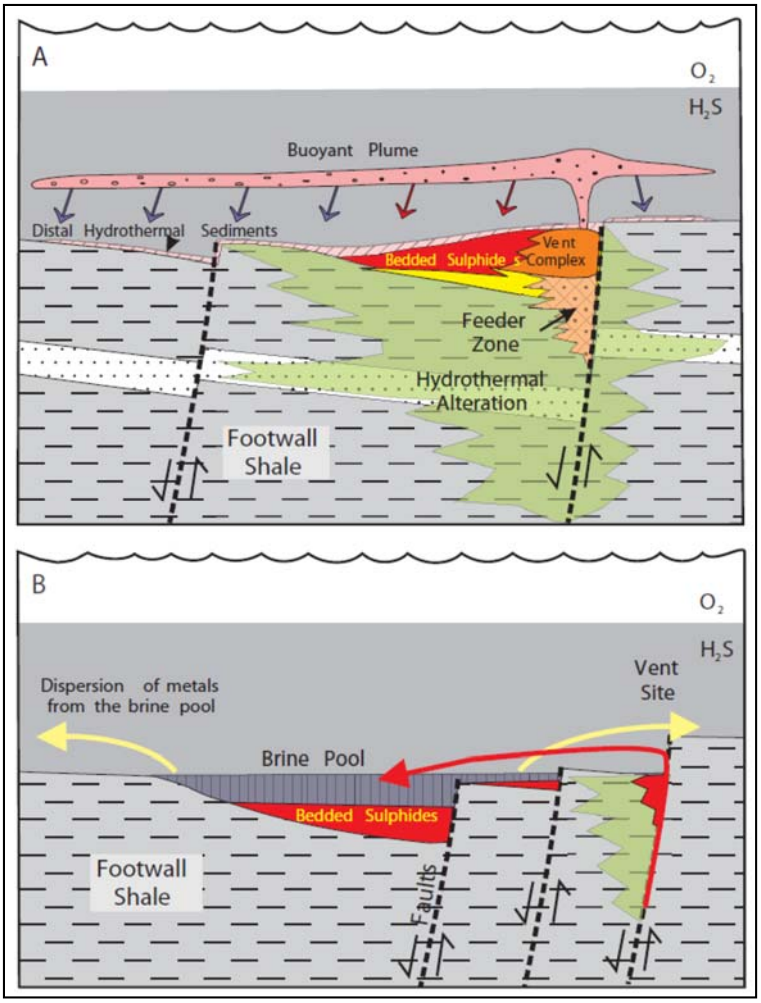

Figure 6-2: Vent-proximal and vent-distal sub-type of Selwyn Basin SEDEX type deposits (Goodfellow & Lydon 2007).

generally thought that these SEDEX deposits are formed from the precipitation of sulphide and sulphate minerals from metalliferous brines exhaled out onto the seafloor along re-activated rift faults that are generated by rapidly subsiding graben or half-graben structures (MacIntyre, 2008; Goodfellow and Lydon, 2007). The metal-bearing fluids are likely derived from dewatering of fine to coarse grained clastic sediments or carbonate hydrothermal reservoirs (Goodfellow and Lydon, 2007) where leaching has scavenged the zinc and lead and other elements (Figure 6-1). In the Selwyn Basin and the Kechika Trough the coarse clastic grits of the Windermere Super Group are thought to have acted as the hydrothermal reservoir for the mineralizing fluids (MacIntyre, 2008).

Goodfellow and Lydon (2007) recognized two sub-types of SEDEX deposits: vent-proximal and vent-distal. The two type of deposits result from either a buoyant metalliferous brine that precipitates sulphides in close proximity to the source fault structure or a bottom hugging brine that precipitates sulphide mineralization within localized third order basins at a distance from the source fault structure (Figure 6-2). Examples of the vent-proximal deposits include Sullivan, Tom, Jason and Rammelsberg and are characterized by four distinct features including: bedded sulphides; a recognized vent complex; a stringer zone; and distal hydrothermal sediments (Goodfellow and Lydon, 2007). Vent-proximal deposits are typically wedge-shaped, exhibiting a moderately high aspect ratio of length versus thickness. In contrast, vent-distal deposits have well-bedded sulphides, are generally weakly zoned and their morphology conforms to the local basin. This type of deposit is typically tabular to sheet-like in nature with very high aspect ratios (Goodfellow and Lydon, 2007).

Typically, SEDEX deposits are hosted in basinal marine sediments such as fine-grained clastics, carbonaceous chert and shale. In some cases, the shale can be interbedded with turbiditic siltstone and sandstone and localized coarse grained sediments (Goodfellow and Lydon, 2007).

The mineralogy associated with this type of deposit is relatively simple with pyrite, sphalerite, galena and barite being most common. Associated with these minerals are a suite of elements that may include: Fe, Mn, P, Ca, Mg, Hg, Cd, As, Sb, Se, Sn, Ga, Bi, Co, Ni, and Tl (Goodfellow and Lydon 2007). Typically the gold content of this type of deposit is quite low; however, deposits found in Anvil district (Vangorda, Dy) of the Selwyn Basin in the Yukon territory contained mineable grades of the precious metal

(Goodfellow and Lydon, 2007). These elemental enrichments commonly exhibit a refined zonation across many of the deposits allowing specific ratios to be utilized as exploration tools guiding exploration towards possible source vents and economic deposits (Goodfellow and Lydon, 2007). Common metal ratios include: Zn/Pb, Pb/Ag, Cu/(Pb+Zn), Pb/(Pb+Zn), Fe/Zn, Ba/Zn and SiO2/Zn (Goodfellow and Lydon, 2007).

7.0 Exploration Program

7.1 Introduction

The 2014 exploration program on the Yuen North property was based out of a trailer camp located at the 24.5 kilometre mark of the Akie mainline forestry service road. The camp is situated in an old Canfor forestry cut block (Plate 7-1). The seasonal camp can accommodate up to a maximum of 50 people and re-opened in early June to support the drilling program occurring concurrently with exploration on the Yuen North property. A couple of reconnaissance flights of the property were conducted on the 12th and 18th of June to inspect snow loads in the vicinity of the planned work. The field program began on the 26th of June and continued until the 4th of July. The camp was closed and winterized on 20th of July. Exploration personnel for the duration of the program consisted of seven people.

An expediter in Mackenzie provided logistical support for the camp, arranging the shipment of major supplies. Minor supplies were obtained locally from the village of Tsay Keh Dene located at the northern end of the Williston Lake reservoir. There were a variety of contractors on site providing services to the program. The key contractors are listed below.

- **Coast Mountain Geological Inc.:** Provided logistical support and technical staff such as geologists and geotechnicians.
- **Yellowhead Helicopters:** Provided helicopter support to the project.
- **ESS:** Provided catering and management services for the camp.
- **Kwadacha Natural Resources LP and Chu Cho Industries LP:** Provided field assistants and local labour services.

Plate 7-1: Akie camp photograph (Photo by G. Graham 2011)

Claimed expenditures on the Yuen North property during the 2014 exploration program total $55,906.77 spent primarily on the soil sampling program. The breakdown of these costs can be found in Section 12.0 Statement of Expenditures.

7.2 Program Objectives

The 2014 exploration program on the Yuen North property consisted of a small soil sampling program focused on the confirmation, infill and expansion of the historical soil anomalies defined over the western panel of Earn Group stratigraphy.

7.3 Field Protocol

The field procedures implemented during the course of the 2014 exploration program are outlined below

7.3.1 Sampling Procedures

Soil samples were collected at 50 metre stations along a series of regularly spaced lines across the western panel of Earn Group stratigraphy on the Yuen North property. An approximate 500 gram sample was collected from the B soil horizon, if possible, after the removal of humus and other overburden and placed into a paper Kraft bag. Soil samples were marked in the field with fluorescent flagging tape tied nearby and each sample was GPS located and described. Bags were then sealed and transported to camp in clear polypropylene bags. Once in camp, soil sample bags were hung to dry. Once dry, the soil samples were laid out in order and bundled together in approximate groups of 20 and placed into a clean and clear polypropylene plastic sample bag. The samples were packed in such a manner to give the sample bag a brick like shape and taped shut. Two or three bricked bundles were then placed into large rice bags and sealed with a zap strap ready for shipment to the laboratory.

Grab rock samples of key lithologies and outcroppings of interest were collected, described, and placed into a clear polypropylene sample bag. Each sample was GPS located and given a sample tag, also placed in the bag and sealed with flagging tape. In camp samples were properly sealed with zap straps and placed into a large rice bag with 5 to 10 samples in each bag. The rice bags were sealed with zap straps and ready for shipment to the laboratory.

7.3.2 Analytical Procedures

Acme Analytical Laboratories Ltd., now a Bureau Veritas Commodity Canada Ltd. company, analyzed all of the 2014 soil and rock samples. The laboratory is located at 9050 Shaughnessy St. in Vancouver, British Columbia. The Vancouver facility is an ISO 9001 and ISO/IEC 17025:2005 accredited laboratory.

<u>Soil Samples</u>

The preparation of all soil samples were completed using Acme's SS80 package which involves drying the samples at 60 degree Celsius and sieved using an 80 mesh screen. The screens are cleaned by brush and compressed air between samples. After preparation, a number of analytical packages were conducted on the samples.

All samples were analysed using Acme's AQ250-EXT package (Group 1F legacy code). A 0.5 gram sample is taken from the sieved material and digested with a modified Aqua Regia solution consisting of equal parts of concentrated HCL, HNO3, and DI H2O in a heating block or a hot water bath. The sample is made up to a volume of dilute HCL and analysed for a suite of 54 elements using inductively coupled plasma

emission spectrometry (ICP-ES) as well as inductively coupled plasma mass spectrometry (ICP-MS). The key elements are Pb, Zn, Ag, Tl, and Fe. Due to the insoluble nature of barite whole rock analysis was completed using Acme's LF300/302 package (Group 4A legacy code). This involves a total fusion of a 0.2 gram split of the pulp using a lithium metaborate flux followed by digestion in dilute nitric acid. Subsequent analysis by inductively coupled plasma emission spectrometry (ICP-ES) returns a suite of 11 major oxides and 9 elements. The key element of interest was barium (Ba) with a lower detection limit of 5 ppm and an upper limit of 50,000 ppm.

Rock Samples

All rock samples were prepared using Acme's PRP70-250 package which involves crushing the samples to the point where 70 % of the material passes through 10 mesh (2mm) sieve. A 250 gram sub-sample is then pulverized to 85 % passing through a 200 mesh (75 microns). The crusher and pulveriser are cleaned by brush and compressed air between routine samples. The equipment is also cleaned after any high grade samples, changes in rock colour and at the end of each sequence of samples with a granite/quartz wash.

All samples were analysed using the same analytical packages described above. For litho-geochemical purposes the entire suite of 11 oxides and 9 elements were reported on from the LF302 package.

Sample Security and QA/QC

All samples were stored and kept dry in a canvas tent located in close proximity to the office trailer to await transportation. Prior to shipping, the contents of each rice bag are catalogued and weighed. A copy of the analysis forms and the shipment catalogue are placed in the first bag of the shipment. Additional copies of the forms are sent to the lab in advance of a sample shipment and a copy is kept in camp for sample tracking purposes. The samples are then shipped backhaul via Gautier Ventures to Mackenzie and temporarily stored under the supervision of the camp expediter, Vicki Podgorenko. From Mackenzie the samples are then shipped to Acme Analytical Laboratories in Vancouver via bonded carriers such as Canadian Freightways and Liberty Transport.

Acme Labs implement a strict QA/QC program beginning at the sample preparation stage with cleaning in between each sample as mentioned above. During analysis, the lab utilizes a series of analytical blanks, duplicates and standards that are regularly inserted into the sample stream to monitor analytical precision, accuracy and variations within the samples. Prior to release each job is rigorously reviewed and validated by a certified assayer. Using Acme's online "Lims" system the client can monitor the progress of a given sample batch from arrival, preparation through to analysis. The certificates are delivered via email in Pdf format and the data is also provided in spreadsheet .csv format. Copies of these certificates and spreadsheets are archived on the Lims system, accessible by the client at any time.

7.4 Soil Sampling Program

The 2014 soil sampling program was conducted within a NW-SE trending river valley, the adjacent saddle and a west-facing cirque that is centrally located on the Yuen North property. The grid consisted of thirteen NE-SW trending 400 or 200 metre spaced lines oriented perpendicular to the trend of the topography and known geological strike. Samples were collected every 50 metres. The 400 metre spaced lines covered the known soil anomalies and the 200 metre spaced lines at the SE end of the grid provided infill and expansion coverage. A total of 222 samples were collected. Due to the poor development of the soil profile, samples were collected from a variety of horizons including A, B, C and soils mixed with talus where a soil profile was not present. Maps displaying sample locations and key elements along with a table of results is presented in Appendix 2. The analytical certificate is presented in Appendix 4.

The target of the planned sampling was the western panel of Earn Group stratigraphy that transects the property, host to a number of mapped barite horizons (Appendix 1), and is situated along strike from the Mt. Alcock Main Barite showing to the northwest (Plate 7-2) and the Cirque deposit to the southeast (Plate 7-3). Previous work had outlined a linear 2.8 kilometre long by 250 metre wide Ba anomaly which contained localized Pb anomalies and a 1 kilometre long by 150 wide Zn anomaly with corresponding elevated Ag values.

Plate 7-3: Soil sampling grid on the Yuen North property looking SE towards Yuen and Cirque properties. (Photo by N. Johnson 2014).

7.4.1 Results

The historical soil sampling programs focused strictly on Pb, Zn, Ba with some Ag analyses. Samples from the 2014 program were analysed for a suite of 54 elements with the key elements being Pb, Zn, Ag, Tl, Fe and Ba. Some basic statistics for the key elements of interest are summarized in the Table 7-1 below.

Element	Samples (n)	Population (~)	Mean (ppm)	Std Dev (ppm)	90% (ppm)
Pb	222	Bimodal (?)	36	31	76
Zn	222	Normal	342	382	831
Ag	222	Left Skewed	807 (ppb)	700 (ppb)	1703 (ppb)
Ba	222	Left Skewed	4274	4521	10,068
Fe	222	Normal	2.21 (%)	1.60 (%)	4.26 (%)
Tl	222	Left Skewed	0.84	1.29	2.49

Table 7-1: Summary of basic statistics from the 2014 soil sampling program.

A general comment regarding the statistics is necessary. Due to the lack of a well-defined soil profile across the sampled grid the statistics presented above are not representative of a single preferred soil horizon but rather represent the sample set as a whole with samples taken from several soil horizons. Despite this limitation some general observations can be made. A brief description of the results for each of the key elements is presented below.

ESRI's ArcView software package was used to generate the contours and interpretive rasters presented in Figures 7-2 to 7-10. Interpolation of the key elements was conducted utilizing the software's nearest neighbor technique producing a raster image bounded strictly to the 2014 soil grid. No extrapolation of information was allowed beyond the defined edges of the soil grid. Contours of a specified value were then extracted from the raster images and displayed.

Lead

The Pb population from the 2014 dataset appears to display a possible bimodal distribution with a second population centered on ~100 ppm (Figure 7-1), however the data to support this conclusion is limited and larger population of soil samples would be required to determine its validity. The second population does however coincide with the 90th percentile value of 76 ppm. Alternatively, this second population may simply represent samples taken from one of the other soil horizons, which is a strong possibility.

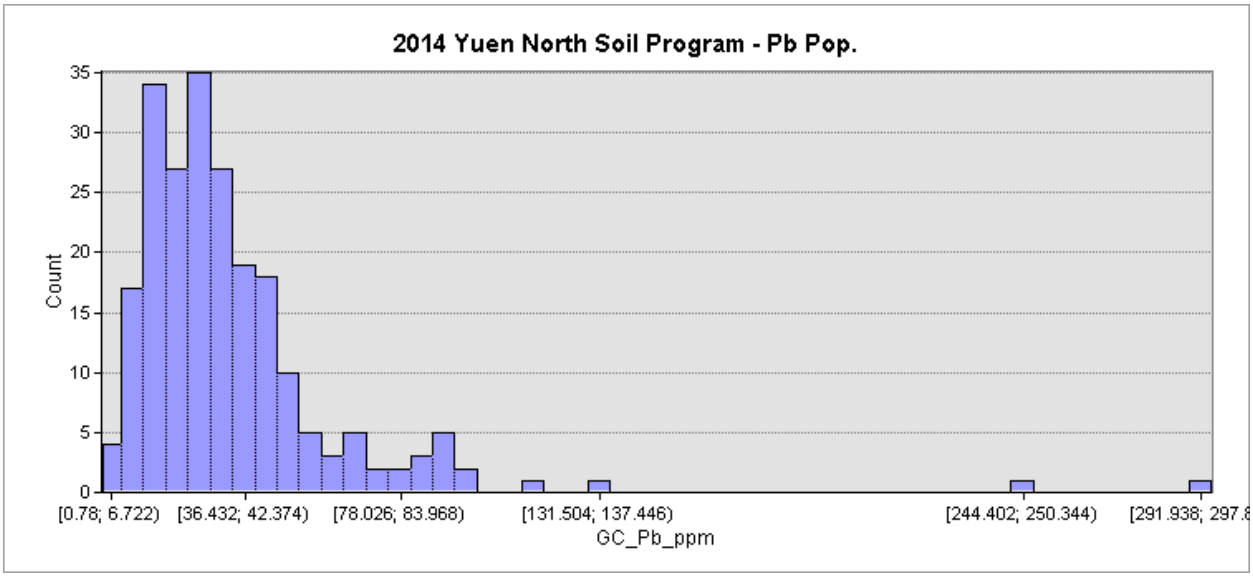

Figure 7-1: Pb population distribution with possible second population above 75 ppm.

An examination of the Pb data across the soil grid indicates the presence of three distinct areas of elevated values (Figure 7-2). The first, and most prominent, trend is linear in nature extending for approximately 2 kilometres across much of the grid and appears to be open ended along the western edges. Values range from the 60th percentile value of 44 ppm up to 247.24 ppm. The second trend is also linear extending across five lines for approximately 800 metres and is located within a west-facing cirque along the western edges of the grid. It appears to be open ended. Lead values range from the 60th percentile value of 44 ppm to a maximum of 132.46 ppm. The third area is a single station soil sample located in the central portion of the grid with a value of 98.8 ppm surrounded by numerous samples above the 60th percentile value of 44 ppm. Elsewhere on the grid there is a scattering of elevated values that demonstrate little continuity. A detailed map with all of the Pb values is presented in Appendix 2. The analytical certificate is presented in Appendix 4.

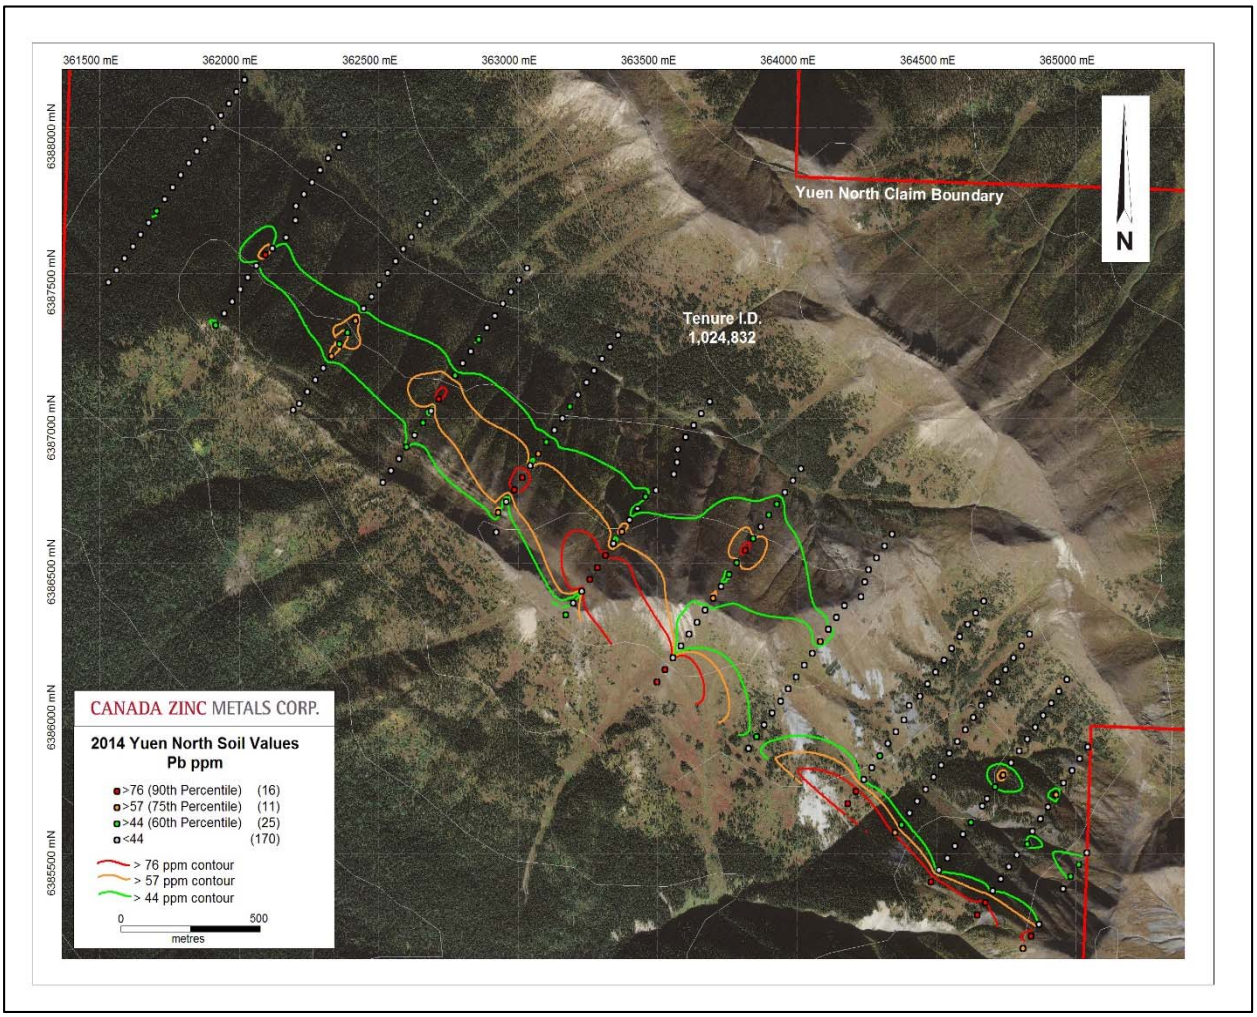

Figure 7-2: Interpolation of the 2014 Pb soil results.

Zinc

Zinc values across the grid display similar trends to the Pb values (Figure 7-3). A prominent linear trend extends across the central portion of the grid for approximately 2.4 kilometres with Zn values ranging from the 60th percentile value of 439 ppm up to a maximum of 2,484.1 ppm. This trend is coincident with the trend observed in the Pb values. There are a couple of single station values situated near the valley bottom along the eastern edges of the grid that show some continuity across two lines with values of 1,968.9 and 1,697.8 ppm . A single station sample located in the cirque along the southeastern portion of the grid with an elevated Zn value of 1,321.1 ppm is coincident with the Pb trend. Elsewhere on the grid the Zn values are scattered demonstrating little continuity. A detailed map with all the Zn values is presented in Appendix 2. The analytical certificate is presented in Appendix 4.

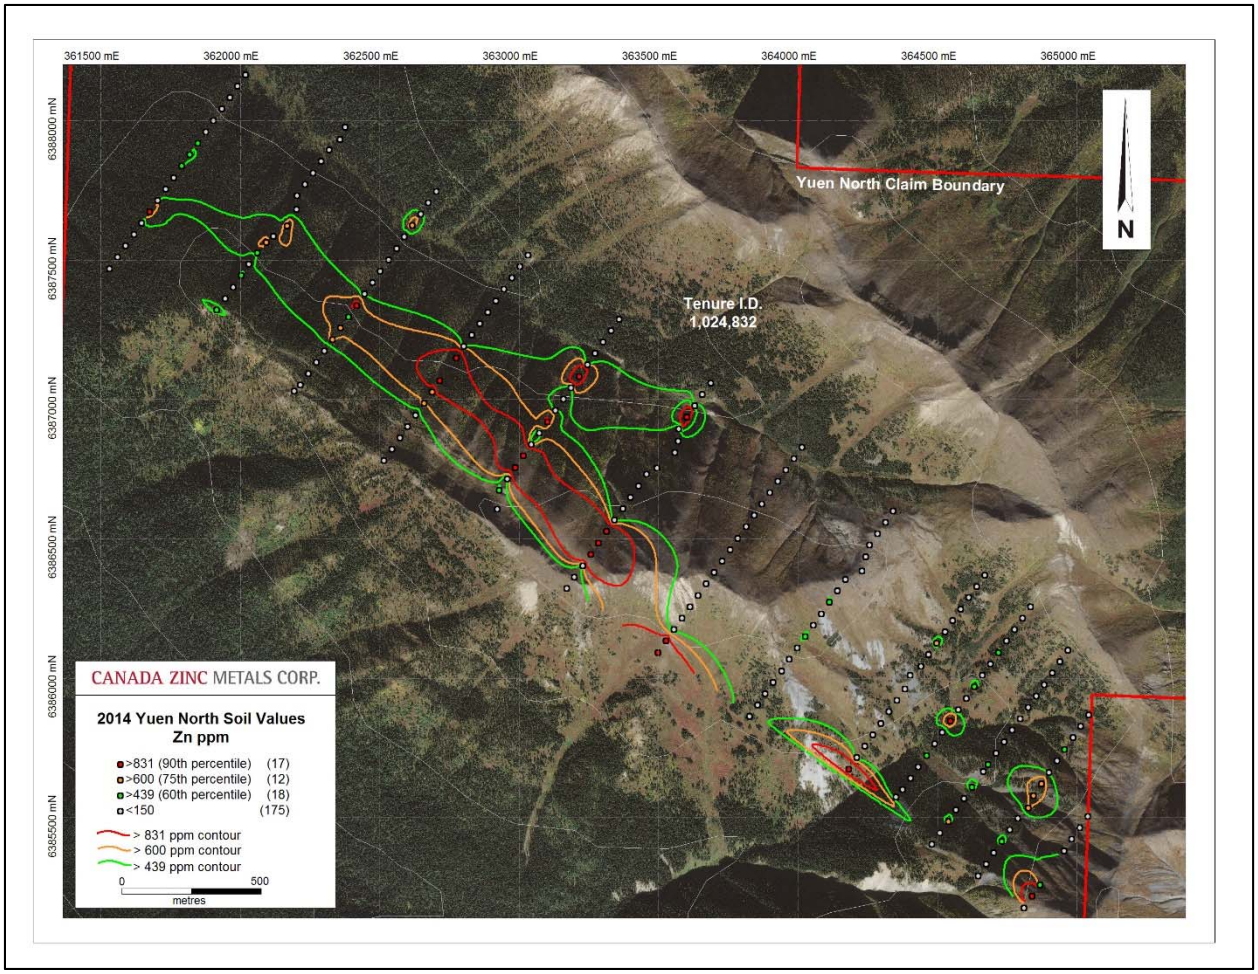

Figure 7-3: Interpolation of the 2014 Zn soil results.

Silver

There appears to be two distinct areas of elevated Ag values on the grid (Figure 7-4). The main linear trend, mimicking Pb and Zn, extends across the main portion of the grid covering 2.2 kilometres with values ranging from the 60th percentile of 984 ppb up to a maximum of 4,318 ppb (4.3 ppm). The second is a wide, roughly linear area located along the southeastern edges of the grid extending over six lines. Silver values range from the 60th percentile of 984 ppb up to a maximum of 5,127 ppb (5.1 ppm). The second area appears to be open ended on the southeastern and western edges and roughly coincides with the Pb and Zn trends observed in this area. A detailed map with all the Ag values is presented in Appendix 2. The analytical certificate is presented in Appendix 4.

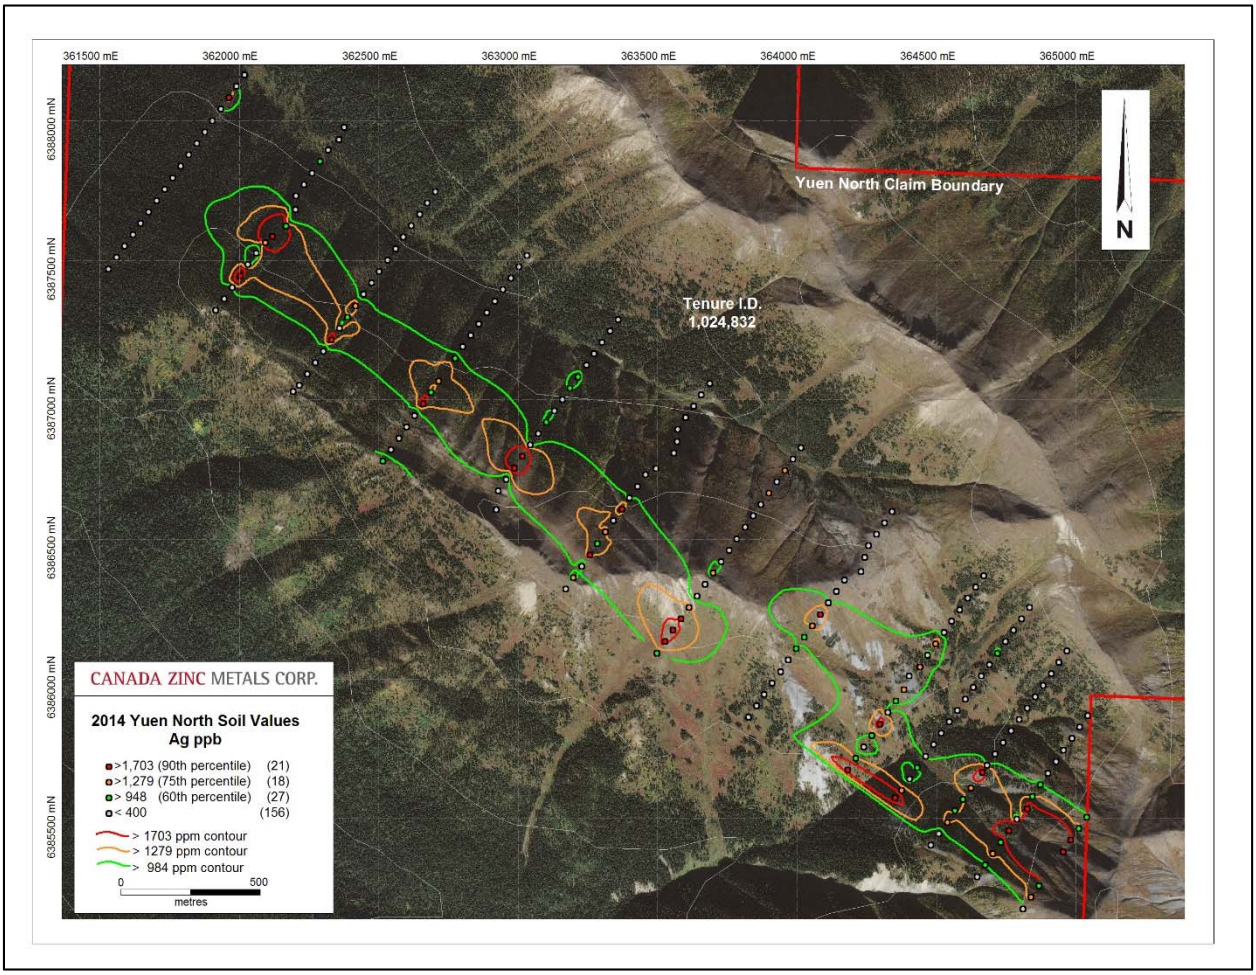

Figure 7-4: Interpolation of 2014 Ag results.

Thallium

Thallium, a known trace element of the Cardiac Creek deposit has a somewhat contrasting response compared to the other elements (Figure 7-5). There is a roughly linear area of elevated values covering five lines along the western edges of the grid in the southeast. This area is roughly 800 metres long and 150 metres wide with values ranging from the 60th percentile of 1.17 ppm up to a maximum of 14.81 ppm. This area is coincident with the larger Ag and smaller Pb and Zn areas described previously. The prominent Pb, Zn, and Ag trend observed across the main portion of the grid is poorly defined by Tl values slightly above background. In central portion of the grid there is a multi-station area with a weakly defined linear trend with values ranging from the 60th percentile of 1.17 ppm up to a maximum of 2.99 ppm. A detailed map with all the Tl values is presented in Appendix 2. The analytical certificate is presented in Appendix 4.

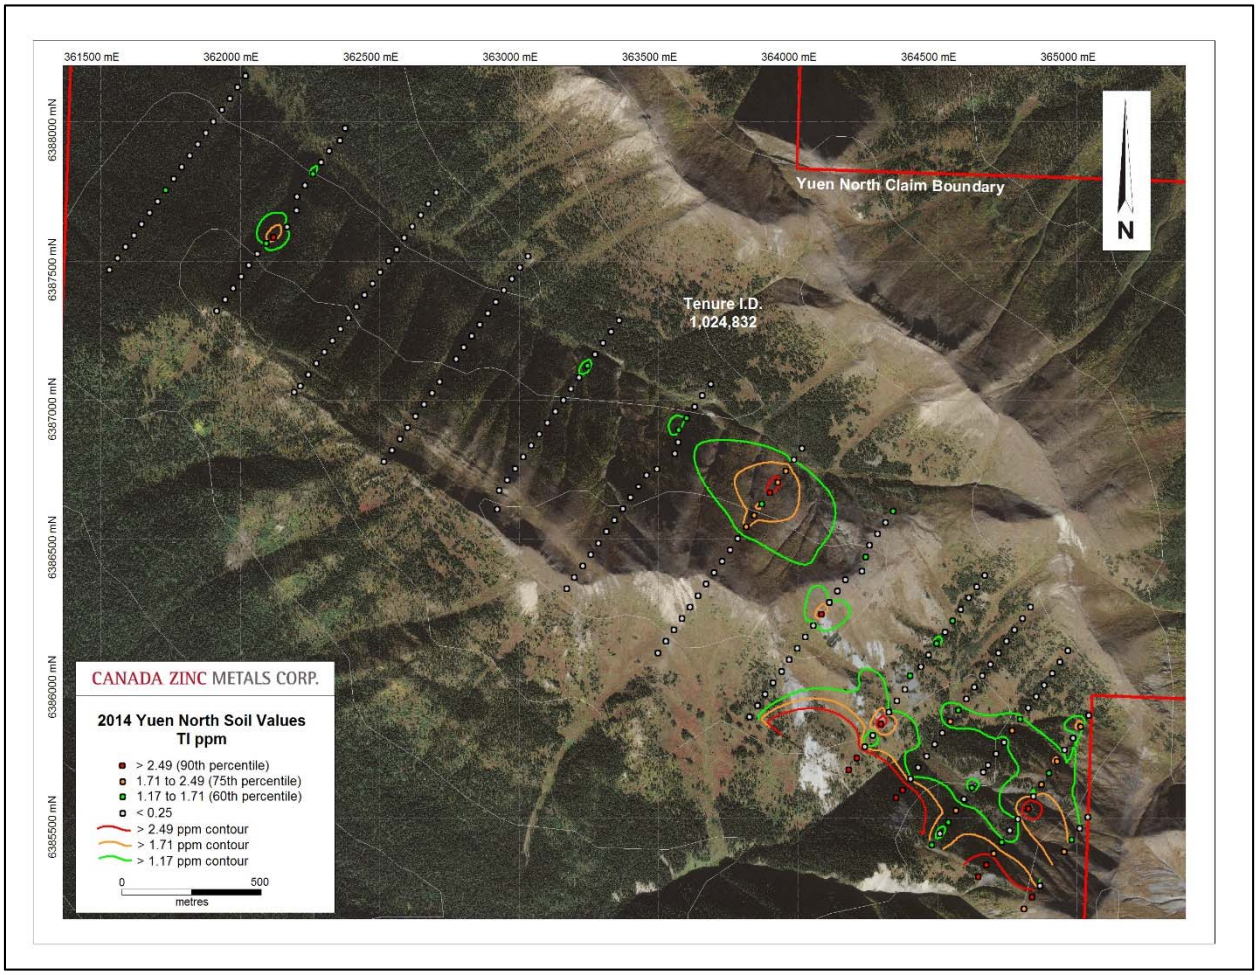

Figure 7-5: Interpolation of the 2014 Tl results.

Iron

The Fe response is quite similar to Tl with two distinct areas of elevated values (Figure 7-6). The first is coincident with the Pb, Zn, Ag, and Tl response in the southeastern portion of the grid along the western edge and situated in the valley bottom of a west facing cirque. Iron values range from the 60th percentile of 2.62 % up to a maximum of 11.62 %. A three line linear trend of elevated Fe values defines the second area that is located and runs parallel to the valley bottom. Values ranges from the 60th percentile of 2.62 % up to a maximum of 14.52 %. This trend is coincident with the Tl response and several isolated values of Pb, Zn and Ag. The prominent Pb, Zn, Ag linear trend across the central portion of the grid is very poorly defined by values slightly exceeding background. A detailed map with all the Fe values is presented in Appendix 2. The analytical certificate is presented in Appendix 4.

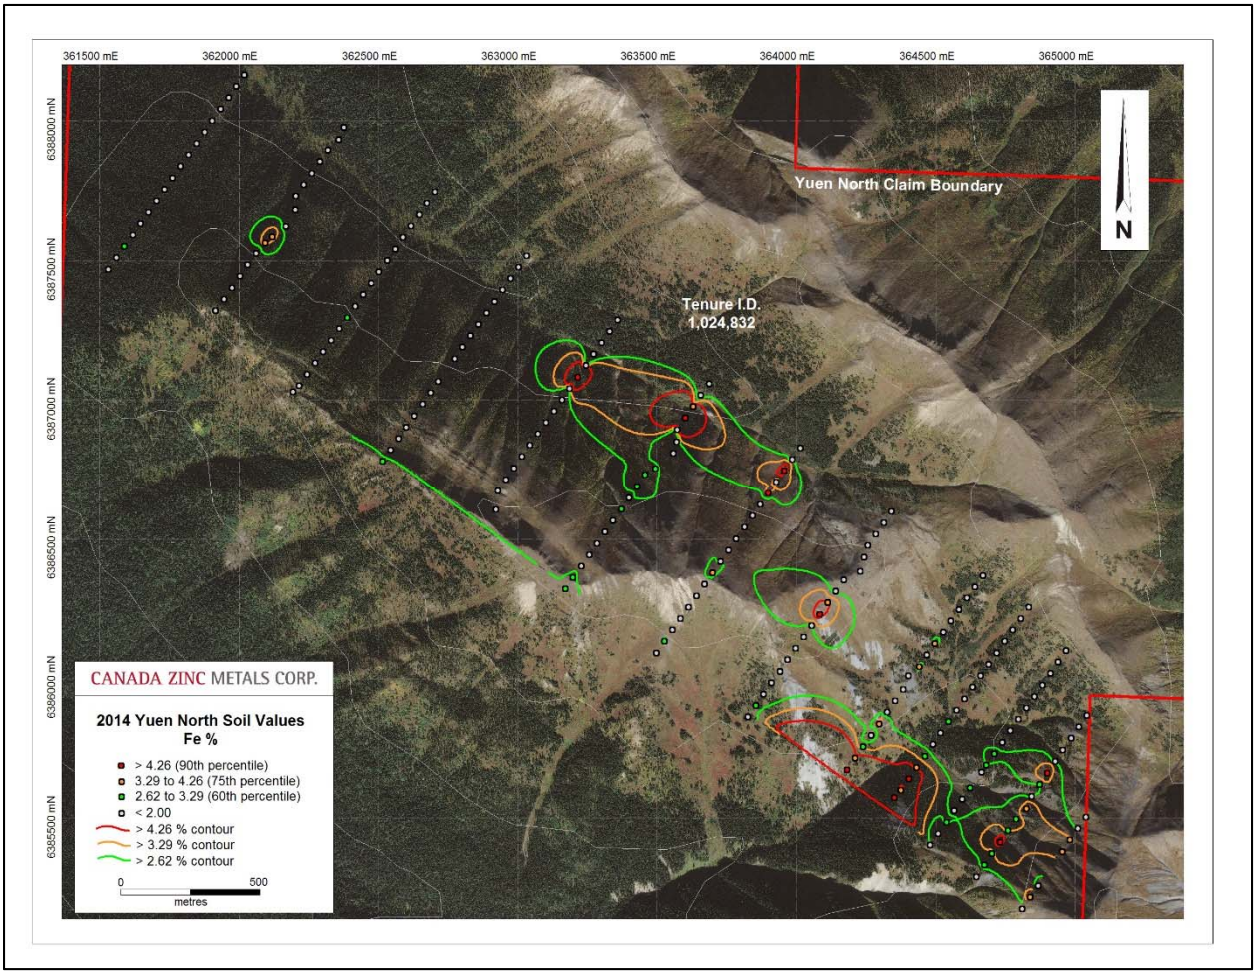

Figure 7-6: Interpolation of the 2014 Fe results.

Barium

There appears to be two distinct areas of elevated Ba values across the grid. The first is a very strongly defined linear trend extending across almost the entire grid for 2.8 kilometres that is situated along the eastern edges of the grid running parallel to the valley bottom. At the northwest end of the grid it appears that a weaker secondary trend merges with the main trend at an angle and is coincident with the prominent trend defined by Pb, Zn and Ag. Ba values range from the 60th percentile value of 5,419 ppm up to a maximum of 27,736 ppm (2.77 %). The second area is located in the southeastern portion of the grid along its western edges and is coincident with the area defined by Pb, Zn, Ag, Tl, and Fe. Values range up to a maximum of 21,619 ppm (2.16 %). A detailed map with all the Ba values is presented in Appendix 2. The analytical certificate is presented in Appendix 4.

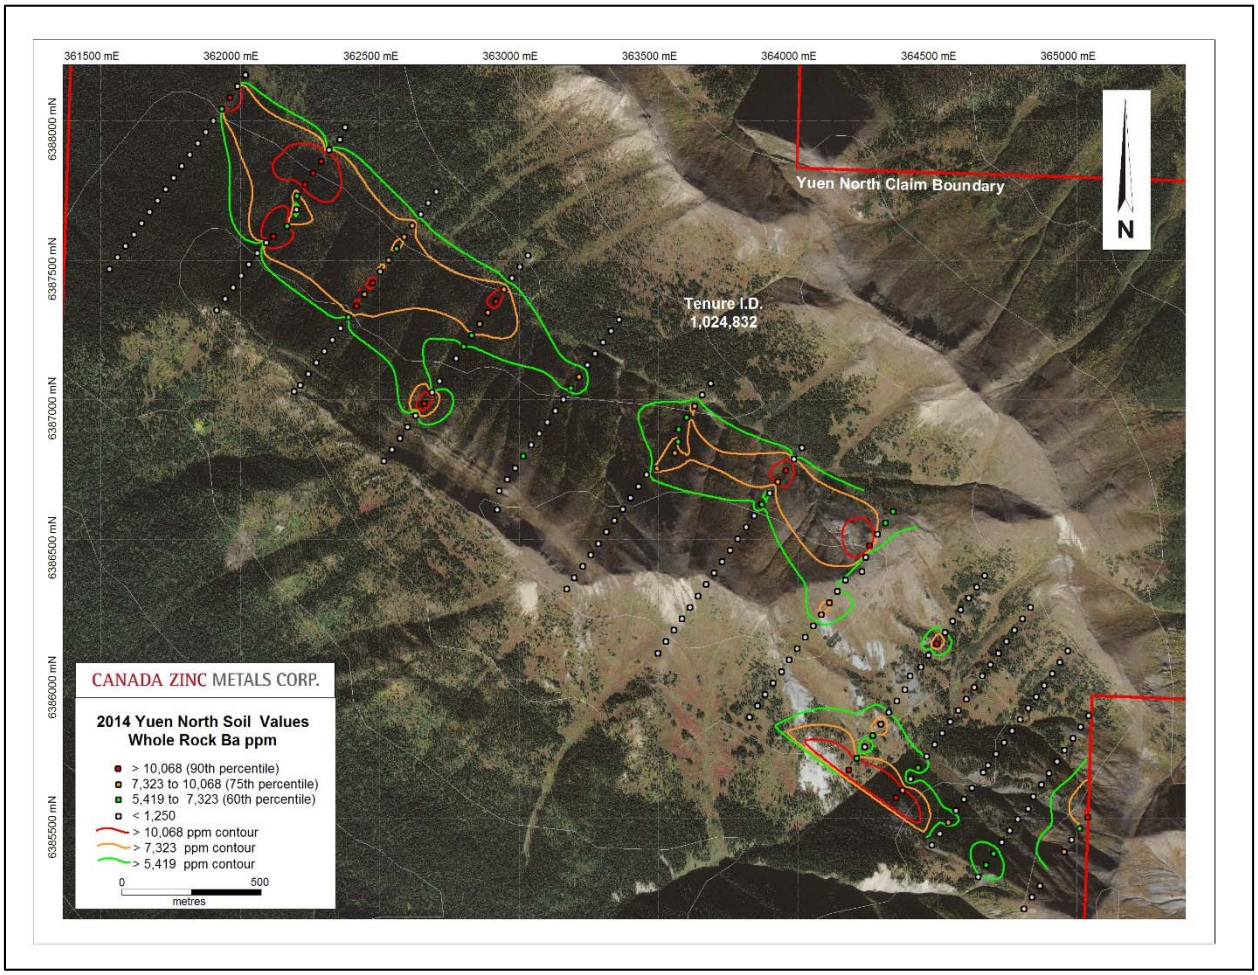

Figure 7-7: Interpolation of the 2014 Ba results.

7.5 Rock Sampling

A total of 17 rock samples were collected during the soil sampling program. Several samples were highly anomalous in barium (>1 %) due to the presence of nodular to laminar bedded barite however there were no other significant results. Maps displaying sample locations and values for Pb, Zn, Ag, Tl, Fe, and Ba along with a table of results are presented in Appendix 3. The analytical certificate is presented in Appendix 4.

7.6 Discussion

A general comment regarding the 2014 soil sampling program in relation to the historical programs. Given the difficulty in obtaining the preferred soil horizon due to the lack of a well-defined soil profile it is suspected that the historical programs in 1980 and 1981 would have encountered similar problems in areas above the tree line with little vegetation.

The primary objective of the soil sampling program was to confirm the historical soil anomalies outlined in the 1980 and 1981 programs. The most comprehensive soil sampling program on the Yuen North

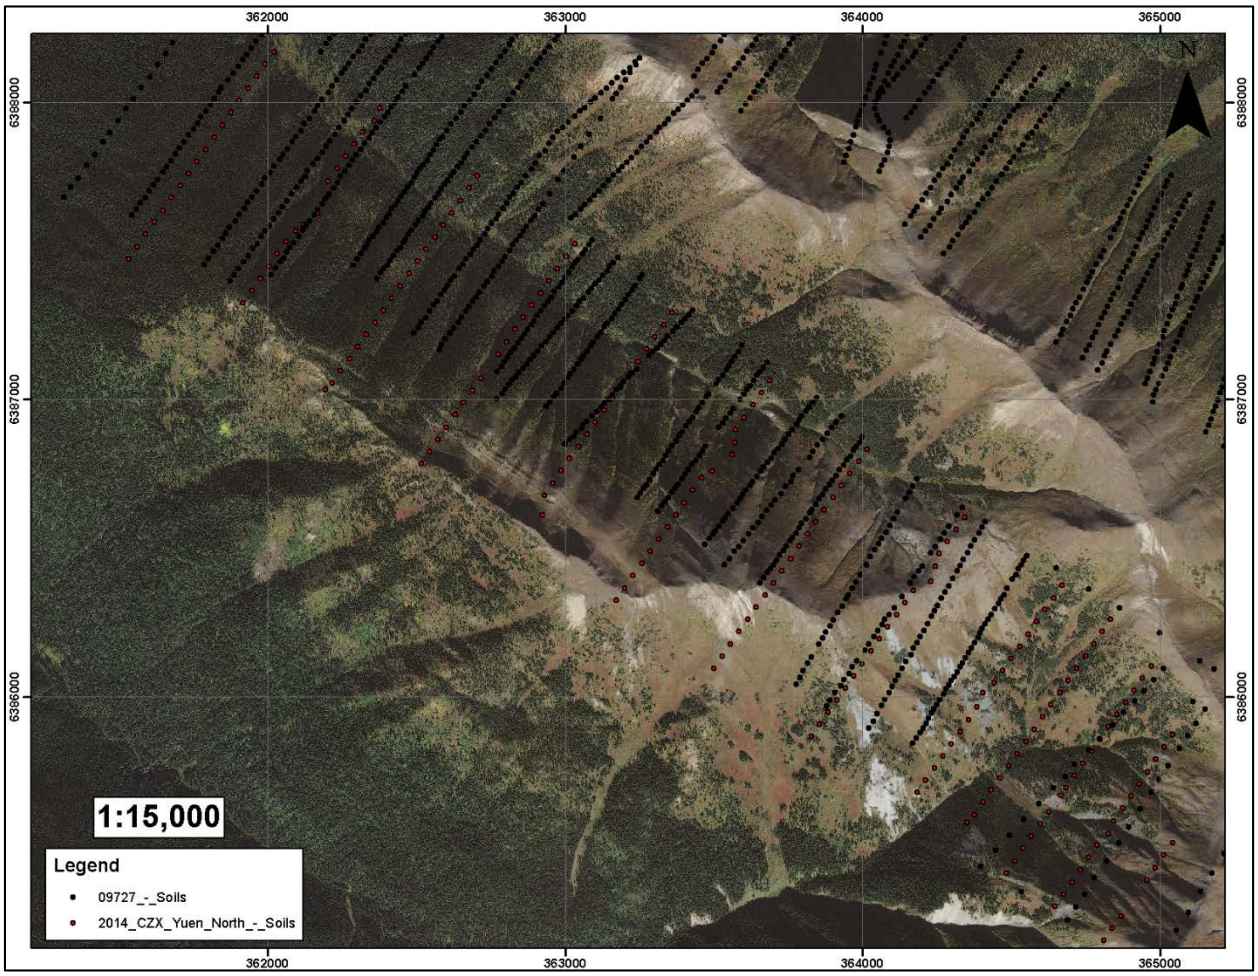

Figure 7-8: The 1981 soil sample locations (black) compared to the 2014 soil samples (red).

property (historically named the South Kwad property) was conducted in 1981 by Cominco Ltd. Figure 7-8 displays the 1981 soil samples, as presented in Assessment Report 09727 in relation to the 2014 soil sampling program.

The 1981 program analysed strictly for Pb, Zn, Ag and Ba and no other elements. The results of this early work outlined a number of Pb, Zn, Ag, and Ba anomalies over the western panel of Earn Group stratigraphy based on the following thresholds: 50 ppm Pb, 1,000 ppm Zn, 1 ppm Ag, and 5,000 ppm Ba (Waters 1981). Interpolations of these anomalies using the thresholds as determined by Waters in (1981) are presented in comparison with the 2014 results in Figures 7-9 and 7-10. The correlation of the Pb results (Figure 7-9) appears to be quite good with only minor variations between the 1981 interpolation and 2014 results. Additionally, the 2014 sampling appears to have extended the known Pb anomalies further to the west.

Both Zn (Figure 7-9) and Ag (Figure 7-10) display some inconsistencies between the 2014 results and the 1981 interpolation. The 2014 Zn results appears to correlate with the main trend present in the 1981 interpolation however there are scattered elevated values elsewhere that are not present in the interpolation. The 2014 Ag results show excellent correlation with the 1981 interpolation in the southeast section of the grid however there is a mixed response across the main portion of the grid with some low 2014 values present over the highs in the interpolation and vice versa.

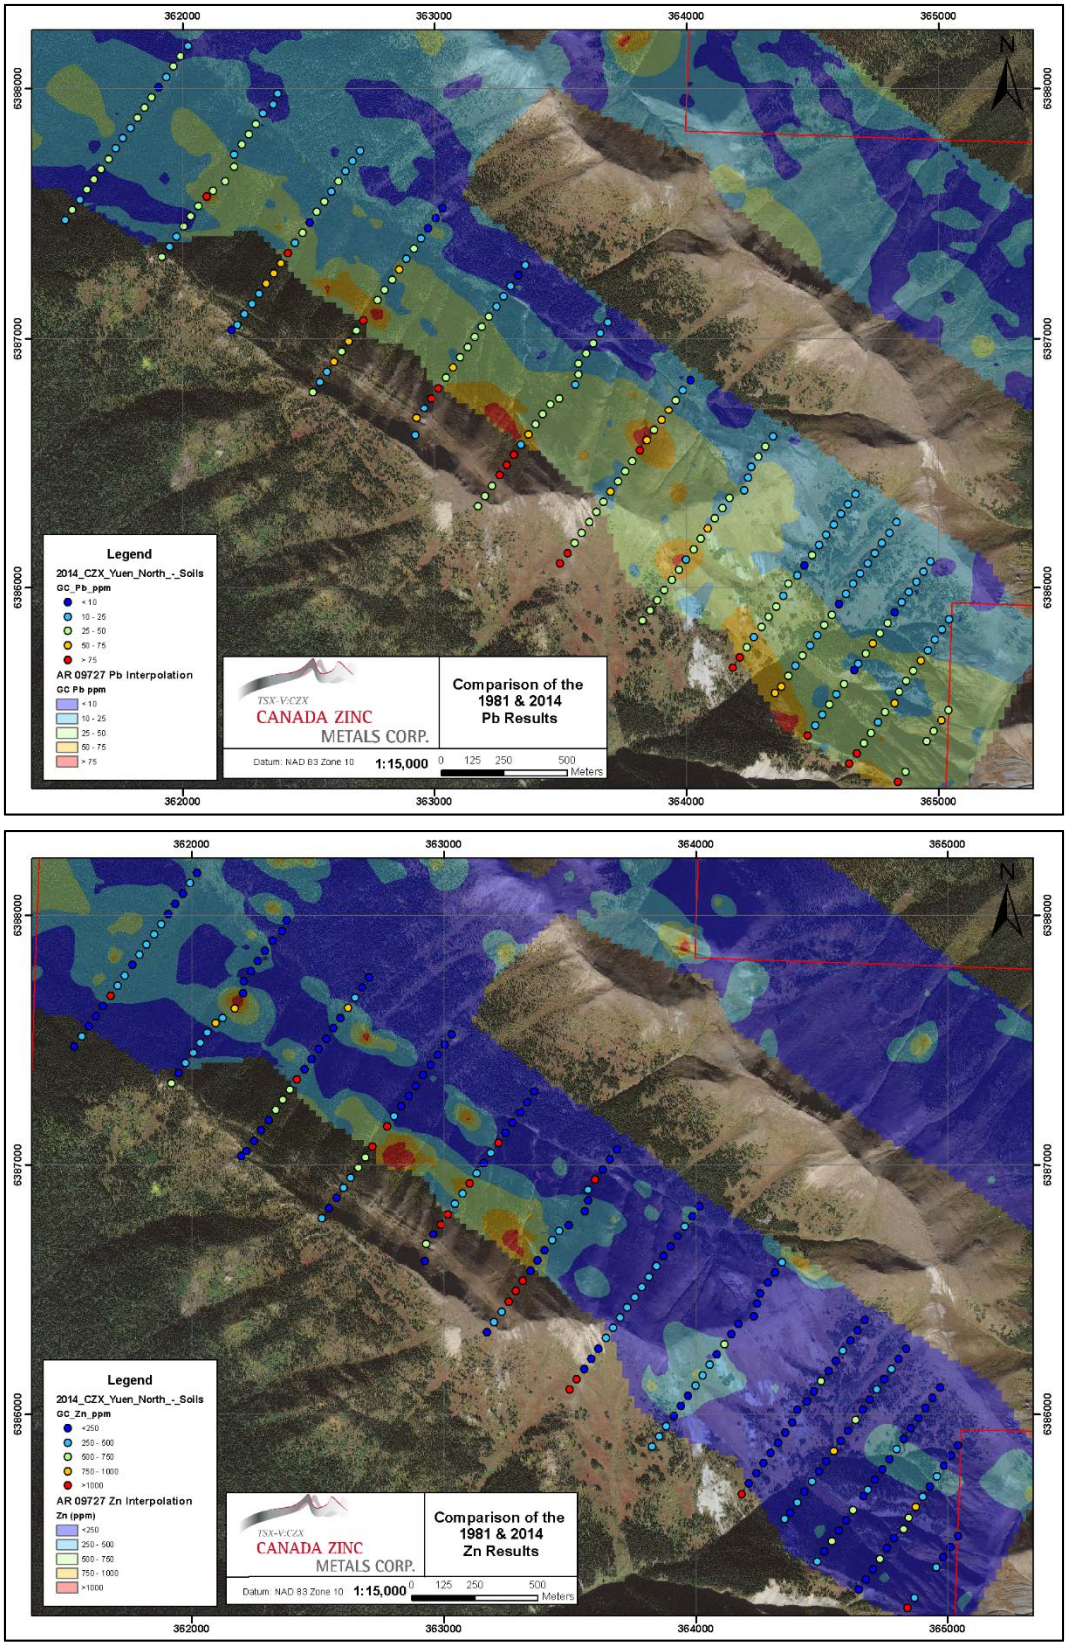

Figure 7-9: Comparison between the 1981 (interpolation) and 2014 Pb (top) and Zn (bottom) results.

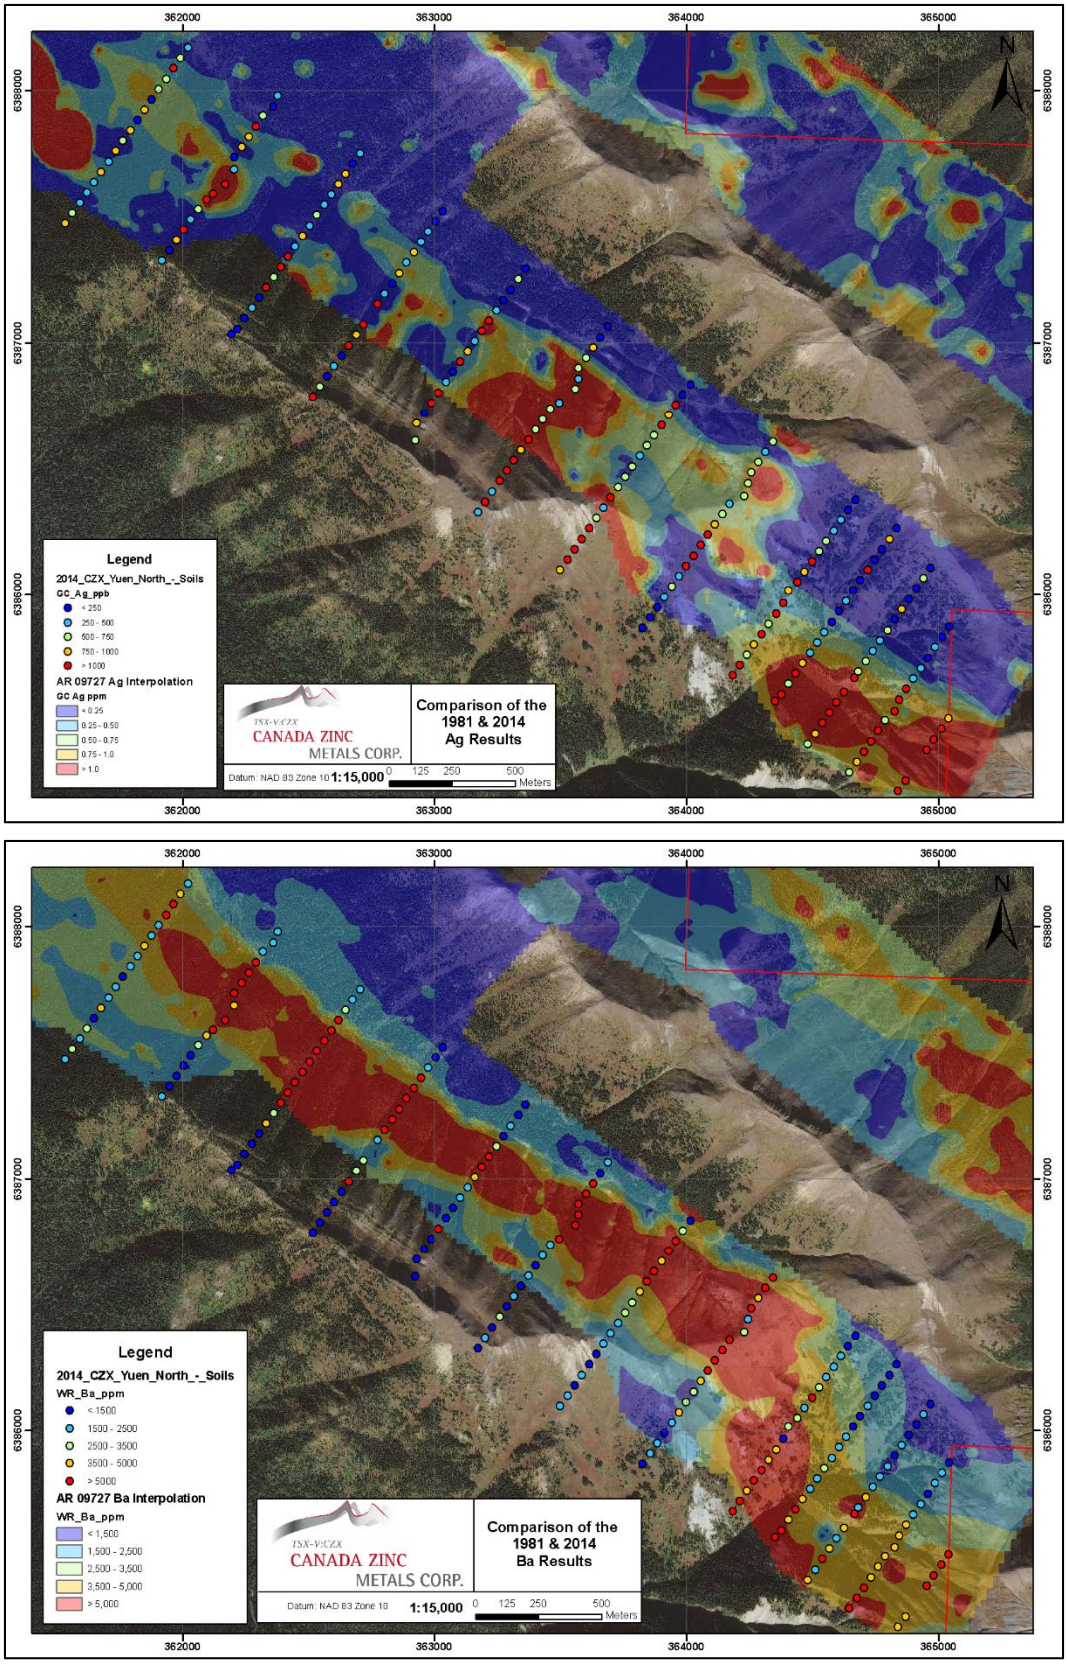

Figure 7-10: Comparison between the 1981 (interpolation) and 2014 Ag (top) and Ba (bottom) results.

The Ba results (Figure 7-10) demonstrate the best correlation between the 2014 results and the 1981 interpolation with a well-defined trend present in both datasets. There appears to be good correlation between the two datasets. The difference in sample locations can account for the minor differences present.

The results from the 2014 soil sampling program defined three areas of interest that require further discussion (Figure 7-11).

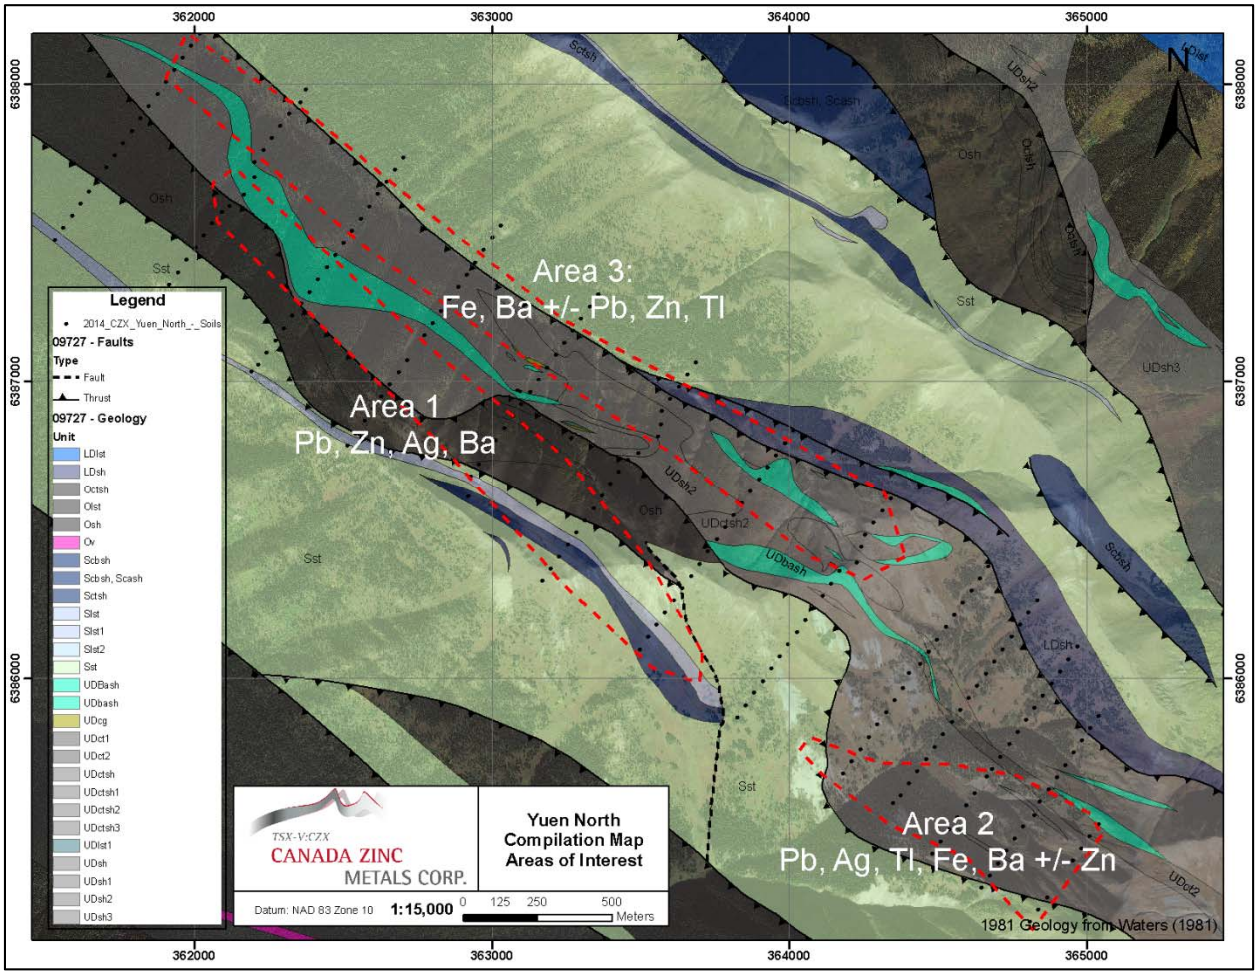

Figure 7-11: Yuen North compilation map with areas of interest from the 2014 soil sampling program.

The first area (Figure 7-11) is a linear trend oriented roughly at 134 degrees cutting across the main portion of the grid and coincident in Pb, Zn, Ag and Ba. This trend is approximately 2.4 kilometres long and 200 metres wide. In comparison with the 1981 Cominco geology its appears that this trend correlates with the known Earn Group stratigraphy in the northwest but transects across a mapped thrust fault and into Road River Group rocks. It is likely that the trend terminates at the mapped thrust fault and the elevated values within the Road River Group are associated with different lithologies.

The second area (Figure 7-11) is located in a west-facing cirque at the southeastern end of the grid. This anomaly is defined by coincident elevated Pb, Ag, Tl, Fe and Ba values with a weaker Zn response that is centered around a linear feature at the west edge of the grid that is approximately 800 metres long and oriented NW-SE at 126 degrees. In comparison with the 1981 geology, the anomaly appears to be hosted

along the western contact of the Earn Group stratigraphy and adjacent to the overriding thrust fault (Figure 7-11). The area is host to numerous iron seeps and ferricrete deposits, the most prominent of these was nicknamed Crème Brulee Creek due to the thick deposition of ferricrete (Plate 7-4). These local seeps and ferricrete deposits could represent the source for the elevated Zn, Fe and other elevated elements in the immediate area. Alternatively, work by Lett and Jackaman (1995) analyzing spring waters associated with liminotic and ferricrete deposits in the vincitiy of the Bear occurrence and Driftpile deposit concluded that there were two types of spring water (A & B). Type B spring waters were associated with the known Pb-Zn-Ag mineralisation at the Bear occurrence and were neutral to slightly acidic and highly anomalous in Ba, Al, Pb, and Tl. Secondary precipitates such as ferricrete and limonitic deposits in the area were also anomalous in Pb with elevated Ag, Co, Ni, Zn and As. Based on the suite of elements that define this area, the work by Lett and Jackaman (1995) is suggestive that this area might be associated with presence of possible sulphide mineralisation. Further work is required to determine the source of this multi-element area of interest.

Plate 7-4: Mouth of Crème Brulee Creek looking upslope. (Photo by J. Lewis 2014).

The third area (Figure 7-11) is also a linear feature extending approximately 2.8 kilometres across the main section of the grid in a NW-SE orientation. It is defined by Ba and Fe with locally elevated values of Pb, Zn and Tl. The anomaly is hosted completely within the Earn Group stratigraphy as depicted in the 1981 Cominco geology and correlates well with the mapped barite horizons. Waters (1981) concluded that this prominent trend as defined by barium in soil was likely sourced from the nearbye barite outcroppings in Gunsteel Formation shale. The results from the 2014 program appear to confirm this conclusion as well. Also, based on the thresholds used by Waters (1981) the Ba results depicted in figure 7-10 suggests that areas 2 and 3 are simply one continuous trend hosted within the Earn Group stratigraphy.

In addition to the common elements associated with known Pb-Zn-Ag deposits in the district, a number of sample sites displayed elevated values in the following elements Ni, U, Tl, Re +/- Zn, Pb, Co, As, Sb, V, Hg, P, and Se. A map displaying a number of the key elements is presented in Appendix 2. All of these sample sites are hosted within the Earn Group stratigraphy primarily concentrated in the southeastern area of the grid and in general, coincide with the second area of interest described above. Nick-style sulphide mineralisation discovered in recent drill core from the Akie property also exhibits a similar suite of elemental enrichment associated with debris flows within the Paul River Formation and or the unconformable contact between the Kwadacha limestone and the Silurian siltstones (Table 7-2, Plate 7-5).

	A-10-72	A-13-103	A-13-106

Table 7-2: Table of elemental enrichments from Nick style mineralised intersects in drill core from the Akie property (from Johnson 2014)

Plate 7-5: Nick style mineralisation at the unconformable contact between the Kwadacha limestone and the Silurian siltstone in drill hole A-13-103 @ 252.37 metres (Photo by N. Johnson 2013).

The Nick deposit in the Yukon was discovered through reconnaissance stream sediment sampling by the Geological survey of Canada in 1977 who reported anomalous values of Ni, Zn, Mo, and U. Follow up work in 1981 subsequently discovered the thin horizon of Ni-Zn rich mineralisation known as the Nick mineralisation (Hulbert et al 1992). The Nick mineralisation has a similar enrichment of elements that includes Ni, Zn, PGE's, Re, Se, As, Mo, P, Ba and U (Hulbert et al 1992). It is possible that the element signature present in the soil samples is representative of Nick style mineralisation though information is still very limited.

8.0 Conclusions and Recommendations

The 2014 exploration program on the Yuen North property was successful. The soil sampling program was completed in full despite the challenge at some sample stations to acquire the preferred soil horizon. A number of conclusions can be made based on the results from the 2014 exploration program.

1. The development of the soil profile across the grid was poor, especially at higher elevations with little vegetative cover. This hindered the collection of the preferred B soil horizon.

2. The 2014 Pb, Zn, Ag and Ba results correlated well with historical trends though the Zn and Ag results displayed some differences between the two data sets across the main portion of the grid. The Ba results from the historical dataset also suggest that the 2nd and 3rd areas of interest represent a single trend.

3. The 2014 soil sampling program outlined three areas of interest with coincidence in elevated values of Pb, Zn, Ag, Tl, Fe and or Ba, across the central and southeast areas of the grid. The first and second areas (Figure 7-11) both require further work to determine the potential source of the elevated values whether these trends are thrust or iron seep related or due to the possible presence of mineralisation.

4. A number of soil sample sites exhibited elevated values in a unique suite of elements including Ni, U, Tl, Re +/- Zn, Pb, Co, As, Sb, V, Hg, P, and Se. This suite of elements bears some similarities with the recent discovery of Nick style mineralisation in drill core at the Akie property and the Nick deposit in the Yukon. The source of these values is unknown and requires further follow up work.

5. The rock samples taken as part of the soil sampling program returned no significant results aside from a few samples highly anomalous in Ba due to the presence of nodular to laminar barite.

Based on the results of the program and the conclusions, a number of recommendations are offered for future exploration programs on the Yuen North property and the surrounding area.

1. Further mapping on the Yuen North property is recommended with a focus on the western and eastern panels of Earn Group stratigraphy in order to refine the stratigraphy outlined in the 1981mapping program. An effort should be made to confirm the Orodvician graptolitic black shales that are mapped in thrust contact with the Earn Group stratigraphy on the western panel as well as refine the thrust fault that marks the boundary between the two units.

2. Prospecting and rock sampling done in conjunction with the mapping efforts should attempt to determine the source of the multi-element anomaly present in the second area of interest located in the west-facing cirque.

3. Due to the difficult nature in discerning between the different black shales present within the Earn Group stratigraphy and Ordovician black shales litho-geochemical rock sampling is recommended to produce a series of geochemical profiles of the different rock types to assist the mapping efforts.

4. Additional soil sampling is recommended to infill the 2014 soil sampling grid refining and expanding upon the trends defined in this program. Expansion of the soil grid towards the Mt. Alcock property to the northwest is also recommended. The lower elevations and vegetative cover should provide a better soil profile for sample collection.

5. Further analysis of the historical data from the 1980, 1981 and 1986 programs should be completed to identify additional areas of interest for follow up prospecting and exploration activities. This should include an evaluation of the eastern panel of Earn Group rocks defined in the historical mapping.

6. The suite of elements associated with the Nick style of mineralisation should be considered in future exploration programs. Mapping efforts should investigate the contact between the unconformable contact between the Kwadacha Limestone and the underlying Silurian siltstone where Nick-style mineralisation is known to occur.

10.0 Statement of Qualifications

I, Nicholas L. Johnson, do hereby state:

1. That I am a resident of Ontario, with an address of 69 Inverness Crescent, Kingston, Ontario, K7M 6P2.
2. That I am a graduate of Queens University (B. Sc. Hons in Geology, 2001);
3. That I have been continuously employed in the mineral exploration industry since May of 2002 after graduating from Queens University.
4. That I am currently under the employ of Canada Zinc Metals Corp. a British Columbia corporation with a business address of Suite 2050 1055 West Georgia Street, Vancouver, B.C., V6E-3P3.
5. I oversaw the work described in this report and I am the sole author of the report entitled "The 2014 Soil Sampling Program on the Yuen North Property: Summary Report"

Dated in Vancouver, B.C., on the 6th of January 2015.

Nicholas L. Johnson, B.Sc. (Hon.)

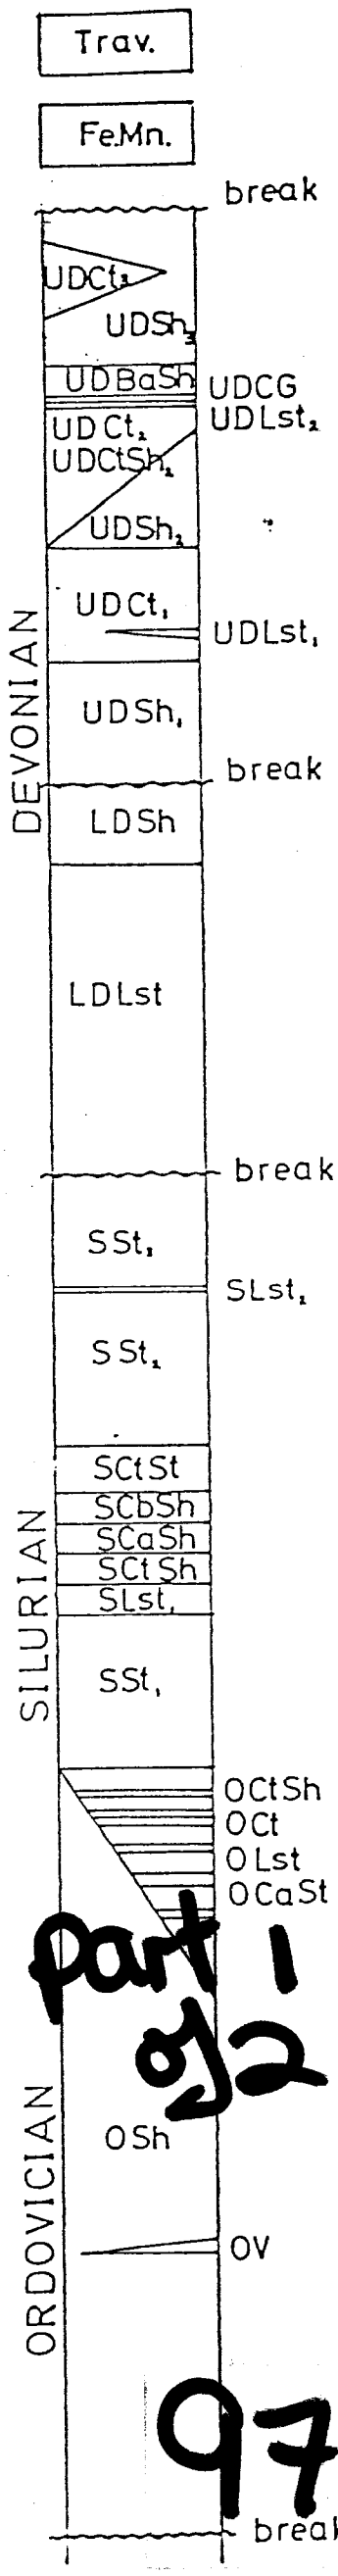
0 250 500 1,000 Meters

TABLE 2. (From Waters 1981)



Trav	Cream yellow vuggy travertine.
FeMn	Fe Mn cemented breccia deposits.
UDSh	Unassigned Upper Devonian shale.
$UDCt_3$	Grey weathering and or Fe stained black cherts and cherty shales. (0-50 m)
$UDSh_3$	Fe stained weathering black carbonaceous shale and silty shale. (200 m?)
UDBaSh	Fe stained weathering black carbonaceous shale and silty shale. (0-20 m)
UDCG	Slightly pyritic and baritic 'Chert Grit' variably sized angular grit fragments in a very fine grained matrix. (0-2 m)
$UDLst_2$	Black coarsely crystalline fetid (strong smelling) limestone. (0-1 m)
$UDCt_2$	Dark grey to black carbonaceous chert.
$UDCtSh_2$	Fe stained weathering black cherty shale. (50-200 m)
$UDSh_2$	Fe stained weathering dark grey to black silty shale. (50-200 m)
$UDCt_1$	Black cherts and cherty shales. (?-150 m)
$UDLst_1$	Black coarsely crystalline fetid limestone. (2 m)
$UDSh_1$	Fe stained weathering silty shale. (?-150 m)
	GUNSTEEL.
LDSh	Brown weathering black carbonaceous calcareous silt and silty shale. (50-100 m)
LDLst	Light grey weathering dark grey to black limestone with occasional fossils. (0-400 m?)
SSt	Unassigned Silurian siltstone.
SSt_3	Brown weathering mottled calcareous silty shales, calcareous silts and semi-quartzites. (50-150 m?)
$SLst_2$	Grey brown weathering medium grey variably silty limestone. (0-5 m)
SSt_2	Brown weathering homogenous calc siltstone with pyrite filled burrows. (50-200 m?)
SCtSt	Grey brown or reddish purple weathering siltstone with 1-2 cm long lenses of dark grey or black chert. (0-20 m)
SCbSh	Black carbonaceous silty shale. (0-20 m)
SCaSh	Grey brown weathering calcareous shale. (0-20 m)
SCtSh	Black cherty and carbonaceous shale. (0-20 m)
$SLst_1$	Grey brown weathering silty or Crinoidal limestone. (0-20 m)
SSt_1	Grey brown weathering calc silt and silty shale. (0-200 m)
OSh	Variably carbonaceous, calcareous and silty shale with occasional thick pyrite lenses.
OCtSh	Black carbonaceous cherty shale. (10-20 m beds)
OCt	Black carbonaceous chert - (rare sphalerite grains). (1-2 m beds).
OLst	Lensoid bodies of black coarsely crystalline limestone. (1-2 m beds)
OCaSt	Grey brown weathering calc silts. (1-2 m beds)
	(200-300 m)
	1000m.
OV	Orange weathering green vuggy tuffs and lavas. (10 m?)

CERTIFICATE OF ANALYSIS VAN14002293.1

CLIENT JOB INFORMATION

Project:	AKIE
Shipment ID:	CZX 10 July 2014
P.O. Number	YUEN NORTH
Number of Samples:	17

SAMPLE DISPOSAL

RTRN-PLP	Return
DISP-RJT	Dispose of Reject After 90 days

Acme does not accept responsibility for samples left at the laboratory after 90 days without prior written instructions for sample storage or return.

SAMPLE PREPARATION AND ANALYTICAL PROCEDURES

Procedure Code	Number of Samples	Code Description	Test Wgt (g)	Report Status	Lab
BAT01	1	Batch charge of <20 samples			VAN
PRP70-250	17	Crush, split and pulverize 250 g rock to 200 mesh			VAN
LF302	17	LiBO2/Li2B4O7 fusion ICP-ES analysis	0.2	Completed	VAN
AQ250_EXT	17	1:1:1 Aqua Regia digestion Ultratrace ICP-MS analysis	0.5	Completed	VAN
DRPLP	17	Warehouse handling / disposition of pulps			VAN
DRRJT	16	Warehouse handling / Disposition of reject			VAN

ADDITIONAL COMMENTS

Invoice To: Canada Zinc Metals Corp.

This report supersedes all previous preliminary and final reports with this file number dated prior to the date on this certificate. Signature indicates final approval; preliminary reports are unsigned and should be used for reference only.
All results are considered the confidential property of the client. Acme assumes the liabilities for actual cost of analysis only. Results apply to samples as submitted.
"*" asterisk indicates that an analytical result could not be provided due to unusually high levels of interference from other elements.

This report supersedes all previous preliminary and final reports with this file number dated prior to the date on this certificate. Signature indicates final approval; preliminary reports are unsigned and should be used for reference only.
All results are considered the confidential property of the client. Acme assumes the liabilities for actual cost of analysis only. Results apply to samples as submitted.
"*" asterisk indicates that an analytical result could not be provided due to unusually high levels of interference from other elements.
