SUMMARY

The Silver Dollar property is located approximately 45 kilometers southeast of Revelstoke and 15 kilometers north-northeast of the community of Trout Lake, British Columbia. The property consists of 34 contiguous mineral claims in the Revelstoke Mining District that cover a total area of approximately 3855 hectares. The property is within the historical Camborne gold-silver mining camp and there is good access and infrastructure.

The Silver Dollar claims are situated within Lower Paleozoic rocks of the Kootenay Arc and are primarily underlain by northwest -southeast trending metasedimentary rocks of the Lardeau Group, Broadview Formation. Locally metavolcanic rocks of the Jowett Formation occur on the property. The Silver Dollar claims cover a portion of the 40 km long Camborne fault system, a key locus of mineral deposits in the district.

The property covers a number of historical high-grade, past-producing gold-silver-lead-zinc mines and developed prospects dating from around the 1890's. The property has seen sporadic exploration, underground mining and development into the 1980's. Historical surface exploration included geology, geochemical surveys, limited trenching and drilling. More recently, geological mapping and sampling was conducted between 2006 and 2009. After acquiring the property in 2012, Happy Creek Minerals conducted a Lidar topographic, airborne magnetic and spectrometer survey, as well as prospecting, geological investigations and rock sampling.

Numerous mineralized zones occur within the Camborne Fault, a 40 km long, regional structure containing small scale past producers and prospects of base metal-gold-silver, and gold+/- silver. The Silver Dollar property is underlain by grey phyllite with inter beds of argillaceous shale. The foliation is northwest trending and dips are sub vertical to the west and east, however tight isoclinal folding is apparent. Locally abundant white quartz veins and vein breccia occur and are parallel to cross-cutting the rock foliation. In some areas, quartz veins are strongly folded and brecciated. The veins range from centimeters to about half a meter in width and form a zone of quartz veins, veinlets, stockwork and breccia, within a broad envelope of silicification and are carbonate.

In 2015, the Company acquired mineral tenure 1035898 that covers the historical Goldfinch mine. The Goldfinch was developed by underground workings and produced gold and silver ore with samples containing up to 300 g/t gold. In 1979, a 281 tonne shipment from

the 1023m level adit of the Goldfinch was sent to the Trail smelter and assayed 10.9 g/t gold, 14.3 g/t silver. Drilling in the late 1980's on the Goldfinch returned encouraging values including 41.2 metres of 2.32 g/t gold with a higher grade section of 1.8 metres of 28.9 g/t gold.

Historical data from the Goldfinch was entered into the ARC-GIS system and maps and sections created of the historical workings and drilling. Although historical assays are not available for all drill core, results of this work indicate two sub-parallel zones that are from 10-30 metres or more in width and 100 metres apart trend northwest and are interpreted to be potentially saddle-reef style gold-bearing zones.

Based on the above work, the 2015 Goldfinch soil sampling was focussed southeast of the Goldfinch prospect, and beyond the historical workings and drill holes. Sampling was performed on 25 metre stations on lines 50 metres apart and covered an area 500 metres by 500 metres in dimension. Soils were analyzed for gold by two different methods. On the southern-most grid line, nine of 10 continuous samples contain over 111 ppb gold and up 2,500 ppb gold. This corresponds to a zone, approximately 225 metres in width that remains open to the south and east. Two adjacent lines to the north contain similar values up to 868 ppb gold over 175 and 100 metre widths, respectively. Another zone containing moderately positive values up to 625 ppb gold is from 100 to 200 metres in width and extends over a distance of 350 metres on the west side of the grid. This zone also remains open in extent to the west and south.

The closely-spaced soil grid and using a large sample size with INNA analysis has provided good control and identified clear anomalies of gold in the soil. Moderate to strongly positive gold values occur in two zones, northwest-southeast trending, and extend over 500 metres beyond the historical Goldfinch workings, and they remain open in extent. The zone is thought to be part of the main regional scale Camborne structure and continues from the Goldfinch southeastward to the Menhinick Creek adits, a distance of approximately one kilometre.

Results from the Company's 2015 work on the Silver Dollar property confirm the Camborne structure to be a key feature for mineralized zones at the Goldfinch zone. With positive grades from historical production and drilling, together with the large scale of positive

gold in soil from the 2015 program, there is thought to be an opportunity for both high gold grades and large tonnage in a near-surface setting.

It is recommended that a thorough compilation of historical data, detailed surface geology, a review of historical drill core, and expanding the soil geochemical grid be performed. Prospecting and trenching of the 2015 soil geochemical anomalies are also recommended. Drilling to test the numerous targets at various depths will be required to outline the size and continuity of the mineralized zones.

1 Location, Access, Infrastructure and Physiography

The Silver Dollar property is located approximately 45 kilometers southeast of Revelstoke and 15 kilometers north-northeast of the community of Trout Lake, British Columbia (Figure. 1). The property is immediately east of the historic mining town of Camborne on the Incomappleux River. The Incomappleux River flows into the northeast arm of Upper Arrow Lake.

The claims are accessible via Highway 23 from the Galena Bay ferry on Upper Arrow Lake (Figure 2). From the ferry landing, it is 18 km to the Beaton/Camborne junction, then an additional 18.5 km through the area once occupied by the historic mining town of Camborne. From this point, the property may be accessed by a variety of logging and historic mine access trails (Incomappleux FSR and Scott Creek Rd) (Figure 3). Access along these trails is most easily achieved using all-terrain vehicles. The summer exploration season is typically between late May and late November.

The claim group is situated within rugged terrain. Most of the valley bottom areas are covered with glacial overburden, vegetation and talus. Much of the property consists of heavily timbered and logged-over slopes with some rock bluffs and with more open alpine areas at higher elevations. Most of the rock outcrop is covered by a heavy layer of moss, making prospecting and geological mapping a slow process. The Silver Dollar claims are bisected and incised by Mohawk Creek, a northwest flowing tributary of the Incomappleux River. Elevations vary from 900 m above sea level, along Mohawk Creek at the north end of the property to 2580 m above sea level in the southeastern portion of the property.

The property is located on the eastern slope of Comaplix Mountain, located in the Duncan Range of the Selkirk Mountains. The elevations on the property range from about 500 to 1500 meters, with the Goldfinch showings around the 1000-meter elevation. The Goldfinch lies on a topographic shoulder or bench with moderate slopes. The Silver Dollar claims are bisected and incised by Mohawk Creek, a northwest flowing tributary of the Incomappleux River.

In the area of the Goldfinch and Silver Dollar there is a number of old cabins and relicts from historical past-producing gold-silver mines and developed prospects dating from around the 1890's. The property has seen sporadic exploration, underground mining and development into the late 1980's.

2 Claim Status

The Silver Dollar property comprises 34 contiguous mineral claims that cover a total area of approximately 3855 ha (Figure 4, Table 1). The property includes an area surrounding the former Goldfinch and Dorothy past-producers at the north end of the Silver Dollar claims. The Dorothy is not part of the Silver Dollar property and consists of 5 crown grants held in an estate and formerly operated by Cayenne Resources. The Silver Dollar claims are centered at 458000 East and 5624000 North, UTM zone 11N on NTS map sheet NTS 82K/13E (82K.072) in the Revelstoke Mining District. All claims are recorded as 100% owned by Happy Creek Minerals Ltd. The claims have not been legally surveyed. Although most historical crown grants have reverted, several small survey parcels or lots still exist within the claims that according to Gator Land Titles have only surface rights attached and are owned by the crown. The Beatrice prospect has two crown grants for which the surface/sub-surface rights are unknown.

3 Exploration and Development History

The historic Camborne mining camp dates to the early 1900's with the discovery of gold mineralization on the historic Eva and Iron Dollar claims. Between 1900 and the mid 1920's work was focused on the Eva mine which produced 543.9 kilograms of gold and 165.5 kilograms silver from 88,763 tonnes of mined material (BC Government MINFILE 082KNW066). There are a number of historical precious and base metal showings. These include the Spider (Sunshine Lardeau), Mohawk, Wheelbarrow, Homestake, Gillman, Mountain Boy, Silver Dollar, Iron Dollar, Beatrice and Rainy Day. The showings have seen varying amounts of exploration and development work mainly up to around 1986; however exploration effectiveness was affected as most of the crown grants were held by numerous private owners.

Work on Goldfinch Group consisted of drilling, pits, trenches, two adits (600 feet), a Riblet aerial tramway and ten stamp mill. Recorded production was 1,450 tons at 0.46 oz gold and 0.12 oz silver. In 1976, Eaton Mining optioned the property to Elgin Mining and drilled the Goldfinch claims. Drill hole number 3 returned 3.35m of 25.3 g/t gold, 5.48 g/t silver, (W.S. Read P. Eng., Report 1980 Exploration Program on Goldfinch Mineral Claims). In 1979, a 281

tonne shipment of ore from the 1023m level adit of the Goldfinch was sent to the Trail smelter and assayed 10.9 g/t gold, 14.3 g/t silver (B.C. Production Report 082KNW076).

Adjoining the Goldfinch to the northwest, the Dorothy/ Independence Group of claims were also explored, and developed. During the 1986 field season, Granges Exploration Ltd. Had optioned both the Goldfinch and Dorothy claims and carried out a 61hole diamond drill program on the “Windflower project”. The main zone of the Dorothy structure was traced with diamond drilling over a strike length of 1300 ft. with widths between 6 and 30 feet. The zone had been tested to a vertical depth of 300 feet. From July 1987 to November 1987, a total of 63 diamond drill holes were drilled on the property for a total of 7,428.84 meters. Diamond drilling on the Windflower project collectively over the 1985, 1986 and 1987 seasons indicated a strong gold-bearing vein structure over a strike length of 400 metres (Main zone). Diamond drilling outlined a potential gold deposit containing a preliminary estimated resource of 169,800 tonnes at a grade of 7.2 grams. Underground exploration commenced in 1988 on the Dorothy. Recoverable mineralized material was later estimated to be 111,375 tonnes at a grade of 5.6 grams.

In 2012 Happy Creek Minerals conducted a Lidar topographic survey and a Heli-GT, three axis magnetic gradient and spectrometer survey consisting of 345.5 km of data was completed over the Silver Dollar property, south of the Goldfinch. The airborne geophysical data combined with Lidar topography survey shows a good correlation with the Camborne fault. The Camborne fault is a key structure for mineralization and most of the mines and showings on the Silver Dollar property occur in proximity to this structure.

The Company also completed a geological evaluation on the Silver Dollar, Gillman and Wheelbarrow areas, collecting 38 rock samples for analysis. Of 38 rock samples, 12 returned silver values in excess of 200 g/t (including 4496 and 2219 g/t Ag) and four samples returned gold values in excess of 35 g/t (including 50.3 and 40.7 g/t Au). A 1.8 metre chip across the Silver Dollar vein returned 16.8% zinc, 3.92% lead, 1.67 g/t Au and 241 g/t silver.

During 2014, geological prospecting and sampling at both the Goldfinch and Silver Dollar areas provided more information about petrology and geochemical distributions of precious metals outside of the Camborne Fault structure. Wide spread samples of quartz vein

material returned generally very low precious metals, and the closer the sample to the Camborne structure, the more positive the geochemical results.

Of the various precious metal showings located on the Silver Dollar claims, the Goldfinch, Gillman, Silver Dollar and Iron Dollar occurrences has the most exploration and development. The Silver Dollar vein was accessed by two connected adits developed 15. 0 meters apart vertically. In 1947, Silver Pass Development Syndicate processed 6 tonnes of ore and recovered 9,860 grams silver, 1,378 kilograms lead and 1009 kilograms zinc. Between 1952 and 1957, Monteray Mining Company Limited completed a 590-meter exploration diamond drilling program and carried out 197 meters of underground development work. In 1974, Resoursex Ltd. completed a very limited geological program to assess the various quartz veins for further work. Two samples from existing trenches were collected at that time, both returning low gold and silver values (Allen, 1974).

In 1983, B and B Mining (Canada) Limited completed a trenching program to remove overburden 170 m of the Gillman vein. The vein was then sampled with gold assays confirming historical assays (1.64 to 1.84 ounces/ton gold) (Sampson, 1983). The remaining showings located in the Gillman area have received minor exploration work and development.

In 1984, Fleck Resources Ltd. carried out a diamond drilling and sampling program on the property. The most significant drill intersection at the Silver Dollar prospect included 2.10 meters grading 229 g/t silver, 1.0 g/t gold, 10.95 % zinc, 4.04% lead and 0.29% copper (BC MINFILE 082KNW101). Another hole at the Gilman returned 0.70 metres of 38.0 g/t gold, and much of the core remains un-sampled. Exploration efforts within the area of the Gillman – Silver Dollar and Iron Dollar has focused on trying to trace the various quartz veins on surface, primarily through trenching and soil sampling.

In 2006, 2008 and 2009, Manson Creek Resources Limited completed three limited geological evaluations on the Silver Dollar property. In 2008, a new showing was located at the southern end of the property called the Jack pot where samples returned positive lead, zinc, silver and trace gold.

A summary of historical exploration work on Silver Dollar Property is presented in Table 2 and Figure 5. Photos 4 to 8 present images of some historical activities at Goldfinch Mine.

4 Geological Setting

The following regional and property geology description is after Church, and Jones 1998, Chernish, 2009, and from prospecting performed by the Company between 2012 and 2015.

4.1 *Regional Geology*

The Camborne camp in general and the Silver Dollar claims in particular, are hosted within rocks of the Kootenay Arc, early Paleozoic to Mesozoic in age and sedimentary, volcanic and metamorphic in composition. The Kootenay Arc is bordered to the east by the Windermere-Purcell anticlinorium. The Monashee and Shushwap metamorphic complexes bound the western and northwestern margins of the terrane. The Kootenay Arc is the locus of a significant change in structural style from up-right folds in the Purcell anticlinorium to coaxially folded westward – verging isoclinal folds within the Kootenay Arc (Fyles, 1964). Metasedimentary rocks of the Lardeau Group underlie the majority of the Silver Dollar claims (Figure. 6). The Lardeau comprises a lower calcareous section overlain by phyllitic schists, quartzites and lenticular greenstone formations. The Jowett Formation is a greenstone unit consisting of volcanic breccias and pillow lavas altered locally to chlorite schist. The Jowett Formation is intercalated upwards with the Broadview Formation. The predominant lithology of the Broadview Formation is grey green, gritty quartz wacke or subarkosic wacke with interbeds of grey to black or green slate or phyllite. Two important bands of quartzite, within the Broadview Formation, are an exceedingly hard, compact, dark blue rock invaded extensively by numerous quartz stringers.

Many batholiths and arrays of small stocks cut older, deformed stratigraphic units throughout the Kootenay Arc. The Kuskanax and Nelson batholiths, apparently middle or late Jurassic in age, are predominantly granite and granodiorite in composition although diorite, monzonite and syenite occur locally. The Nelson batholith and related granitic stocks may have been controlled by antecedent structures. Medium-size plutons and small stocks of fresh granite, monzonite and syenite, Cretaceous and Tertiary in age, also occur.

4.2 *Property Geology*

The property is located in the northern end of the Kootenay Arc. The general area is part of the Selkirk Allochthon -a large east directed thrust slice between the Upper Arrow Lake and the Rocky Mountain Trench. The Selkirk Allochthon contains rocks of ancient North American affinity in its east part and rocks of the suspect Kootenay Terrane of the old "Kootenay Arc" in its west part. The Menhinick Creek area is underlain by rocks of the Lardeau Group which are the oldest stratigraphic unit of the Kootenay Terrane.

The Lardeau group ranges in age from Lower Cambrian to Upper Devonian or Lower Mississippian. It is subdivided into three main formations. The Index Formation is a black slate at the base, overlain by the Jowett Formation consisting of a largely chloritic greenstone, metatuff and other pyroclastic rocks. These are overlain by the Broadview Formation comprised of a fine grained clastic unit composed mainly of phyllite and grit with minor dolomitic horizons.

The Incomappleux River cuts through several regional NW trending upright folds that appear to result from NE -SW compression by the Galena Bay and Kuskanax Plutons to the SW and the Battle Range Batholith to the NE. These plutons are mid -Jurassic in age and the bulk of first order folds visible in the area are interpreted to be of that age.

The rocks in the northern part of the Silver Dollar property, in the vicinity of the Goldfinch prospect is part of the Incomappleux River are in the west limb of the Silver Cup Antiform, an overturned to the west, tight to isoclinal fold with a NE dipping axial surface. The rocks on the property are grouped into two units:

- 1) a series of silver to grey to dark grey gritty phyllite with local carbonaceous seams and layers of carbonate -sericite rock.
- 2) A medium green, non-bedded to streaky phyllite greenstone with dark green clasts and local silicic pebbles of pyroclasts.

The major deformation appears to have been during the mid-Jurassic. The mineralized zones appear to have accompanied the last phase of folding. The main zone at the Goldfinch appears to be associated with an axial plane shear. The zones are in the shape of elongated, flattened pod or lenses, and terminate with abrupt pinch outs. The veins consist of quartz, quartz-carbonate +/-fuchsite with minor disseminated siderite pods and contain 5 to 30% pyrite

and minor chalcopyrite, galena and sphalerite. Gold and silver is generally associated with the sulphide mineralization. Visible gold occurs.

The central and southern portion of the Silver Dollar claims are situated within Lower Paleozoic rocks of the Kootenay Arc and are primarily underlain by northwest -southeast trending metasedimentary rocks of the Lardeau Group, Broadview Formation. Black slates, carbonaceous schist, grey and reddish-brown weathering grits and quartzite and greenish grey talcose schist underlie the property. Locally metavolcanic rocks of the Jowett Formation occur near the north end of the property. The metasedimentary succession typically displays a northwest – southeasterly strike of 140° and dips between 50° and 80°, averaging 65° to the northeast. The lithological sequence has been folded such that dip angles show considerable variation. Joint planes are locally developed within the stratigraphic succession and oriented perpendicular to regional strike, and dip 40° to 80° to the northwest.

The Silver Dollar claims cover a broad shear zone called the Camborne fault. The regional trend of the Camborne fault is between 140° and 160° azimuth and dips on the order of 50° to the northeast. The various quartz veins on the property are developed parallel, or sub-parallel to the fault. The foliation observed generally parallels this trend as well. The developed quartz veins proximal to this fault appear to be on the order of 0.5 to approximately 3.0 metres in width and display boudinage. Quartz veins and stringers also occur some distance from the main fault. Within this broad shear zone, the numerous quartz veins are commonly associated with graphite – chlorite schist partings and locally host significant concentrations of precious and base metals.

Where observed, the Broadview Formation sequence is dominated by black, grey to green phyllite and psammite that is locally graphitic. Bedding is on the centimeter to metre scale, and bedding is generally quite recognizable. Minor quartz veining, ± iron carbonate, is common parallel to or cross-cuts bedding parallel foliation.

The airborne magnetic and spectrometer geophysical data combined with 2012 Lidar topography survey shows a good correlation with the Camborne fault over the Silver Dollar property. The Camborne fault is thought to be a key structure for mineralization and most of the prospects on the Silver Dollar property lie along or adjacent the structure.

5 Mineralization

Mineralization on the Silver Dollar property is related to the Camborne shear zone structure where numerous locations contain significant concentrations of precious and base metals. These prospects consist of quartz veins, veinlets, stockwork and locally vein breccia that vary from several centimeters to several meters in width and commonly have graphite and quartz-carbonate-ankerite chlorite schist partings and wall rock. Precious metal mineralization occurs with variable concentrations of pyrite and base-metals both within the quartz veins and along the vein selvages. Locally massive sulphide zones occur which have remobilization or replacement textures and abundant carbonate. Quartz and sulphide minerals observed are suggested to be in order of deposition: ankerite, quartz, pyrite, sphalerite, chalcopyrite, and fine to coarse grained galena (MINFILE 082KNW049). Argentiferous tetrahedrite and arsenopyrite also occur locally. Native silver, argentite, polybasite, ruby silver, stephanite and electrum occur (Church and Jones, 1998). Gold is present in small quantities and is rarely seen as native gold or electrum as it generally occurs mixed within sulphides. It is suggested that the carbon in the phyllite has assisted in the precipitation of gold contained in the mineral-bearing solutions as the highest grade of gold occurs around the carbonaceous inclusions (Church, and Jones 1998). Chernish (2006) notes an association between gold, pyrite and minor graphitic lamina and silver mineralization that is broadly associated with tetrahedrite and galena.

Gillman Deposit: Located 10 kilometres southeast of Camborne and on the north side of the East fork of Mohawk Creek, the prospect is at 1800 metres elevation. The area is underlain by metasedimentary rocks of the Lower Paleozoic Lardeau Group, which includes medium grey to greenish quartzite, greywackes, carbonaceous phyllite and quartz sericite schist. A northwest striking, east dipping quartz vein, 2 metres wide, cuts the metasediment. The vein contains galena, pyrite and sphalerite. A sample assayed 109 grams per tonne silver and 124 grams per tonne gold (Annual Report 1914, page 263). In 1933, a tonne of ore returned 62 grams of silver, 62 grams of gold, 22 kilograms of lead and 23 kilograms of zinc. A drill hole in 1986 returned 0.70 metres of 38.0 g/t gold, however much of the core remains un-sampled.

Silver Dollar Vein: The Silver Dollar vein was accessed by two connected adits developed 15.0 meters apart vertically. In 1947 Silver Pass Development Syndicate processed 6 tonnes of ore and recover 9,860 grams silver, 1,378 kilograms lead and 1009 kilograms zinc. Between

1952 and 1957 Monteray Mining Company Limited completed a 590 meter exploration diamond drilling program and carried out 197 meters of underground development work. In 1984 Fleck Resources Ltd. carried out a diamond drilling and sampling program on the property. The most significant drill intersection included 2.10 meters grading 229 g /1 silver, 1.0 g /1 gold, 10.95 % zinc, 4.04% lead and 0.29% copper (BC MINFILE 082KNW101).

During 2012 Happy Creek Minerals performed geological prospecting and rock sampling on the Silver Dollar, Gillman and Wheelbarrow deposits. Sample analyses have returned encouraging assay results including high gold and silver values associated with elevated to substantial copper, lead and zinc values. Locally positive indium values up to 4.89 g/t also occur. Of 38 rock samples, 12 returned silver values in excess of 200 g/t (including 4496 and 2219 g/t Ag) and four samples returned gold values in excess of 35 g/t (including 50.3 and 40.7 g/t Au). The data suggests a rough correlation between silver and gold values. A 1.8 metre chip across the Silver Dollar vein returned 16.8% zinc, 3.92% lead, 1.67 g/t Au and 241 g/t silver.

Goldfinch Deposit: The Goldfinch mineralization trends northwest, with two separate zones, each having widths of approximately 10-30 metres. The zones consist of quartz and quartz-carbonate-sulphide veins, stock work and silicified phyllite containing pyrite, and locally sphalerite, chalcopyrite and tetrahedrite. Individual sample assays range from less than 0.03 up to 302.62 g/t gold and trace to 330 g/t silver. Drilling and underground development also indicates gold and silver values occur within pyrite-bearing silicified or quartz-carbonate altered phyllite as well. Historical reports from the Goldfinch indicates visible gold occurs in drill core with samples up to 0.85 metres of 141.58 g/t gold, or wider intervals of 41.2 metres of 2.3 g/t gold including a higher grade section of 1.8 metres of 28.93 g/t gold.

Historical drill holes were not completely sampled and there are gaps between mineralized zones in most holes. Some holes have high grade samples with no sampling on either side, and some holes ended with samples containing positive values up to 1.02 g/t gold. Overall, a mineralized structural zone that is 75-150 metres in width and extending for several hundred metres may be viewed as a potential bulk tonnage, open-pit target and it remains un-defined and open in extent in several directions.

6 2015 Exploration, Soil Geochemical Survey

In 2015, Happy Creek Minerals extracted data from historical drill holes and underground mining reports (Assessment Reports # 14597, 15401, 16753 and 17929A). The data was compiled in ARC-GIS software and used to create surface plan and cross section assay maps of the Goldfinch zone (Appendix 3). Interpretation of the data suggests that mineralized zones can pinch and swell, roll, and trend northwest-south east overall. It is thought possible the mineralized zones may be of a saddle-reef type, however further geological work is required. Results of the work suggests potential for mineralized zones to occur along strike to the southeast of the Goldfinch prospect, an area having little historical work.

In September 2015, the Company collected 203 soil samples from the Goldfinch claim southeast of the historical workings and previous drill holes (Figure 7). The samples were collected from B horizon (25-30cm depth) 25 metres apart on east-west oriented lines that are 50 metres apart. The samples were dried at 60°C and sieved through minus 80 mesh. The resulting 100 g samples were dried again at 60°C and analyzed for gold and multi-elements by two methods at Act Labs of Kamloops, B.C. For one method, a 0.5-gram sample was digested by aqua regia then ICP/MS analyses performed with gold results reported in parts per billion (ppb), and 51 other elements in ppm or %. All samples were also analyzed for gold by Fire Assay and Neutron Activation (INNA) using a 10-gram pulp sample. Sample bags were labeled with the corresponding sample ID numbers from the sample booklets. The sample ID tag was also inserted into the sample bag prior to sealing. The sampling site was labeled with blue flag.

For the INNA analyses, samples range from 1.1- 2550 ppb (2.55 g/t) gold, and 46 samples contain greater than 100 ppb gold and 29 contain over 200 ppb gold. For the 0.5 gram ICP/MS method, samples range from 0.5 to greater than 10,000 ppb (10 g/t) gold, and 21 samples contain greater than 100 ppb gold and eight contain over 200 ppb gold. Comparative analyses of the two methods and analytical duplicates suggest some gold is relatively coarse grained and that a nugget effect exists (Table 4).

Interpretation suggests the larger sample size and Fire Assay along with INNA provide good quality analyses, although ICP-MS results would provide a reasonable geochemical indication for anomalous zones of interest. Log Normal probability of the INNA data suggests a range of gold values in soil between 37 and 75 ppb are moderately positive and those over 75 ppb, strongly positive.

7 Geochemistry Results and Discussion

The 2015 prospecting and rock samples collected southeast of the Goldfinch area indicates limited outcrop occurs and consists of grey phyllite with inter beds of argillaceous shale and quartz veins containing iron carbonate, oxide and pyrite. The strike of the foliation is northwest trending with dips about sub vertical (Photos 1 to 3). Locally abundant white quartz veins and locally vein breccia cut through the unit, and strike parallel to the rock foliation. In some areas, quartz veins are strongly folded and brecciated. The veins range from centimeters to about half a meter width.

The 2015 soil sampling program was completed in a 500 metre by 500 metre tightly spaced grid and southeast of the Goldfinch workings and historical drilling. The results of geochemical analyses indicate moderate to strongly positive gold values occur in a northwest-southeast trend that extends over 500 metres beyond the historical Goldfinch workings (Figures. 8a, 8b). The zone is thought to be part of the main regional scale Camborne structure connecting the Goldfinch and Menhinick Creek adits, a distance of approximately one kilometre. On the southern-most grid line, nine of 10 continuous samples were over 111 ppb gold and up 2,500 ppb gold (Table 4, Figure 8b). This corresponds to a zone, approximately 225 metres in width, that remains open to the south and east (Figure.9). Two adjacent lines to the north contain similar values up to 868 ppb gold over 175 and 100 metre widths, respectively.

A second zone containing moderately positive values up to 625 ppb gold is from 100 to 200 metres in width and extends over a distance of 350 metres on the west side of the grid. This zone remains open in extent to the west and south. For both of these geochemical zones, evidence of historical drilling or other work was not observed.

Soil samples locations and gold and silver analytical results are listed in Table 4. Silver assay results containing values up to 2.84 ppm are plotted in Figure 8c. Assay results are listed in Appendix 1 and Certificate of analyses provided in Appendix 2.

Results from the Company's 2015 exploration on the Silver Dollar property confirm the Camborne structure to be a key feature for gold-mineralized zones at the Goldfinch zone as well as ten kilometres southeast at the Silver Dollar and Gilman zones.

Interpretation of the regional mineral prospects suggests the Camborne fault system is host to two hydrothermal and mineralizing events, or possibly telescoping of a single event controlled by doubly verging asymmetrical and isoclinal folds and thrust faults (Colpron et al, 1998, Figure 10). Base metal-silver-gold vein and replacement style, and quartz-pyrite-gold-silver style mineralized zones occur. Although many samples of quartz veins have returned low values, several areas adjacent or sub-parallel the central Camborne fault have provided encouraging results in outcrop and stream sediments that are thought to be an opportunity to discover additional mineralization. A thorough understanding of the structural, lithological and hydrothermal alteration controls of the various mineralized zones and substantial drilling is anticipated to effectively target and outline the deposits. The length and potential depth extent of the Camborne fault and numerous mineralized zones associated with it suggest potential for a large scale mineral system having tectonic control and modification.

8 Conclusions and Recommendations

The Silver Dollar property consists of 34 contiguous mineral claims that cover a total area of approximately 4325.5 hectares, and located southeast of Revelstoke, B.C., Canada. The property is within the historical Camborne gold-silver mining camp with excellent access and infrastructure.

The Silver Dollar property spans a distance of 14 km, covering significant sections of an approximately 40km long structure known as the Camborne fault, in which numerous high grade gold-silver-lead-zinc historical producers and prospects occur. Most of gold-silver-lead-zinc prospects on the Silver Dollar property occur along the Camborne fault trend, and there is potential for blind deposits. The length and potential depth extent of the Camborne fault and numerous mineralized zones associated with it suggest potential for a large scale mineral system having tectonic control and modification.

The 2015 geochemical survey has identified two zones with strongly positive gold values in soil up to 200 metres in width, extending southeast from the historical Goldfinch workings and previous drilling. The two zones are open in extent. These do not appear transported, and occur along the trend of the Camborne fault. The soil results along with historical results suggest the Goldfinch hosts potential for both high gold grades and large tonnage in a near-surface setting.

It is recommended that a thorough compilation of historical data, detailed geology and interpretation be performed. Additional geochemical surveys to expand upon the 2015 results and trenching at Goldfinch is also recommended. Future drilling to test existing and newly developed targets at various depths will be required.

Respectfully Submitted,

10 Statement of Qualifications

I, Sassan Liaghat, Ph.D, of Coquitlam, British Columbia, do hereby certify:

That I am a senior geologist with an office at #460 - 789 West Pender Street, Vancouver, BC, V6C 1H2.

That I am graduate from the Ecole Polytechnique of Montreal with a Ph. D of Engineering degree in Economic Geology in 1992.

That I am a graduate of the Mineral and Exploration Diploma Program (MINEX) in 1988, and a Master of Science, Economic Geology program in 1989 from McGill University.

That since 1992, I have been involved in research, teaching and mineral exploration activities for base and precious metals in various areas of Canada.

That I have been actively engaged in the mining and mineral exploration industries in British Columbia since 2006.

That, I managed, in part, the 2009, 2010 exploration programs on the Rateria and West Valley properties.

That I am the author or co-author of more than 70 international scientific papers or local reports.

That I have been granted Share options of Happy Creek Minerals Ltd.

Dated in Vancouver, B.C., February 2, 2016

“Sassan Liaghat”

Sassan Liaghat Ph.D.

I, David E. Blann, P.Eng., of Squamish, British Columbia, do hereby certify:

That I am a Professional Engineer registered in the Province of British Columbia since 1990.

That I am a graduate in Geological Engineering from the Montana College of Mineral Science and Technology, Butte, Montana, 1987.

That I am a graduate in Mining Engineering Technology from the B.C. Institute of Technology, 1984.

That I have been actively engaged in the mining and mineral exploration industry since 1984.

Dated in Vancouver, B.C., February 2, 2016

Table 2, SUMMARY OF EXPLORATION HISTORY

The historic Camborne mining camp dates to the early 1900's with the discovery of gold mineralization on the historic Eva and Iron Dollar claims

Between 1900 and the mid 1920's the area centered on the EVA mine produced 543.9 kilograms of gold and 165.5 kilograms silver from 88,763 tonnes of mined material

Between 1899 and 1984 the reported production from the Beatricemine included 558 grams gold, 1832 kg silver, 182,939 kg lead, 10,894 kg zinc from 618 tonnes of ore.

Between the discovery of the Spider mine in 1910 and mine closure in 1958, 371 kg gold, 53,451 kg silver, 85 tonnes copper, 10,845 tonnes lead, 11,519 tonnes zinc, 65 tonnes cadmium and 4 tonnes antimony were recovered from 124,436 tonnes of milled ore.

In 1947, Silver Pass Development Syndicate processed 6 tonnes of ore and recover 9,860 grams silver, 1,378 kilograms lead and 1009 kilograms zinc from Silver Dollar.

Between 1952 and 1957, Monteray Mining Company Limited completed a 590-meter exploration diamond drilling program and carried out 197 meters of underground development work.

In 1974, Resoursex Ltd. completed a very limited geological program to assess the various quartz veins of the Silver Dollar.

In 1983 B and B Mining (Canada) Limited completed a trenching program to remove overburden from a 170 m length of the Gillman vein.

In 1984, Fleck Resources Ltd. carried out a diamond drilling and sampling program on the Silver Dollar property.

In 2006 Manson Creek Resources Limited completed a limited geological evaluation of the Silver Dollar calims.

In 2008 Manson Creek Resources Limited completed a limited geological prospecting program in the Silver Dollar claims.

In 2009, Manson Creek Resources Limited completed a limited prospecting program on the Silver Dollar claims.

In 2012 Happy Creek Minerals conducted a Lidar topographic survey and a Heli-GT, three axis magnetic gradient and spectrometer survey consisting of 345.5 km of data was completed over the Silver Dollar property. The Company also completed a geological evaluation on the Silver Dollar, Gillman and Wheelbarrow areas, visiting some showings and collecting 38 rock samples for analysis.

In 2014, geological prospecting and sampling at both the Windflower and Silver Dollar areas provided more information about petrology and geochemical distributions of precious metals in proximity to the Camborne Fault. Of 55 analyses samples, some sample have returned positive geochemical results, including 6.17 ppm Ag and 49 ppm Ag from adjacent the Goldfinch and Gillman prospects, respectively. Rock samples from the Gillman prospect returned values of 0.13% lead and 8.29 g/t gold

Appendix 2

Certificates of Analyses, 2015

Quality Analysis ...

Innovative Technologies

Date Submitted: 14-Sep-15

Invoice No.: A15-07749

Invoice Date: 19-Oct-15

Your Reference: Goldfinch

Happy Creek Minerals Ltd
#460-789 West Pender Street
Vancouver BC V6C 1H2
Canada

ATTN: David Blann

CERTIFICATE OF ANALYSIS

203 Soil samples were submitted for analysis.

The following analytical package was requested: Code 1A1 Au - Fire Assay INAA

REPORT **A15-07749**

This report may be reproduced without our consent. If only selected portions of the report are reproduced, permission must be obtained. If no instructions were given at time of sample submittal regarding excess material, it will be discarded within 90 days of this report. Our liability is limited solely to the analytical cost of these analyses. Test results are representative only of material submitted for analysis.

Notes:

*If value exceeds upper limit we recommend reassay by fire assay gravimetric Code 1A3.

Assays are recommended for values >10,000 for Cu and Au. The Au from AR-MS is only semi-quantitative.
For accurate Au data, fire assay is recommended.

CERTIFIED BY:

A handwritten signature in black ink, appearing to read "Emmanuel Eseme".
