

## ASSESSMENT REPORT TITLE PAGE AND SUMMARY

**TITLE OF REPORT: 2016 Geochemical Report on the Forrest Kerr Property**

**TOTAL COST: \$ 88,007.90**

AUTHOR(S): Cornell McDowell

SIGNATURE(S):

A handwritten signature in blue ink that appears to read "Cornell McDowell".

NOTICE OF WORK PERMIT NUMBER(S)/DATE(S):

STATEMENT OF WORK EVENT NUMBER(S)/DATE(S) : 5629959

YEAR OF WORK: 2016

PROPERTY NAME: Forrest Kerr

CLAIM NAME(S) (on which work was done):

502751, 501895, 501812, 502758, 502738, 501227, 592381, 507426, 1044513, 507455, 1045518

COMMODITIES SOUGHT: Au, Cu, Ag, Pb, Zn

MINERAL INVENTORY MINFILE NUMBER(S),IF KNOWN:

MINING DIVISION: LIARD Mining Division

NTS / BCGS: NTS 104B

LATITUDE: 56°54' N

LONGITUDE: 130° 37' W

UTM Zone: 9-U EASTING: UTM 401000 E NORTHING: 6307800 N

OWNER(S): Aben Resources Ltd.

MAILING ADDRESS: #1610—777 Dunsmuir, Vancouver, B.C., V7Y 1K4

OPERATOR(S) [who paid for the work]: Aben Resources Ltd.

MAILING ADDRESS: as above

REPORT KEYWORDS

Forrest Kerr Fault, Stikine Assemblage: Hazelton & Stuhini groups, Paleozoic, Triassic, Jurassic

## **SUMMARY**

The Forrest Kerr property consists of 56 contiguous mineral claims covering 23,397 hectares of mountainous terrain in northwestern British Columbia. The property is accessible to its southern portion via the Coast Mountain Hydro project road and to its northern portion via the Galore Creek mine road. The remainder of the property is currently accessible only by helicopter. The Coast Mountain Hydro project is a run-of-the river hydro project located at the confluence of the Iskut River and Forrest Kerr creek that generates 297 MW of electrical energy to the BC power grid via the 287 kV Northwest transmission line. The hydro facilities are operated by AltaGas and include a 300 person camp located in the southernmost portion of the property, which has sufficient space to accommodate several mineral exploration crews. The Galore Creek Mining Corporation maintains a 100 person camp adjacent to the northern portion of the Forrest Kerr Property. The nearest community is the port of Stewart, located approximately 90 kilometres to the south, which has a deep-water concentrate & loading facility.

The Forrest Kerr property represents a consolidation of three mineral properties in addition to several claims staked by Aben Resources in 2016. From north to south, the RDN claims are currently held by Kiska Metals Corp. (“Kiska”), the Forgold claims are owned by Carl Von Einsiedel and the Forrest claims are owned equally by Pamicon Developments Ltd. (“Pamicon”) and Equity Exploration Consultants Ltd. (“Equity”). Aben Resources (“Aben”) has option agreements to earn 100 % of all the claims by incurring three million dollars in exploration expenditures on the various properties before June 2020.

The Forrest Kerr property lies within the Stikine Terrane, near the boundary between the Intermontane and Coast Tectonic Belts of the Canadian Cordillera. The property straddles the Forrest Kerr Fault (“FKF”), a major lineament that can be traced in excess of 55 kilometres along strike. In general on the property, rocks to the west of the fault represent the Paleozoic members of Stikinia while those to the east are Mesozoic members, namely Triassic Stuhini and Jurassic Hazelton volcanic and sedimentary assemblages. There are numerous occurrences of early to middle Jurassic intrusive rocks throughout the property, which have close spatial and genetic links with many mineral deposits. The property is located in the center of the Golden Triangle of British Columbia, an area that hosts significant Au-Cu±Mo porphyry deposits, intrusion-related Au±Ag vein deposits and high-grade Au-Ag volcanogenic massive sulphide deposits. In fact, the Golden Triangle has a mineral endowment exceeding 100 million ounces of gold in N.I. 43-101 compliant resources and historical production within 50 kilometres of the Forrest Kerr property. There have been up to four distinct phases of Late Devonian to Tertiary deformation imposed onto the rocks of Stikinia.

Exploration work on the three separate claim packages began in the late 1980’s during a flurry of activity that was spurred by the discovery of the Snip and Eskay Creek mineral deposits. On the RDN claims a total of 80 drill holes have been completed between 1990 and 2005. Drill results from 1990 reported 125 g/t Au over 0.85 metres and 91.0 g/t Au over 1.95 metres (RG91-21) from the Carcass Creek area and 33.7 g/t Ag over 27 metres (RDN05-42) from the RTB zone. A total of 5 holes were drilled in 1991 on the Forgold claims, although subsequent events have caused the claim boundary to be adjusted and now only one historic hole lies within the Forgold

boundary. Two significant intersections of gold mineralization were reported; 3.9 g/t Au over 1.58 metres in drill hole FG-2 and 19.2 g/t Au over 0.82 metres in drill hole FG-3 (Bond, 1992). Two narrow zones of copper mineralization were reportedly intersected in hole FG-5, located approximately one kilometre south of the other 4 holes (2.97% copper over an interval of 0.31 metres and 1.14% copper over an interval of 1.16 metres). The Forrest claims had 35 drill holes in 1990 and 1995. The best drill intersections at the Creek zone averaged 0.77% Cu and 1.97 g/t Au over 39.7 metres of core length (16.8m true width) and 4.05 g/t Au over 3.15 metres of core length (1.6m true width).

Over 40 polymetallic mineral occurrences have been described within the current boundaries of the Forrest Kerr property. Mineralization styles range from discrete intrusion related Au + Cu +/- Ag veins to breccia, shear and stockwork zones in addition to areas with massive sulfide potential.

## **INTRODUCTION**

This report has been prepared for Aben Resources Ltd. for the purpose of fulfilling reporting requirements in order that assessment credits may be applied to the claim group. The author was present throughout the 2016 exploration program which ran from September 8-21 and involved the collection of 362 soil, 35 rock and 11 stream sediment samples. The focus of the program was to both confirm historically reported surface sample analytical results and to evaluate the potential for mineralization across the property. The author has undertaken a thorough data compilation of all information provided and available on a property wide basis. Information in this report was derived from publicly-available assessment reports, private reports from various operators, and government maps and publications. A complete list of references is provided in Appendix A.

## **RELIANCE ON OTHER EXPERTS**

The author is not relying on a report, opinion, or statement of another expert who is not a qualified person, or on information provided by the issuer, concerning other legal, political, environmental, or tax matters relevant to the technical report. Information regarding exploration programs prior to 2016 was derived from various assessment reports and private company reports, rather than first-hand experience. There is no reason to believe that any of this information is incorrect and portions were validated by the author in the field. The author has made no attempt to verify the legal status and ownership of the three separate properties, nor is he qualified to do so.

All dollar figures are in Canadian dollars (CDN) and g/t refers to grams/tonne.

## **PROPERTY DESCRIPTION AND LOCATION**

The Forrest Kerr property represents a consolidation of three properties (RDN, Forgold, and Forrest) in addition to 10 recently staked claims by Aben Resources. The property is centred at 56° 54' N latitude and 130° 37' W longitude (UTM NAD 83 401000 E 6307800 N), within the Liard Mining Division on map sheets 104B/15E and 104G/2E (Figure 1). The property consists of 56 contiguous mineral claims which cover 23,397 hectares in northwestern British Columbia (Figures 2). Claim data has been sourced from Mineral Titles Online (MTO), a division of the British Columbia Ministry of Energy and Mines. All of these mineral claims are governed by the Mineral

Tenure Act and the Mines Act (British Columbia) and are subject to a required assessment work or cash in lieu. All tenure data is summarized in Table 1. The author knows of no environmental liabilities associated with the property.

There are portions of certain claims within the claim group that are covered by staking reserves related to the potential development of hydroelectric power. Collectively, Order-in-Council 1589 (1972) and Order-in-Council 440 (1983) state that ground below 580 metres elevation is subject to flooding for hydroelectric development. Mineral exploration and development may be carried out in these staking reserves, but no compensation will be payable in the event of flooding. Claims located at lower elevations in the More Creek valley that may be partially affected by these two orders include; 502751, 502752, 502756, 518112, 501812, 501895, 501927 and 1044993. Also, conditional staking reserves #378962 and #385934 cover elevations below 480 metres on these claims located along the Forrest Kerr creek and Iskut river; 597143, 597144, 842682, 1044514, 1044989, 1044988 and 1043752.

In the event that a commercially exploitable mineral deposit is discovered in an area subject to these reserves, a subsequent decision by the Government of British Columbia to flood the area for water resource or hydroelectric generating purposes will not entitle the title holders to any form of compensation. To date, no significant mineralized occurrences have been identified in areas subject to the Orders-in-Council or staking reserves.

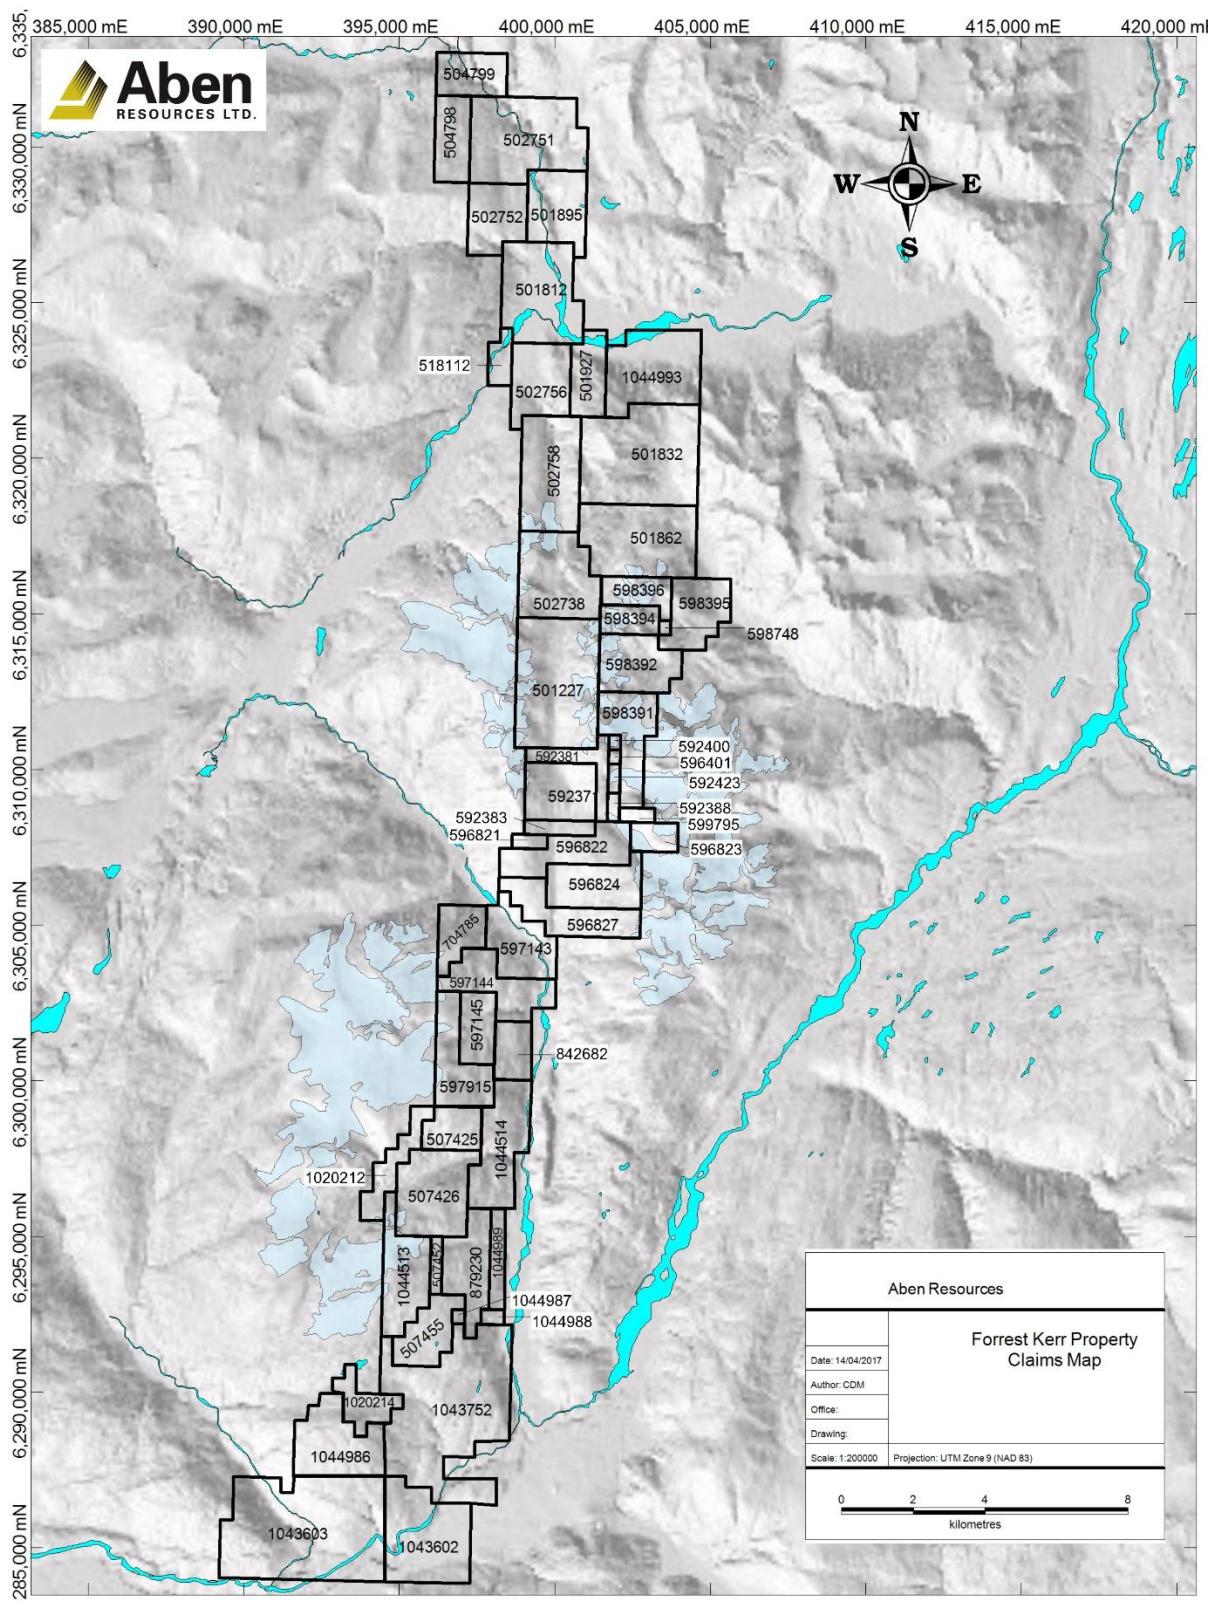

Surface rights are held by the Crown, as administered by the Province of British Columbia. There are no placer rights within the Forrest Kerr property. The ownership of other rights (timber, water, grazing, etc.) over the Forrest Kerr property has not been investigated by the author.

The Forrest Kerr property lies within the traditional territory of the Tahltan First Nation. Land claims have not been settled in this part of British Columbia and their future impact on the property's access, title or the right and ability to perform work remain unknown.

Aben Resources Ltd. has entered into separate agreements with the three owners of the respective claim groups to acquire a 100% interest in the various properties, details of which follow. Aben has entered into an agreement with Rimfire Minerals, a wholly owned subsidiary of Kiska Metals, whereby Aben may acquire a 100% interest in the RDN property by issuing 4 million shares and expending \$1,000,000 in exploration expenses on the RDN claims before June 30, 2020. Rimfire retains a property wide net smelter return (NSR) of 1.33% for which no buy back provision exists. Rocky Saliken and Randy DeBock share equally a 1% royalty interest (on all RDN claims except tenure 504799), of which 50% can be purchased for \$500,000. In addition, Rimfire owns a 2% NSR on claims 504798 & 504799 that are fully buyable for \$2,000,000. A 100% interest in the Forgold group of claims can be attained by the issuance of 1 million common shares to the current claim owner. These claims are subject to a 2% NSR, half of which can be purchased for the sum of \$1,000,000. Aben can acquire a 100% interest in the Forrest group of claims through the issuance of 2 million common shares and by incurring direct exploration expenses of \$500,000 by June 30, 2020. The Forrest claim group is subject to a 2% NSR, half of which may be purchased for \$1,500,000.

Table 1: List of tenures

## **ACCESSIBILITY, PHYSIOGRAPHY AND CLIMATE**

The Forrest Kerr property lies in the 'Iskut' area of the Coast Mountains in northwestern British Columbia. The center of the property is approximately 100 kilometres northwest of the deep water port of Stewart, British Columbia and 200 kilometres southwest of Dease Lake, British Columbia. Travel time to the project from Terrace or Smithers is approximately 6 hours. Both Smithers and Terrace serve as centers for mining and mineral exploration with several drill, helicopter, geological and support contractors based locally.

The property is road accessible to both its southern and northern regions. The southern route is via the controlled-access gravel Coast Mountain Hydro road (formerly the Eskay Creek mine road), which intersects the Stewart Cassiar highway (Hwy 37) 4 kilometres south of the Bob Quinn airstrip (20 km east of property). The Forrest Kerr run-of-river hydro facility is located 44 kilometres along this road and within the claim boundary of the Forrest Kerr Project. This facility is operated by AltaGas and comprises a 300 person camp and 3 generating facilities that supply 297 MW of electricity to the province through the 287 kV Northwest transmission line. The northern access is achieved by travelling 12 kilometres north of Bob Quinn on Hwy 37 and then travelling 40 kilometres west along the Galore Creek Mining Corporation ("GCMC") road. GCMC maintains a 100 person camp (Ch'iyone) at km 37.5 on this road, which is currently scaled back to a 10 person camp performing care and maintenance duties on the Galore Creek project.

The Bob Quinn airstrip is suitable for fixed-wing aircraft of any size and is serviced by NT Air with 5 flights/week during the summers from Smithers. Alternatively the Property can be accessed by helicopter from Bronson airstrip (air access only) located on the south side of the Iskut River approximately 20 kilometres to the southwest.

The Forrest Kerr claim block covers several tributaries of the Iskut River, principally More, Downpour, and Forrest Kerr creeks. Topography is rugged, typical of mountainous and glaciated terrain, with elevations ranging from 490 metres on More Creek and 930 metres on Downpour Creek to over 2000 metres on unnamed peaks. Alluvium, till and outwash fill the bottom of the three valleys. Much of the property lies above treeline, covered by open alpine vegetation. Tag alder and alpine fir are common below treeline, which averages 1400 metres in elevation. Most of the claims along More Creek are covered by mature spruce and hemlock, with open patches of tag alder and devil's club. Both summer and winter temperatures are moderate although annual rainfall may exceed 200 centimetres and several metres of snow commonly fall at higher elevations. The property can be worked from early June at lower elevations, or mid-July at higher elevations, until late September or early October.

## **EXPLORATION HISTORY**

The consolidated Forrest Kerr Property has hosted extensive exploration activities by a variety of operators throughout the last thirty years. The following summary is presented under the subheadings of the three separate claim groups.

## RDN Claims

The following section on the exploration history of the RDN claims was taken from Jones (2006).

The original RDN 1-4 claims were staked in November 1987 to cover a small but intense gossan (the “Marcasite Gossan”) on which no work had previously been reported. At the time, the Iskut River district was undergoing exploration for gold-bearing quartz-sulphide veins similar to those which were later developed into the Skyline and Snip mines. The following September, Neil DeBock carried out three days of prospecting on the RDN claims. Two rock samples from the Marcasite Gossan exceeded 50 g/t Ag, with the best assaying 207.6 g/t Ag (DeBock, 1989). All exploration work carried out on the area covered by the RDN property is summarized in Table 2.

Noranda Exploration Company staked their GOZ claims immediately north of the RDN property in October 1989, optioned the RDN 1-4 claims and did limited sampling on them. Gold and silver values were generally low in rock and talus fine samples, but rock samples from the Marcasite and South Gossans contained anomalous arsenic and antimony, with up to 1196 ppm Sb and 831 ppm As. A heavy mineral concentrate from Downpour Creek returned 2410 ppb Au and a silt sample taken from one of its tributaries contained 164 ppb Au (Savell, 1990a).

Table 2: Exploration history of the RDN claims

Years	Company	Claims	Geochemistry	Geophysics	Drilling, Trenching
1988	Neil DeBock	RDN 1-4	10 silts, 27 rocks		
1989-90	Noranda	RDN 1-8, 11-13	32 heavy minerals, 91 silts, 1384 soils, 464 rocks	Airborne: magnetics/EM Ground: 20 line-km magnetics, 14.9 line-km VLF-EM, 14.9 line-km HLEM	15 DDH: 1546m (5072')
1991	Noranda	RDN 1-8, 11-13	15 silts, 275 soils, 200 rocks	Ground: magnetics, IP, HLEM	15 DDH: 2087m (6847')
1990-91	Skeena	RDN 14-17, Luc, Narby, Bogden, LL1-2, KC1-2	221 silts, 799 soils, 384 rocks	Ground: 1.8 line km IP, 2.66 line kms mag, 1.6 line km VLF	Blast and hand trenching, 106 m
1990	Adrian	RDN 9-10	14 silts, 3 soils, 37 rocks		
1990	Noranda/Skeena	RDN 9-10	2 heavy minerals, 20 silts, 404 soils, 35 rocks	Ground: 13.1 line-km magnetics, 4.5 line-km EM	
1991	Noranda/Skeena	RDN 9-10	12 silts, 59 soils, 27 rocks	Ground: IP	
1991-92	Adrian/Noranda/Skeena	RDN 9-10	279 soils, 22 basal tills, 109 rocks	Ground: 11 line-km VLF-EM	Blast-trenching
1994	Pathfinder	RDN 1-6	6 silts, 3 soils, 67 rocks, 24 whole rocks		
1995	Pathfinder	RDN 1-8	574 soils, 8 rocks		
1996	Pathfinder	RDN 1-10	2 silts, 448 soils, 110 rocks, 44 whole rocks	Ground: 28 line-km magnetics, 28 line-km VLF-EM	
1997	Rimfire	RDN 1-10	648 soils, 156 rocks, 4 whole rocks		

1998	Rimfire	RDN 1-10, 1318	1727 soils, 179 rocks, 33 whole rocks		Backhoe trenching: 129 m
1999	Rimfire	RDN 1-13	16 silts, 425 soils, 159 rocks, 35 whole rocks	Ground: 7.4 line-km magnetics, 7.4 line-km VLF-EM	9 DDH: 574.2 m (1,884')
2000	Newmont/Rimfire	RDN 1-4, 6, 1013	12 silts, 165 soils, 32 rocks, 4 whole rocks	Ground: 26.8 line-km UTEM	
2001	Newmont/Rimfire	RDN 2, 4, 11, 13		Ground: 0.525 line-km Max- Min II	13 DDH: 2,255.8 m (7,401')
2002	Homestake/Rimfire	RDN 1,3, 5-12, 14, 16	37 silts, 207 soils, 93 rock, 10 whole rock		9 DDH: 1,125.9 m (3,694')
2003	Homestake/Rimfire	RDN 3,4,13,14, 16, MOR 2	3 silts, 108 soils, 164 rock, 17 whole rock		
2004	Rimfire/Northgate	RDN 3,4,13,14, 16, MOR 2	23 silt, 499 soils, 78 rocks, 32 whole rocks, 2 age dates		9 DDH, 2498.7m (8198'), 1534 core samples
2005	Rimfire/Northgate	501227,502738, 502758,502751, 502752,501895	3 silt, 579 soil, 244 rock including 31 channel, 48 whole rock, 1 fossil date		6 DDH, 1470.66 m (4825'), 917 core samples
2006	Rimfire/Northgate		16 silt, 178 rock including 98 chip & 35 whole rock, 331 soil	740 line km airborne EM-Mag	4 DDH, 1350.05 m (4429") 965 core samples
Total			34 heavy minerals, 501 silts, 8917 soils, 2751 rocks, 286 whole rocks	Ground: magnetics, VLF-EM, UTEM, Max-Min II, Airborne EM	80 DDH: 12,908.4 m (42,350'), 129 m trenching

In 1990, Noranda and High Frontier Resources Ltd. carried out a joint exploration program over the RDN and GOZ claims (Savell, 1990b). They laid out sixty kilometres of grid over the gossanous felsic volcanics, with a baseline oriented at 010° and crosslines every 100 metres, and carried out ground geophysics to detail airborne anomalies (Savell, 1991). Prospecting resulted in the discovery of several gold-bearing quartz-sulphide veins within dacitic tuffs on the GOZ claims, accompanied by a large Au+Ag+As+Pb+Zn±Cu soil geochemical anomaly. Fifteen BGM core holes were drilled on the GOZ claims, with the best intersection grading 11.7 g/t Au across 4.4 metres of a brecciated quartz-sulphide vein (Savell, 1990b).

In 1991, Noranda and High Frontier continued exploration on the RDN and GOZ properties (Savell and Grill, 1991). A new grid was established in the Gossan Creek/Carcass Creek area, almost entirely within the felsic tuffs and their subvolcanic porphyries. Its baseline was oriented at 155°, with five crosslines at 065° spaced 200 metres apart. All lines were surveyed with HLEM and two were surveyed with induced polarization (IP) techniques. At the southern end of the GOZ/RDN claims, they laid out east-west lines at 200 metre intervals from a north-south baseline on the Boundary Zone and collected soil samples at 25-metre intervals (Savell, 1992). Fifteen more BTW holes were drilled in 1991. Of the 30 holes drilled by Noranda in 1990 and 1991, all but four were targeted at quartz-sulphide veins or silicified zones in the intermediate to felsic volcanics and their subvolcanic porphyries. Results from the other holes, designed to test the property's potential for Eskay Creek-style mineralization, were all inconclusive. Two of these

holes, RG91-26 and 27, were drilled within sediments and diorite on the RDN 2 claim, but failed to reach the felsic/sediment contact. The other two, RG90-12 and 13, were targeted at anomalous Au-As soil geochemistry (the “Jungle Anomaly”), but were abandoned in overburden.

Following the 1991 program, Noranda terminated their option on the RDN claims and allowed their GOZ claims to lapse. As the GOZ claims came open, they were gradually re-staked as the RDN 58 and 11-13 claims in May 1994, March 1995, October 1997 and October 1998. All of Noranda’s drilling and grid work lie on the current RDN property.

In September 1989, Skeena Resources Ltd. staked a large claim package (the Arctic claims) on the north fork of More Creek to cover an area thought to be underlain by Hazelton Group stratigraphy similar to that hosting the Eskay Creek deposit. In 1990, Skeena carried out reconnaissance silt sampling and mapping/prospecting traverses, identifying felsite and orbicular rhyolite with local flow banding over several kilometres along both sides of More Creek (Bobyn, 1990). Skeena also investigated several scattered showings with detailed mapping, trenching, grid soils, and local induced polarization geophysical surveys in 1991 (Tucker, 1991). The Downstream Showing, consisting of “narrow chalcedonic quartz veins...[which]...host massive pyrite stringers up to 5 cm in width” within pyritic felsite/rhyolite, returned grab samples with up to 75,000 ppb Hg, 580 ppm Sb and 4860 ppm As (Bobyn, 1991). The KC Showing consists of pyrite-magnetite-chalcopyrite stringers in epidotized volcanic rocks along the sheared contact with Paleozoic granite. As well, several grab samples of carbonate veins and lenses in sedimentary strata at the mouth of Black Bear Creek returned strongly elevated results for Au, Ag, Pb, Zn, Hg, and Cu. Skeena’s claims were allowed to lapse and the RDN 14-18 claims were staked in October 1997 to cover the Downstream Showing and the rhyolitic package along More Creek.

In March 1990, Adrian Resources Ltd. and Skeena each staked claims between Noranda’s GOZ and Skeena’s Arctic claim groups, and contested ownership. Exploration work was done by each group that summer. Adrian carried out reconnaissance mapping and limited sampling (Dunn, 1990). Noranda optioned Skeena’s More claims, cut a north-south baseline with east-west cross-lines every 200 metres and carried out soil sampling and ground geophysics over their grid (Savell and Wong, 1991). The following year, Noranda carried out two test lines of IP and did minor sampling, but no results are available.

In 1991, Adrian optioned the More claims from Skeena and Noranda and carried out grid-based geological mapping and added infill soil lines at 100 metre spacings to Noranda’s grid. The soil geochemistry showed a 200 x 700 metre northerly-trending, Pb+Zn+Au+As+Ag+Cu anomaly with peak values of 460 ppb Au, 620 ppm Pb, 1200 ppm Zn and 352 ppm Cu, in an area underlain by dacitic volcanics. Two mineralized zones were reported from within silicified and carbonate-altered dacitic volcanics. The Main Zone had grab samples grading up to 4.6 g/t Au and 10.6% Zn. The Gem Zone, located 1,000 metres to the south in a separate soil geochemical anomaly, returned values up to 2.2 g/t Au (Campbell et al, 1991). Blast trenching was apparently carried out by Adrian the following year, but was never recorded and no results are available. The More claims lapsed on March 21, 1995 and were re-staked the following day as the RDN 9 and 10 claims.

Pathfinder Resources Ltd. optioned the RDN property in 1994 and carried out reconnaissance exploration on the RDN 1-6 claims for Eskay Creek-style stratiform Au-Ag-Pb-Zn mineralization, focusing on six kilometres of felsic/sediment contact. Six thin sections from subvolcanic porphyry intrusives and variably altered dacitic/trachytic lapilli tuff revealed intense potassic alteration. No

massive sulphide mineralization was discovered, but altered dacite beneath the Marcasite Gossan felsic/sediment contact assayed up to 141 g/t Ag. Similar float four kilometres to the north assayed 11.6 g/t Au with anomalous Ag, Pb, Zn, Cu, As, Sb, Hg and Bi (Awmack, 1995a).

In 1995, Pathfinder performed a grid-based soil geochemical survey over the RDN 1-8 claims, designed to cover known or suspected portions of the felsic/sediment contact. Soil samples were taken at 25 metre intervals from short crosslines run 100 metres apart from a cut north-south baseline (the “Downpour Grid”). Results were spotty, with several isolated anomalous soil samples (Awmack, 1995b).

The following year, Pathfinder carried out 48 man-days of geological mapping, prospecting, soil sampling and geophysical surveying over the RDN 1-10 claims. Soil sampling on the Downpour Grid confirmed an Au+As geochemical anomaly (the “Jungle Anomaly”) north of the mouth of Gossan Creek. A magnetic/VLF-EM survey was run over the southern half of the Downpour Grid, showing a VLF conductor along the felsic/mafic contact above the Marcasite Gossan. On the RDN 9-10 claims, two infill soil lines run west from the 1990 Noranda baseline corroborated the reported soil geochemical anomaly. Previously blasted exposures of the Main Zone breccia vein were chip sampled, assaying 3.1 g/t Au, 0.49% Pb and 1.13% Zn across a true width estimated at 8.3 metres (Awmack, 1996).

The RDN property was acquired by Rimfire Minerals Corporation in July 1997 and Rimfire contracted Equity Engineering Ltd. to carry out exploration programs from 1997 to 1999. From 1997 to 2005, Rimfire or their partners have conducted exploration in each field season, as summarized below.

### **1997 Exploration**

In August 1997, Rimfire carried out mapping, prospecting and soil sampling in the More Grid, Cole Creek, Jungle Anomaly and Marcasite Gossan areas (Awmack, 1997). Infill soil lines on 50-metre centres were run in the Jungle Anomaly area west of Downpour Creek and reconnaissance lines at 100 metre intervals to the east.

The 1997 More Grid sampling showed the More soil geochemical anomaly to lie almost entirely over the central fault slice of felsic volcanics, covering an area of 250 x 800 metres. To the north, the anomaly is truncated by the swamp marking the edge of the More Creek flood-plain. To the south, no anomalous values are found south of 1700N. Campbell et al (1991) inferred a fault trending 070° at approximately 1725N, based on discontinuities in VLF-EM conductors. No geological evidence was seen for such a fault, but it would help explain the southern termination of the soil anomaly. To the west, the soil anomaly continues down for at least 50 metres into the western fault slice of Betty Creek Formation andesite. This is thought to represent downslope dispersion from the strongest sections of the main anomaly.

The Jungle Au+As+Ag+Pb soil geochemical anomaly was defined over an area of 100 x 450 metres; a cobble of silicified, pyritic argillite from within it assayed 25.44 g/t Au. Noranda had targeted two diamond drill holes at the Jungle soil anomaly, with holes RG90-12 (-48°, 46.0m) and RG90-13 (-60°, 30.5m) abandoned in overburden after coring through boulders of “black siltstone and oxidized felsic volcanic”. Both of these holes were drilled down a 35° hillside, undoubtedly worsening drilling conditions. A multi-element soil anomaly lies on the western end of line 7500N, between 7450 Creek and 7500 Creek, and covers the wide zone of faulting

associated with the Carcass Fault, including silicified slivers of felsic volcanics and sheared argillite subcrop.

Geological mapping and prospecting was carried out at a scale of 1:2,500 over portions of the More and Downpour Grids, with emphasis on the Marcasite Gossan, Cole Creek, the Jungle soil anomaly and the More Grid Au+Pb+Zn soil anomaly. A total of 156 rock geochemical samples were taken (31 from the More Grid and 125 from the Downpour Grid) during the course of geological mapping and prospecting. Three thin+polished sections were described by Dr. Jeff Harris (1997) to identify lithologies and styles of mineralization. One of which was determined to be a sample of a brecciated shale with a possible volcanic component and containing pyrite and sphalerite.

Mapping of the Marcasite Gossan showed it to be a seafloor magmatic/hydrothermal vent. The Steen Vein was discovered in Cole Creek; it assayed 279 g/t Ag across a true width of 2.0 metres, flanked by 20 metres of hanging wall stockwork grading 20 g/t Ag. On the More Grid, another quartz-sulphide vein breccia (the “Baseline Showing”) was discovered 240 metres southwest of the Main Zone, assaying 6.21 g/t Au across 1.1 metres (Awmack, 1997).

### **1998 Exploration**

In August and September 1998, Rimfire carried out 160 man-days of line-cutting, geological mapping, prospecting, soil sampling and backhoe trenching on the RDN property (Awmack and Baknes, 1998). Gridwork and soil sampling were conducted in five areas: Arctic Grid, NE Downpour Grid, Jungle Anomaly, South Downpour and Marcasite Gossan.

Three trenches totalling 129 metres were excavated on the Jungle soil geochemical anomaly using a Kubota KX-41 backhoe, operated under contract by Peak Explorations Ltd. of Smithers, B.C. No outcrop was encountered by the trenching, but homogeneous colluvium, thought to be locally derived, was present in each trench.

Geological mapping and prospecting was carried out at a scale of 1:2,500 over the new grids and between the Marcasite Gossan and Cole Creek. Three thin+polished sections were described by Dr. Jeff Harris (1998) to identify lithologies and styles of mineralization. One of these specimens was determined to be a pyritic exhalative chert with altered volcanic inclusions. Four fossils were collected and dated by Dr. Paul Smith of the University of British Columbia, however dating was inconclusive.

The NE Downpour Grid was laid out over the northeastern strike projection of the Jungle Anomaly, on the east side of Downpour Creek where no previous mapping had been done. There are no significant geochemical anomalies on the NE Downpour Grid.

The South Downpour gridwork consisted of a southward extension of the existing Downpour Grid to cover the projected extension of favourable stratigraphy onto the newly-acquired RDN 13 claim. Soil geochemistry is problematic through this area because of numerous talus fans and moraines, which have the effect of masking soil anomalies derived from residual soils. Limited soil sampling by Savell (1992) had indicated the presence of elevated Au values near the property's southern boundary, associated with the Boundary Zone Au-Cu veins. This was confirmed by the 1998 sampling, with two Au-rich samples from the vicinity of veining and the 1991 drilling.

Elevated Au values extend discontinuously for 1200 metres in a north-south direction from the head of Nelson Creek, through the pass into the headwaters of Downpour Creek and down

Downpour Creek to Sand Lake. No sampling has been done along this trend north of Sand Lake, leaving the anomaly open in this direction. The Au values are not readily attributable to downslope dispersion nor can they be attributed to some sort of placer concentration. This anomaly marks the transition from the dacitic/trachytic volcanic package to the overlying mafic volcanic/sedimentary package on the west limb of the Downpour Anticline. This stratigraphic contact is equivalent to the host contact for Eskay Creek's 21 Zone ore-bodies. The Au soil anomalies could mark the presence of Au-bearing Eskay Creek-style stratiform sulphides.

A strong, multi-element Pb+Zn+Ag+Ba±Cu soil geochemical anomaly covers an area of about 400 x 700 metres. The anomaly remains open in the unsampled area to the north and may extend through an unsampled area into an anomaly 700 metres north. To the south, this anomaly extends discontinuously to the property's southern boundary, and is truncated by a north-south fault and Stuhini Group volcaniclastics to the east. Grab sample 459809 was taken just upslope from the heart of the anomaly; it contained 1.60% Pb and 3770 ppm Zn from patches of galena and sphalerite in weakly silicified dacite.

A restricted Pb±Au±Zn soil anomaly extends from 1100N 5250E to 1200N 5500E, with peak values of 558 ppm Pb, 85 ppb Au and 656 ppm Zn. Grab sample 130284, with 1.36% Pb, 190 ppb Au, 2930 ppm Zn and 2190 ppm Cu, was taken from sheared maroon agglomerate with patchy sulphides in the heart of this anomaly. This style of mineralization, which may be responsible for the remainder of the anomaly, appears to hold limited economic significance. A strong Cu-only soil anomaly covers an area of 600 x 200 metres along the western slope of Downpour Creek between lines 1900N and 2500N. It remains open to the west, where the highest Cu values are also present, suggesting a source upslope from the soil grid. Grab sample 459827, with 1660 ppm Cu and 25 ppb Au, was taken from malachite-stained phyllitic argillite upslope and north of this soil anomaly, from rocks thought to be Paleozoic. Alternatively, the Cu soil anomaly could reflect unrecognized mineralization or higher background Cu levels in Paleozoic mafic volcanics(?) which appear to underlie this slope west of the inferred Forrest Kerr Fault.

Soil sampling, consisting of further 50-metre infill lines to the north, were established to ensure that the Jungle anomaly was closed off. This infill sampling confirmed previous results, adding definition to the main Au+As±Ag±Pb soil anomaly. In addition, a line through the heart of the Jungle anomaly, with a shallower "B" horizon soil sample and a deeper "C" horizon soil sample at each site returned very similar or slightly higher values for the deep samples relative to the shallow ones.

The reconnaissance-scale Arctic Grid was laid out on the west side of the north fork of More Creek. Previous mapping had indicated the presence of Hazelton Group rhyolite in this area; this was confirmed during mapping concurrent with the soil sampling. Analysis of soil percentile levels show the Arctic Grid to be almost entirely devoid of elevated base and precious metal values. Those which are present occur primarily as isolated 1-3 sample anomalies which do not extend between lines. The most noteworthy of these single-station anomalies occurs at 5400E 5800N, which lies between the Arctic and Bear Magnet Faults, on the eastern flank of a ridge of aphanitic rhyolite. No mineralization has been found to explain this anomaly.

## 1999 Exploration

In July 1999, Rimfire carried out an initial evaluation of the newly-staked RDN 11 and 12 claims from a fly camp in the Carcass Creek valley (Awmack, 1999). This was followed in August by a nine hole diamond drilling program based from a drill camp immediately north of the Marcasite

Gossan. Geological mapping, prospecting, soil sampling and VLF-EM surveying were concentrated on the newly staked RDN 11 and 12 claims, which cover the bulk of Noranda's 1990-91 drilling and a large, open-ended, multi-element soil geochemical anomaly reported by them. Geological mapping and prospecting were carried out at a scale of 1:2,500 over several areas on the property.

The Carcass Grid was laid out to cover the Noranda soil geochemical anomaly (the "Wedge Anomaly") east of Carcass Creek and extend it to the north and west. This anomaly covers an area of 800 x 2,600 metres, remaining open to the north and west. The Wedge Anomaly is entirely underlain by the package of dacitic/trachytic volcanics which extends north from the Gossan Creek subvolcanic porphyry. It fringes the highly altered and pyritic subvolcanic porphyry, which is itself generally overlain by only background geochemical values; the porphyry may have served as the hydrothermal source for mineralization in the area of the Wedge Anomaly. Quartz-sulphide veining (collectively, the Wedge Zone) is common throughout the area underlain by the Wedge Anomaly. The southern portion of the Wedge Anomaly is dominated by Pb, Zn and As, with only erratic Au and Ag values. This corresponds to the Wedge Zone quartz-sulphide veins sampled in this area, with low ratios of precious to base metals.

The strongest portion of the Wedge Anomaly, particularly for Au, Ag, Cu and Hg, extends for 1,100 metres north along the eastern slope of Carcass Creek from the toe of the Carcass Glacier. The Waterfall, Pear and Mick Zones and the Au-bearing veins intersected by Noranda's Wedge Zone drilling all lie immediately upslope from the southern 500 metres of this anomaly. However, the northern 500 metres is the strongest part of this anomaly and remains unexplained by the limited drilling done to date. The western portion of this anomaly, on the gentle slopes approaching Carcass Creek, is underlain by lateral moraines containing abundant boulders of quartz-sulphide vein float derived from Wedge Zone veins upslope and up-valley. The high soil values for this part of the anomaly have been transported and do not reflect underlying mineralization.

A clay-rich terminal moraine extends northeasterly from about 9900N 7725E on the Carcass Grid, effectively truncating the Wedge geochemical anomaly. However, beyond the northern edge of the end moraine, a few anomalous soil samples were taken; one sample on the northernmost line sampled contained 165 ppb Au, indicating the need for further geochemistry to the north. Gold-bearing quartz-sulphide float was also found in this area, which lies near the contact between the same dacitic package that hosts the Wedge Zone veins and the stratigraphically overlying upper Hazelton Group clastic sediments.

Two lines of contour soil samples and two lines of creek bank soil samples were run in the vicinity of a large rhyolite outcrop northeast of the Carcass Grid. Soil values were at background levels, with the exception of spotty high As, Cu and Hg values. The source of these high values is unclear; rock samples from this area were not anomalous.

A 7.4 line-km magnetic/VLF-EM survey was performed over the Carcass Grid in 1999, in order to define the location of the Forrest Kerr Fault and the areal extent of black argillite exposed in Carcass Creek. Most of the grid overlies thick lateral moraines, with outcrop control only on the eastern and extreme southern edges of the grid. This survey was conducted by Amerok Geosciences Ltd., the following discussion is largely based upon Power (1999).

"The VLF-EM survey detected a very weak, primarily contact-type anomaly...[that] follows the argillite/dacite contact where known from mapping and drill hole information...The character of the geophysical response strongly suggests that the contact between the two rock units is

stratigraphic and not structural.” The entire length of this contact anomaly is covered by moraines, but it does fit well with mapped outcrops at the extreme southern end of the grid. North of the grid, the argillite is in stratigraphic contact with dolomitic wacke; this anomaly shows the contact between argillite and an “electrically resistive rock”, which is likely dacite at the southern end of the grid, but may be dolomitic wacke or another lithology further north. An enigmatic VLF-EM response, extending from 9700N 75257700E to 9800N 7500-7725E “is tentatively ascribed to conductive overburden or possibly to a flat to very gently dipping, shallow conductive rock unit.” The overburden in this area between Carcass Creek and the Forrest Kerr Fault does not appear different from elsewhere, consisting of prominent ridges of lateral moraine; the conductor’s source remains unknown.

“The total magnetic field survey recorded relief in the order of 120 nT over the entire grid. A region of positive magnetic response in the eastern portion of the grid area is coincident with the dacite unit. There are several isolated positive anomalies west of the dacite including a high amplitude response on the extreme western portion of the grid at 9800N 7450E.” The Carcass Grid only crossed to the west side of the Forrest Kerr Fault on a few lines; the magnetic high at 9800N 7450E is underlain by weakly magnetic Devono-Mississippian basalt . This magnetic high helps to constrain the location of the Forrest Kerr Fault.

Nine holes totalling 574.2 metres (1,884') of ATW and BTW core were drilled in August and September 1999. Microprobe analysis was done on one core specimen from hole RDN99-05 to verify the presence of rhodochrosite. One thin section from a 1998 rock sample was described petrographically by Dr. Jeff Harris (1999) and one core specimen was analyzed for mineralogy by SEM/EDS (Raudsepp and Pani, 1999). Thin section examination and whole rock geochemical interpretations classify this sample as a breccia flow or tuff of rhyolite to rhyodacite/dacite composition.

## 2000 Exploration

The RDN property was optioned by Newmont Exploration of Canada Limited in early 2000 (Awmack, 2000). Newmont carried out a UTEM ground geophysical survey in June and July 2000, accompanied by limited mapping, prospecting and soil geochemical sampling. Limited geological mapping was done by the author during the layout and surveying of the UTEM grid. In addition, mapping, prospecting and contour soil sampling were carried out in the previously unexplored terrain between the Carcass and More Grids on the RDN 10 and 11 claims.

Contour soil sampling, carried out entirely in the relatively barren “hanging wall” clastic/basalt sequence of the Hazelton Group did not yield any significant soil anomalies. Silt samples results were uniformly low, reflecting the relative lack of mineralization in the Hazelton Group “hanging wall” clastic/basalt package and the Devono-Mississippian rocks which these streams drain.

The UTEM survey, totalling 26.8 line-km, was designed to test 6.7 kilometres of the “Eskay-equivalent” stratigraphic contact between the “footwall” felsic volcanics and the “hanging wall” mafic/clastic package. UTEM survey lines, spaced 200 metres apart, were chained, slope-corrected and cut where necessary, mainly from existing cut baselines. Due to heavy snow, the lines in the South Downpour area (L900N-L2500N) had to be run from a new baseline. Stations were marked by blue pickets and green flagging, to differentiate them from the existing soil stations with pink and blue flagging. In keeping with the orientation of the pre-existing soil grid, UTEM survey lines were run at 088.5°/268.5° on the Downpour Grid and 090°/270° on the Carcass Grid. The existing baseline “200E” was relabelled “5200E” from L2700N to L5100N, to

fit with nomenclature on the South Downpour Grid. The UTEM survey was contracted to S.J. Geophysics Ltd. of Delta, B.C. and results and interpretation were reported separately by Jim Wright of Newmont (Wright, 2000).

Wright (2000) described six UTEM conductors *comments by Awmack (2003) in italics*:

**Zone A (Carcass Creek and Downpour Creek):** This corresponds to the Forrest Kerr Fault on the twenty-three (23) lines which crossed the fault. The fault is interpreted to have graphite and/or sulphides on the fault plane. This graphitic material coupled with the relatively large size of the conductor produces the very low channel responses.

**Zone B (Carcass Creek, lines 9000-10200N):** This zone lies within the prospective lithologies and is of a scale similar to Eskay Creek. The responses on lines 9200 and 9400 indicate a good to excellent conductor. Sulphides are indicated. A depth to source of 30 metres is indicated with a westerly dip. The lessening of channel responses to the north and south would be consistent with an Eskay type anomaly, where variable conductivity is to be expected. From a geophysical standpoint, this is the most attractive anomaly on the property. *This conductor coincides well with the position of the dacite/clastic contact inferred from the 1999 VLF-EM survey. Where exposed upslope to the east, the dacite is altered and host to widespread gold-bearing quartz-sulphide veining, which could represent footwall alteration/mineralization to an Eskay Creek-style seafloor mineralizing system.*

In particular, the Waterfall Zone is a >20m wide zone of intense sericitization with abundant discontinuous quartz-sulphide veining which trends 280-300° and dips steeply to the north, hosted by the footwall dacite. Noranda reported up to 44.3 g/t Au in a 1-metre chip sample from one of these veins. The vein/alteration zone appears discordant to the felsic stratigraphy and may represent a feeder system similar to Eskay's 109 and Pumphouse zones. It projects to the felsic/clastic contact at L9400N/7675E, very near the axis of Zone B.

**Zone C (Downpour Creek, lines 6300-6700N):** This is a flat-lying conductor near the Jungle Zone. The conductivity is not very high, but the zone appears to be of significant volume. Width of the flat-lying body approaches 200 metres. This should be examined as a possible overburden response. *The central portion of this anomaly overlies thick ferricrete; the northern and southern parts are not well-exposed.*

**Zone D (Marcasite Gossan area, lines 4100-4900N):** This is a conductor of intermediate conductivity. Its axis passes between the Upper and Lower Marcasite Gossans and was cut by drill hole RDN99-05, which did not intersect a conductive lithology. However, black argillite was mapped a few tens of metres to the south along strike and clastic massive pyrite cobbles are thought to have been derived from syngenetic sulphides deposited above the Lower Marcasite Gossan. The clastic massive sulphides cobbles, however, contain low base and precious metal values.

**Zone E (east of Marcasite Gossan, lines 3300-4300N):** The surface trace of the zone falls within the overlying mafic volcanics. Depth to source on line 4100N is approximately 150 metres; however, the long wavelength nature of the response makes a definitive interpretation difficult. The northern part of the zone (i.e. lines 4100N and 4300N) may be indicating a conductor at the favourable horizon. *This would be down-dip from the Marcasite Gossan, where we have documented sea-floor venting of hydrothermal fluids, certainly an interesting spot to search for more sea-floor sulphide accumulation, possibly with better grades.*

Zone F (Nelson Creek, line 900N): One line response near the Boundary Zone, perhaps an extension of the Boundary Zone. There is no outcrop in the immediate vicinity of this conductor, but hole RG91-30 was drilled within dacite, a few tens of metres to the south. Veining in the Boundary Zone area is felsic-hosted massive pyrite-chalcopyrite; the response may be due to one of these veins.

South of Zone C, Wright (2000) marked an unnamed conductor at L6100N/1025E. This lies very close to the sphalerite-bearing altered dacite outcrops described in Section that have been described as possible footwall alteration; the conductor should be re-examined in that light. East of Sand Lake, at the head of Downpour Creek, Wright indicates a two-line conductor (lines 2500-2700N), along the contact between dacite and the “hanging wall” basalt. Immediately downslope is the unexplained South Downpour Au soil geochemical anomaly which parallels this contact for 1,300 metres and could be related to Eskay Creek style mineralization along it.

## 2001 Exploration

Newmont carried out a two phase exploration program of ground electromagnetic surveying and diamond drilling in June and July, and September 2001 (Stammers and Montgomery, 2001). Limited frequency domain (Max-Min II+) electromagnetic surveying, totalling approximately 525 line-metres on two lines in the Wedge and Marcasite Gossan Zones, was conducted by SJ Geophysics Ltd. to confirm 2000 UTEM anomalies. The Max-Min survey confirmed the presence and location of UTEM anomalies on these two lines, and that other UTEM anomalies could be reliably drilled with no additional groundwork. The Max-Min survey did not add significantly to interpretations of the UTEM data and was not as effective as UTEM surveying in this terrain.

A total of 2,255.82 metres (7401 feet) of NQII diamond drill holes were cored in 13 holes, including ten holes in the Wedge Zone, and one hole each at the Boundary, Sand Lake and Downpour Creek Zones. The holes were drilled by the Major Drilling Group of Smithers, BC. utilizing a JT2000 portable fly rig. The drill holes, which ranged in length from 90 to 300 metres, targeted UTEM electromagnetic conductor axes. Each hole was logged for lithology, alteration, mineralization, structure, core recovery, and rock quality density (RQD). Diamond drill core is stored at two locations; core (Holes RDN01-10 to -13 and RDN01-17 to -22) from the Wedge Zone is stored in durable 4 x 4 post racks at More Creek camp while holes RDN01-14 to -16 are safely cross-stacked near the 1999 core at the Marcasite camp site on Downpour Creek.

Seven samples from drill core were selected for petrographic examination by PetraScience Consultants Inc. (Gale and Thompson, 2001a and 2001b). Two samples from drill hole RDN01-11 and RDN01-13 were determined to be pervasively silicified and sericite-siderite altered feldspar-porphyritic volcanic rocks containing sphalerite, pyrite, chalcopyrite, galena, tennantite, and tetrahedrite. SEM analysis of the sample from RDN01-13 identified native Bi and an unidentified species of Pb-Bi-Ag. A second sample from RDN01-11 was determined to be a breccia with potassium feldspar-rich lithic and crystal fragments that contains orpiment, sphalerite, chalcopyrite, tetrahedrite-tennantite, galena and pyrite. The remaining four samples were from hole RDN01-17, the most significant of which consists of a sericite-quartz-carbonate zone in contact with massive sulphides comprising sphalerite, chalcopyrite, pyrite, galena and tetrahedrite-tennantite. Contact relations suggest that the massive sulphides are not of vein origin and may be of replacement origin. The other specimens are of; flow breccias with feldspar-biotite porphyritic lithic clasts, sphalerite, pyrite and tetrahedrite-tennantite, and sericite-carbonate-

calcite altered porphyritic rock with potassium feldspar, quartz and plagioclase phenocrysts, sphalerite, pyrite, chalcopyrite, galena and tetrahedrite-tennantite.

## **2002 Exploration**

Subsequent to Newmont electing to terminate their option in 2001, the property was then optioned to Homestake Canada Inc. Homestake staked additional claims and conducted detailed geological mapping, sampling, prospecting, soil and stream sediment sampling, and diamond drilling in 2002 (Gale et al, 2003). Nine angled NQII drill holes, including one auto-wedge hole, totalling 1,092.11 metres (3,582 feet) were cored by Hytech Drilling Ltd. of Smithers, B.C. utilizing a Tech4000 portable fly rig. Eight of these holes, which ranged in length from 20 to 320 metres, were cored in the Jungle Zone area and the ninth hole was collared 700 metres to the northwest of the Jungle Zone and targeted the stratigraphy around the Carcass Creek Fault. Each hole was logged for lithology, alteration, mineralization, and structure. A temporary logging and core sampling facility was set up at Equity's Marcasite Drill Camp on Downpour Creek and 2002 core is safely cross stacked at this camp.

Geological mapping on the RDN and MOR properties was ongoing throughout the drilling program, and the main focus was examining areas that had received limited attention in the past and that are underlain by volcanic rocks similar to the Eskay Creek stratigraphic package. These areas included, from north to south; the Arctic Grid, the DK area (situated approximately 2 km northeast of the Wedge Zone), the Carcass Fault, and the valley west of the South Gossan.

Significant soil anomalies were identified in two zones; the DK and MOR 2 Zones. The DK Zone anomaly consists of an As-Hg-Sb anomaly (highest As, 5<sup>th</sup> highest Hg, and the 2<sup>nd</sup> highest Sb value in the 2002 program). The anomalous sample is underlain by mudstone/siltstone about 100m west of rhyolite. The MOR 2 claim area northeast of the DK Zone is also significant because of four samples with multi-element anomalies underlain by tuffaceous dacite, mudstone/siltstone and tuffaceous andesite. In addition to numerous single element anomalies, this area is marked by anomalous Ag, Sb, Zn, As, and Hg.

## **2003 Exploration**

Exploration by Barrick in 2003 (Mann and Gale, 2004) consisted primarily of field checking rock, silt and soil geochemical anomalies stemming from work in 2002. The work was focused on the Arctic and Boundary (South Downpour) areas based on the presence of felsic volcanic rocks and/or Eskay-type geochemistry. Geological mapping identified pyritic rhyolite units in both areas. In the Arctic area, a contact between rhyolite and mudstone was traced 1.9 kilometres across the Arctic West grid. Silt sampling and soil sampling for mobile metal ion (MMI) analysis did not detect any anomalous results. However, high organic content in the samples essentially discounted the MMI results. In the Boundary area, work focused on a small rhyolite outcrop area, later to be called the RTB Zone, and altered rocks within Hazelton stratigraphy near the east edge of the claim block. Sampling did not detect significant gold mineralization but returned values up to 300 g/t Ag. The results were interpreted to indicate no Eskay-style deposit in the Boundary area.

High grade gold results from outcrop and float boulders on the west side of the Forrest Kerr Fault were also investigated. A discontinuous, sulphide vein in Paleozoic rocks returned 5.24 g/t Au (sample 02313). The source of auriferous float, which assayed 6.18 g/t Au (2002 sample 02329), was not located.

## 2004 Exploration

In 2004, Northgate Minerals Corporation agreed to terms with Rimfire to option the RDN property and completed a large, comprehensive exploration program aimed at drill testing the Wedge Zone, Marcasite Gossan, and Jungle Anomaly. As well, geological mapping, prospecting and soil sampling was done in several under-explored areas of the property including the Blind Fault area, Marcasite Gossan hanging wall area, the north Downpour Creek area, and the Arctic area. The 2004 diamond drilling program, totalling 2498.74 metres of core in nine holes (2420.41 m NQ, 78.33 m HQ), was directed at the potential for Eskay Creek-style VMS mineralization along the contact between the lower Jurassic dacite and the “hanging wall” basalt/clastic sediment package, particularly in the Wedge Zone. Three holes were directed at similar targets in the Marcasite Gossan (RDN04-038, 039) and Jungle Anomaly (RDN04-037) areas. Each hole was logged for lithology, alteration, mineralization, and structure. The core was logged and stored at the camp at the mouth of Carcass Creek.

Sampling indicated an anomaly north of the Blind Fault that is defined by highly to very highly anomalous Pb, Zn, Ag, and Sb soil and rock geochemistry. These results are associated spatially with a clastic to pyroclastic, porphyritic dacitic volcanic package and cover an area of 850 metres north-south and 450 metres east-west. The anomaly is cut off to the south by an area of relatively poor soil sampling medium in the area of the RTB Zone, and so the anomaly may be considered open in this direction. To the north, the anomaly is limited primarily by the extent of sampling. Highly to very highly anomalous results for arsenic are more restricted, more closely associated with faults identified in the RTB-Red Creek area and the Bench Fault which bounds the Jurassic stratigraphy on the east. Highly anomalous mercury shows a still narrower trend, possibly indicating structural control, extending north along the RTB-Red Creek trend for about 500 metres, from about 100 metres south of the RTB. As well, spotty anomalous mercury in soils and, to a lesser extent, gold follow the general trace of the Blind Fault for about 1000 metres southwest towards the Boundary Zone. Moderately to highly anomalous copper geochemistry occurs peripheral to the main showings, and lies above the RTB Zone, adjacent to the Bench Fault.

Limited soil sampling detected several arsenic-mercury-antimony anomalies along the north-south baseline east of More Creek in the Arctic Area. The section of the baseline from Cougar Creek to south of Slime Creek is moderately to very highly anomalous for arsenic, mercury and copper, with weakly anomalous results for antimony and gold over 1200 metres. Another section of the baseline has moderately to highly anomalous results for arsenic and weakly to moderately anomalous results for antimony and mercury from Grizzly Creek to 450 metres south. A third anomaly is present about 500 metres up Black Bear Creek, north of More Creek. Soil samples scattered over an area of 600 by 600 metres have moderately to highly anomalous results for copper and gold. One very highly anomalous result of 124 ppb Au in soil occurs in this area, associated with very highly anomalous arsenic and antimony. This area surrounds two rock samples that contained over 800 ppb Au and 1000 ppb Au in carbonate altered and quartz veined volcanic rocks.

Soil sampling in the steep terrain of the North Downpour area consisted of a few contour sample lines at points where the slope was traversable. These lines tended to be fairly high up the east-facing slopes and as such do not test the eastern, or lower, section of the stratigraphy in this area. Soil sample results do not define any anomalies of significant size. Two contour lines, covering an area 450 by 250 metres on the upper slope, have moderately to very highly anomalous arsenic with spotty highly anomalous copper and weakly anomalous antimony. This anomaly occurs in

the same area as anomalous nickel in silt results. The anomaly is probably related to a gabbro to diorite intrusion within the sedimentary-volcanic package.

## **2005 Exploration**

In 2005, Northgate funded another large exploration program on the RDN property for Rimfire. The program included detailed grid soil sampling and mapping in the Arctic East grid area, detailed mapping and surface rock sampling in the Blind Fault area, and follow up diamond drilling. The 2005 diamond drilling program, totalling 1470.66 metres of core in six holes, was directed at the potential for Eskay Creek-style VMS mineralization in two areas; 4 holes on the RTB Zone in the Blind Fault area, and two holes on the rhyolite-mudstone contact in the Arctic Grid area.

Grid soil sampling off BL 5000E was done on the east Arctic Grid areas in 2005. Soil results from the area along Baseline 5000E, from 7500N to 8300N and approximately 4900E to 5300E, commonly have highly to very highly anomalous values for arsenic and mercury, with spotty moderately to highly anomalous results for silver and gold. This anomaly contains up to 7730 ppb Hg and 560 ppm As. Gold values range up to 60 ppb but significant samples are scant. Another similar As-Hg soil anomaly trends north-northeast and lies west of and along baseline 5000E from 9000N to 10000N. This anomaly apparently corresponds with interbedded volcanic units in a coarse clastic sedimentary section and is 150 to 250 metres wide. This anomaly contains samples with up to 481 ppm As.

The area north of More Creek and west of Grizzly Creek did not produce any significant soil geochemical anomalies. However, a large portion of this area is inundated with glacial drift and the boulder population does not reflect the local geology.

## **2006 Exploration**

A multi-faceted exploration program was completed in 2006 (Jones, November 2006) in the northern portion of the RDN claims over the Arctic area. Activities included an airborne geophysical survey, diamond drilling, geological mapping, prospecting and soil geochemical sampling. A 740 line kilometre geophysical survey was completed using Fugro's RESOLVE electromagnetic-magnetometer system, which produced magnetic, resistivity, and conductor maps. A complete report on this geophysical survey can be read in the 2006 Assessment report by Jones (November, 2006).

Four diamond drill holes totaling 1350.05 metres of NQ core were collared in the Arctic west area in search of potential for Eskay Creek style VMS mineralization. Three holes tested the upper contact of the rhyolite and fine to coarse grained clastic sediment while the fourth encountered difficult ground conditions and was stopped in the sedimentary unit. No significant mineralized horizons were intersected aside from disseminated pyrite and localized elevated Pb, Zn and Ag values.

Geochemical sampling produced 178 rock, 16 silt and 331 soil samples. Thirty five whole rock samples were taken from a combination of rock and core samples. The sixteen silt samples tested moderately anomalous for Au, Ag, Hg, Cu and Zn and alternately highly anomalous for Sb, Mo and As. The fill-in soil sampling was successful in identifying a fairly continuous narrow linear anomaly that tested moderately to highly anomalous in As, Sb and Hg and moderately anomalous in Au and Ag.

## Forgold Claims

This section on historical exploration on the Forgold claims was taken from von Einsiedel (2004). Exploration on the current Forgold Property group dates back to the 1980's. The current Forgold Property covers several historic exploration properties. To simplify the summary of previous exploration work the current Forgold Property is subdivided into three areas: the Forgold northeast area, the Forgold central area and the Forgold south area. There is one reported Minfile mineral occurrence (Minfile No.104B-376: Forgold) on the current Forgold Property. The exploration history that has occurred within Forgold north, central and southwest is discussed below and is summarized in Table 3.

Table 3: Exploration History of the Forgold Claims

Operator	Geochem	Geophysics	Trenching	Drilling	Reference
Ecstall Mining Corp Omega Gold Corp	17 rock, 27 silt				Nicholson (1989) ARIS: 19634
High Frontier Resources	171 rock, 194 silt, 30 moss mat, 4 soil				Walker & Gal (1990) ARIS: 20598
Ecstall Mining, Omega Gold and Manridge	90 rock, 30 silt, 15 moss mat, 1 soil				Termuende (1990) ARIS: 20540
Carmac Resources	24 rock, 24 silt				Atkinson and Leriche (1990) ARIS: 20533
Canadian Cariboo Resources	54 rock, 19 silt, 876 soil				Pegg (1990) ARIS: 20932
Santa Marina Gold Ltd.	116 rock				Malensek et al. (1990) ARIS: 20722
Gold Fields Canadian Mining	244 rock, 1475 soil				Ronning (1991) ARIS: 21868
Homestake Canada	24 rock, 3 silt, 101 soil				Marsden and Bozek (1991) ARIS: 21016
Kennecott Canda Inc.		425 km VLF-EM, Mag, Resistivity			Fields (1992) Aris: 22102
Gold Fields Canadian Mining	670 rock			5 holes	Bond (1992) ARIS: 22623
Northgate Exploration	15 rock, 5 silt				Edmunds (2003) ARIS: 27172
Rimfire Minerals Northgate Minerals	51 rock, 7 silt, 308 soil				Jones (2006) ARIS: 28106
Azincourt Resources Corp.	281 soil				Nicholson (2011)
Azincourt Resources Corp.	1743 soil, 127 rock				von Einsiedel (2013)
<b>TOTALS:</b>	<b>1603 rock, 309 silt, 4789 soil, 45 moss mat</b>				

### **Forgold—Northeast**

In 1988 the Forgold northeast area was staked as the For Property for Ecstall Mining Corporation and Omega Gold Corporation to cover favourable Triassic volcanic rocks and Jurassic volcanic and sediment rocks mapped in the area by the Geological Survey of Canada. The 1989 exploration program included geologic mapping, reconnaissance stream sediment survey (27 silts) and reconnaissance rock sampling (171 rocks). A number of silt and rock sample assay results were encouraging and combined with the reconnaissance mapping resulted in Nicholson (1989) to recommend further prospecting and sampling in the areas of encouraging assay results. In 1990 the area was revisited and a detailed mapping and sampling project (171 rock; 194 silt; 30 moss mat; 4 soil) corroborated previous (1989) anomalies and delineated new target zones. Several samples reportedly returned copper assays with 1-2% copper and one assay up to 15% copper. Copper mineralization was found to be hosted in narrow fractures. Walker & Gal (1990) recommended that anomalous values of copper, lead and zinc should be followed up to ascertain whether the mineralization is restricted to thin fractures, or if larger mineralized bodies are present. In 1991 an airborne magnetic, electromagnetic and VLF-EM survey flown by Kennecott covered the For Property. A total of 425 linear kilometres was flown with 100m line spacing. The survey identified one conductor on the property. The geophysical survey was never followed up and none of the anomalous base or precious metal samples were followed up by detailed soil geochemical surveys that can be used to identify larger buried mineralized bodies.

### **Forgold—Central Area**

In 1989 the Forgold central area was staked for Ecstall, Omega Gold Corporation and Manridge Exploration Limited. Preliminary stream sediment sampling (30 silt and 15 moss mat samples) of the west-facing slope of the Nelson Creek valley returned very encouraging concentrations of gold, silver and copper, as well as anomalous lead, zinc and mercury values. Both base and precious metal mineralization were located apparently related to an extremely leached, sericitic alteration zone trending north-northwest to south-southeast along the west facing valley wall and the focus of work was shifted to this area.

In 1990, Santa Marina Mining optioned the claims from Ecstall, Omega Gold Corporation and Manridge Exploration Limited. Santa Marina Mining collected 116 rock samples that reportedly returned anomalous base and precious metal assays.

In 1991, GoldFields optioned the claims from Ecstall. GoldFields collected 244 rock samples and 1475 soil samples for assay. The soil geochemical survey was successful and identified three anomalous zones (Zone A, B and C in Figure 4) within the leached, sericite altered zone along the west side of the valley. The rock samples confirmed the presence of widespread copper, lead, zinc, silver and gold mineralization.

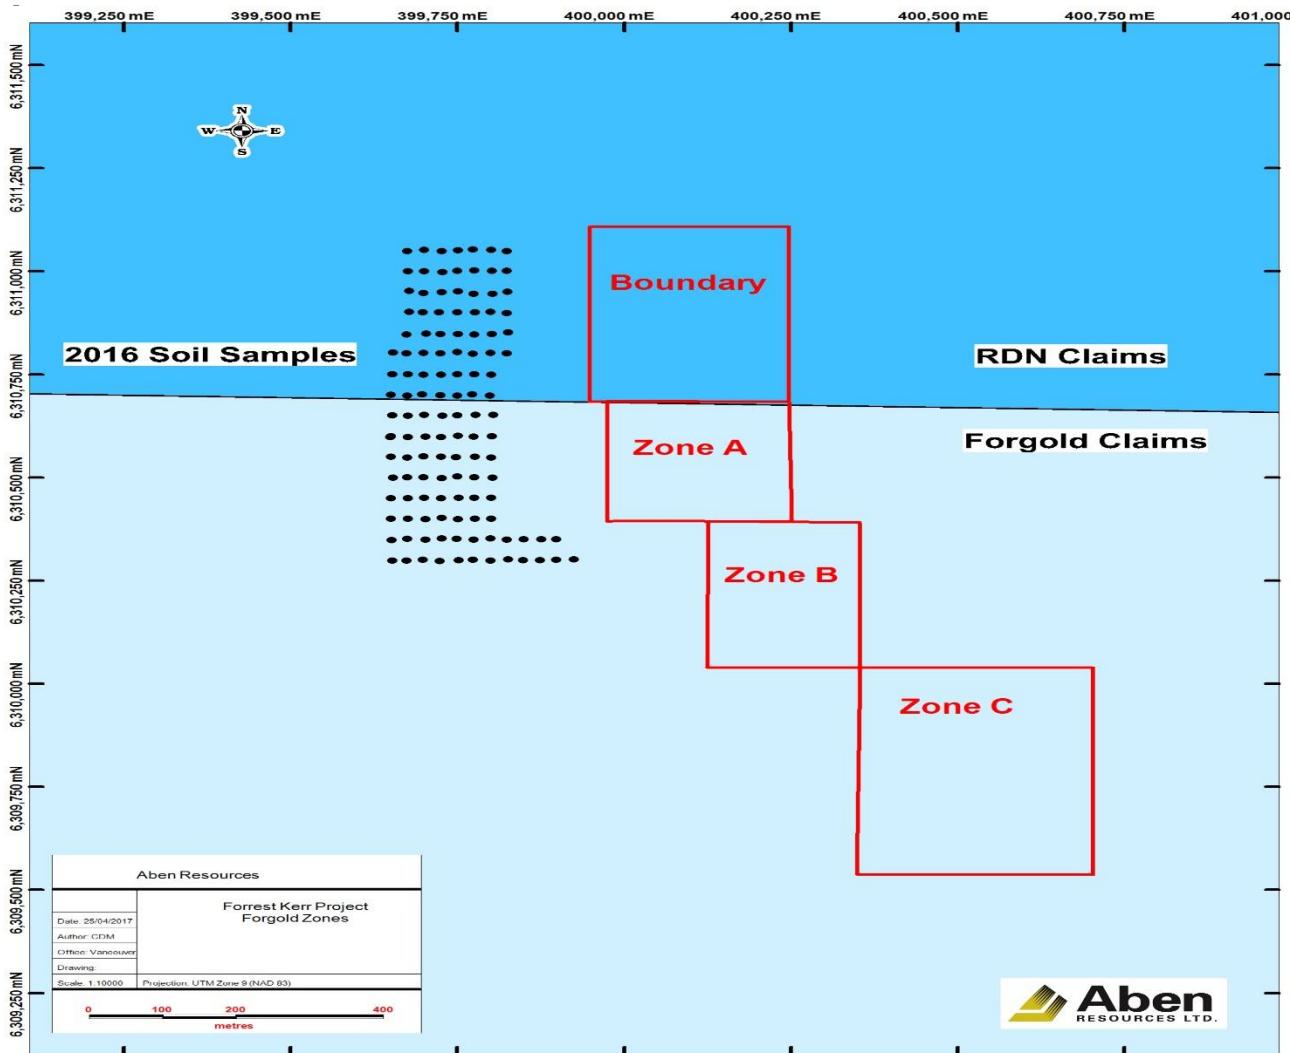

Figure 4: Forgold zone locations

Later in 1991, Goldfields carried out a limited drill program completing a total of 935m from 5 holes in the northern part of the 2,000 metre long soil geochemical anomaly that was defined by the soil sample data. The first four drill holes (FG - 1, 2, 3, and 4) were designed to test the southern strike extent of the Noranda/High Frontier drill intersection which reportedly intersected an 11.6 metre interval that averaged 23.9 g/t Au (The Northern Miner, Sept. 1991). Two significant zones of gold mineralization were intersected in holes FG-2 and FG-3 (0.113 oz/ton or 3.90 g/t) Au over 1.58m and 0.56 oz/ton (19.20 g/t) Au over 0.82m respectively). Hole FG-5 did not encounter any significant gold mineralization but did intersect two narrow zones of copper mineralization (2.97% Cu over 0.31 m and 1.14% Cu over 1.16 m respectively). It is important to note that subsequent re-staking of the claims resulted in the boundary between the properties being shifted several hundred metres to the south and as a result drill holes FG 1-4 are actually located on the RDN claims immediately north of the current Forgold Property claim boundary.

No rigorous statistical analysis of the soil sample results was ever done. The results were interpreted by plotting them on plan maps and inspecting them for significant patterns. For each element certain values were selected and plotted on the plan as contours to help distinguish patterns. Based on the drilling Bond (1992) concluded that the gold mineralization is narrow and discontinuous, however, the amount of drilling to date has not tested the highly anomalous geochemical signature that extends well over 2 km in a north-south trend and is over 500m wide. A geophysical survey was referred to by Ronning (1991) and Bond (1992), however, no accompanying results or interpretation has been made available in the public domain.

### **Forgold-- Southwest**

The Forgold southwest area has been staked by several mining companies since 1989 including Rimfire Minerals and Northgate Exploration, Homestake Canada, Canadian Cariboo Resources and Carmac Resources. Reconnaissance type geochemical surveys and prospecting have been carried out and several anomalous sample results have been reported. A systematic evaluation of the historic data is required to define targets for follow-up exploration.

### **2012-2103 Exploration**

The Forgold central area was the target for the 2012 and 2013 exploration programs, 1743 soils and 127 rocks were collected during this two year program. Tightly spaced soil grids were concentrated over the previously mentioned Zones A-C (figure 4). A small soil grid was also completed on the RDN Boundary Zone. The soils were collected from north-south lines at 10 metre intervals. The lines were spaced 25 metres apart except the northern portion of the RDN Boundary Zone where the lines were spaced 50 metres apart. The soils were collected from well developed "C" horizon at a depth of 20 to 50cm.

The RDN Boundary Zone grid was established to understand the mineralization and soil geochemistry of Goldfields drilling program. The grid contains 300 soil samples and 19 rock samples. The area contained around 15% rock outcrops in creek draws and small cliff sets surrounded by steep slopes of wildflowers and weeds. The geology was predominantly volcanics with small zones of intense quartz-carbonate veining and a few small mafic dykes.

The northern extent of the grid is located 430 metres north of the Forgold claim block and contains 6 soil lines, 350 metres long and spaced 50 metres apart. Samples were collect at ten metre intervals and covered the area of four of the historic drill holes FG-1 to FG-4 including two old BQ sized drill holes that were never recorded for work. Anomalous rock samples from this area include a 30 cm chip sample of siliceous veinlets in a volcanic host rock with massive chalcopyrite that returned values of 53.9 ppm Au, 188 ppm Ag and 25.0% Cu (sample 1132956) and a 30cm wide shear zone with weathered pods to 15cm of coarse grained chalcopyrite returning values of 153 ppm Ag, 1.9% Pb and 22.6% Cu (sample 1132955). The soil grid returned values as high as 4520 ppm Cu with 4.6 ppm Ag (sample 050950) and numerous anomalous copper values from 1500-2460 ppm Cu near the old drill holes.

Another small, tighter soil grid covered the remaining 80 metres to the Forgold claims. The grid ties into the Zone A grid and contains twelve north trending soil lines, 70 metres long spaced 25 metres apart. Soil samples were collected at 10 metre intervals and covered a steep creek draw and associated small cliffs that contained numerous quartz-calcite veins with localized zones containing abundant chalcopyrite. This zone also covers the southern extent of two north trending mafic dykes, one contains 61.8 ppm Au, 13.3 ppm Ag and 2.47% Cu (sample 1050864), and

another 56 metres west containing 0.34 ppm Au, 153 ppm Ag and 21.1% Cu over 50cm. The soils on this grid correlated moderately well with the rock samples collected and introduced the mafic dykes as a new target for exploration.

Zone A ties the “Boundary Zone” on the RDN claims into the Central Area of the Forgold property. This zone has a marked decrease of outcrops with about 5% of the zone as rock. The soil grid consists of 12 lines at 25 metre spacing with samples at 10m intervals for a total of 348 samples. The copper values showed a weak correlation with the rock samples that were collected, with only a small anomalous zone containing one or two samples directly downslope from known mineralization. The best example of this is a zone containing a 50cm wide massive chalcopyrite vein trending NNE. The vein was traced out to 6.5m in length before it disappears under thick overburden on both sides. A 50cm chip sample across the vein returned 0.36 ppm Au, 211 ppm Ag and 30.8% Cu (sample 1050870). A soil sample directly below the showing returned a copper value of 2,590 ppm (sample 150590) with one single soil sample 28 metres downslope from this zone returning 1,235 ppm Cu (sample 125580) surrounded by low soil values. An area deemed the Willy showing was located on a steeply incised creek valley that drained west into Nelson creek. This area encompasses a 30x15 metre zone of moderate to intense quartz-carbonate veining and quartz flooding in grey volcanics containing large amounts of chalcopyrite and minor galena. Rock samples from this area ranged from 0.136% to 1.095% Cu with one sample returning 6.45 ppm Au, 25.4 ppm Ag and 4.7% Cu (sample 1050769). A minor soil anomaly consisting of six soil samples surround the showing with values up to 861 ppm Cu (sample 225520).

The downslope dispersion distance for mineralization in soils for copper, and the lateral extent appears quite limited. This indicates the importance of each anomalous copper value in individual soil samples and that a tight soil grid is essential to delineate the mineralized zones.

Zone B grid consists of 360 soil samples collected from 10 soil lines spaced 25 metres apart with samples collected at ten metre intervals that cover an area with historic high gold values. Rock outcrop is limited to three steeply incised creek draws and a total of 16 rocks were collected from the grid area. The soil samples outlined two large anomalous zones trending downslope, and follow the outskirts of the creek draws. Some of the more interesting rock samples located within this grid includes a sample of quartz-sericite schist with 9.52 ppm Au and 4.1 ppm Ag (sample 1132963), a 25cm wide siliceous horizon with sphalerite and chalcopyrite containing 3.34 ppm Au, 10.4 ppm Ag and 19.85% Zn (sample 1132567) and a sample of siliceous volcanic with minor calcite veins and sphalerite containing 10.9 ppm Ag and 21.5% Zn (sample 1132566).

Zone C was established in 2013 to cover the gold and copper in soil anomalies from historic work. The grid consists of 735 soil samples from 15 north-south lines. The lines were spaced 25 metres apart with 10 metre samples intervals. This grid zone had very little rock outcrop but the soil assays outlined a large copper in soil anomaly on the eastern portion of the grid with numerous samples over 1000 ppm Cu. A very interesting zone of siliceous volcanics with quartz veins was located on the west side of Nelson creek. Samples collected from this area includes a grab sample volcanic host rock with numerous small quartz veins with chalcopyrite that returned values of 28.3 ppm Au, 18.7 ppm Ag and 2.31% Cu (sample 1132551).

During the 2013 field season DGW Explorations completed a reconnaissance geophysical survey program on the Forgold property. The mandate of the program was to carry out a total magnetic field survey over the soil geochemical surveys to determine if a magnetic and soil anomaly

relationship exists and to aid in the geological interpretation of this area. The Forgold geophysical survey consisted of 13 North-South lines and 5 east-west line. A total of 13 line km of magnetic data was collected over these north-south east-west lines, covering an area of 1.3km<sup>2</sup>. At total of 1500 individual magnetic readings were collected at 1500 stations. Station spacing was 10m. Labels for the grid were based on UTM positions of the stations.

## Forrest Claims

This section on historical exploration on the Forrest claims is taken from Awmack (2013). Table 4 summarizes all known exploration work carried out on the ground currently comprising the Forrest property.

Table 4: Exploration History on Forrest Claims

Operator	Geochemistry	Geophysics	Drilling/ Trenching	Reference
Pamicon (1988)	rocks			AR 18316 (Todoruk and Ikona, 1988)
Avondale (1989)	15 heavy minerals, 16 silts, 3913 soils, rocks	Ground: 54.6 km EM16R-resistivity, 54.6 km magnetics	trenching	(Todoruk et al., 1990)
Avondale (1990)	2899 soils, 356 rocks	Ground: 24.5 km VLF, 24.5 km magnetics, 1.5 km IP, 6.0 km UTEM	34 trenches (1,471m); 24 BQ DDH (2,498m)	AR 20562 (Stammers and Ikona, 1990; Stammers et al., 1991)
Abacus (1994)	209 soils, 66 rocks		trenching	AR 23629 (Todoruk, 1994)
Meridian Peak (1995)	86 soils, 52 rocks	Ground: 16.3 km VLF, 16.3 km magnetics	11 NQ DDH (1,421m)	AR 24156 (Scott and Ikona, 1995; Visser, 1995)
Central (2007)	rocks			AR 31193 (Jones, 2009)
Misty Creek/Pamicon (2009)	19 rocks			AR 31193 (Jones, 2009)
Astar (2011)	32 silts, 573 soils, 57 rocks			AR 32548 (Lehtinen, 2011)
Astar (2013)	7 silts, 452 soils, 23 rocks	Airborne: 428 km VTEM/ magnetics/radiometrics Airborne: 428 km VTEM/ magnetics/radiometrics		Awmack (2013), Fiset et al. (2013)
Totals:	15 heavy minerals, 55 silts, 7934 soils, rocks	Ground 95.4 km magnetics, 1.5km IP, 6.0 km UTEM	35 DDH (3,919 m) trenching	

The original Forrest claims were staked by Pamicon in October 1987 to cover quartz veins exposed above tree-line. No previous work had been documented in the property area, but the entire Iskut River district was undergoing extensive exploration following the discovery of the Johnny Mountain and Snip gold deposits thirty kilometres to the southwest. In 1988, Pamicon carried out initial prospecting of their Forrest claims, identifying a number of Cu and Au-bearing occurrences in four areas distributed in a band seven kilometres long on the west side of the West Slope Fault, a NNE-striking fault of regional extent (Todoruk and Ikona, 1988).

In 1989, Avondale Resources Ltd. (“Avondale”) optioned the property and carried out a comprehensive exploration program that summer, comprising conventional silt and heavy mineral stream sediment sampling, extensive soil sampling over the Forrest and South Central grids and along contour lines, mapping, prospecting and blast-trenching of showings. The geochemical surveys showed extensive Au and base metal anomalies. A magnetometer/EM-16R resistivity survey was carried out over both grids (Todoruk et al., 1990).

In 1990, Avondale carried out extensive exploration on the Forrest property, including mapping, prospecting, grid-based geochemical and geophysical surveys, mechanical trenching and drilling. Three test lines of induced polarization (“IP”) were run in the Goldpan Showing area, revealing a strong chargeability high subsequently shown by drilling to be due to graphitic phyllite. Nine UTEM lines were surveyed over the Forrest and Fifty zones without revealing significant conductors. VLF-EM and magnetometer surveys were run over several mini-grids and test lines, helping to define lithological trends and faults. Soil sampling was done over three new grids (North, Central and South), with limited infill sampling on the two existing grids and a few contour soil samples. Grid sampling was generally done at 25 metre intervals along lines spaced 100-200 metres apart. The soil geochemical results showed numerous  $\text{Au} \pm \text{Cu} \pm \text{As}$  anomalies, both associated with known mineralization and in other areas. By 1990, thirty mineralized showings had been recognized along 8.4 kilometres of the West Slope Fault. Drilling tested nine showings with mixed results; the best drill intersections were from the Creek Showing (90A-05: 39.7m @ 1.97 g/tonne Au, 0.77% Cu: 90A-13: 12.0m @ 5.79 g/tonne Au, 0.83% Cu) and Canyon Showing (90A-15: 1.5m @ 19.4 g/tonne Au) (Stammers and Ikona, 1990; Stammers et al., 1991).

Avondale relinquished its option on the Forrest property and Abacus Minerals Corporation (“Abacus”) optioned it in 1993. The following year, Abacus commissioned a limited program of mapping, prospecting, hand-trenching and soil sampling focused on the Crooked Creek Showing, which was believed to be the strike extension of the Creek Showing located 1,200 metres to the southwest across Gossan Creek with a similar orientation and style of mineralization. This work confirmed the presence of Au-Cu mineralization at the Crooked Creek Showing for 100 metres down-dip and 75 metres along strike from its previously-recognized extent (Todoruk, 1994).

By 1995, Meridian Peak Resources Corporation (“Meridian Peak”) had optioned the Forrest property. Meridian Peak carried out magnetic/VLF-EM surveying over three small grids (Visser, 1995) and drilled five showings, including two previously undrilled ones, with 11 core holes (1,421 metres). The best drill intersection averaged 4.05 g/tonne Au across 3.15 metres in hole F95-11, testing the Creek Showing (Scott and Ikona, 1995).

A brief program of rock sampling was apparently initiated by Central Resources Corp. (“Central”) in September 2007 but was cut short by weather problems. This work has not been documented.

No further work was reported on the Forrest property until 2009, when Misty Creek Ventures Ltd. (“Misty Creek”) and Pamicon owned the property equally and carried out limited rock sampling and mapping focused on the structural framework of mineralization (Jones, 2009).

In August 2011, Astar optioned the Forrest property from Pamicon and Equity Exploration Consultants Ltd. (“Equity”), the successor company to Misty Creek. Later that year, Astar carried out a program of mapping, prospecting and geochemical sampling, which resulted in the discovery of the JAM-2 Cu-As±Au showing and collection of three silt samples from the southwestern part of the property which were highly anomalous in As-Cu-Mo-Sb-Zn±Ag (Lehtinen, 2011).

In 2013, Equity Exploration Consultants Ltd. was contracted to carry out mapping, prospecting, geochemical sampling and an airborne geophysical survey on the Forrest property. The airborne geophysical component of this program was subcontracted to Aeroquest Airborne of Aurora, Ontario, with the flying carried out from Bell II Lodge from July 24-28, 2013. The fieldwork was carried out by a 4 person field crew with daily set-outs by Quantum Helicopters Ltd. from the Eskay Creek mine-site from August 23-29, 2013. A magnetic declination of  $20^\circ 07' E$  was used

for all compass measurements. All maps and UTMs are referenced to the 1983 North American Datum (NAD-83).

The helicopter-borne geophysical survey consisted of coincident Versatile Time-Domain Electromagnetic (VTEM), magnetic and radiometric surveys. It was flown with a nominal 30m terrain clearance along lines oriented at 102°, roughly perpendicular to the major faults and lithological contacts on the property. Essentially the entire property was covered with lines spaced 200 metres apart; ten intermediate lines reduced line spacing to 100 metres over the well-mineralized Gossan Ridge area in the centre of the property, an area which includes the Forrest and Creek zones.

A total of 23 rock samples, 7 silt samples and 501 (including 49 QA/QC) soil samples were taken from the Forrest property in 2013. Mapping was concentrated on the Forrest Zone. Prospecting concentrated on the little explored southwestern part of the property. Rock samples were taken from mineralized and altered rocks during the course of prospecting and mapping. Silt samples were collected from the active parts of previously unsampled streams in the southwestern part of the property. Both silt and rock sample sites were marked in the field by pink and blue flagging and aluminum tags.

Soil sampling was confined to the southwestern part of the property in 2013. The soil geochemical grid was extended 800 metres to the south over favourable geology, with samples taken at 25 metre intervals along five east-west lines spaced 200 metres apart. In addition, three contour soil lines at 1,300m, 1,400m and 1,500m elevation were sampled across the drainage where three 2011 silt samples contained highly anomalous As, Cu, Mo, Sb, Zn and Ag values. All sites were located by GPS. Wherever possible, soil samples were collected from the B horizon at 15-40 cm depth, but samples were taken from talus fines or glacial and fluvial material where "B" horizon soils were non-existent. Field notes were recorded and each site was marked with orange flagging and a Tyvek tag. Blanks and field duplicates were included with the soil sampling for quality assurance.

## GEOLOGIC SETTING

### Regional and Property Geology

The following section on regional and property geology has been summarized from Jones (2006). While the following summary will provide a general overview of both regional geology and local geology as it pertains to the RDN and Forgold claim groups, the reader is advised to consult Jones (2006) for a very comprehensive geologic description. A separate subheading for the Forrest claims will follow the summary of regional and local geology below.

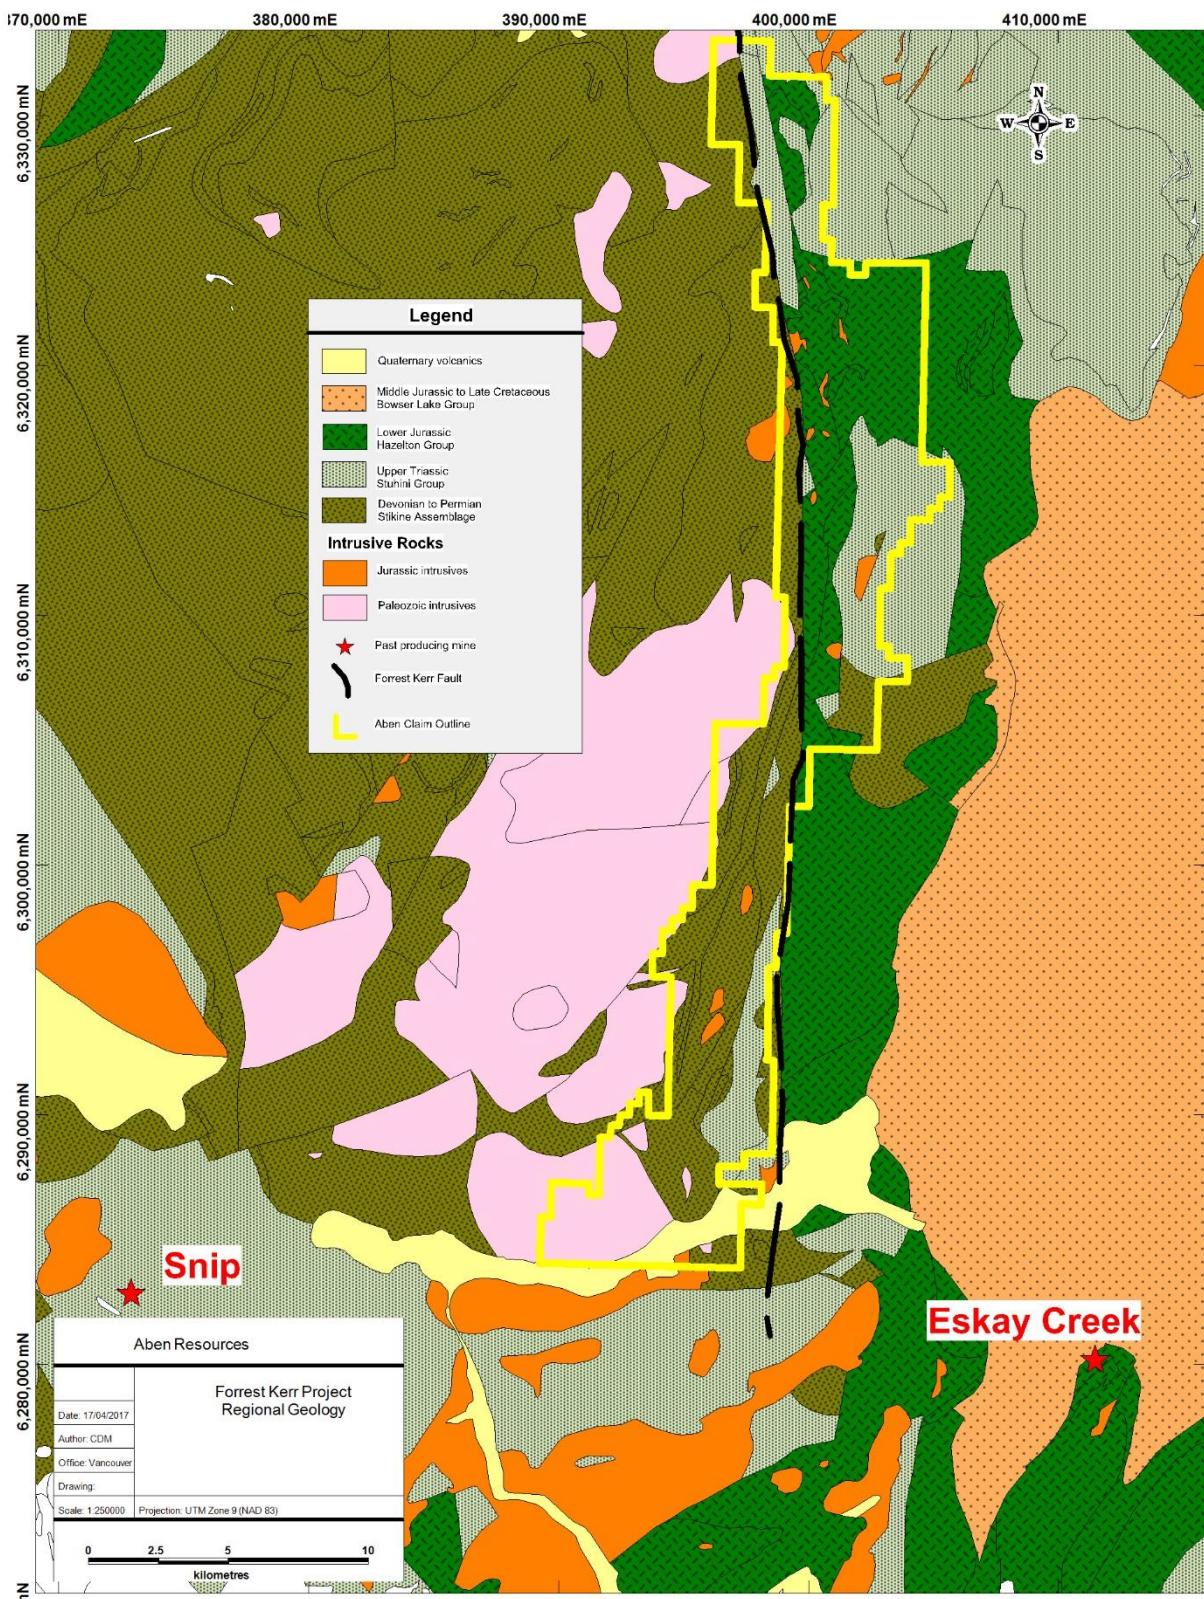

Figure 5: Regional geology around the Forrest Kerr Property

The regional geology surrounding the Forrest Kerr property consists of mid-Paleozoic and Mesozoic island arc successions which are overlapped to the east by clastic sediments of the Bowser Basin. Regional mapping has been carried out at a scale of 1:50,000 by Logan et al (1990a, b; 1992a, b; 1997) of the BCGS and by Read et al (1989) of the GSC. Recent mapping has been done in the Forrest Kerr area by the B.C. Geological Survey (Alldrick et al, 2005).

The Paleozoic Stikine Assemblage in the vicinity of the Forrest Kerr property comprises variably foliated mafic to intermediate volcanic rocks, chert and fine clastic sedimentary rocks. These have been intruded by the Late Devonian to Early Mississippian More Creek and Forrest Kerr composite batholiths, with phases ranging from granite to diorite. The Paleozoic rocks lie entirely on the western side of the Forrest Kerr Fault, with Mesozoic rocks exposed to the east. The Stikine Assemblage is unconformably overlain by island arc volcanic and sedimentary rocks of the Upper Triassic Stuhini Group. At the base of the Stuhini Group is a thick package of fine-grained volcaniclastic and sedimentary rocks, dominated by volcanic wacke, arenite and interbedded siltstone and argillite. These units inter-finger with overlying massive green tuff.

The Early to Middle Jurassic Hazelton Group unconformably overlies the Stuhini Group, and comprises five regional units (MacDonald et al, 1996); which are summarized below in Table 5. For clarity, Table 5 includes correlations to rock units used at Eskay Creek by Logan et al (1997) and for the northern portion of the Forrest Kerr property (Figures 6).

The basal coarse clastic unit, which contains Upper Hettangian to Lower Sinemurian ammonites, is a few tens or hundreds of metres thick, overlying the Stuhini Group along a disconformity or angular unconformity. It is conformably overlain by the sequence of andesitic to dacitic volcanics, which includes the previously defined Betty Creek Formation (Anderson, 1993). It is characterized by extensive variations in thickness and facies; Macdonald et al (1996) report a U-Pb date of 193 Ma for one of its flows. The intermediate volcanic and volcaniclastic strata are locally overlain by regionally discontinuous felsic calc-alkaline volcanic flows and tuffs with U-Pb dates from 186.5 to 194 Ma. The overlying sedimentary unit is distinguished from the basal unit by the absence of the granitoid-clast conglomerate and by clasts derived from the underlying intermediate volcanic packages. Fossils within the sedimentary unit range from Upper Pliensbachian to Upper Aalenian.

The Upper Sequence of the Hazelton Group is dominantly a bimodal tholeiitic volcanic assemblage with lesser tuffaceous, calcareous and argillaceous rocks, thought to represent intra-arc rifting (Roth et al, 1999). At Eskay Creek, this unit consists of felsic volcanic rocks overlain by a basaltic volcanic-sedimentary package, but regionally these stratigraphic relations are more complex and locally reversed. Fossils constrain this unit between Late Aalenian and Early Bajocian; U-Pb dates on rhyolites indicate a range of 181-172 Ma (Childe, 1996).

Middle to Upper Jurassic Bowser Lake Group marine and terrestrial mudstones, sandstones and conglomerates conformably overlie the Hazelton Group. These basinal clastics lack volcanic components and contain clasts of rock types from adjacent terranes, indicating a change in the local and regional tectonic setting (Roth et al, 1999).

Table 5: Hazelton Group Stratigraphic Units (from Jones 2006)

<b>McDonald et al (1996) Unit</b>	<b>Lithology</b>	<b>Eskay Creek</b>	<b>Logan et al (1997)</b>	<b>Forrest Kerr</b>
<b>Upper Sequence</b> Bimodal volcanic Dacite tuffs and flows, rhyolite flows, basalt rocks <b>(181 to 173</b> pillow to massive flows, breccias and <b>Ma.)</b> hyaloclastite, interstratified mudstone and tuffaceous mudstone	Hanging Wall Basalt, Contact Mudstone, Eskay Rhyolite,	Jw, Jwcg mJHsl, mJHb	mJRY, mJBA, mJDI, mJSE, I-mJRY	
<b>Lower Sequence</b> Sedimentary unit Turbiditic siltstone to sandstone, heterolithic <b>(Upper</b> cobble conglomerate, bioclastic calcareous <b>Pliensbachian to</b> siltstone, lesser tuffaceous sandstone <b>upper</b> <b>Aalenian)</b>		IJHsl	mJSE <sub>7</sub> , IJSA <sub>8,13</sub>

Basal coarse Locally fossiliferous calcareous sandstone, clastic unit trough cross-stratified granitoid clast <b>(Hettangian-Sinemurian boundary)</b> conglomerate, rare welded dacite lapilli tuff	Lower Footwall Unit		IJS <sub>2</sub> , IJSA	

Read et al (1989) mapped several small feldspar+quartz porphyry plugs and dykes near the Forrest Kerr Fault. Souther (1972) had previously assigned these plugs a Late Cretaceous to Early Tertiary age, but Read noted cobbles of this unit in basal conglomerates of the Middle to Upper Jurassic Bowser Lake Group. He postulated the felsic plugs and dykes to be subvolcanic feeders to the Early to Middle Jurassic Hazelton Group dacitic/trachytic volcanic rocks. Diorite sills and dykes are associated with the upper Hazelton Group basalt extrusive rocks and are thought to be subvolcanic equivalents.

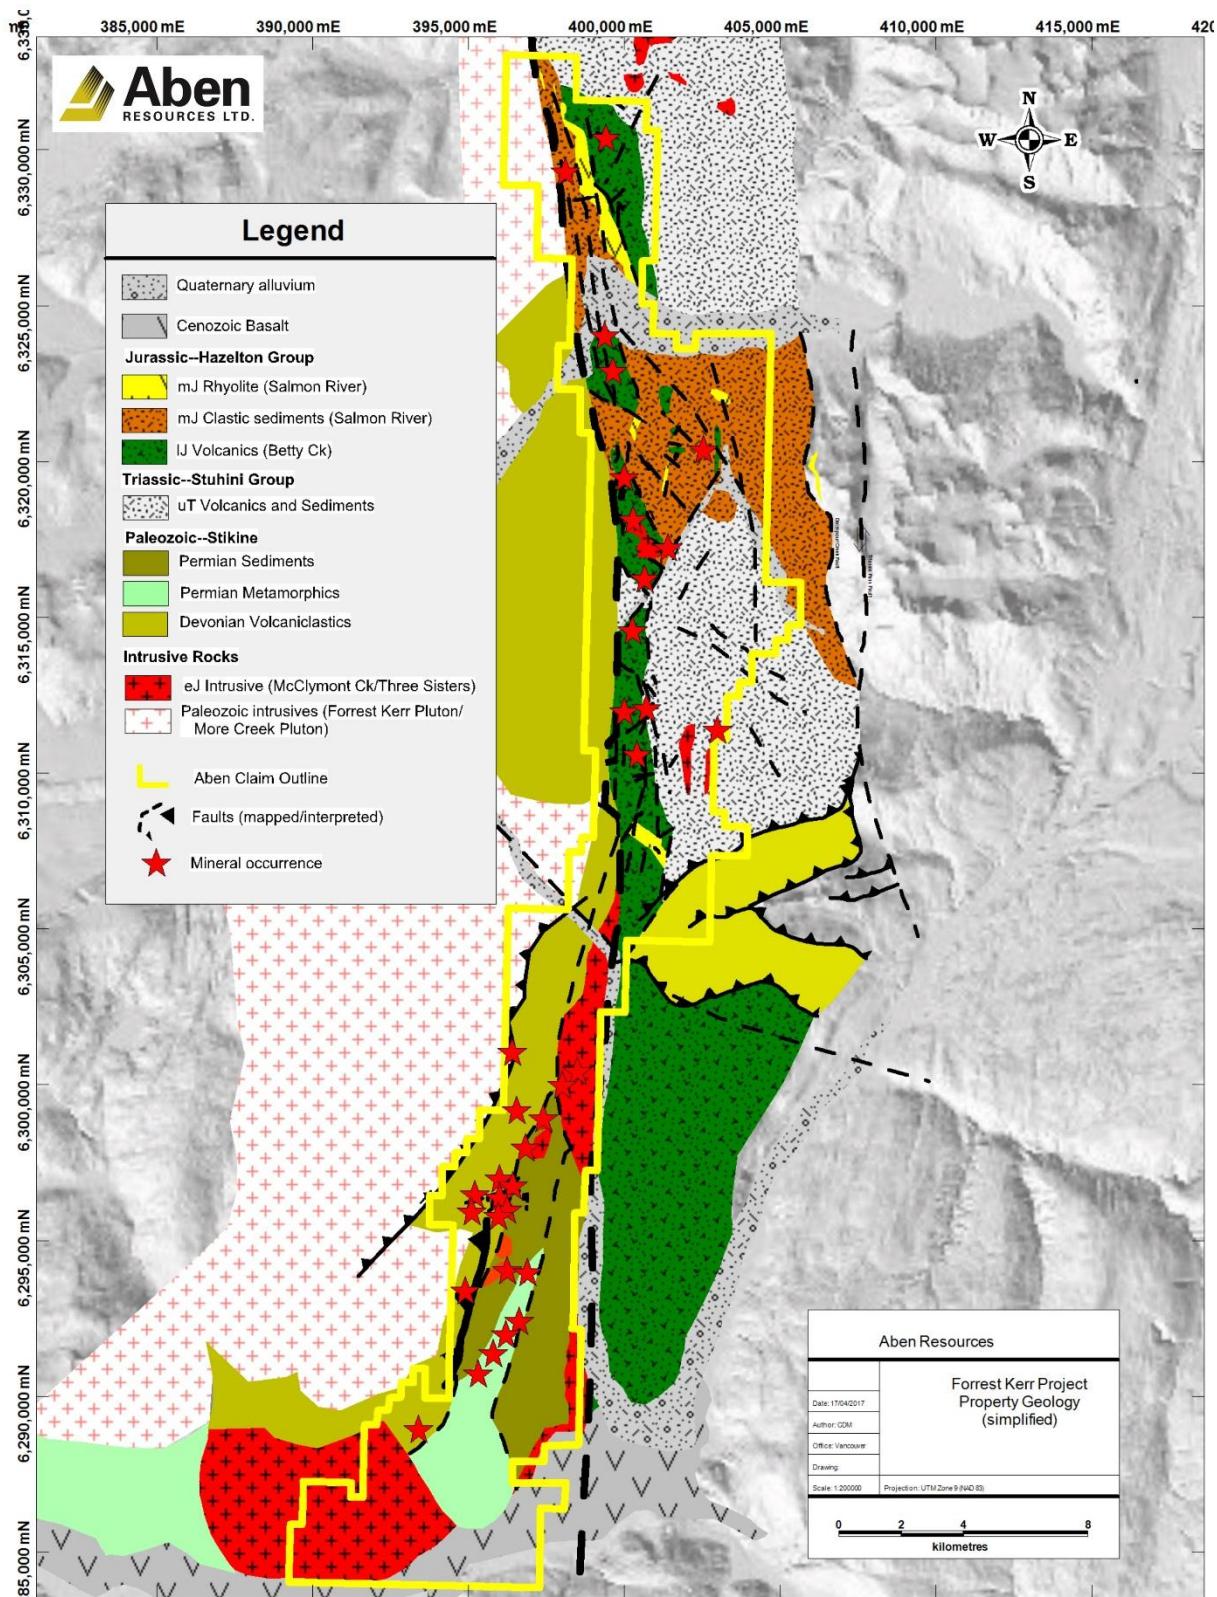

Figure 6: Forrest Kerr Property Geology

The first phase of structural deformation in the area is evident as widespread phyllite and foliated greenstone in Lower Permian and older rocks (Read et al, 1989). A second, post-Jurassic phase of folding produced northerly-trending upright folds. Bowser Lake Group rocks are affected by a third phase of deformation, with folding about northwesterly trending axial planes. Fault trends are complex, with a northerly trending set and an anastomosing east-northeast set. The sub-vertical Forrest Kerr Fault, which runs through the Forrest Kerr Property, is a major northerly-trending fault which can be traced for more than 40 kilometres. Read et al (1989) estimate a left-lateral horizontal displacement of 2.5 kilometres and a minimum vertical displacement of 2 kilometres (east side down). Britton et al (1990) suggest that south of the property, across the Iskut River, the Forrest Kerr Fault steps eastward and continues south for another 20 kilometres as the Harrymel Creek Fault. This fault, which truncates Hazelton Group stratigraphy immediately west of the Eskay Creek deposit, is "a zone of recent faulting that may represent a long-lived crustal break" (Britton et al, 1990). This "crustal break" may have localized Jurassic felsic volcanic centres at Eskay Creek, the Four Corners Complex (Alldrick et al, 2005) on the Forgold claims and on the RDN claims.

## **Forrest Geology**

The following description of the Forrest geology has been adapted from Jones (2009) and Awmack (2013).

In the southwest part of the Forrest property, Devonian coralline and crinoidal thin bedded carbonate and calcareous sedimentary rocks are thrust southeasterly over Permian and older strata by the West Lake fault. The latter strata comprise a lower unit dominated by plagioclase and/or pyroxene-phyric andesite flows and schistose lapilli tuffs, with an upper unit, both structurally and stratigraphically, dominated by mixed metasedimentary and metavolcanic clastic rocks including black, graphitic and sericitic phyllite, thin bedded siltstone, cherty sediments and a variety of ash and lapilli tuff units. Rapid lateral and vertical facies changes are characteristic of the stratified members. To the southeast, Upper Triassic Stuhini units comprising carbonate, volcaniclastic, sediment and porphyritic plagioclase andesite flows and breccias unconformably overlie Permian stratigraphy. These rocks are juxtaposed against the Permian and older rocks to the west by the West Slope Fault. Immediately east of the claims, across the Forrest Kerr fault, lower Jurassic Hazelton Group tuffs, minor conglomerates with granitic clasts and grey siltstones are overlain by an extensive succession of Middle Jurassic basic pillow lava and breccia.

Several intrusions are present on the property, varying from small stocks of diorite, quartz diorite and feldspar porphyry to large plutons of granodiorite to granite. The Late Devonian to Early Mississippian Forrest Kerr Pluton, of mainly biotite granite and tonalite composition, is located in the upper plate of the West Lake Fault along the western property boundary. The Stikine assemblage is bounded on the southwest by the McLymont Creek pluton which is an Early Jurassic hornblende, biotite, potassium feldspar megacrystic granite of the Texas Creek Plutonic suite. Granodiorite plugs of unknown age form a linear trend along the western side of the Forrest Kerr Fault, intruding Upper Triassic strata along the length of the eastern boundary of the property. A similar intrusion occurs within the Paleozoic rocks adjacent to the gossan on the north side of Gossan Creek. The rocks underlying the Forrest Zone were reinterpreted in 2013 as forming a northerly-elongated diorite stock approximately 750 metres wide and at least 900 metres long, of indeterminate age. Immediately south of Gossan Creek and along Gossan Ridge, dacitic or

monzonitic quartz-feldspar megacrystic porphyry dikes intrude the Paleozoic strata. These dykes are believed to represent sub volcanic feeders for Lower and Middle Jurassic Hazelton Group volcanic rocks.

Elsby (1992) carried out structural mapping over much of the Forrest property, recognizing four phases of deformation. Regional east-west compression ( $D_1$ ) during the Late Paleozoic to pre-Late Triassic produced a northeast-trending penetrative transposed foliation and widespread east-vergent recumbent structures. Axial planes generally dip moderately to gently northwest with shallow to moderate southwest-plunging fold axes. During this event, lower greenschist facies metamorphism was initiated and, as deformation progressed, was accompanied by the formation of low-angle ductile-brittle fault zones which resulted in fault-bounded panels of variably strained rocks.

In the Late Triassic and Jurassic, east-vergent  $F_2$  folds were accompanied by increasing metamorphism and ductile shearing along established  $D_1$  low angle fault zones and  $F_2$  axial plane surfaces. During  $D_2$  deformation, the northwest-dipping West Lake fault and numerous other thrusts developed subparallel to  $D_1$  geometry and mylonite formed along their traces. It is equivocal whether the West Slope fault is another of these thrusts or an east-dipping normal fault. A moderate to strong north-south compression ( $D_3$ ) superimposed upright  $F_3$  folding and fracturing on all rock types, representing a ductile-brittle transition during the waning stages of metamorphism.

$F_3$  folds and their related cleavage are almost orthogonal to  $F_1$  and  $F_2$  folds, with steeply south-dipping axial planes and gently plunging fold axes.  $D_4$  records a dominantly east-west compression regime, with open upright folds which trend northeast and plunge gently to the southwest, most notably warping the surface trace of the West Lake fault; it may be associated with movement along the Forrest Kerr Fault (Elsby, 1992).

## DEPOSIT TYPES—ECONOMIC GEOLOGY

Geological and geochemical evidence indicates that the Forrest Kerr claim group has the potential to host a variety of deposit types. Historic prospecting and diamond drilling has encountered significant polymetallic mineralization in lithologies that are analogous to strata that host mineral deposits throughout the region. On the property, auriferous quartz veins are associated with sheared and brecciated zones both within and adjacent to Early to Middle Jurassic intrusive bodies, which are recognized as important drivers of mineralization in the Golden Triangle.

### Submarine Exhalite Massive Sulfide Deposits (VMS)

Exploration since 1990 on the Forgold & RDN claims has largely focused on the pursuit of submarine exhalite massive sulfide deposits. This style of mineralization offers significant economic potential due to the precious metal-rich high grade nature of similar deposits such as the Eskay Creek mine, situated 30km to the SE of the central part of the Forrest Kerr property. Total production to December 2001 at the Eskay Creek Mine totalled 1.04 Mt grading 61.5 g/t Au and 2721 g/t Ag with proven and probable reserves estimated at 1.3 Mt grading 43.1 g/t Au and 2000 g/t Ag (Rogers, 2002). The Forrest Kerr property hosts many kilometres of rock that is age and genetic equivalent to the footwall and hanging wall zones at Eskay.

#### Intrusion related Au-Ag-(Cu) veins

Polymetallic mineralization in quartz and quartz-carbonate veins formed by structurally focused hydrothermal fluids. These types of deposits are normally associated with regional faults, fault sets and fractures although veins are typically associated with second order structures. Veins typically occur in the central parts of discrete shear zones within a larger regional fault, where the rotational or simple shear strains predominate. Vein systems are tabular, sub vertical structures of varying thickness and lateral extent. The Snip mine, located 17km west of the southeren portion of the Forrest Kerr property, is an auriferous shear vein system hosted in Upper Triassic Stuhini Group metasediments that have been intruded by Early Jurassic age stocks.

#### Porphyry copper-gold deposits

Porphyry copper-gold deposits, both alkalic and calc-alkaline, occur throughout the Intermontane Belt in both the Stikinia and Quesnellia terranes. These types of deposits are common in the Golden Triangle, comprising over 25% of the reported mineral occurrences. Alteration patterns for alkalic type porphyry deposits are distinctly different from those of classic calcalkaline deposits, which are characterized by concentric phyllitic-argillic-propylitic zones. The alkalic deposits typically have a central potassic or sodic plagioclase zone, which passes outward into a propylitic zone. These often overlap and are overprinted by retrograde metasomatic alteration. There are numerous Early to Middle Jurassic intrusives on the Forrest Kerr property that have not been explored for their mineralization potential. The Kerr, Sulphurets, Mitchell and Snowfield deposits are all porphyry deposits located within 40 km of the Forrest Kerr property.

## **2016 EXPLORATION**

Exploration work in 2016 involved the collection of 362 soil, 35 rock and 11 stream sediment samples by a four man crew from September 8-21<sup>st</sup>. Sampling areas were located in several discrete zones across the property (Figure 7). Rock samples were sourced mainly from areas with previously reported high grade base and precious metal values to both confirm historic information and to correlate mineralization with alteration types. Soil samples were targeted in areas adjacent to existing soil grids in an effort to discover if known mineralization trends continue across mapped structures and within previously untested lithologies. Soil samples were sourced from the conventional 'B' soil horizon where possible. Many of the sampling areas were located above treeline where a well-developed soil profile was not available so 'talus fines' were sampled and described appropriately. A complete list of all samples can be found in Appendix C.

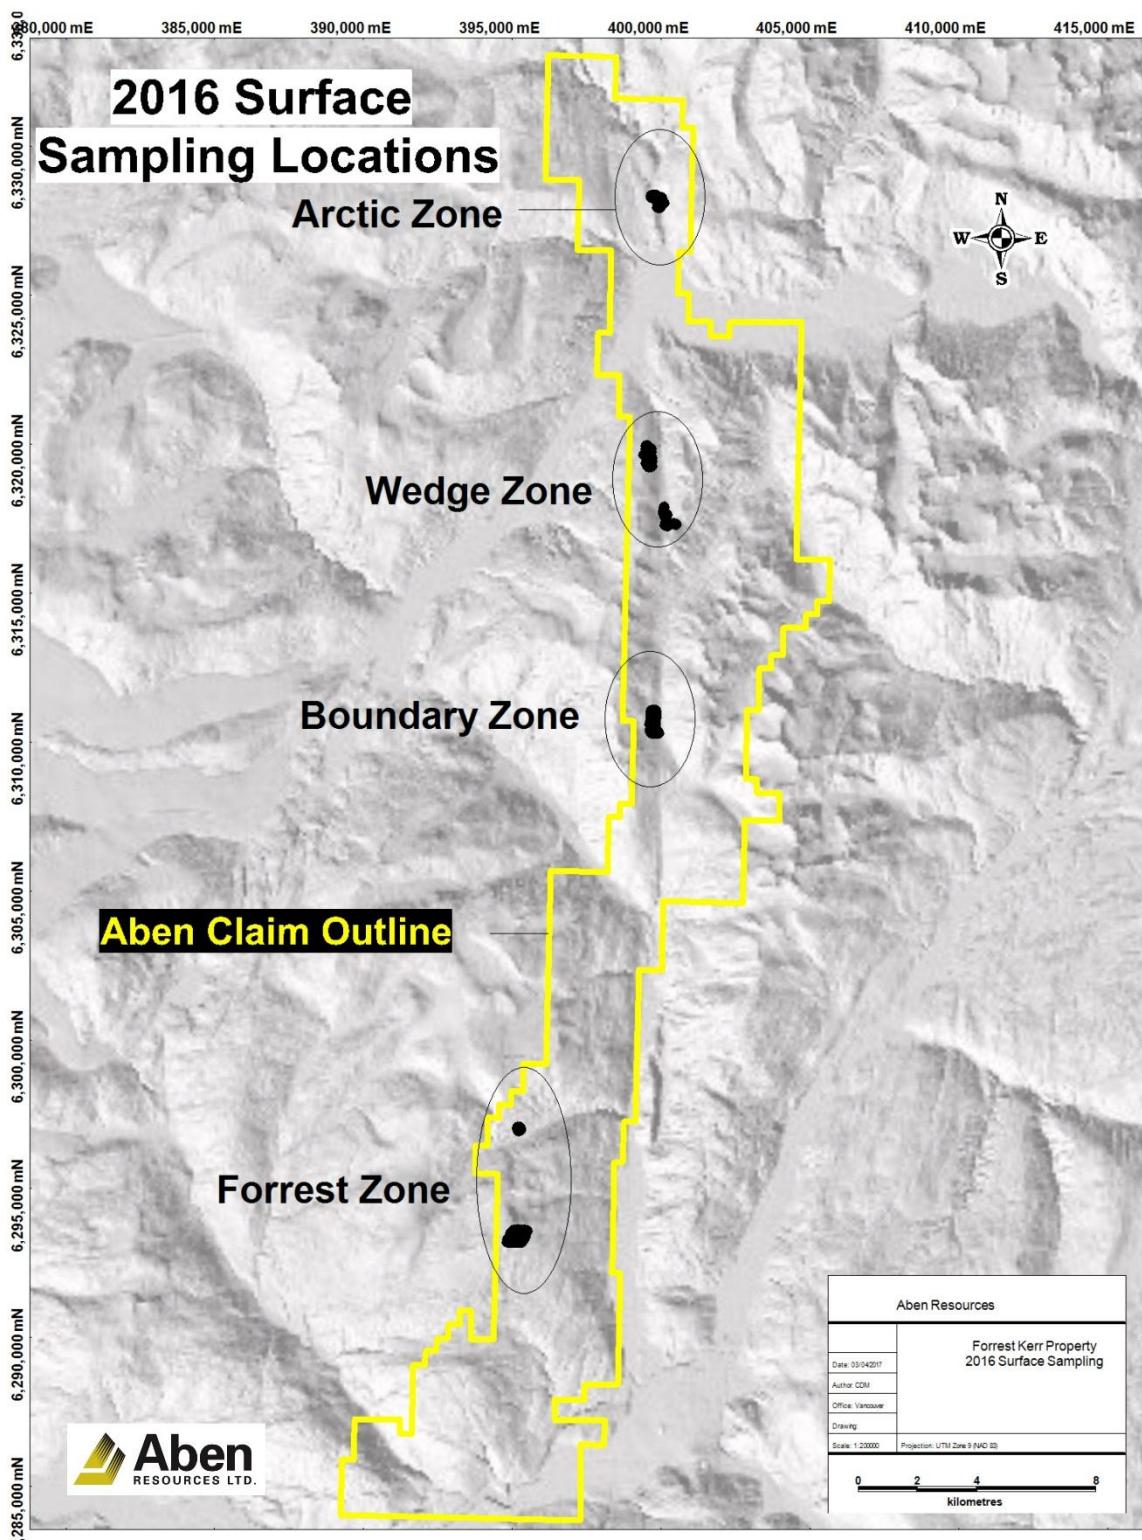

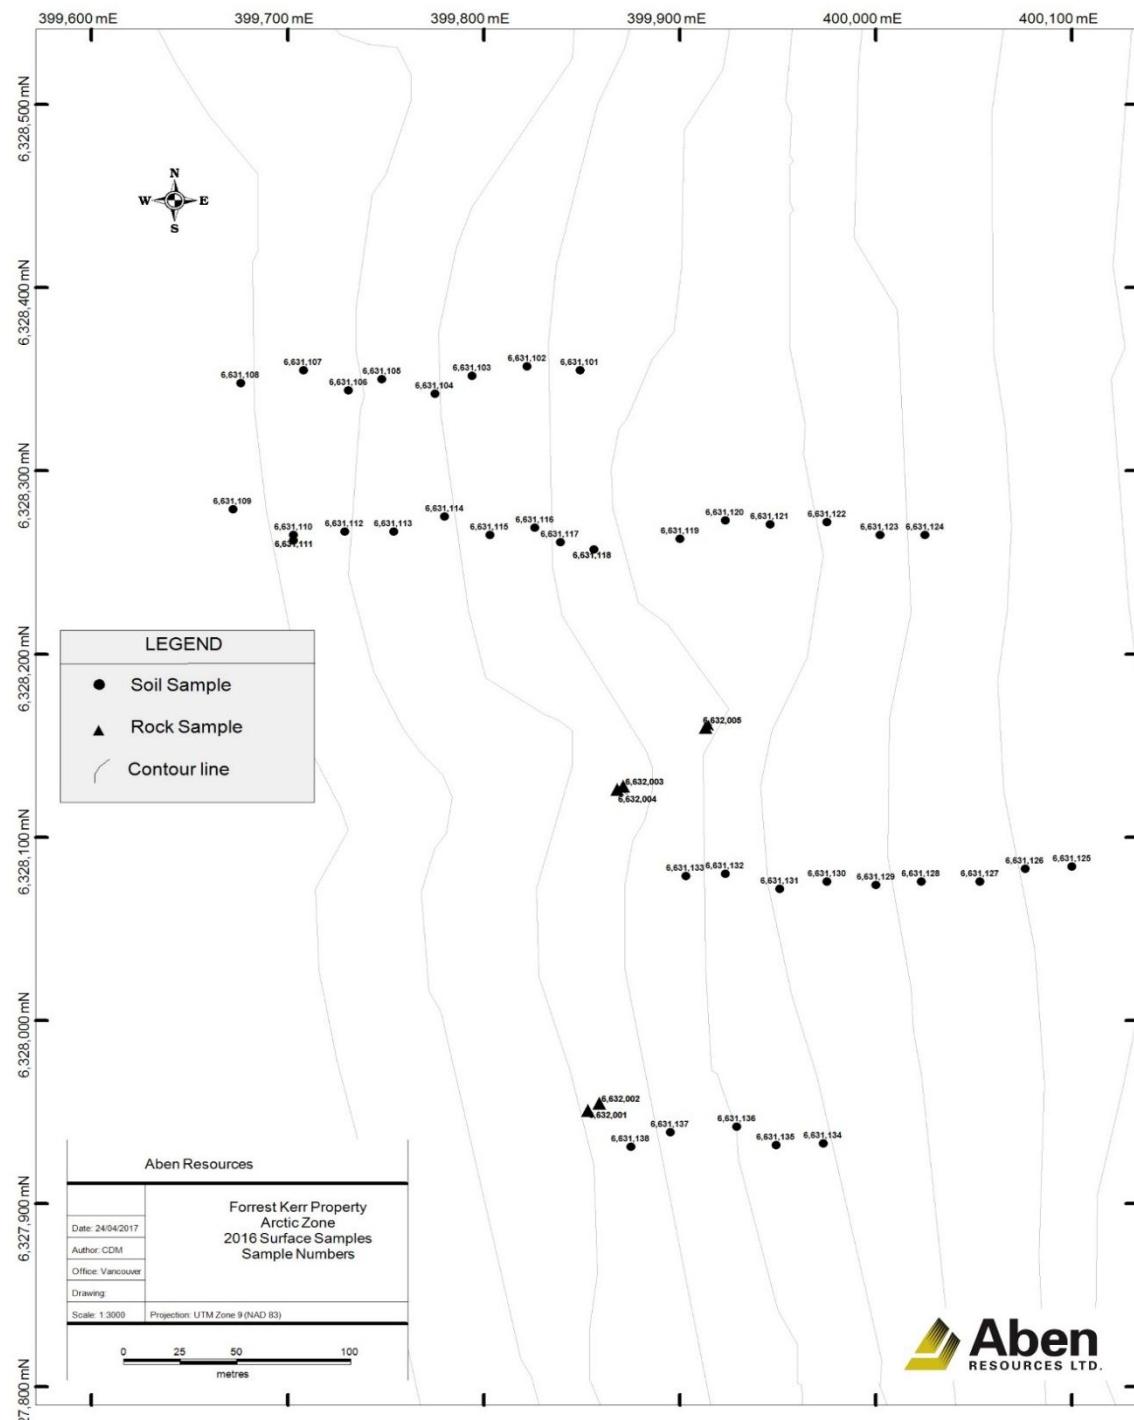

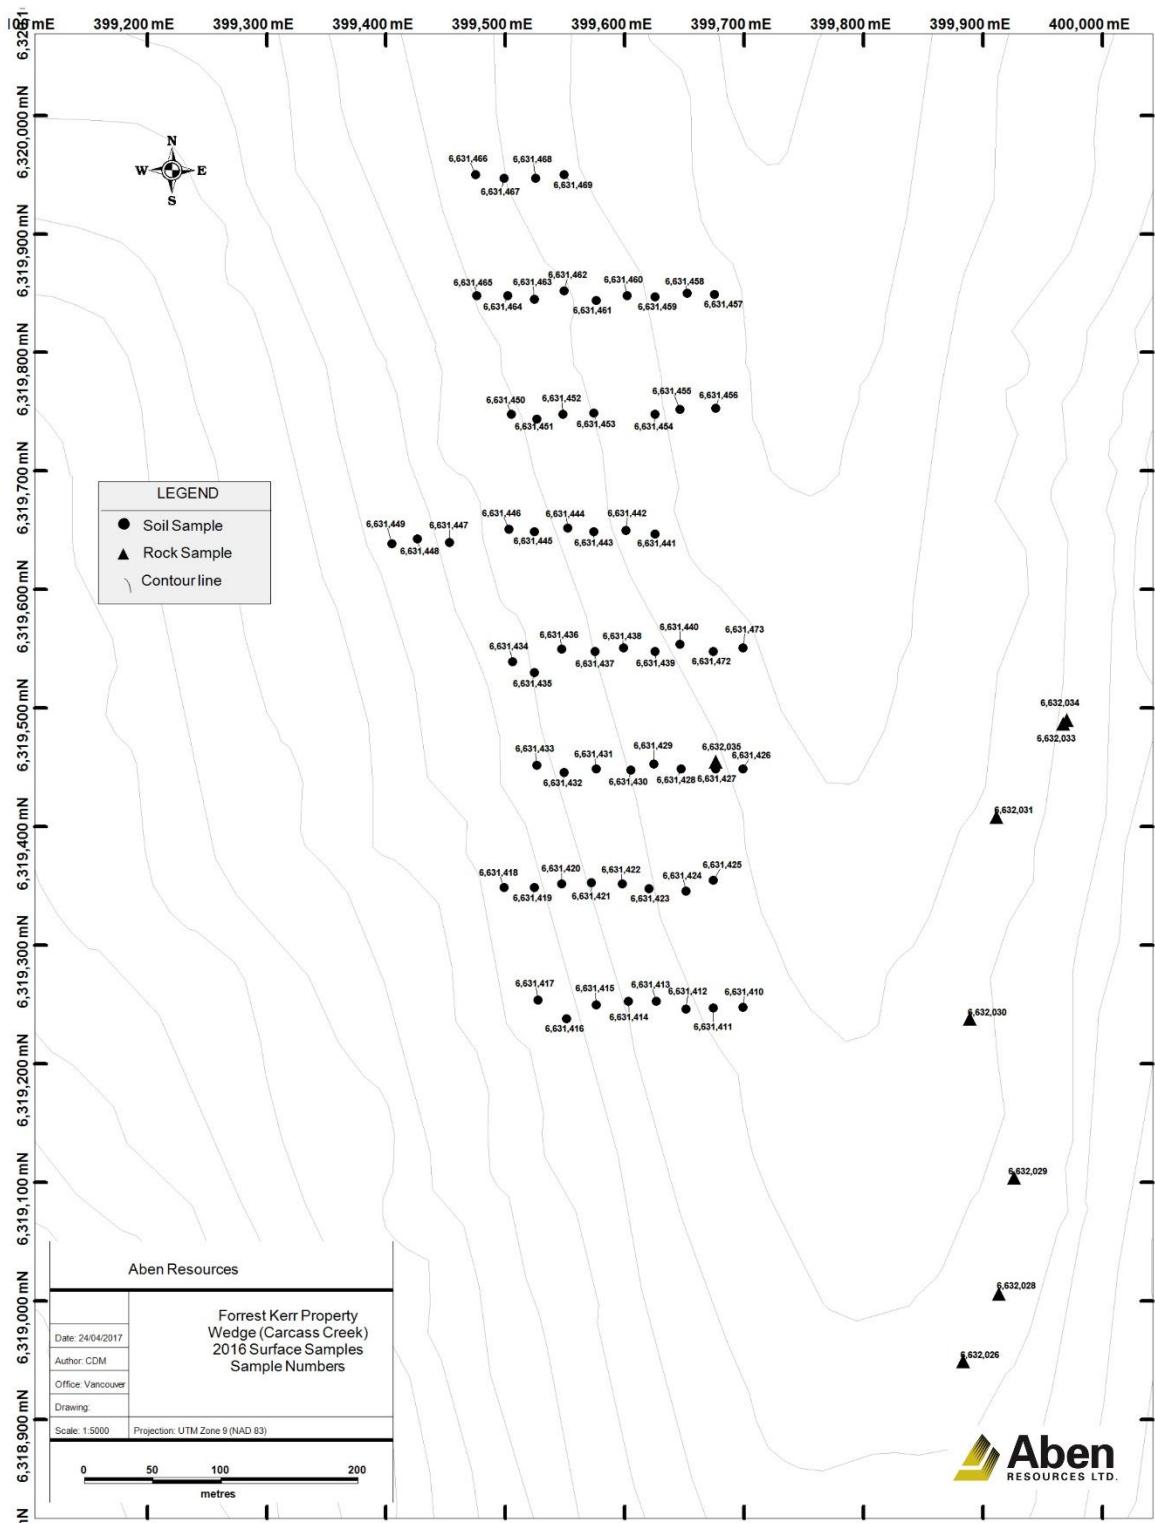

Figure 7: Plan of sampled areas in 2016.

Thirty eight soil samples and five rock samples were taken in the Arctic zone near Slime Creek in order to fill in and extend an existing Pb-Zn-As-Sb soil anomaly. This area has a well-developed soil profile so the geochemical signature is more muted than elsewhere on the property. All of the following sample location maps have corresponding Au & Cu value maps in Appendix D.

**Figure 8: Arctic area surface samples**

A total of 62 soil and 6 rock samples were taken in the Carcass creek area, located in the Wedge zone, where the majority of historic drilling has taken place on the RDN claims. The soil

**Figure 9: Carcass Creek surface samples**

samples were sourced from the western side of Carcass creek to determine whether the strong Au in soil anomaly extended westward from the area of previous sampling. Rock and soil sampling in the Wedge south zone was targeted toward confirmation of historic sampling and to test some

previously mapped structures. Several historic drill pads were located in order to compare their UTM coordinates with those listed in the existing database.

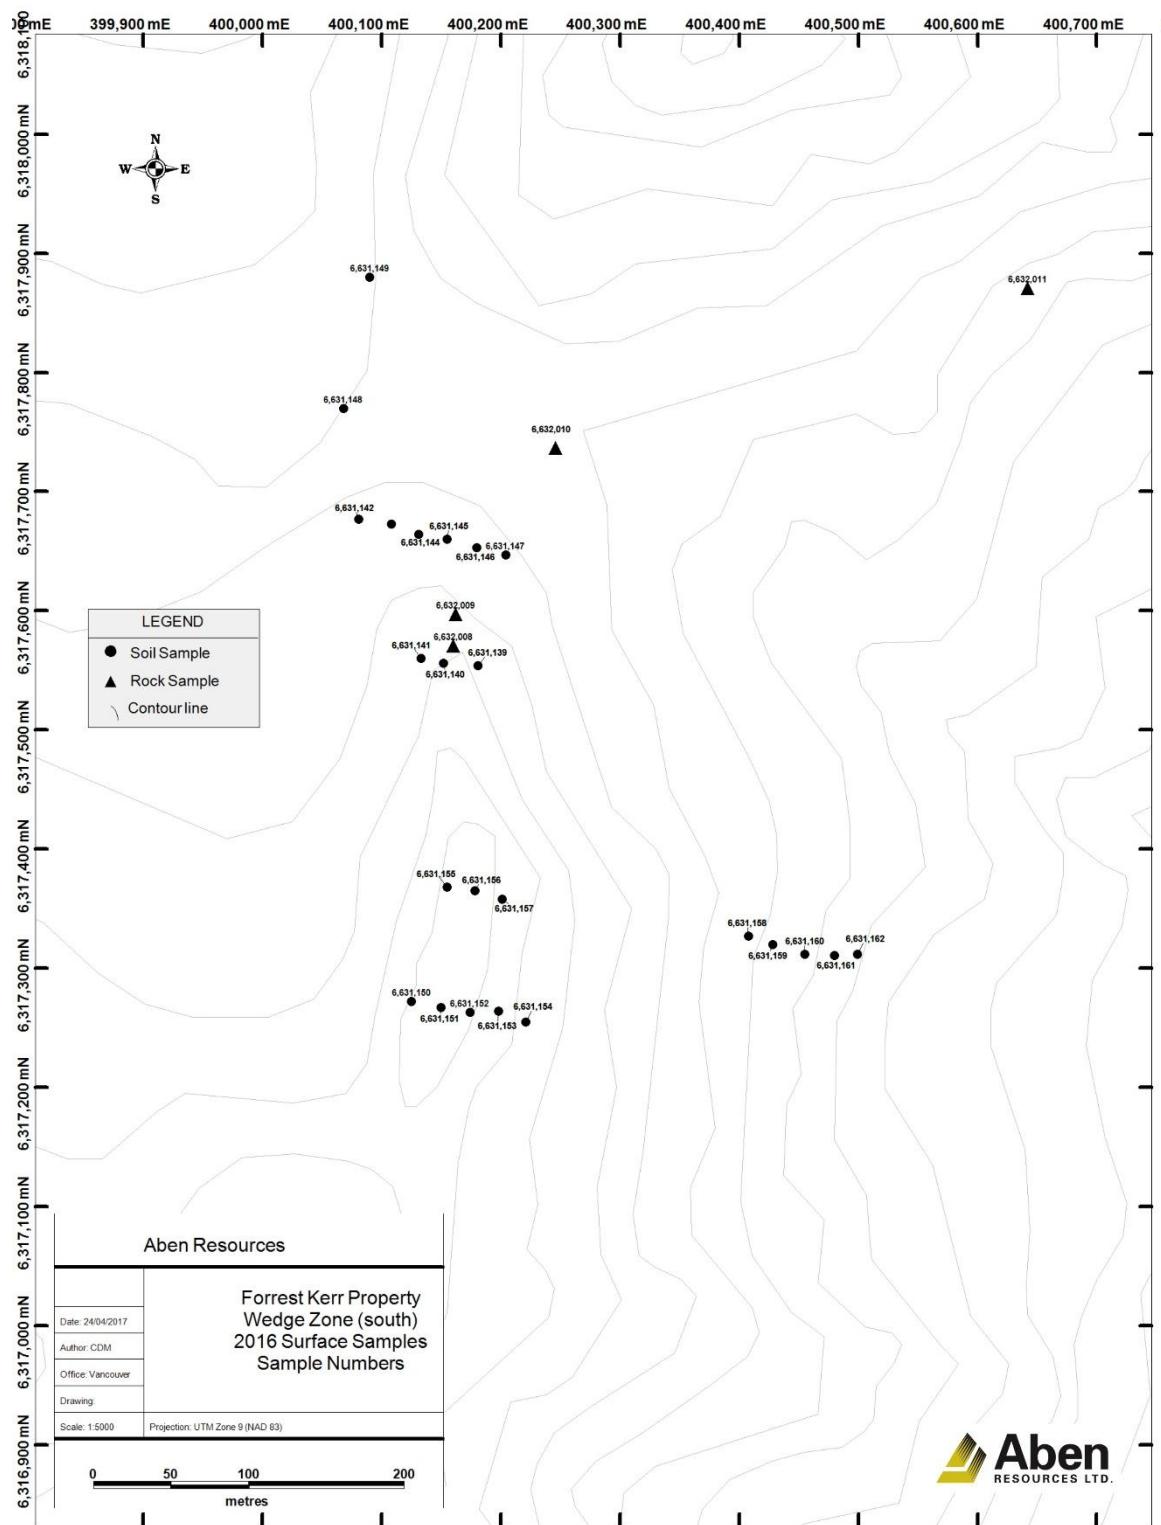

Figure 10: Wedge south zone surface samples

Over 100 soil samples were taken on the west side of the creek at the Boundary zone to test for mineralization across the mapped location of the Forrest Kerr fault and determine if a reported NE-SW trend in mineralization was evident. Four rock samples (float and outcrop) were taken in the vicinity of the historic Boundary drill locations in order to confirm historic grab sample grades.

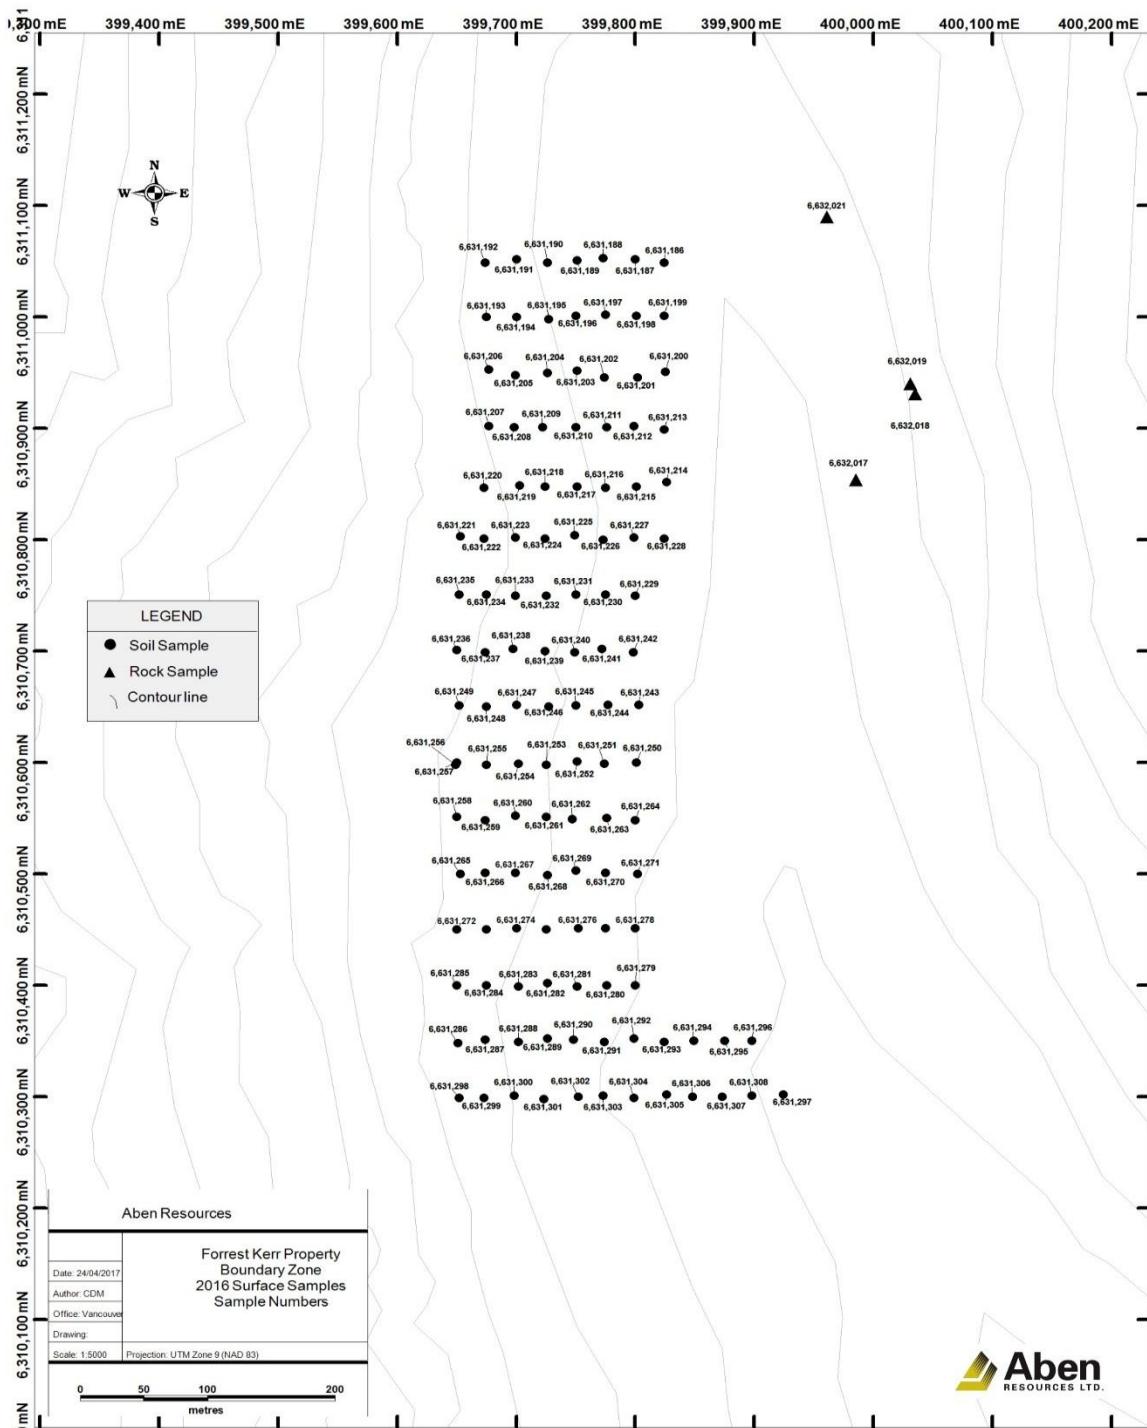

Figure 11: Boundary zone surface samples

Over 100 samples were taken on the Forrest claims in two separate areas. Sampling at Forrest creek was limited by adverse weather and prohibitive vegetative cover. A grid was completed at the goldpan zone, located 3km south of Forrest creek, over an area that covered two mineral occurrences that had not previously been sampled.

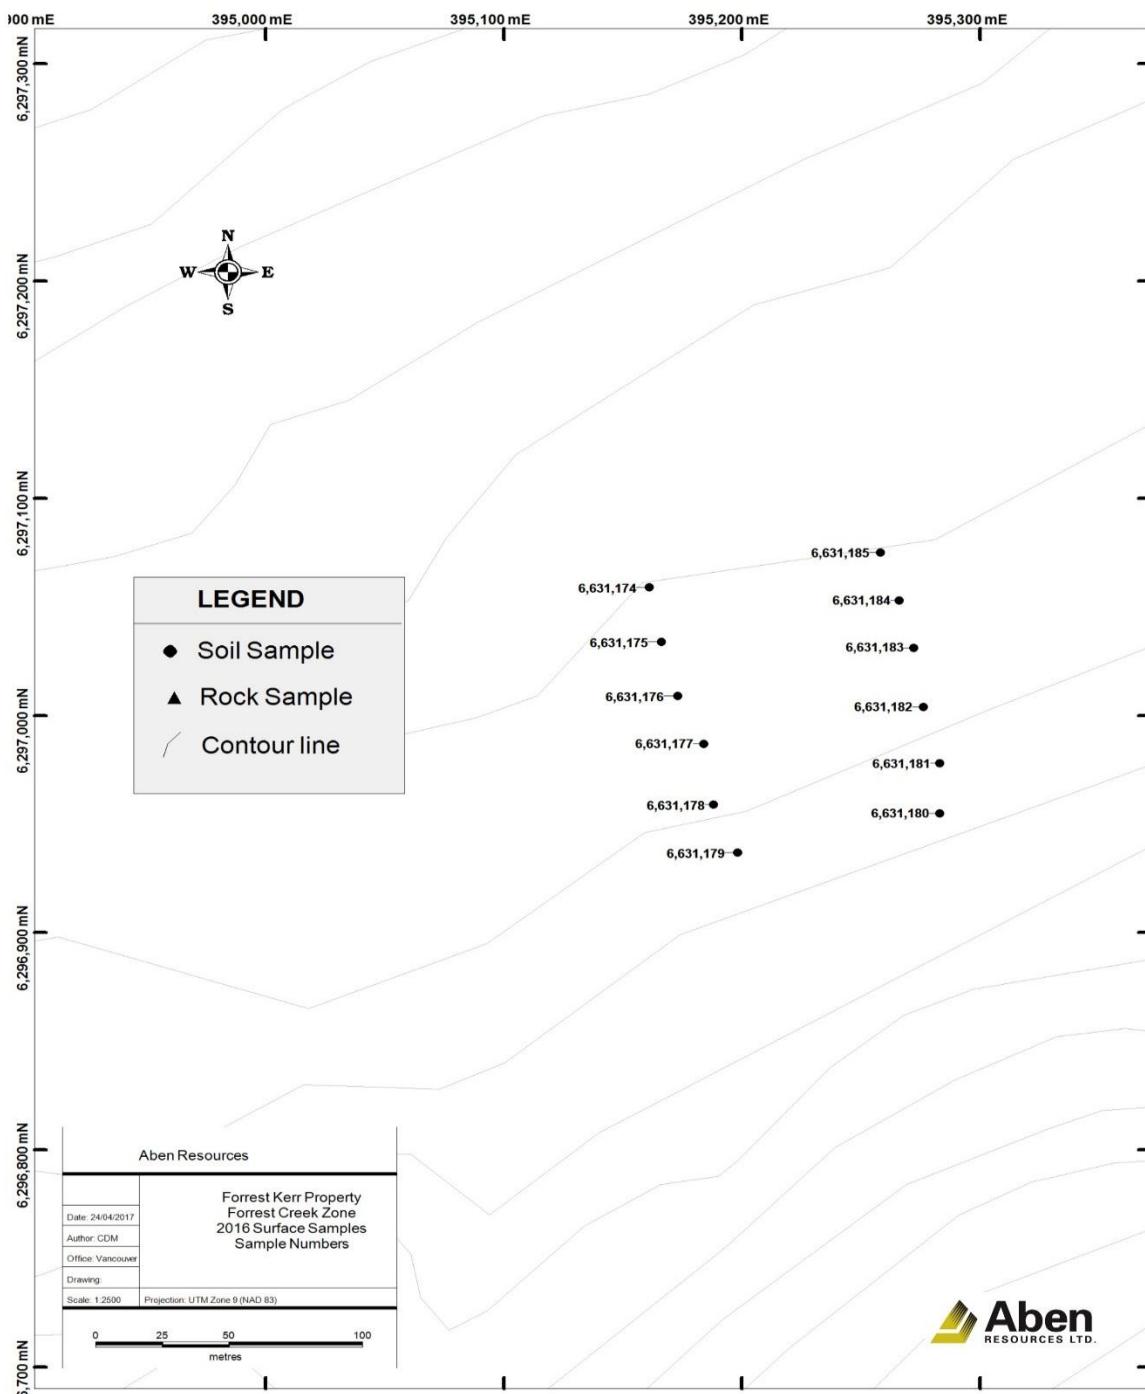

Figure 12: Forrest Creek surface samples

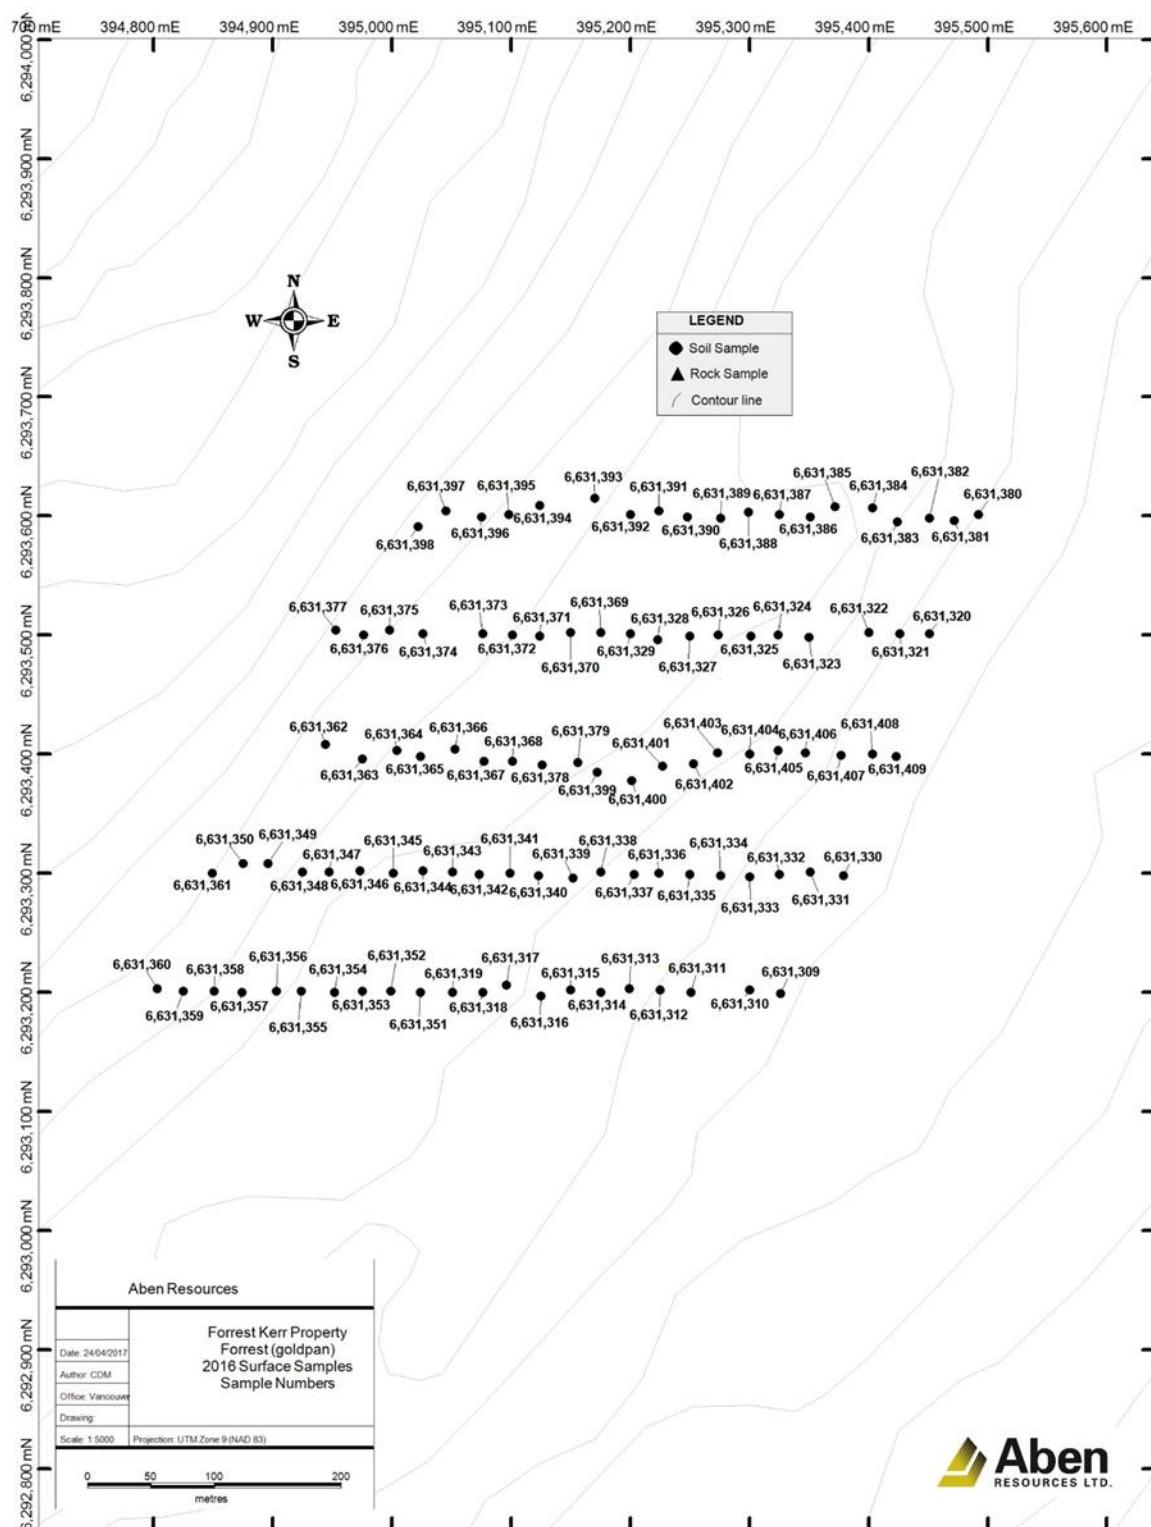

Figure 13: Forrest goldpan zone surface samples

Eleven stream sediment samples were collected from an active channel on the Beauty Ten claim (tenure#1045158). This was the only non-contiguous claim in the claim group and it has subsequently been dropped by Aben. Assessment credit for the work was credited to the main claim group by temporarily staking claim #1048511 to make both tenures contiguous with the main claim package and thereby allowing transfer of credit. Figure 14 shows the location and number of the stream sediment samples and location of the dropped claims. Assay results for the stream sediments can be found in Appendix C.

Some field time was spent locating historic drill holes across the property in order to establish more definite spatial control on subsurface structurally controlled mineralization. As the majority of exploration work on the Forrest Kerr Property was conducted previous to modern GPS technology, the establishment of good ground control through the use of a common datum (NAD 83) will be very important for future exploration work.

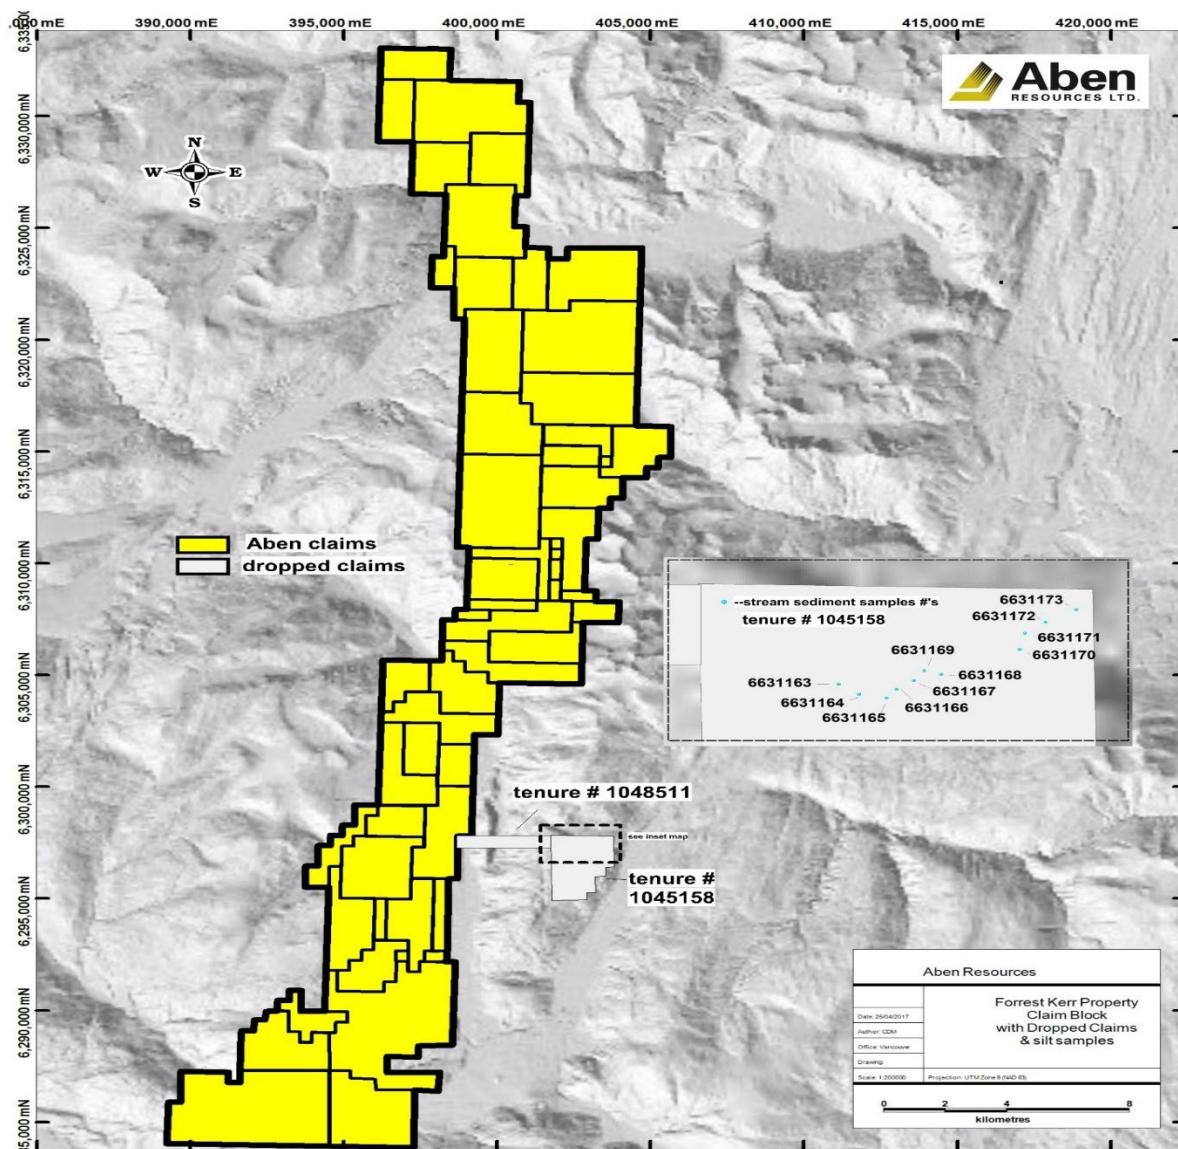

Figure 14: Stream sediment samples on dropped claims

## **SAMPLE PREPARATION, ANALYSES AND SECURITY**

A total of 408 rock, soil and stream sediment samples were sourced from the Forrest Kerr Property in 2016. All samples were placed in individual bags with a sample tag and sealed with a zip tie in the field. Groups of individual samples were then placed in rice sacks, sealed with tamper proof zip ties and transported by Aben personnel to AGAT laboratories receiving facility in Terrace, British Columbia. The sample shipment was then transported to AGAT's Mississauga headquarters for preparation and analysis. In Mississauga the samples were dried to 60°C if required and crushed to 75% passing 10 mesh (2mm) with a Rocklabs Boyd crusher. Each sample was then split to 250 g using a Jones riffler splitter of rotary split and pulverized to 85% passing 200 mesh (75 µm) using a TM-2 pulverizer. All samples were fused with sodium peroxide in a muffle furnace for one hour (protocol MIN-200-12001). The resultant melt is dissolved in a weak hydrochloric acid and diluted to 250 mL with de-ionized water. Analysis for 24 elements by ICP-OES was conducted using a PerkinElmer 7300DV instrument. Determination of gold was completed by AGAT protocol MIN-200-12006 lead fusion fire assay. Using this technique, 30 g prepared samples are fused with lead, then cupelled and parted with nitric acid. For samples with greater than 5 ppm Au a gravimetric finish is completed with a Mettler Toledo XP6 microbalance.

Field blanks and duplicate samples were inserted into the sample stream by Aben personnel. Blank material for the soil samples was taken from a field near Smithers while basalt material sourced near the AltaGas camp was used for blank rock sample material. All blank material reported acceptably low values for both base and precious metal. Duplicate samples in both the soil and rock returned values within acceptable error margins. AGAT laboratories maintains an in-house quality assurance & quality control (QA/QC) program through the use of replicate samples and certified reference materials. AGAT confirms that their QA/QC protocol for these samples were sufficient to ensure contamination, reproducibility and accuracy.

## **INTERPRETATIONS AND CONCLUSIONS**

The consolidated Forrest Kerr Property has over 40 documented mineral occurrences that contain significant Au-Ag-Cu-Pb-Zn mineralization in a variety of depositional styles. The property straddles the Forrest Kerr fault, a regional fault zone with many associated splays, fractures and shear zones that portray a complex structural history in a region of extensive mineralization. Much evidence of a long-lived robust hydrothermal system exists in the rock record, both in outcrop and from historic drilling across the claim group. The property-wide database contains over 18,000 soil, 2000 rock and 500 stream sediment samples that exhibit elevated base and precious metals with high concentrations of pathfinder elements. A majority of the prospective areas documented through sampling and prospecting remain under-explored or untested by drilling.

Initial exploration on the RDN claim group in the early 1990's targeted quartz-sulfide veins. Drilling in 1990 & 1991 hit intercepts that returned 14.5 g/t Au over 7.8m (RG90-07) and 91 g/t Au over 1.5m (RG91-21). At the Boundary zone, located near the border of the RDN and the Forgold claims to the south, hole RG91-16 reported 326 g/t Au over 0.4 m (average 60 g/t Au over 5.5m). After the discovery of the metal-rich Eskay Creek mine 40 km to the south, exploration between 1994 and 2005 was directed toward the potential of the RDN claims to host precious metal-enriched volcanogenic massive sulphide (VMS) mineralization. The potential for the property to host VMS mineralization is still valid based on strong stratigraphic and lithologic similarities to

Eskay over 10 km of strike length. In addition, the RDN claims host numerous structural targets outlined in historic geophysical surveys that remain under-investigated.

The Forgold claims, located in the central portion of the Forrest Kerr Property, are host to a highly anomalous Au-Cu geochemical signature that extends for over 2 km along strike and in excess of 750m laterally. Rocks taken from across the Forgold claims display well developed sericitic alteration providing evidence that a large scale hydrothermal system was present in the area. Samples from Forgold outcrop have returned up to 15 % Cu and 9 g/t Au along a linear trend within a zone of highly fractured and faulted rocks associated with the Forrest Kerr fault. Only one drill hole has been collared within the present Forgold claim boundary and the claim group has not been properly tested with geophysics. In particular, the under-explored Four Corners zone has good potential to host precious metal enriched massive sulphide mineralization based on stratigraphic, lithologic and depositional field observations.

The Forrest claim group is located wholly on the west side of the Forrest Kerr fault and therefore underlain by mainly Paleozoic rocks of the Stikine assemblage with occurrences of Triassic Stuhini Group and Jurassic intrusives, interpreted to be important drivers of mineralization in the region. The 20+ documented Au+Cu mineral occurrences in this area are located along large scale fault structures that parallel the Forrest Kerr fault to the east and the West Lake thrust fault to the west. Exploration in 1990 & 1995 targeted Au + Cu mineralization located near the edge of a diorite stock that hosts extensive sheeted quartz veining. Drilling at the Creek showing returned 5.79 g/t Au and 0.83% Cu over 8.49 metres (A90-13) and 1.7 g/t Au and 0.77% Cu over 39.3 metres (A90-05). Only limited field work has been conducted at Forrest since drilling was completed in 1995. A 2013 property wide VTEM/Radiometrics/Magnetics airborne survey helped to confirm the location of mapped lithologic and structural controls and also delineated areas with good potential to extend known mineralization. In addition, three conductive zones were indicated, one of which lies adjacent to the Creek zone in an area with very limited geochemical sampling or detailed mapping.

The majority of exploration on the consolidated Forrest Kerr property has been guided through the application of the 'Eskay Creek' exploration model. The use of this model is well justified due to the compelling stratigraphic and lithologic similarities between Eskay and a large portion of the Forrest Kerr property. Given the relatively small footprint of a high grade VMS deposit and the widely-spaced drilling completed thus far over most of Forrest Kerr property, many more viable targets remain to be tested. Modern discoveries within the Golden Triangle have emphasized the wide range of deposit styles and their potential for high grade mineralization throughout the area. Common to many of these deposits is their position within Hazelton Group rocks near the unconformable contact with Stuhini Group rocks with Jurassic intrusives in close proximity. The Forrest Kerr property combines these lithologic criteria with evidence of widespread hydrothermal activity through an extensive fault system that acted as a conduit for the mineralizing fluid. The property merits further exploration in light of the recent success using a variety of target models.

## APPENDIX E: Certificate of Qualified Person

### APPENDIX E: Certificate of Qualified Person

#### CERTIFICATE. C. McDowell

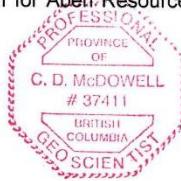

I, Cornell McDowell, of 3507 108st NW Edmonton, Alberta, do hereby certify that:

- 1) I am a professional geologist providing consulting services to the exploration industry with an office at 3507 108st NW Edmonton, Alberta.
- 2) I graduated from the University of Alberta in 2005 with a B.Sc., Specialization in Geology.
- 3) I am a member in good standing in the Association of Professional Engineers and Geoscientists of the Provinces of British Columbia and Alberta.
- 4) I have practiced my profession continuously since 2005. I have had 12 years' experience in ore deposits and mineral exploration while working on a variety of ore deposit types.
- 5) I have read the definition of "qualified person" set out in National Instrument 43-101 and certify that by reason of education and relevant experience I meet the requirements of a Qualified Person as defined in National Instrument 43-101.
- 6) I am the author of this assessment report "2016 Geochemical Report on the Forrest Kerr Property" and am responsible for all parts of it.
- 7) I was present every day on the Forrest Kerr Property during the 2016 field program.
- 8) I act in the capacity of Vice President of Exploration for Aben Resources and therefore am not independent of the issuer.

Dated this 28th day of April, 2017

Cornell McDowell

(signed) C. McDowell, P.Geo.

(Sealed)

E6632030 (7878403)	19.9		
E6632031 (7878404)	16.5		
E6632032 (7878405)	0.84		
E6632033 (7878406)	151		
E6632034 (7878407)	25.7		
E6632035 (7878408)	0.70		

Comments: RDL - Reported Detection Limit

7878060-7878408 Au determination by this method is semi-quantitative due to small sample size.
