1 EXECUTIVE SUMMARY

The Dome North property is situated in the Babine Range approximately 38 kilometres east of the town of Smithers. The property is situated close to major infrastructure including power transmission lines, railway and major highways and is readily accessible by all-weather gravel roads.

The Dome North property is predominantly underlain by rocks of the Jurassic Hazelton Group. The basal Telkwa Formation is the thickest and most extensive component of the Hazelton Group. The Nilkitkwa Formation conformably to disconformably overlies the Telkwa Formation and is an important host for mineral occurrences in the area. The Smithers Formation disconformably overlies the Telkwa Formation and Nilkitkwa Formation.

The Dome North property consists of seven claims that cover 2,893.95 hectares in the Omineca Mining Division. The property is 'L-shaped' and adjoins the former producing Dome Mountain gold mine, currently under development for re-opening by Metal Mountain Resources Inc. The Dome North property covers a portion of the Dome Mountain gold vein system and includes at least one known polymetallic quartz-carbonate-sulphide prospect, the Jane Vein.

Despite its short duration, the 2015 ground magnetic survey identified several anomalies that may represent possible, unevaluated extensions of the Jane vein and/or other previously unidentified structures of unknown significance. Prospecting located several old showings including the Jane Adit; these vein showings were resampled and produced values up to 27.7 g/t Au and 387.0 g/t Ag. Prospecting also documented a new stratabound/stratiform silver-lead-copper showing that assayed 592.0 g/t Ag, >1% Cu and 1% Pb.

It is recommended that additional work be completed on the property to further asses its potential to host economic concentrations of polymetallic vein mineralization similar to that being developed on the adjacent Dome Mountain property. Additional ground magnetic surveying is recommended to add detail to and to expand upon the coverage provided by the 2015 survey. Infill and step-out lines should be on 25m spacings with stations spaced at 12.5m along each line. Additional prospecting and systematic, close-spaced channel sampling of mineralized veins should also be considered in order established surface dimensions and average grades of known structures and to determine priorities for possible future shallow diamond drilling. The estimated cost for a follow-up program of ground magnetic surveying, prospecting and sampling is $35,000.

The Dome North property, and specifically the area of the Jane Adit, is a project of merit.

2 INTRODUCTION

This report summarizes the exploration history, geology, mineralization and potential of the Dome North property of Guardsmen Resources Inc. (Guardsmen), and provides results from a modest geophysical survey and prospecting program completed in August, 2015. Guardsmen is a private mineral exploration company based in West Vancouver, BC.

The author managed and participated in the 2015 exploration program at the request of Guardsmen, but has no ownership in the mineral tenures that comprise the Dome North property nor any direct or indirect interest in Guardsmen.

2.1 LOCATION AND ACCESS

The Dome North property is located in the Babine Range approximately 38 kilometres east of the town of Smithers. The property is 'L-shaped' and adjoins the former producing Dome Mountain gold mine, currently under development for re-opening by Metal Mountain Resources Inc. (Figure 1). The project was situated on NTS mapsheet 093L/10. The 2015 work program was centred at approximately Latitude 54˚ 44' 19.6" N and Longitude 126˚ 38' 24.1" W (NAD83, Zone 9N).

Access to the property from Smithers is provided by a 64 km, all-weather gravel road which leaves Highway 16 about 4 km south of Smithers and travels northeast along the Babine Lake road for approximately 40km. A further 16 km south along the Chapman Lake, the road reaches the base of the slope on the east side of Dome Mountain. From this point a gated, private 4 km road winds up the side of the mountain to the Dome Mountain mine area. A series of rough dirt roads and a rugged, seasonal quad trail provides access to the northern part of the Dome North claims.

2.2 PHYSIOGRAPHY AND CLIMATE

The Dome North property is situated in the Babine Range at the southern extension of the Skeena Mountains. Elevations vary between about 1070 m near Guess Creek to more than 1730 m at the peak of Dome Mountain. The area is crossed by numerous creeks. Lower elevations are described as Sub-Boreal Spruce and are covered by stands of spruce, fir and balsam. Alpine Tundra marked by sedges, grasses and stunted juniper occur at higher elevations.

Colluvium and till deposits are 1 to 5 metres thick on mid to upper slopes, but have formed thicker accumulations at lower elevations. Bedrock exposure is good at higher elevations, but sparse at lower elevations and in valley bottoms. During the last glaciation, the Coast Mountains to the west were the primary influence in directing ice flow to the southeast.

Winters are moderate to cold with typical snow accumulations of approximately one to two metres. The area is generally free from snow between May and October. Summers are moderate to warm.

2.3 PROPERTY STATUS AND OWNERSHIP

The Dome North property presently consists of seven contiguous mineral claims covering approximately 2,893.95 hectares of land in the Omineca Mining Division (Table 1; Figure 2). Guardsmen acquired the claims by ground staking in January, 2000, and by online staking in January, 2006, and in March, 2011. All of the claims that comprise the Dome North property are currently 100%-owned by, and registered in the name of, Guardsmen Resources Inc. (Free Miners Certificate: 131812). Guardsmen owns one additional claim in the area of the Dome North group of claims, but it is not the subject of this report.

2.4 LOCAL INFRASTRUCTURE

The Town of Smithers, with a regional population of approximately 15,000, is a major centre for resource industries operating in northwest British Columbia. It is located approximately 400 kilometres from deep water ocean ports in Prince Rupert, Kitimat and Stewart, has an airport with daily service to Vancouver, and has access to the CN rail-line. Several exploration companies and diamond drill contractors have bases in the town. Smithers has readily available, skilled mine and construction work force as well as connections to electric power and natural gas.

2.5 EXPLORATION HISTORY

The Dome Mountain area has a long history of exploration that culminated in the commencement of underground mining in 1991. A capsule description of the exploration, development and production history of the Dome Mountain gold mine, taken from Hanson (2008), is updated below. This history is relevant because the Dome North property adjoins the Dome Mountain gold mine on two sides, and hosts mineralized veins similar to those that host reserves at the mine.

The exploration history of the Ascot prospect, also located on the Dome North property was compiled in detail by previous workers, including Peatfield and Loudon (1968), Awmack (1995) and Lane (2014), but is not repeated herein.

2.5.1 Dome Mountain

The first mineral claims to be staked on Dome Mountain were recorded in 1898 by W.B. Forrest. Considerable surface and underground work was conducted from 1923 to 1924 by the Dome Mountain Mining Company Ltd. (DMM), a subsidiary of American Smelting and Refining Company of New York City. Exploration conducted on the property from the 1940s to the 1970s was very limited.

Modern exploration and development began in 1980. Through the 1980s, significant exploration programs were conducted by Noranda Exploration Company Limited, Canadian-United Minerals Inc., Teeshin Resources Inc., and Total Erickson/Erickson Gold Mining Corp. In 1990, Teeshin purchased Canadian-United's interest in the property and intersected several zones of "hanging wall" mineralization in a ten hole (2,376 m) diamond drilling program. In 1991, a joint venture agreement between Teeshin and Timmins Nickel Incorporated (TNI) was formed, with TNI as the operator. Teeshin then changed its name to Habsburg Resources Inc. (Habsburg) and commenced mining. Underground mining began in August 1991 and ceased in May 1993. During this period 43,900 tonnes at an average grade of 12.0 grams per tonne gold were reportedly mined from shrinkage stopes accessed from trackless development on the 1290 and 1370 levels. The ore was shipped off-site to either the Equity Silver mill near Houston, BC or to the Westmin Premier mill near Stewart, BC for toll milling. A total of 373,478 grams (or 12,008 ounces) of gold and 157,607 grams (or 5,067 ounces) of silver were reportedly produced (Schroeter and Pardy, 2004).

Habsburg later changed its name to Dome Mountain Resources Ltd. and then to DMR Resources Ltd. (DMR). DMR was delisted in 2001 and in 2005 transferred ownership of the Mining Lease and their remaining claims to Angel Jade Mines Ltd., K. Coswan, A. L'Orsa and J. L'Orsa (Hanson, 2013).

Little additional significant exploration was conducted on Dome Mountain until Eagle Peak Resources Inc. (Eagle Peak) optioned many of the core claims and began a re-assessment of the property. In 2008, Eagle Peak conducted soil geochemistry, 3D induced polarization and magnetic surveys over the Boulder Vein system and its projected extension to the east. In 2009, the company completed 46 HQ drillholes totaling 5,705 metres, most of which targeted the Boulder Vein system, and conducted considerable underground sampling on the 1290 level. In October, 2009, Metal Mountain Resources Inc. (Metal Mountain), a

company associated with Eagle Peak, acquired the Dome Mountain project. Early in 2010, Metal Mountain conducted a small exploration and condemnation drilling program (10 holes, 1680 m). Gavin Mines Inc. (Gavin), a subsidiary of Metal Mountain, later became the operator of Dome Mountain and completed underground rehabilitation and development work in 2011 and 2012 extracting 5000 tonnes of ore and 17,000 tonnes of waste.

Historical "in-situ reserves" for the Boulder and Argillite veins total 200,768 tonnes grading 14.9 g/tonne gold (George Cross Newsletter, No. 68, April 11, 1994). A NI 43-101 compliant resource has not been released publically by the company.

3 REGIONAL GEOLOGY

The Dome North property is located in the Babine Range of west central British Columbia within the Intermontane Belt, a morpho-geological region composed of the Stikine, Quesnel and Cache Creek terranes.

The Babine Range is a northwest-trending horst of folded and faulted Jurassic and Cretaceous volcanic and sedimentary rocks bounded to the west and east by grabens containing Late Cretaceous and younger rocks (Figure 3). The regional stratigraphy has been described by Tipper and Richards (1976) and refined by MacIntyre et al. (1987a and 1987b). The Babine Range is underlain primarily by Early to Middle Jurassic calc-alkalic island arc rocks of the Stikine Terrane.

The structural setting is analogous to the Basin and Range province of the US Southwest and structural development is probably related to Late Cretaceous to Early Tertiary extensional tectonics. This tectonic regime is characterized by northeast-trending shearing, which offsets the horst and graben boundaries on major north-trending transcurrent faults.

4 PROPERTY GEOLOGY

The property is predominantly underlain by rocks of the Lower to Middle Jurassic Hazelton Group. The basal Telkwa Formation is the thickest and most extensive component of the Hazelton Group. The Nilkitkwa Formation conformably to disconformably overlies the Telkwa Formation and is an important host for mineral occurrences. The Smithers Formation disconformably overlies the Telkwa Formation and Nilkitkwa Formation.

The Telkwa Formation (lJHT) has been subdivided into four mappable units, which are from oldest to youngest: (1) polymictic conglomerate; (2) porphyritic andesite); (3) fragmental volcanic rocks; and (4) phyllitic maroon tuff. Units 2 and 3 are considered to be proximal vent facies rocks.

The Nilkitkwa Formation (lJHNk) is composed of transgressive marine sediments that overlie rhyolite, basalt and red epiclastic rocks. The formation has been subdivided into four mappable units. In ascending stratigraphic order they are: (1) interbedded red epiclastics and amygdaloidal flows; (2) rhyolitic volcanic

rocks; (3) tuffaceous conglomerate, cherty tuff and siltstone; and (4) thin-bedded argillite, chert and limestone.

The Smithers Formation (mJHSms) comprises fossiliferous sandstone and siltstone, with intercalated felsic tuff that was deposited during a marine regression. It disconformably overlies the Nilkitkwa and Telkwa Formations. Typically, it is comprised of medium to thick-bedded, dark grey limy siltstone and mudstone and weathers orange to brown.

Stratigraphically higher in the section, but occurring in structural contact with the older rocks are intermediate to felsic volcanics and sediments of the Late Cretaceous Kasalka Group (uKK). Rocks of the Bowser Lake Group (Ashman Formation) do not occur on the property, but outcrop to the north where they conformably overlie the Smithers Formation. Eocene lapilli tuffs and porphyritic andesite flows (EEvl) outcrop near the southern edge of the property.

Mapped intrusive rocks in the vicinity of the property are rare. Those that have been mapped are foliated diorites that are considered to be coeval with the Lower Jurassic volcanic rocks.

On a local scale, the sulphide bearing quartz veins are situated along east-trending shear zones which are interpreted as structures reactivated during Late Cretaceous volcanism. The veins trend both northwest and east-west, and are disrupted by northwest-trending post-ore faults.

The Jane Adit area of the property is underlain predominantly by weakly foliated fragmental volcanic rocks and phyllitic maroon tuffaceous rocks of the Telkwa Formation. Younger, overlying Nilkitkwa Formation lies to the south of the Jane Adit.

5 MINERALIZATION AND GEOLOGICAL MODEL

5.1 POLYMETALLIC QUARTZ-CARBONATE-SULPHIDE VEINS

The polymetallic quartz-carbonate veins at the Dome Mountain mine occur within a 12 km, roughly northwest-southeast band that extends from southeast of Dome Mountain to Mt. McKendrick. At least 14 polymetallic quartz-carbonate veins have been identified (Hanson, 2013). The veins are characterized by white to clear quartz with lesser ankerite and calcite and a suite of sulphide minerals (primarily pyrite, sphalerite and chalcopyrite with minor galena, tetrahedrite and arsenopyrite) that comprise up to 10% of the veins (Hanson, 2009).

The veins both parallel and cross-cut foliation and some have been folded and brecciated and were emplaced during the early stages of folding (MacIntyre et al., 1987). The controlling structures for the veins are faults that strike east to southeast with moderate to steep dips. Importantly, there is potential for these structures to extend westward onto the Dome North property.

5.2 JANE VEIN

The principal zone of mineralization on the Dome North property is the Jane Vein, a polymetallic quartz-carbonate-sulphide vein consistent with those that occur elsewhere in the Dome Mountain area.

6 2015 EXPLORATION PROGRAM

The 2015 exploration program was completed by a team of two workers under the direction of geologist R. A. (Bob) Lane. The two additional workers were prospectors Scott Gifford and Harry Huffels of Mountainside Exploration Management Inc.

The program consisted of erecting a temporary base camp on level ground near Metal Mountain's access road into the Dome Mountain minesite, utilizing an ATV on a series of trails to gain access to the area of interest, and completing a ground magnetic survey and limited prospecting program. The area investigated during the program is shown in Figure 6. The field component of the program required 5 full days; an additional four full days for mobe and demobe from Vancouver were also required.

The 2015 magnetic survey and prospecting effort was focused on the Jane Adit area, an area underlain principally by calc-alkaline intermediate tuffaceous volcanic rocks of the Telkwa Formation (Jurassic Hazelton Group). The survey totaled 11.225 line-kilometres. A summary of the results is provided below, and a detailed account of the survey parameters and an interpretation of the collected data is provided by Trent Pezzot of GeoSci Data Interpretation Ltd. (Appendix A).

A total of five rock samples were collected from this area, three of which came from previously evaluated areas including the Jane Adit. A summary of the results is provided below, and detailed assays are provided in Appendix B.

6.1 GROUND MAGNETIC SURVEY RESULTS

The 2015 magnetic survey covered the Jane Adit area. The evaluation extended from the vein northward and eastward to claim boundaries and well westward to look for magnetic features that could be indicative of extensions to the Jane Vein or of other mineralized structures. The magnetometer survey grid consisted of 17 north-south oriented lines spaced at 50 m intervals. Total magnetic field intensity measurements were recorded on a GEM systems GSM-19 Magnetometer at 25 m stations along each line.

The following summary comments are paraphrased from Pezzott (for a full discussion see Appendix A):

1) A strong magnetic dipole coincides with a newly recognized copper-bearing showing. The source of the signal is likely at or near the surface and should be identifiable by normal ground prospecting techniques or shallow trenching; the area requires more detailed surveying.

2) Subtle northeasterly and southeasterly magnetic lineations that cross the survey area are thought to have a geological source. The northeasterly trend may be reflective of regional foliation, whereas the southeasterly is consistent with some of the Dome Mountain vein directions and should be further investigated.

3) A strong magnetic high at the north end of the grid cannot be unexplained by examination of existing available geological mapping data. Further assessment beyond this area to the north may determine if the anomaly is a localized feature or more regional in extent.

The ground magnetic survey has proven to be an effective mapping tool and has identified several anomalies and trends that require further investigation.

6.2 ROCK GEOCHEMICAL SAMPLING RESULTS

A total of five rock samples were collected during one day prospecting effort that covered the area of the ground magnetic survey. Sample 827665 was a 0.35cm chip sample collected from a quartz-pyrite vein trending 105/64°N that is exposed in the margin of an old blasted trench. Sample 827666 was a 0.65cm chip sample collected from a quartz-pyrite-chalcopyrite vein trending 150/42°N that is exposed in a nearby stripped area. Host rocks to both veins are moderately to strongly foliated, pale maroon crystal lapilli tuffs. The two vein samples graded 12.9 g/t Au and 404.0 g/t Ag, and 27.7 g/t Au and 387.0 g/t Ag, respectively, with anomalous copper, lead, bismuth and tellurium values.

Sample 827667 was taken from a copper showing discovered by Scott Gifford during the collection of magnetic survey data. The showing consists of stratabound and stratiform discontinuous bands of tetrahedrite and fine-grained galena with accompanying rhodochrosite, and malachite and azurite staining, within an iron carbonate-altered volcanic rock. The extent of the zone is uncertain, but it appears to be gently-dipping and more than a few centimetres thick. The sample graded 592.0 g/t Ag, >1% Cu and >1% Pb, with anomalous gold, antimony and arsenic.

Sample 827668 was collected from an area of dry-looking, narrow quartz veins. The veins were weakly iron-stained and displayed minor boxwork and drusy textures. The vein sampled is oriented 148/35°N. The sample did not produce encouraging results.

Sample 827669 was collected from the Jane Adit dump and consisted of crudely banded quartz-pyrite-chalcopyrite. The vein exposed in the adit back just inside the opening trends was not sampled due to safety concerns; it has a trend of 128° with a footwall contact that dips 30°N and a sheared hangingwall contact that dips 82°N. The sample of vein material graded 20.3 g/t Au, 194.5 g/t Ag and >1% Cu, with anomalous lead, bismuth, antimony and arsenic.

Analytical results for rock samples analyzed, along with their UTM coordinates, and a brief description are provided in Table 3. Full analytical results for rock samples are provided by the laboratory certificates presented in Appendix B.

6.3 SAMPLING METHOD AND APPROACH

The purpose of the exploration program was to identify possible extension to the Jane Vein and/or other structures that could potentially host similar polymetallic vein mineralization.

6.4 SAMPLING PREPARATION, ANALYSIS AND QUALITY CONTROL

Each rock sample received by the lab was individually crushed and pulverized following Acme's PRP70-250 procedure: samples were jaw crushed until 80% passed through a 10 mesh screen. From this material a 250 g riffle split sample was collected and then pulverized in a mild steel ring-and-puck mill until 85% passed through a 200 mesh screen. A 0.25 g split of the milled sample was evaluated for 45 elements, including silver, by a four acid digestion followed by ICP-MS analysis (MA200). A 30 g split of each milled sample was evaluated for gold by lead collection fire assay fusion with an AAS finish (method FA430). Samples returning more than 10 ppm Au were re-analyzed utilizing lead collection fire assay with a gravimetric finish (method FA530) on a 30 g sample.

There were no blanks or standards inserted into the sample stream by the author; a review of Acme's duplicate analysis showed acceptable consistency of results.

Table 2: Dome North - 2015 Rock Sample Results

Sample ID	LOCATION-NAD 83 Easting	Northing	Au (ppb)	Ag (ppm)	Cu (ppm)	Pb (ppm)	Zn (ppm)	Descriptive Field Notes

7 DISCUSSION AND CONCLUSIONS

The Dome North property covers a portion of the Dome Mountain gold vein system and includes at least one known polymetallic quartz-carbonate-sulphide prospect, the Jane Vein.

Despite its short duration, the 2015 ground magnetic survey identified several anomalies that may represent possible, unevaluated extensions of the Jane vein and/or other previously unidentified structures of unknown significance. Prospecting located a new stratabound/stratiform silver-lead-copper showing.

The Dome North property, and specifically the area of the Jane Adit, is a project of merit. It is recommended that additional work be completed on the property to further asses its potential to host economic concentrations of polymetallic vein mineralization similar to that being developed on the adjacent Dome Mountain property.

8 RECOMMENDATIONS

The ground magnetic survey identified several anomalies and trends that require further investigation. Additional surveying is recommended to add detail to and to expand upon the coverage provided by the 2015 survey. Infill and step-out lines should be on 25m spacings with stations spaced at 12.5m along each line

Additional prospecting and systematic, close-spaced channel sampling of mineralized veins should also be considered in order established surface dimensions and average grades of known structures and to determine priorities for possible future shallow diamond drilling.

The estimated cost for a follow-up program of ground magnetic surveying, prospecting and sampling is $35,000.

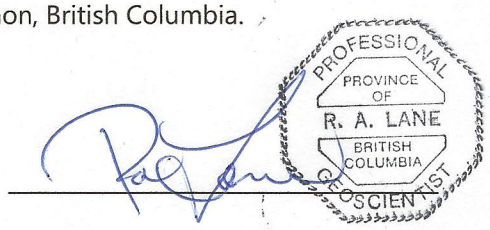
11 STATEMENT OF QUALIFICATIONS

I, Robert A. Lane, PGeo, residing in Prince George, B.C., do hereby certify that:

- I am currently employed as a consulting geologist by Plateau Minerals Corp., located at 3000 18th Street, Vernon, British Columbia, Canada.
- I obtained a Master of Science degree in Geology in 1990 from the University of British Columbia.
- I have worked as a geologist for 26 years since my graduation from university.
- I am a Professional Geoscientist (PGeo) registered with the Association of Professional Engineers and Geoscientists of British Columbia, license #18993, and have been a member in good standing since 1992.
- I planned the 2015 exploration program and visited the Dome North property on August 16-18, 2015.
- I am the author of this report entitled: "2015 Assessment Report on the Dome North Property" dated December 11, 2015.

Dated this 11th day of December, 2015, at Vernon, British Columbia.



R. A. (Bob) Lane, M.Sc., P.Geo.

Memorandum

To: Guardsmen Resources Inc.

From: E. Trent Pezzot

Date: November 3, 2015

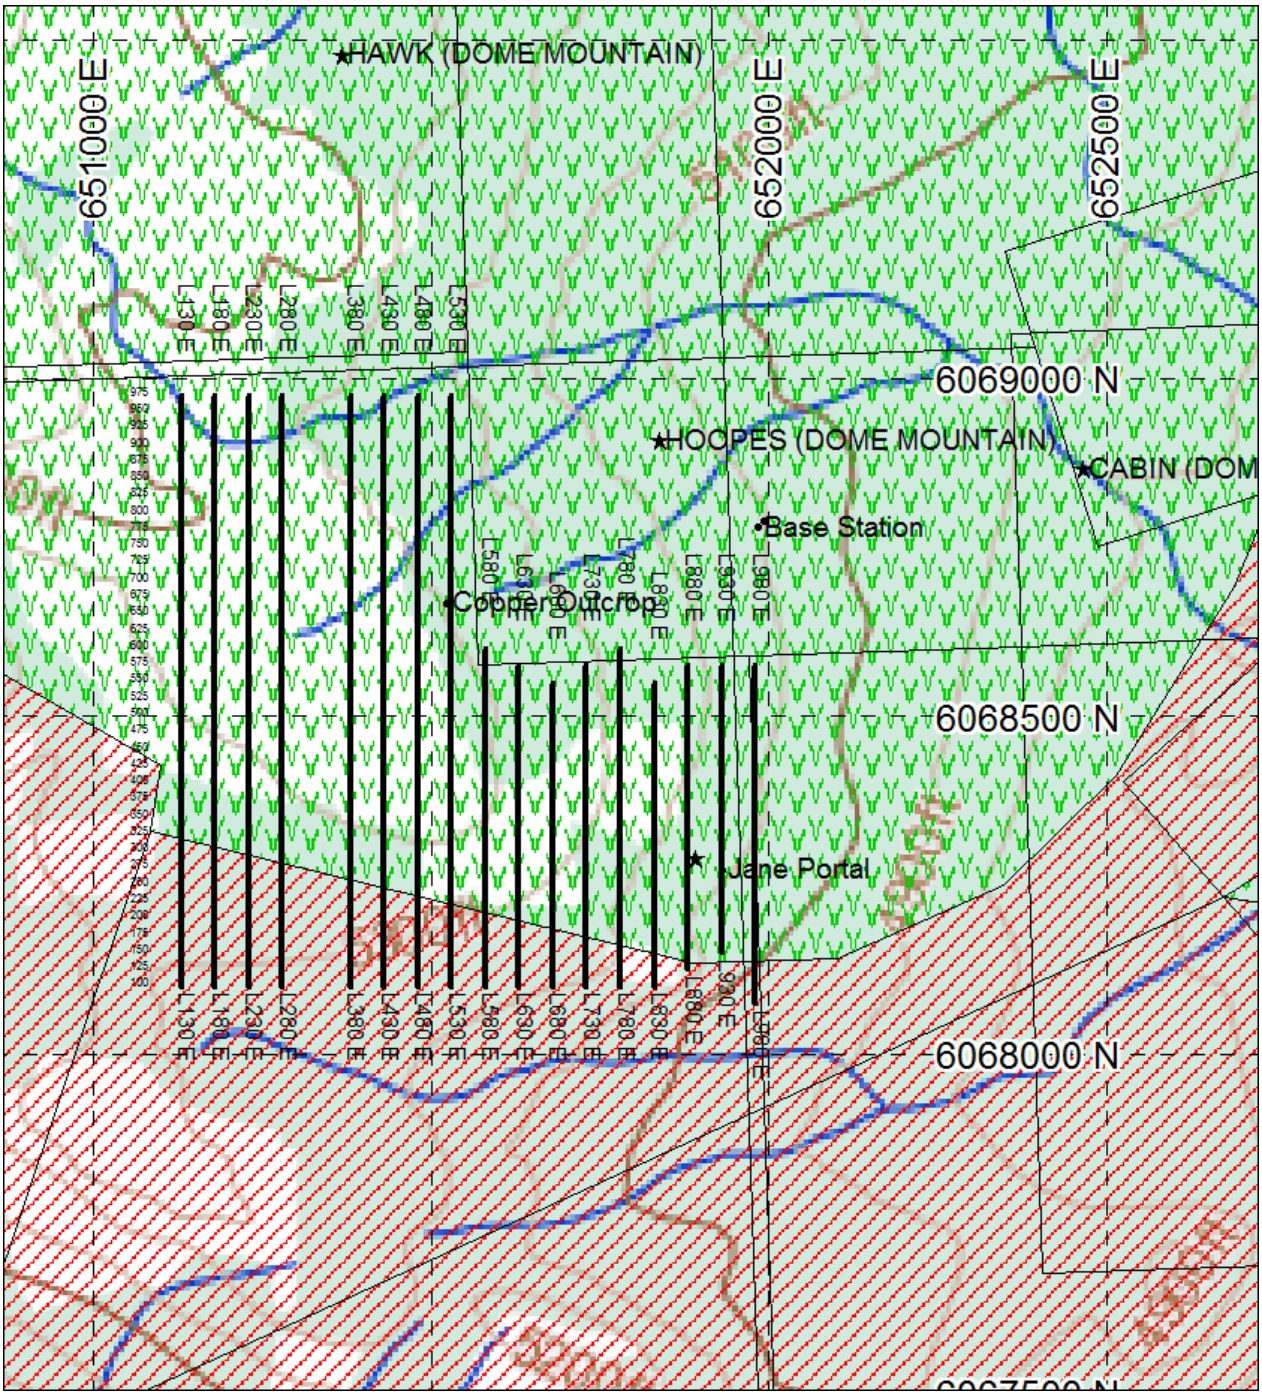
Re: Dome Mountain magnetic survey

In August, 2015 Guardsmen Resources Inc. personnel conducted a small program of geological mapping and magnetic surveying over a portion of their Dome Mountain project claims in central B.C., some 33 km east of Smithers and 39 km north of Houston. The survey area is located in the Omineca Mining Division and NTS 93L10. The work was completed to qualify for assessment credits.

The goal of the magnetic survey was to identify any geological structures or trends in the area. All data is registered to the NAD83, Zone 9N UTM coordinate system.

The magnetic data was provided as ASCII text files to Geosci Data Analysis Ltd. for processing, plotting and interpretation. This memo describes the results of these efforts and is intended to be referenced or included in an assessment report being compiled that describes the entire exploration program. Readers are referred to that document for details concerning topics such as the claim ownership, previous work, geology and cost breakdown.

The survey grid is located on the southeastern slope of Dome Mountain, between 5000' and 5500' elevation. The BC geological mapping shows the survey area to be primarily underlain by calc-alkaline volcanic rocks of the Hazelton Group – Telkwa formation. An east-west contact divides these rocks from undivided sedimentary rocks of the Hazelton Group – Nilkitkwa Formation which are mapped across the southern ends of all of the survey lines. The study area is located west of several of the Dome Mountain minfile occurrences, reporting gold in quartz vein mineralization.



Survey Grid over topography, claims and geology base maps

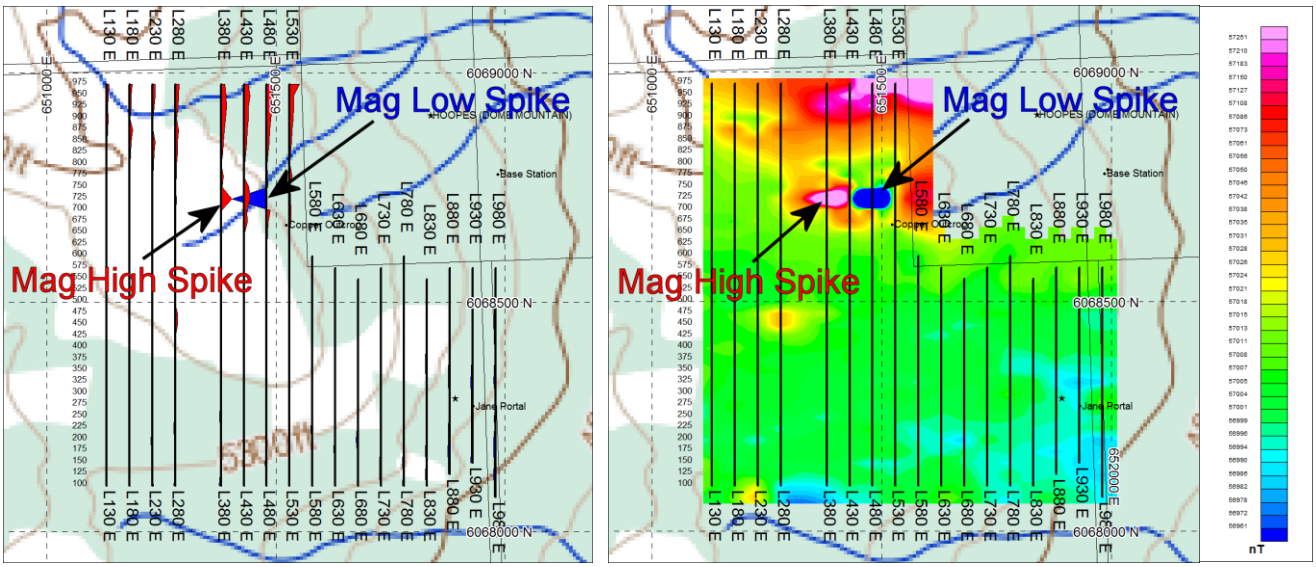
IJHT - Mesozoic - Hazelton Group - Telkwa Formation calc-alkaline volcanic rocks

The magnetometer survey grid consists of 17 north-south oriented lines spaced at 50 metre intervals. Total magnetic field intensity measurements were recorded on a GEM systems GSM-19 magnetometer at 25 metre stations along the lines. Excluding duplicates and repeats, 466 readings were taken for a total of 11.225 kilometres of survey. Line numbers (130E to 980E) were derived from the last three digits of the lines easting coordinate. Station labels (100N to 975N) were derived from the last three digits of the northing coordinate. One line (320E) was unintentionally not surveyed. The western most lines extended for 875 metres. The easternmost lines were shorter (100N to 600N), terminating at a claim boundary. Time synchronization with a base station, located in the northeastern portion of the study area was used to remove diurnal variations from the magnetic data.

Magnetic data was gathered over 4 days, from August 14 to 17. A technical problem caused a failure of the base station magnetometer near the end of the day on August 14. This resulted in no diurnal corrections being applied to the data south of station 350N on line 830E and all of line 780E. The base station data for August 14 was examined and it was determined that in the period leading up to the loss of synchronization, the diurnal was varying linearly at a rate of -0.18474 nT/min (-11.08 nT/hour). Diurnal corrections were estimated for the affected data by adding a pro-rated correction (based on the time since loss of synchronization times the calculated rate) to the last measured correction (+907 nT at 830E/350N). No obvious discontinuities or shifts are observed in the resulting maps and profile plots.

The diurnally corrected magnetic data is plotted in both stacked profile and colour contour formats.

A linear plot of the magnetic data is dominated by two extremely strong, single station anomalous readings: a +500 nT reading at grid coordinates 380E/725N and a -1480 nT reading at 480E/725N that form an east-west dipole response. While these two readings appear to be valid, in that they were confirmed by taking several repeat readings, they have not been adequately resolved. It is likely that the source(s) are very small and at or near the ground surface. This type of response might be generated by a cultural item such as steel drill rods or logging chain. The source might also be geological, possibly a narrow, magnetite rich sill or dyke. It will be necessary to gather data on a more detailed grid in this region in order to properly delineate and interpret these responses.



(a) (b)

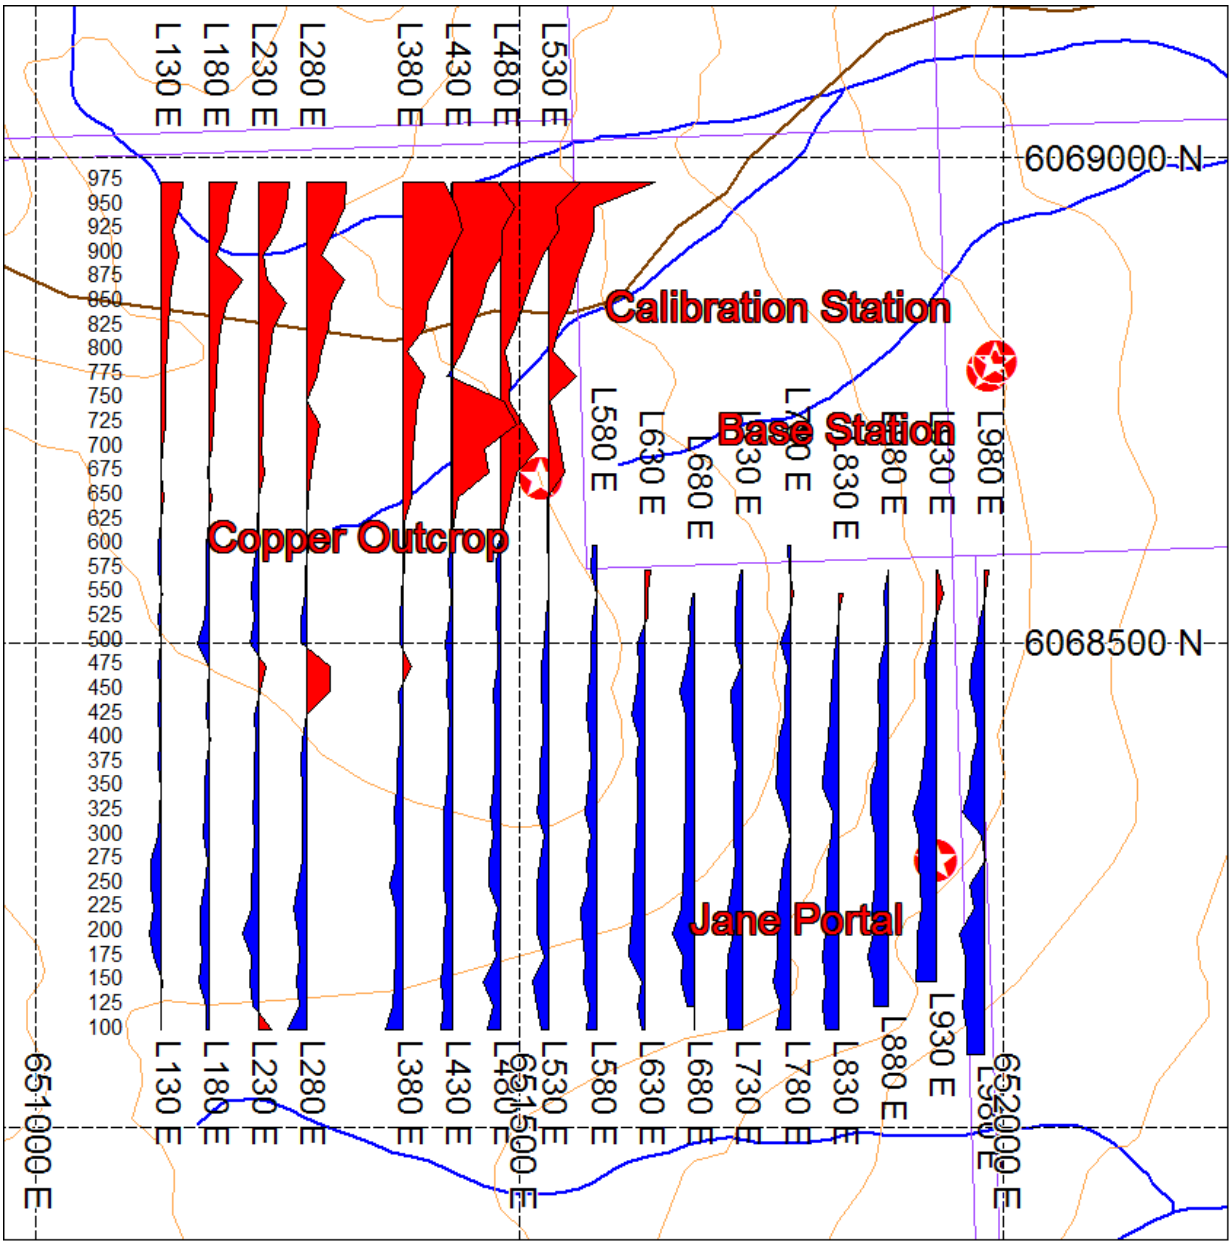
Total Magnetic Field Intensity Maps

(a) Stacked Profiles – baseline=57050, vertical scale 20 nT/m, positive to east (1000 nT between lines).

(b) False Colour Contour Map – linear colour distribution

These displays also show a significant magnetic high covering the northern ends of the western survey lines. The southern edge of this response appears to trend NW-SE. Across the central and southern part of the grid, the magnetic responses are very quiet, falling within a 20 nT range and showing a subtle gradient that decreases to the southeast.

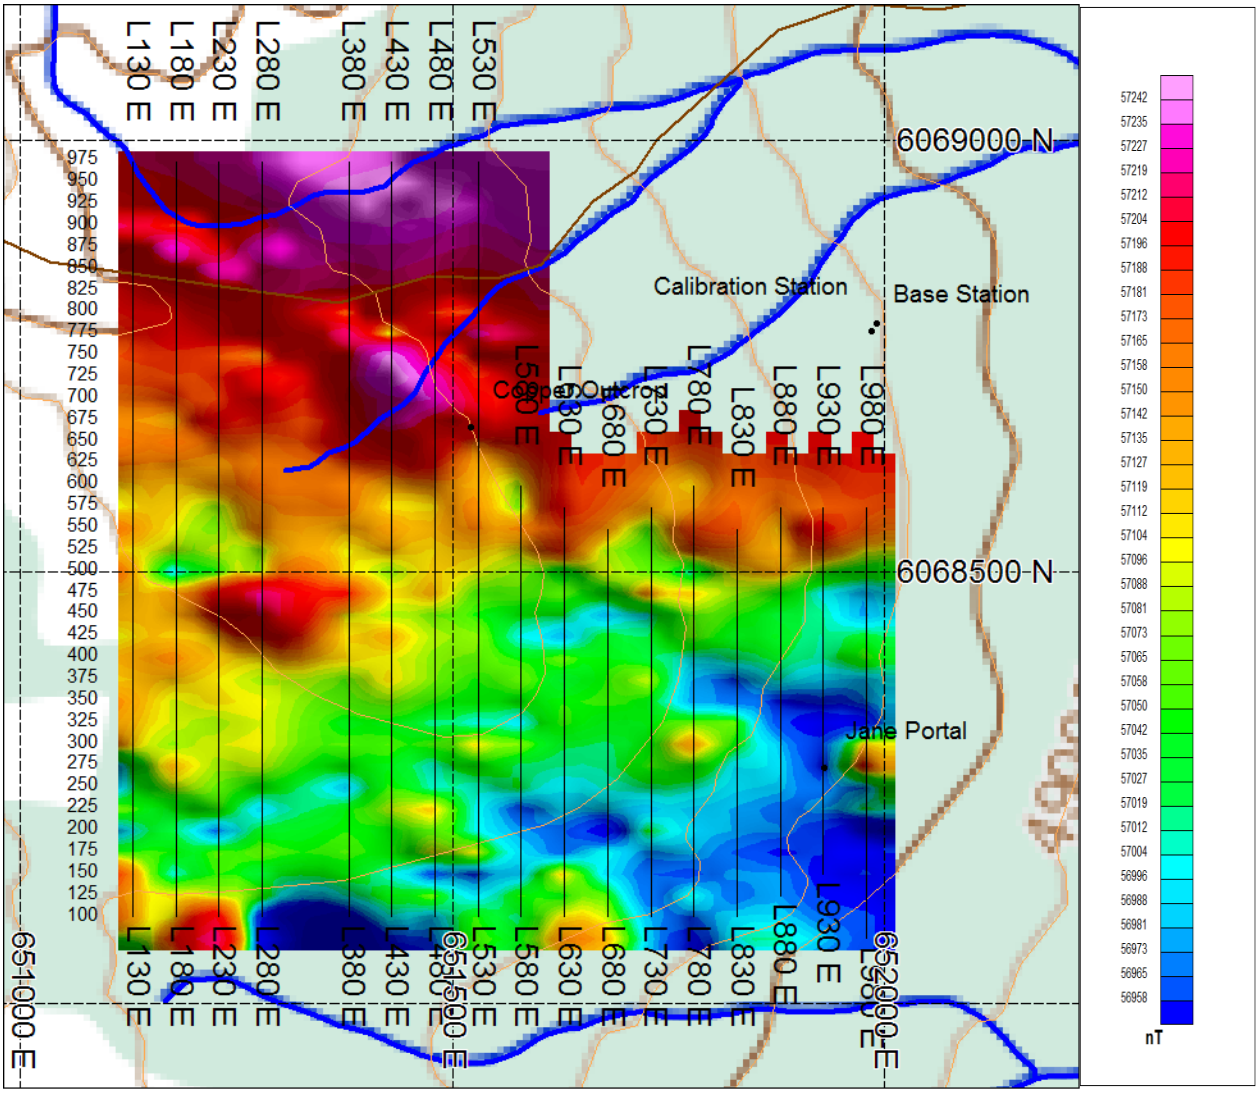
Removing these two anomalous entries from the database produces grid and profile maps that reveal more subtle magnetic trends.



Total Magnetic Field Intensity Stacked Profile Map (mag spikes removed)

Baseline = 57040 nT, Vertical scale = 4 nT/m positive to east (200m between lines)

Filled Red >57040 nT, Blue < 57040 nT

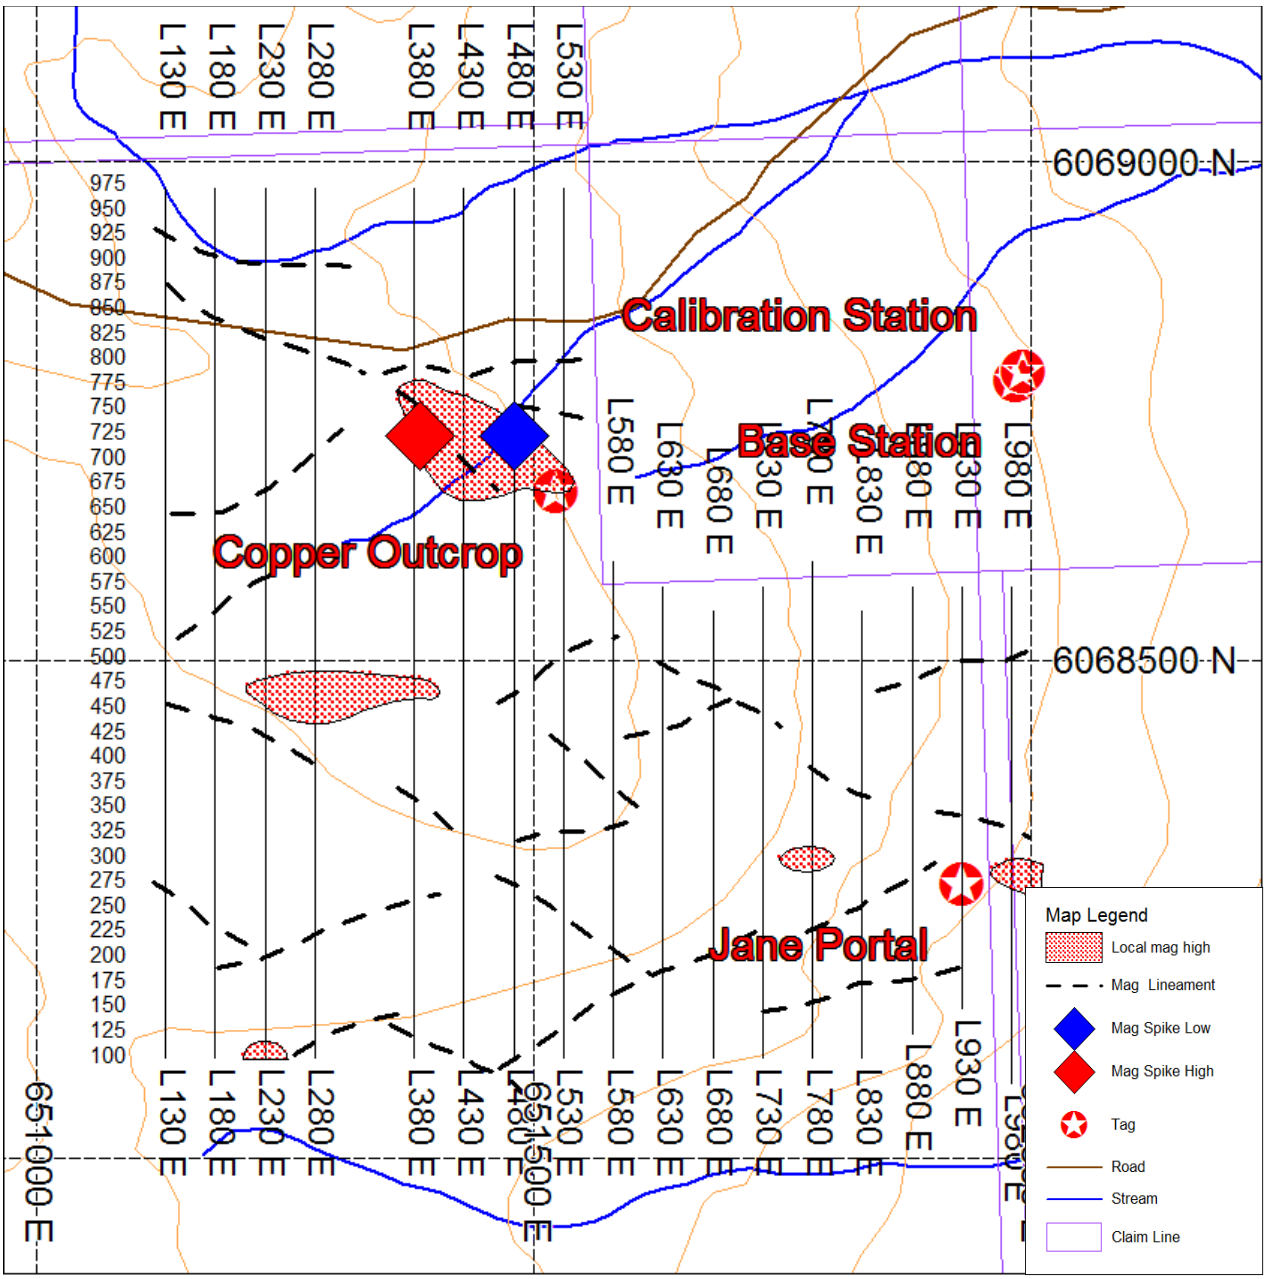


Total Magnetic Field Intensity False Colour Contour Map (mag spikes removed)
Histogram Equalization Colour, Shadow Illumination from northeast

Coloring the contoured data with a histogram equalization method that emphasizes subtle amplitude variations enhances the southeasterly trending magnetic gradient and highlights several low amplitude and small, isolated magnetic high anomalies. The largest of these forms a NW-SE trending pod, some 150m long that underlies the area of the anomalous magnetic spike dipole (centred at 430E/725N). A copper outcrop, identified by ground prospecting is located at the southeastern end of this magnetic anomaly. A second narrow, E-W oriented pod centred at 280E/475N also appears to be around 150m length. Several smaller pods, one immediately east of the Jane Portal, are scattered across the southern half of the grid.

Shadow enhancement image processing highlights two distinct orientations of subtle magnetic lineations. The more prevalent trend is northeasterly (70^0 +/- 10^0) and the other is southeasterly (120^0 +/- 5^0). The Jane portal, located at 930E/275N, is located at the intersection of

two of the strongest of these magnetic lineations. None of these trends are identified on the BC geological mapping. They are likely geological and may reflect a foliation or facies changes.



Geophysical Interpretation Map

In summary, the ground magnetic survey has proven to be an effective mapping tool and has identified several anomalies and trends that require further investigation.

The strong magnetic dipole, located near a copper outcrop, requires more detailed surveying. The source is likely at or very close to the ground surface and should be identifiable by normal ground prospecting techniques or shallow trenching.

Subtle northeasterly and southeasterly magnetic lineations crossing the area likely have a geological source. If the existing geological and prospecting mapping does not identify these trends, future exploration should be directed to these areas to determine the sources.

The strong magnetic high at the north end of the grid is unexplained by the BC geological mapping. Further surveying to the north will be required to map the extent of this response to determine whether it is a localized anomaly or more regional geological feature.

APPENDIX B

LABORATORY CERTIFICATES FOR ROCK SAMPLES

BUREAU VERITAS MINERAL LABORATORIES Canada

www.bureauveritas.com/um

Bureau Veritas Commodities Canada Ltd.
9050 Shaughnessy St Vancouver BC V6P 6E5 CANADA
PHONE (604) 253-3158

Client: **PPM Phoenix Precious Metals Corp.**
4302 Dundas St.
Burnaby BC V5C 1B3 CANADA

Submitted By: Scott Gifford
Receiving Lab: Canada-Vancouver
Received: September 08, 2015
Report Date: December 11, 2015
Page: 1 of 5

CERTIFICATE OF ANALYSIS VAN15002318.2

CLIENT JOB INFORMATION

Project: LAWYERS
Shipment ID:
P.O. Number
Number of Samples: 104

SAMPLE DISPOSAL

PICKUP-PLP Client to Pickup Pulps
PICKUP-RJT Client to Pickup Rejects

Bureau Veritas does not accept responsibility for samples left at the laboratory after 90 days without prior written instructions for sample storage or return.

SAMPLE PREPARATION AND ANALYTICAL PROCEDURES

Procedure Code	Number of Samples	Code Description	Test Wgt (g)	Report Status	Lab
PRP70-250	94	Crush, split and pulverize 250 g rock to 200 mesh			VAN
SLBHP	10	Sort, label and box pulps			VAN
FA430	104	Lead Collection Fire - Assay Fusion - AAS Finish	30	Completed	VAN
MA200	104	4 Acid digestion ICP-MS analysis	0.25	Completed	VAN
DRPLP	104	Warehouse handling / disposition of pulps			VAN
DRRJT	94	Warehouse handling / Disposition of reject			VAN
FA530	4	Lead collection fire assay 30G fusion - Grav finish	30	Completed	VAN
AR401	3	1g/100mL Aqua Regia Digestion by AAS	1	Completed	VAN

ADDITIONAL COMMENTS

Version 2 : AR401-Ag included.

Invoice To: PPM Phoenix Precious Metals Corp.
4302 Dundas St.
Burnaby BC V5C 1B3
